According to a recent report by electric grid experts (NERC, CMC, WECC), the mass charging of EVs as penetration levels increase "may have catastrophic consequences for grid reliability" and may cause "cascading blackouts and widespread power interruptions" including causing transmission lines to suddenly go dead, or knocking out a power plant35. This report warns that widespread EV charging may trigger a fault-induced delayed voltage recovery (FIDVR) that utility companies have had to deal with since 2010 due to air conditioning units coming online simultaneously. FIDVRs can ripple from its local neighborhood distribution system through the transmission lines into other distribution systems. A result can be "cascading voltage collapse" and "widespread blackouts"36. [EPA-HQ-OAR-2022-0829-0551, pp. 9-10]

36 https://www.eenews.net/articles/needed-car-experts-to-fend-off-grid-disaster/

Not only will EV charging dramatically increase the US's overall electricity consumption, but the immediate issue is that many EVs will all be charging at the exact same time. As an analogy, [EPA-HQ-OAR-2022-0829-0551, pp. 9-10]

"Imagine a college dorm, where every student switches their 1,800-watt blow dryers on at exactly 8:00 in the morning. Breakers are going to blow. Lights are going to go out. That's similar to the potential nightmare for local electricity providers. If just one or two people on a street have EVs, the load on the local transformers and wires can be met without issues. However, if everyone on the street has an EV, there might be a problem. That's especially true in older neighborhoods, where existing demand may already be straining the infrastructure."37 [EPA-HQ-OAR-2022-0829-0551, pp. 9-10]

37 https://cars.usnews.com/cars-trucks/features/can-the-nations-electrical-grid-support-electric-cars

Organization: Plains All American Pipeline, L.P.

By 2032—less than 10 years from now—the EPA's Proposal would require nearly 70% of light-duty cars and trucks sold in the U.S. to be electric or "zero tailpipe emission." We have a number of concerns with this approach, a few include: [EPA-HQ-OAR-2022-0829-0713, pp. 1-2]

• By focusing on tailpipe emissions alone, most internal combustion engine vehicles that run on gasoline, diesel and biofuels would be unable to meet the standards set forth in the Proposal. This overlooks critical efforts of the energy and automotive industries to pursue continued innovation and optimization of fuel/vehicle systems to improve efficiency and reduce emissions.1 [EPA-HQ-OAR-2022-0829-0713, pp. 1-2]

• Effectively outlawing most liquid fuel-powered vehicles would undercut U.S. energy security,2 harm our domestic energy industry and leave the U.S. more dependent on foreign-controlled supply chains.3 [EPA-HQ-OAR-2022-0829-0713, pp. 1-2]

• Transferring a significant amount of energy demand to electricity will strain already challenged electrical generation and transmission infrastructure. Without substantial additional investment and significant streamlining of electric transmission permitting, it's unclear whether the electrical grid could support charging new EVs at the level necessary to support the proposed emissions reductions.4 [EPA-HQ-OAR-2022-0829-0713, pp. 1-2]

• Traditional energy sources are essential for ensuring effective evolution of the energy landscape-including the manufacture and growth of renewable energy sources and EVs. However, the Proposal would reduce energy investments and increase costs to consumers for all forms of energy. Furthermore, this policy risks the continued viability of critical domestic energy manufacturing infrastructure, which, if idled, would be very challenging to restore. [EPA-HQ-OAR-2022-0829-0713, pp. 1-2]

• Eliminating most new gasoline and diesel vehicles from the market limits consumer choice. Significantly fewer new affordable vehicles are available for sale today5 than a few years ago. Used cars are also increasing in price6 as some automakers warn that they will be forced to cut back on supplying popular gasoline models because of government regulations restricting sales of traditional vehicles.7 [EPA-HQ-OAR-2022-0829-0713, pp. 1-2]

EPA's assumptions for electricity costs are also questionable. EPA uses residential electricity prices from EIA's AEO 2021 without explaining why it has not relied on EIA's price forecasts for electricity "used in the transportation sector" instead.95 Those costs are generally 2% to 4% higher than the residential rates.96 The residential rates also do not reflect the grid mix assumed by EPA.97 For instance, EPA assumes that renewables will account for approximately 80 percent of U.S. electricity generated by 2050.98 Yet EIA's AEO 2021, which EPA has relied on for energy prices, predicts that renewable energy generation will make up only about 42% of electricity generation in 2050.99 The difference in those projections calls into question EPA's choice to rely on the AEO 2021 electricity prices. EPA does not explain whether its own projected grid mix will affect electricity prices, when it almost certainly would differ from the AEO 2021 prices based on a very different energy mix. [EPA-HQ-OAR-2022-0829-0609, pp. 23-24]

96 Id.

97 Id.

98 Id.

99 Id. at 8.

EPA also relies on questionable assumptions regarding the mix of renewable and non-renewable energy sources serving the electric grid. Trinity compared EPA's assumptions to EIA's AEO 2023, and found that EPA is assuming over 20 percent more renewable sources serving the grid by 2050 compared to EIA's "high uptake" most optimistic estimate, including incorporates impacts from IRA incentives for renewables.108 According to Trinity, "[e]ven accounting for the increase in demand for electricity over the period, U.S. EPA claims that GHG emissions from electricity generation will be reduced by about 80% from 2020 through 2030 compared to EIA's forecast of about 50%."109 EPA fails to explain why its estimates of renewables in the grid mix differ so greatly from EIA's. [EPA-HQ-OAR-2022-0829-0609, p. 25]

108 Id.

109 Id. at 10-11.

OnLocation also finds that if BEV upstream emissions are considered, "real-world" emissions to the atmosphere from covered vehicles would be at levels significantly higher than the proposed compliance standards. More specifically, if upstream fuel production emissions are accounted for regarding BEVs, the Proposed Rule's 86 gram per mile target in 2032 cannot be met when using electric grid GHG emission intensities from EIA, the leading U.S. governmental source for independent energy statistics and analysis.116 Note that OnLocation's analysis does not seek to account for battery manufacturing lifecycle emissions, which is addressed in Trinity's report, as described above. As Trinity has shown, "actual BEV lifecycle emissions would be even higher if battery manufacturing impacts are considered."117 [EPA-HQ-OAR-2022-0829-0609, pp. 26-27]

116 Id. at 1, 10.

117 Id. at 10.

OnLocation further finds that "using only tailpipe emissions provides inconsistent incentives between BEV and ICE vehicles, while optimistic projections for the grid carbon intensity and BEV penetration could reduce the effectiveness of the Proposed Rule in reducing carbon."118 Regarding electric grid intensity, OnLocation finds that EPA's Draft Regulatory Impact Analysis (DRIA) using its model shows a 70% reduction of power sector-related CO_2 emissions from current levels by 2055, while EIA's reference case "shows closer to a 50% reduction from current levels and substantially less CO_2 reduction if renewable costs do not decline as quickly as in the Reference scenario."119 While ICE vehicles have incentives under the proposal to reduce their tailpipe GHG emissions, BEVs and the electric grid lack GHG reduction incentives since the Proposed Rule effectively assumes that all electricity used by BEVs is zero carbon.120 [EPA-HQ-OAR-2022-0829-0609, pp. 26-27]

118 Id. at 14.

119 Id.

120 Id. at 16.

U.S. EPA's assumed costs for electricity are another source of concern. As indicated in DRIA Chapter 2.6.6., U.S. EPA used residential electricity prices from EIA's AEO 2021. It should first be noted that AEO also includes price forecasts for electricity used in the transportation sector, which are generally 2 to 4% higher than those for residential electricity. U.S. EPA provides no explanation for the agency's selection of residential electricity prices instead of transportation sector electricity prices. Another issue with the U.S. EPA's selection of AEO residential electricity rates is that they do not reflect the grid mix assumed by U.S. EPA (see Figure 5-8 in Chapter 5 of the DRIA). As shown in Figure 5-8, by 2050 U.S. EPA assumes that renewables (hydro and non-hydro renewables) will account for approximately 80% of U.S. electricity generation by 2050. In contrast, in EIA's AEO 2021, which U.S. EPA relies upon for electricity prices, only about 42% of power generation was forecast to be renewable in 2050. Given that U.S. EPA assumes about twice as much renewable power generation in 2050 than EIA, it is not appropriate for U.S. EPA to use the EIA AEO 2021 prices for electricity without establishing that the price of that electricity as delivered to vehicles will not be higher than the EIA forecasts. Further, this "as delivered" price needs to account for much more than just generation costs (which may be lower than for fossil generating sources) including transmission lines and energy storage. [EPA-HQ-OAR-2022-0829-0609, pp. 59-60]

Organization: Porsche Cars North America (PCNA)

Other areas important to consumer adoption can benefit from additional policy development. Further work is needed to reduce barriers to electrification such as streamlining building codes to futureproof new construction to ease the installation of charging at homes, apartments, and workplaces. The magnitude of the challenge related to a robust charging infrastructure is becoming increasingly clear with updated reports such as the Department of Energy's 2030 assessment.1 This single report indicates a total investment of $53-127 billion dollars for private and public charging which does not even include costs associated with grid upgrades to support the 26 million plus ports that are estimated to be needed. Consumers won't be satisfied with roadblocks that make owning an electric car more complicated than a gasoline model. Actions are also needed to help lower the cost of electricity as a fuel to ensure that EVs are competitive and attractive against gasoline models. [EPA-HQ-OAR-2022-0829-0637, p. 3]

1 The 2030 National Charging Network: Estimating U.S. Light-Duty Demand for Electric Vehicle Charging Infrastructure, US Department of Energy, 2023

Organization: Rivian Automotive, LLC

Rivian is encouraged by the efforts currently underway across state and federal agencies, private companies, national labs, and non-profits to address the key challenges and opportunities with scaling charging infrastructure. One of those challenges is the impact of widespread electrification on the electric grid infrastructure. We applaud EPA for acknowledging this challenge as it is a top concern for many industry stakeholders, but also an area where significant attention is being paid. For example, EPRI has launched its EVs2Scale 2030 initiative, which is focused on increasing collaboration between industry and utilities to increase communication around commercial fleet electrification plans and utility capacity mapping.50 Several deliverables are planned by the group, including key tools focused on helping utilities across the country receive the necessary buy-in from their decision makers to plan for the grid upgrades necessitated by transportation electrification. In addition, as noted in the DRIA, NREL recently published a quantitative needs assessment by state and city for a national charging network focused on personally owned, light-duty vehicles.51 The granularity of the analysis available on the state and city level52 will allow it to serve a similar function as the EPRI effort—increasing utilities' awareness of the forthcoming load on their systems, thus providing more time to make necessary grid upgrades. Overall, increasing transparency and information flow with the broad range of utilities operating in the US will be critical to achieving the electrification goals this rulemaking aims to help meet. [EPA-HQ-OAR-2022-0829-0653, pp. 15-17]

52 See data files for Wood, E., B. Borlaug, M. Moniot, D.-Y. Lee, Y. Ge, F. Yang, and Z. Liu, National Renewable Energy Laboratory, The 2030 National Charging Network: Estimating U.S. Light-Duty Demand for Electric Vehicle Charging Infrastructure (2023), NREL/TP-5400-85654, available at https://data.nrel.gov/submissions/214.

In addition to increasing collaboration with utilities, leveraging load management technologies to reduce the need for additional build out of grid capacity will be imperative. As the DRIA notes, there are many commercially available technologies able to manage charging load, from smart charging to mobile and stationary storage, to vehicle grid integration. In recent years, these technologies have demonstrated their ability to subtract years from their project energization timeframes or even enable the completion of a project that would have otherwise been unable to proceed if a full-nameplate upgrade was required. [EPA-HQ-OAR-2022-0829-0653, pp. 15-17]

While we acknowledge new distribution infrastructure will be necessary, we agree with EPA that commercially available load management technology can leverage the inherent flexibility of EV charging use cases and insert much-needed efficiency into EV-related distribution grid planning and buildout processes. Per EPA's analysis in Figure 5-15 in the DRIA, the majority of charging will be needed at home and at work, which is where load management technologies are particularly impactful due to long dwell times with maximum charging flexibility. [EPA-HQ-OAR-2022-0829-0653, pp. 15-17]

Overall, increased transparency around the location and scale of future charging load will enable utilities and their decision makers to make necessary investments in the electric grid infrastructure as well as increase their adoption of load management technologies. Therefore, we view the near-term finalization of Alternative 1 as a critical step to build on the existing momentum described above and continue it into 2027 and beyond. [EPA-HQ-OAR-2022-0829-0653, pp. 15-17]

Organization: Scott Wilson

You will have read also that EVs are unaffordable. Actually, there are 18 new EV models below the average new car price in the US. (see attached) You will have read there is no charging infrastructure. Not true, since any home with electricity near a parking place can support an EV. However, more long-distance highway charging is needed and is the motivation for the administration's NEVI charger program. You will have read that the grid can’t support an EV fleet. Major electric utility trade groups point out that off-peak charging will become widespread. It’s notable also that 124 business entrepreneurs, executives, and academics have submitted favorable comments. [EPA-HQ-OAR-2022-0829-0515, p. 1]

In addition to concerns about the legality of these proposals, the EPA is forcing this transition to electric vehicles at a time when the capacity and reliability of our nation's electric grid to meet current demand is of increasing concern. A recent American Transportation Research Institute study found that full-scale electrification of the transportation fleet would require the addition of generation and transmission capacity equal to more than 40 percent of our current electricity demand. Grid operators are already raising concerns over other EPA proposals targeting the electricity generation sector that will significantly impact existing capacity and reliability.3 PJM recently released a report highlighting how baseload power retirements are policy driven and "retirements are at risk of outpacing the construction of new resources."4 Concerns like these from electric industry stakeholders draw attention to proposed EPA regulatory mandates on that sector that will decrease the capacity of our nation's grid to meet that existing demand, including the Mercury and Air Toxics Standards, regulations on Coal Combustion Residuals, a new proposal on Effluent Limitation Guidelines, and the recently announced Clean Power Plan 2.0 Rule. Given this upcoming regulatory onslaught on the electric fleet and the chronic delays and uncertainty associated with federal and state permitting of new generation and transmission assets, it is unclear that current levels of electric service can be maintained -much less expanded to replace the latent energy of liquid fuels with electricity to power BEVs. [EPA-HQ-OAR-2022-0829-5083, pp. 1-2]

Organization: Steven G. Bradbury

Where does EPA purport to find this authority in the Clean Air Act?

The logic is as follows:

Because most automakers have announced ambitious timetables for transitioning to the production of EVs going forward and have pledged to make large capital investments to finance this gradual switchover,13 and because Congress has recently approved generous federal subsidies for some EV purchases and charging infrastructure,14 EPA says it can now declare that battery-electric vehicle technology is a “feasible” alternative to the tradi-tional internal-combustion engine (ICE) powertrain.15 And on that basis, EPA is proposing to treat EVs as an available “control technology” for achieving compliance with the tailpipe emissions restrictions under Clean Air Act section 202.16 [EPA-HQ-OAR-2022-0829-0647, pp. 6-8]

13 See 88 FR at 29191, Figure 1 (reproducing a chart prepared by the Environmental Defense Fund depicting the automakers’ announced goals for future electrified vehicle sales as a percentage of total sales); id. at 29193-94 (summarizing automakers’ announced plans for investments in EV technology).

14 See id. at 29195-96; Infrastructure Investment and Jobs Act, Public Law 117–58, 135 Stat. 429 (2021), https://www.congress.gov/117/plaws/publ58/PLAW117publ58.pdf; Inflation Reduction Act of 2022,

Public Law 117–169, 136 Stat. 1818 (2022), https://www.congress.gov/117/bills/hr5376/BILLS117hr5376enr.pdf.

15 See 88 FR at 29194 (light-duty and medium-duty vehicles); 88 FR at 25972 (heavy-duty trucks).

16 See 88 FR at 29284 (for light-duty and medium-duty vehicles); 88 FR at 26015 (for heavy-duty trucks).

This reasoning obviously depends on a kind of feedback loop. The automakers are pledging to invest in the transition to EVs because governments around the world—like China, the EU, the Biden White House, and Governor Gavin Newsom and his climate regulators in California—are demanding that they do so. But everyone knows there is a large looming impediment to this Green Dream: resistance from American consumers. [EPA-HQ-OAR-2022-0829-0647, pp. 6-8]

The American public is not jumping on the electric bandwagon. EVs are expensive— beyond the reach of many American families—and most Americans remain skeptical that EVs will reliably serve the full range of their needs, that quick and convenient charging stations will be widely available, that EVs will maintain their promised driving range over time or in cold weather, that they will have any significant resale or trade-in value down the road, and that insurance carriers will cover the huge costs of battery replacement when the battery wears out or is damaged in a minor accident.17 [EPA-HQ-OAR-2022-0829-0647, pp. 6-8]

17 See Nick Carey, Paul Lienert, and Sarah McFarlane, "Scratched EV battery? Your insurer may have to junk the whole car," Reuters, March 20, 2023, https://www.reuters.com/business/autos-transportation/scratched-ev-battery-your-insurer-may-have-junk-whole-car-2023-03-20/ ("For many elec-tric vehicles, there is no way to repair or assess even slightly damaged battery packs after accidents, forcing insurance companies to write off cars with few miles—leading to higher premiums and under-cutting gains from going electric.").

To push the automakers to convert to EV production in the absence of sufficient mar-ket demand, EPA plans to ratchet down the emissions limits for carbon dioxide and for the traditional criteria and other pollutants associated with smog (such as unburned hydrocar-bons, particulate matter, oxides of nitrogen, and ozone) to super-stringent levels that are technologically impossible for gas-powered vehicles (even hybrids) to satisfy.18 At the same time, EPA is proposing to phase out certain regulatory buffers that allow automakers to report better emissions compliance results, such as "off-cycle credits" for the addition of onboard technologies that improve the fuel efficiency of ICE vehicles.19 [EPA-HQ-OAR-2022-0829-0647, pp. 6-8]

18 See, e.g., 88 FR at 29237-38; id. at 29257-61.

19 See id. at 29249-50.

The automakers' only recourse will be to replace more and more of the ICE vehicles in their fleets (including hybrids) with the "alternative control technology" of battery-elec-tric vehicles. [EPA-HQ-OAR-2022-0829-0647, pp. 6-8]

And here is the trick: For enforcement purposes, EPA applies the emissions limits to each automaker on a fleetwide average basis, and it proposes to reduce these fleetwide averages dramatically each model year from 2027 through 2032 on a ramp rate calculated to achieve the Biden administration's desired percentage mix of EVs in the U.S. auto fleets. [EPA-HQ-OAR-2022-0829-0647, pp. 6-8]

In other words, EPA is now proposing to set fleetwide average tailpipe pollution limits that are intended by design to apply increasingly over time to vehicles that have no tailpipes and that EPA says emit none of the pollutants covered by the regulations.20 [EPA-HQ-OAR-2022-0829-0647, pp. 6-8]

20 Automakers can avoid violating the average emissions limits in certain circumstances with regulatory "credits," earned by producing vehicles, like EVs, that outperform the limits. Under the EPA's rules, credits can be "banked" from one model year to another within limits, "transferred" from one fleet to another (for example, from the automaker's light truck fleet to its passenger car fleet), or "traded" between automakers, which usually involves a privately negotiated purchase. Tesla, which manufactures nothing but EVs and accounts for approximately 70 percent of the U.S. EV market, receives a large portion of its income from selling emissions credits to the other automakers. Predictably, the EPA is proposing to retain this credit system to continue the subsidization of EV manufacturing. See 88 FR at 26245-46.

What is clear is that EPA sees an endless horizon for its new-found power to regulate practically all aspects of the American automotive market. No doubt, for example, the Agency intends to be involved in overseeing the buildout and operation of electric vehicle charging infrastructure around the country—once again, as an incident of the regulators' own expansive conception of their section 202 authority to ensure the adequacy of EPA's chosen control technology. [EPA-HQ-OAR-2022-0829-0647, pp. 10-11]

We can easily imagine that someday this self-assumed mandate will include the power to ration the timing and extent of drivers' access to charging networks, as EPA deems necessary to maintain the general supply of electricity for EVs. California is already doing this. Because the buildout of charging infrastructure will depend critically on gov-ernment subsidies and approvals, government rationing of access to this infrastructure is a very real prospect, especially given the strains on grid reliability that I discuss below. [EPA-HQ-OAR-2022-0829-0647, pp. 10-11]

The bottom line under the Major Questions Doctrine is that section 202, on which the proposed rules rest, contains no clear and express delegation of any authority that could sustain these massively consequential proposals. As the Court observed in West Virginia v. EPA, "Congress certainly has not conferred [such] authority upon EPA anywhere … in the Clean Air Act." [EPA-HQ-OAR-2022-0829-0647, pp. 10-11]

The Analyses and Assumptions on Which the Proposed Regulatory Actions Are Based Are Arbitrary, Fundamentally Flawed, and Fail to Recognize and Account Properly for the Hugely Negative Consequences that Would Result from These Actions [EPA-HQ-OAR-2022-0829-0647, pp. 10-11]

EPA claims that, despite the coercive power and industry-transforming ambition behind its proposals, these rules will somehow deliver a stupendous bounty of net benefits, ranging at the high end from $1.5 trillion to $2.3 trillion for the light-and medium-duty vehicle rule,23 plus another $180 billion to $320 billion for the heavy-duty truck rule.24 [EPA-HQ-OAR-2022-0829-0647, pp. 10-11]

23 Id. at 29200.

24 88 FR at 25937.

Finally, the $1,200-per-vehicle cost figure touted by EPA is simply borrowed and carried over from the EPA's 2021 rulemaking without additional substantive analysis.32 It is not reasonable to assume that the per-vehicle cost of the current proposal for model years 2027 through 2032 would be anywhere close to the same as the estimated cost figure for the 2021 rule covering model years 2023 through 2026 (even if the figure was accurate for the 2021 rule). The current proposal is far more expansive and involves much more draconian reductions in emissions limits. [EPA-HQ-OAR-2022-0829-0647, pp. 13-14]

32 See 86 FR 74434, 74497, https://www.federalregister.gov/documents/2021/12/30/2021-27854/revised-2023-and-later-model-year-light-duty-vehicle-greenhouse-gas-emissions-standards.

The true per-vehicle technology costs of the proposed rules must be far higher than the figure thrown out by EPA. Even accepting the thoroughly implausible "no action" base-line that EPA has posited for future EV sales, EPA is projecting that the regulatory force of the current proposal, considered in isolation, will by itself cause the overall percentage of EV sales nationally to go from 39 percent to 67 percent—a huge increase, nearly a doubling in EV production and sales. Notably, based on EPA's own assumptions, this regulation-forced increase would have to come after all the early adopters have already purchased their EVs. Such an industry-wide transformation in production volumes and sales of EVs to non-early-adopters would involve a massive capital investment and marketing surge, and all the costs associated with that transformation would be attributable to the EPA's administrative rule, if the rule were indeed expected to be the forcing action. [EPA-HQ-OAR-2022-0829-0647, pp. 13-14]

In addition, the comparative lifecycle costs of owning and operating an EV versus an ICE vehicle are not nearly so different as EPA's NPRMs assert. EPA claims huge cost savings for EV owners over ICE owners from the avoided costs of fuel and maintenance and repairs over the life of the vehicle,33 but EPA's analysis fails to include the full costs of owning an EV: [EPA-HQ-OAR-2022-0829-0647, pp. 13-14]

33 See 88 FR at 29200.

EPA also undercounts the cost of electricity charging over the life of the EV. EPA relies on a pricing model that claims to show that electricity prices will somehow not rise significantly in a world where EVs comprise more than half of new cars sold in the U.S., but that claim is wholly unrealistic. Even absent high EV penetration, the Bureau of Labor Statistics reports that electricity prices are steadily rising in the U.S.38 Increased EV charging demand will only cause those prices to rise even faster. Driving a single EV 15,000 miles per year and charging it at home could raise the annual electricity bill for the average family by 50 percent or more.39 If the nation converts to EV ownership at the rates EPA is aiming for, such a large increase in overall electricity demand will inevitably cause electricity rates to rise significantly. [EPA-HQ-OAR-2022-0829-0647, pp. 14-15]

38 See generally https://data.bls.gov/pdq/SurveyOutputServlet (allowing user to generate graph showing the rise from 2003 to the present in the average price of electricity in the U.S.).

39 The Energy Information Agency reports that the average American household uses about 886 kilowatt hours of electricity per month, https://www.eia.gov/tools/faqs/faq.php, and the EPA says the average EV consumes 36 kilowatt hours of electricity per every 100 miles driven, https://www.epa.gov/greenvehicles/comparison-your-car-vs-electric-vehicle. If the family's EV is driven 15,000 miles per year, or 1,250 miles per month, it would consume 450 kilowatt hours of electricity every month.

The EPA's glib premise that car buyers in the U.S. will respond with strong demand for the supposed flood of future EVs (notwithstanding the practical concerns, cost consid-erations, and other uncertainties that surround EVs in the minds of American consumers), is typical of the consistently rosy—almost relentlessly rosy—assumptions about cost factors and consequential risks that underlie all parts of EPA's supporting analysis. [EPA-HQ-OAR-2022-0829-0647, pp. 14-15]

EPA fails to consider the negative societal consequences and second-order cost effects of its proposals. [EPA-HQ-OAR-2022-0829-0647, pp. 15-16]

In putting forward regulatory proposals designed to force upon the American people a vast and rapid industrial transformation, EPA has an obligation to go further than just considering the direct cost effects of its proposals (which are themselves woefully under-estimated, as highlighted above); it must also consider the broader indirect economic con-sequences and negative societal costs that would follow if these rules are finalized as pro-posed. So far in these rulemakings, the Agency has either ignored or deliberately down-played these second-order effects. [EPA-HQ-OAR-2022-0829-0647, pp. 15-16]

Some of the most consequential burdens and negative ramifications of the proposed rules that EPA hides, disregards, or minimizes include the following: [EPA-HQ-OAR-2022-0829-0647, pp. 15-16]

• Stifling consumer choice at the dealership. Many of the vehicle models most pop-ular with American families will no longer be sustainable under the EPA's proposed rules. Automobiles have long been America's favorite freedom machines. When the models of ICE vehicles Americans love the most disappear from dealerships, that will represent an enormous drop in consumer welfare (in basic happiness and well-being) for the average American family and for the U.S. economy as a whole. For many of these ICE vehicle models, there is no EV option likely to be available that could provide the same performance, utility, or recreational value at a comparable price (or at all). EPA makes no real effort to quantify this generational loss of con-sumer welfare. [EPA-HQ-OAR-2022-0829-0647, pp. 15-16]

• Increasing the purchase price of all new vehicles. Notwithstanding EPA's gaming of the numbers, the true costs of the industrial transformation forced by the EPA's proposed rules will be spread across the automakers' fleets, resulting in a significant increase in the prices of all new vehicles, with greater price increases concentrated on those vehicles for which the demand is highest relative to supply. All Americans will be harmed by these price increases, but the biggest losers will be lower-income Americans who cannot afford to buy an EV or to pay more for a gas-powered vehicle at the dealership, as well as those who live in rural areas and need to drive longer distances and for whom EVs are impractical. [EPA-HQ-OAR-2022-0829-0647, pp. 15-16]

• Destroying jobs in the U.S. auto industry. The loss of popular new vehicle options and the significant price increases at the dealership will mean that fewer new vehicles will be purchased—almost certainly far fewer than EPA is predicting. This drop-off in demand will challenge the profitability of the auto industry and lead to a loss of jobs for tens of thousands of America's autoworkers, as well as a loss of jobs in the many U.S. companies that supply inputs for the production of auto-mobiles and heavy trucks.40 The United Auto Workers union has warned of the potential for job losses from the transition to EVs,41 as automakers announce more plant closures and layoffs due to the costs of electrification.42 [EPA-HQ-OAR-2022-0829-0647, pp. 15-16]

40 See Technality, “Ford Just Proved How Far Ahead Tesla Really Is: Profitability May Continue to Be a Struggle for All Legacy Automakers,” May 10, 2023, https://medium.com/tech-topics/ford-just-proved-how-far-ahead-tesla-really-is-6a4d95cff519 (“Despite wanting to be a fully-electric brand by 2035, as of Q4 2022, Ford’s average net margin on the Mustang Mach-E was -40.4%. Unfortunately, that’s a figure that’s only gotten worse since, to the point where Ford is now losing an average of $58,000 for every EV sold.”).

41 See Press statement, United Auto Workers, “UAW Statement on Job Cuts at Stellantis,” April 26, 2023, https://uaw.org/uaw-statement-job-cuts-stellantis.

42 See Michael Wayland, “Stellantis to indefinitely idle Jeep plant, lay off workers to cut costs for EVs,” CNBC.com, December 9, 2022, https://www.cnbc.com/2022/12/09/stellantis-to-idle-jeep-plant-lay-off-workers-to-cut-costs-for-evs.html.

• Causing more deaths and serious injuries on America’s highways. As new vehicle models become unaffordable or unappealing, many American families will be left driving older and older used cars, and the age of the nation’s auto fleet will rise dramatically. Already, the average age of a car on the road in the United States is approaching 13 years, and many cars are on their fifth or sixth owners. The aging of the American fleet has very negative safety consequences, as NHTSA statistics show that older vehicles are much less safe than newer models in an accident.43 [EPA-HQ-OAR-2022-0829-0647, pp. 15-16]

43 See https://www.nhtsa.gov/sites/nhtsa.gov/files/documents/newer-cars-safer-cars_fact-sheet_010320-tag.pdf.

Straining America’s power grid and raising the price of electricity. EPA pre-tends that its rules will not put a colossal additional strain on our already vulnerable national power grid. But that is fantasy, if the forecasted EV sales actually were to materialize. To accommodate EPA’s future fleet of EVs, our national electric grid capacity would need to grow 60 percent or so by 2030 and much more over the long term,52 and that is growth in infrastructure alone, not in power generation. This buildout is simply not practicable in the timeframe EPA is contemplating.53 Even if it could happen, it will have to be paid for, and those costs will inevitably be reflected in higher electricity rates for all users of electricity across the U.S. and higher EV charging fees in particular. EPA says not to worry about grid reliability— utilities and the government will be able to manage the EV charging draw on the grid by rationing the hours for charging.54 American drivers will not tolerate that. [EPA-HQ-OAR-2022-0829-0647, pp. 18-19]

At the same time that EPA is proposing to force the electrification of the American auto fleet, it has just proposed separate rules under the Clean Air Act aimed at forcing power generators to phase out 90 percent of America’s fossil-fuel-powered electric generating capacity.55 Conveniently for the Agency’s cost accounting estimates, EPA’s newly proposed power plan ignores the extra electricity draw that would be required by EPA’s proposed vehicle rules, and the vehicle rules, in turn, fail to account for the electricity supply crunch that would be caused by EPA’s own power plan—a perfect concert of coordinated regulatory analysis, orchestrated to make the costs on Americans appear lower. [EPA-HQ-OAR-2022-0829-0647, pp. 18-19]

55 See https://www.epa.gov/newsreleases/epa-proposes-new-carbon-pollution-standards-fossil-fuel-fired-power-plants-tackle.

Putting the Highway Trust Fund at risk. The Highway Trust Fund, which covers a large percentage of the costs of state and local highway improvements and main-tenance in the U.S., is currently funded through a gas tax. The gas tax is relatively easy to administer because it is paid at the level of wholesale gasoline and diesel fuel distribution by a small number of large distributors. If more than half of new vehicles sold in the U.S. were EVs, as contemplated in the EPA's proposals, the gas-tax revenues for the Fund would drop dramatically, and the solvency and utility of the Fund would collapse. That would threaten the viability of the national high-way system and the capacity of states to maintain highways in good repair. [EPA-HQ-OAR-2022-0829-0647, p. 19]

If the Fund were to be retained in some form, it would require a new source of revenue, such as a tax on all vehicle miles traveled, or VMT. The idea behind a VMT tax is that it would equitably capture the VMT of EVs, just as well as ICE vehicles. However, a VMT tax is likely to be more complicated and costly to ad-minister than the gas tax. There are significant questions about the design and ad-ministrability of a VMT tax that would need to be worked out and proven—for example, through one or more state-wide pilot programs—before implementation. Since EPA is proposing to adopt rules that would cause a national shift to EVs, which in turn would undermine the revenue basis for the Highway Trust Fund, EPA should recognize and consider as part of these rulemakings the upfront costs and dislocations that would be involved in transitioning to a new revenue basis for the Highway Trust Fund, as well as the ongoing higher costs of administering such an alternative tax. [EPA-HQ-OAR-2022-0829-0647, p. 19]

EPA's benefits analysis is flawed and arbitrary.

On the benefits side of the ledger, EPA claims sky-high monetized benefits from the asserted reductions in carbon dioxide emissions—to the tune of upwards of a trillion dollars.64 These estimates are based on predicted reductions in the amount of gasoline and diesel fuel that would be burned if the U.S. auto fleet converts to EVs at the rates projected by EPA. But they completely ignore the very large increase in carbon dioxide emissions that would necessarily occur from the projected expansion in the production of EV batteries. They also ignore the upstream emissions of carbon dioxide from the increased electricity generation that would be needed to charge the projected fleet of EVs. [EPA-HQ-OAR-2022-0829-0647, pp. 22-23]

64 See id. at 29200, 29344.

EPA's refusal to account for these huge offsetting emissions of carbon dioxide fundamentally distorts its analysis of net benefits in a manner that arbitrarily favors the Agency's preferred regulatory outcome. It is, in fact, false and misleading to label EVs "zero-emission vehicles" when the production of EV batteries and the charging of the batteries over the life of the vehicles both generate enormous amounts of carbon dioxide. [EPA-HQ-OAR-2022-0829-0647, pp. 22-23]

EPA's projections of benefits from carbon dioxide reductions are primarily based on the so-called "social cost of carbon" models. However, as summarized in analyses pub-lished by my colleague from The Heritage Foundation, Kevin Dayaratna, these models are deeply flawed and unreliable. Among other things, they depend on outdated assumptions and fail to account for the positive agricultural effects of higher carbon dioxide levels. Using more appropriate assumptions, these models would show a social cost of carbon dioxide emissions that effectively approaches zero.65 [EPA-HQ-OAR-2022-0829-0647, pp. 22-23]

Dayaratna, "Climate Change, Part IV: Moving Toward a Sustainable Future," Testimony before Subcommittee on Environment Committee on Oversight and Reform, U.S. House of Representatives, September 24, 2020; Kevin Dayaratna and David Kreutzer, Loaded DICE: An EPA Model Not Ready for the Big Game, Backgrounder No. 2860, The Heritage Foundation, November 21, 2013, https://www.heritage.org/environment/report/loaded-dice-epa-model-not-ready-the-big-game; Kevin Dayaratna and David Kreutzer, "Unfounded FUND: Yet Another EPA Model Not Ready for the Big Game," Backgrounder No. 2897, April 29, 2014, http://thf_media.s3.amazonaws.com/2014/pdf/BG2897.pdf; Kevin Dayaratna, Ross McKitrick, and David Kreutzer, "Empirically Constrained Climate Sensitivity and the Social Cost of Carbon," Climate Change Economics, Vol. 8, No. 2 (2017), pp. 1750006-1-1750006-12, https://www.worldscientific.com/doi/abs/10.1142/S2010007817500063; and Kevin Dayaratna, Ross McKitrick, and Patrick Michaels, "Climate sensitivity, agricultural productivity and the social cost of carbon in FUND," Environmental Economics and Policy Studies, 22: 433-448 (2020), https://link.springer.com/article/10.1007/s10018-020-00263-w.

Conclusion

If and when the American people feel the true effects of these rules—when they lose the vehicle options they love at the local dealership and find themselves stuck driving older and less safe cars, when the bottom falls out of the job market in the U.S. auto industry, when drivers cannot find convenient charging stations for their electric vehicles—in sum, when American voters realize what the EPA's far-reaching regulatory enterprise has wrought for the nation, they will be angry. [EPA-HQ-OAR-2022-0829-0647, p. 24]

At issue are matters of life, liberty, and prosperity, and the considerations involved are fundamentally political in nature. That is exactly why, under our constitutional republic, it is for Congress, and Congress alone, to make the monumental decisions that EPA is purporting to take upon itself in these proposed rules. For these reasons, EPA should with-draw its proposed tailpipe rules and reconsider the wisdom of these proposals. [EPA-HQ-OAR-2022-0829-0647, p. 24]

Organization: Strong Plug-in Hybrid Electric Vehicle (PHEV)

EPA should consider adding a small bonus for vehicles that have on-board AC bidirectional chargers or are integrated with multiple DC off-board chargers. Alternatively, at minimum, EPA should conduct an analysis on how EPA can advance bi-directional charging in the future. Justification: The promise of bi-directional charging (AC or DC) to address air pollution, GHG and electric grid issues is very significant with BEVs and PHEVS in light-, medium-and heavy-duty vehicles, or off-road equipment. For example, a recent May 2022 presentation by the World Resources Institute using Bloomberg NEF and Energy Information Administration data found the power capacity in 2030 for EVs to be 10 to 20 times more than the 2030 power capacity of stationary storage.8 EPA can and should play a role in helping to unlock this potential. [EPA-HQ-OAR-2022-0829-0646, p. 9]

8 See slide 5 at https://www.slideshare.net/emmaline742/building-resiliency-with-v2g-in-residential-homes-by-camron-gorguinpour

a. For example, the internal combustion engine in a PHEV has a much lower emission signature than a stand-alone, backup generator. [EPA-HQ-OAR-2022-0829-0646, p. 9]

b. Bidirectional charging, like battery stationary energy storage, can reduce GHG and traditional pollutants from fossil fueled power plants by shifting electricity use to renewable energy in the cleanest hours of the day and reducing the need for high-emitting plants (such as traditional peaker power plants). [EPA-HQ-OAR-2022-0829-0646, p. 9]

c. Bidirectional charging can also provide many types of grid services including ancillary services, providing resource adequacy, and helping with the evening transition from renewables to other generation resources. Because the batteries are already paid for by the car and truck owners, utilities can gain a low-cost resource compared to battery stationary storage. [EPA-HQ-OAR-2022-0829-0646, p. 9]

d. The potential value is significant and can contribute to lower operating costs for BEVs and PHEVs.9 [EPA-HQ-OAR-2022-0829-0646, p. 9]

9 California Energy Commission, March 2019, Distribution System Constrained Vehicle-to-Grid Services for Improved Grid Stability and Reliability, Figure 42

While we understand the desire by EPA to simplify the regulation and reduce the use of bonus multiplier credits, we believe a small bonus credit in the final regulation for a few years is justified and needed to unlock this technology because of the large emission reduction benefits and other benefits enabled by bidirectional charging. [EPA-HQ-OAR-2022-0829-0646, p. 9]

Utility Rate Design Reform Will Spur Greater Infrastructure Investment

Additionally, utility investment in grid infrastructure to support EV charging will accrue over the next several years, as evidenced by active proceedings in many jurisdictions.208 As part of this investment, addressing utility demand charges will also play a role in facilitating the expansion of charging infrastructure.209 The combination of low load factors with high demand charges can result in uneconomic operation of charging stations and stymies investment in charging infrastructure in otherwise promising markets where electrification is growing. EPA should recognize that this issue is changing with many utilities now proposing or already having implemented novel approaches to mitigate the impact of demand charges and encouraging time of use rates to facilitate further proactive investments in charging infrastructure.210 Moreover, since BEV charging stations are large upfront investments assessed over a long-time horizon, the longer-term certainty provided in many of these rate reform proceedings will drive greater infrastructure investment. A number of utility proceedings have already addressed these issues including the following: [EPA-HQ-OAR-2022-0829-0792, pp. 32-33]

Additional proceedings addressing these issues will help further facilitate investment and deployment of charging infrastructure, supporting the agency's adoption of a more ambitious light-duty standards. [EPA-HQ-OAR-2022-0829-0792, pp. 32-33]

Organization: Texas Public Policy Foundation (TPPF)

As if that weren't enough, electric vehicles are especially susceptible to damage from flooding and hurricanes. When the grid goes down, those who own electric vehicles will be left at the mercy of the elements, trapped and unable to flee disaster due to the inability to reliably recharge their cars and trucks. And should they survive but their cars take on water, it is likely that the vehicles will catch on fire without warning due to corrosion from saltwater. See Jen Frost, Florida's electric vehicles are catching fire after Hurricane Ian, INSURANCE BUSINESS (Nov. 4, 2022), https://www.insurancebusinessmag.com/us/news/auto-motor/floridas-electric-vehicles-are-catching-fire-after-hurricane-ian-426452.aspx. [EPA-HQ-OAR-2022-0829-0510, pp. 6-7]

In sum, implementing the emission limitations mandated by the LMD Tailpipe Rule will require a massive, nationwide overhaul of our electrical grid and refueling network. By regulating in this manner, the EPA will make driving and daily living more expensive and difficult. [EPA-HQ-OAR-2022-0829-0510, pp. 6-7]

Organization: The Heritage Foundation (Kevin Dayaratna and Diana Furchtgott-Roth)

We know that these effects are serious and costly. Some states, such as California and Texas, have experienced many brownouts and blackouts in recent years as the existing electric grid cannot meet existing demand. Few new net sources of electricity generation are coming online. Electricity is not a fully reliable source of energy in these states. Moreover, it is becoming increasingly expensive. Pacific Gas and Electric has advised its customers that the average electricity bill will be $187 a month as of March 1, 2023, and increase of 5% from January 1, 2023. Over the past two years rates have risen by almost a third.6 Upper-income residents can afford backup generators to deal with blackouts, but poor and middle-income residents cannot. Food spoils in their refrigerators and their children cannot do homework without electricity for lights and computers. [EPA-HQ-OAR-2022-0829-0674, p. 3]

6 California Public Utilities Commission, Rate Change Advisories, https://www.cpuc.ca.gov/industries-and-topics/electrical-energy/electric-rates/rate-change-advisories (accessed April 30, 2023).

Electric vehicles are not emissions free. In addition to batteries made with fossil fuels, increased electricity demand places additional stress on the electrical grid, as California has found out from rolling blackouts. In its proposal, EPA discusses the benefits of reducing pollutants from cars,19 but higher emissions will come from the electricity generated to recharge the cars. This electricity is made with natural gas and coal, because wind and solar powers a small share of America's power. EPA admits that "We expect that in some areas, increased electricity generation would increase ambient SO2, PM 2.5, ozone, or some air toxics."20 [EPA-HQ-OAR-2022-0829-0674, p. 5]

Organization: The Mobility House et al.

While this development was troublesome for the EV industry, there were also clear implications for electric grid resilience following natural disasters. In spring 2022, the Biden Administration took the remarkable step of activating the Defense Production Act (DPA), deeming the shortage a national security threat and giving the Department of Energy temporary power to influence manufacturing of grid components in an attempt to increase supply. This was before the federal government's historic investment in transportation electrification via the Infrastructure Investment and Jobs Act and later the Inflation Reduction Act set timetables for deployment of electric school buses, electric transit buses, and a nationwide network of high-powered direct current chargers for fast refueling on highways, all of which will require unprecedented construction using the same components that were already in dangerously short supply. Congress has declined to fund the DPA activation, making it far less likely that the

United States can manufacture its way out of this situation. [EPA-HQ-OAR-2022-0829-0657, p. 1]

We, the undersigned businesses and organizations support the Biden Administration's new EV emissions standards as proposed. As leaders in transportation electrification, vehicle-grid integration, and power control systems (PCS) implementation, the signatories are uniquely positioned to recognize not only the significance of the Environmental Protection Agency's (EPA's) new proposals, but also the context in which they are made. We urge the EPA and other implementing agencies to prioritize strategies to enable use of PCS to facilitate coherent and efficient secondary and primary upgrade planning. [EPA-HQ-OAR-2022-0829-0657, p. 1]

As a result of industrial consolidation and pandemic-related supply chain disruption in 2020 and 2021, companies engaged in site development for electric vehicles (EVs) watched wait times for switchgear, and thus for site energization, extend from a standard eight weeks to fifty-two weeks. It became apparent in 2021 that transformers, switchgear, and even copper and aluminum for electric lines were increasingly scarce. [EPA-HQ-OAR-2022-0829-0657, p. 1]

While this development was troublesome for the EV industry, there were also clear implications for electric grid resilience following natural disasters. In spring 2022, the Biden Administration took the remarkable step of activating the Defense Production Act (DPA), deeming the shortage a national security threat and giving the Department of Energy temporary power to influence manufacturing of grid components in an attempt to increase supply. This was before the federal government's historic investment in transportation electrification via the Infrastructure Investment and Jobs Act and later the Inflation Reduction Act set timetables for deployment of electric school buses, electric transit buses, and a nationwide network of high-powered direct current chargers for fast refueling on highways, all of which will require unprecedented construction using the same components that were already in dangerously short supply. Congress has declined to fund the DPA activation, making it far less likely that the United States can manufacture its way out of this situation. [EPA-HQ-OAR-2022-0829-0657, p. 1]

On page 5-35 of its draft regulatory impact assessment, EPA recognizes that successful implementation of the new proposed emissions standards will likely lead to increased distribution upgrades. EPA then goes on to note that PCS may mitigate the need for infrastructure upgrades for a range of use cases. While we acknowledge that new distribution infrastructure will be necessary, we agree with EPA that acknowledging the ability of PCS to tap the inherent flexibility of many EV charging use cases will insert much-needed efficiency into EV-related distribution grid planning and buildout processes in the United States. [EPA-HQ-OAR-2022-0829-0657, p. 1]

The signatories of this letter represent a small subset of the universe of companies implementing PCS across market segments and use cases. This class of technologies includes both hardware and software solutions applicable across light, medium, and heavy-duty EV models in the residential, commercial, and fleet segments. PCS can facilitate a number of flexible use-cases, including but not limited to a combination of EV loads with co-sited solar and storage resources, use of batteries to mitigate EV load, intelligent scheduling of networked chargers to minimize aggregate load, batteries integrated into the chargers themselves, home energy management systems, new advanced electrical panels, price-responsive charging, bi-directional charging, enabling communications standards, and new metering technologies. PCS technologies are widely available but have historically been under-utilized as a means of minimizing grid impacts of new loads and integrating EVs to the grid. Simply put, efficiency in these areas was generally not necessary. Now, however, minimization, deferral, or planned phasing of upgrades based on use of PCS is increasingly enabling customers to subtract years from their project energization timeframe or save a project that would have been unable to proceed if a full-nameplate upgrade were required. [EPA-HQ-OAR-2022-0829-0657, pp. 1-2]

Organization: Transfer Flow, Inc

Electric Vehicles require the ramp-up of many new electricity-generating power plants to provide enough power to charge all the projected electric vehicles, and then those electricity-generating power plants must rely heavily on carbon capture technologies to keep the emissions from these electricity-generating power plants out of the atmosphere. Current carbon capture technologies are experimental and may prove dangerous.22 [EPA-HQ-OAR-2022-0829-0496, pp. 3-5]

22 https://www.huffpost.com/entry/gassing-satartia-mississippi-co2-pipeline_n_60ddea9fe4b0ddef8b0ddc8f

In many places, such as rural environments or for use in utility vehicles, electric vehicles are not a practical solution. Utility companies working on phone lines, power lines, and performing construction work all need reliable power sources that can be used for transporting people and powering equipment, as well as function when the electric power grid may be in need of repair. Electric vehicles do not have a network in remote areas or the energy density to effectively transport and power auxiliary equipment needed to, among other functions, install or perform repairs to electric power lines. [EPA-HQ-OAR-2022-0829-0496, pp. 3-5]

Pacific Gas and Electric (PG&E), two years after the historical Dixie Fire, is still powering affected Californians with diesel-powered generators as the infrastructure required to bring electricity into homes has still not been rebuilt. Citizens living in these affected areas would need to charge electric vehicles using electricity created from diesel generators, and the logistics of that simply do not make sense. [EPA-HQ-OAR-2022-0829-0496, pp. 3-5]

Organization: Travis Fisher

Specifically, the EPA's DRIA regarding the impact of the Proposed Rule on the cost and reliability of electricity in the U.S. is gravely flawed. It should be redrafted to enable the EPA Administrator to give appropriate consideration to the cost and safety factors of the Proposed Rule, as required by section 202 of the Clean Air Act.1 Further, the DRIA should address the interactions between the Proposed Rule and other EPA rules—including the recently proposed rule on greenhouse gas emissions from power plants2—as required by Executive Order 12866.3 As written, the Proposed Rule: [EPA-HQ-OAR-2022-0829-0655, p. 1]

2 New Source Performance Standards for Greenhouse Gas Emissions From New, Modified, and Reconstructed Fossil Fuel-Fired Electric Generating Units; Emission Guidelines for Greenhouse Gas Emissions From Existing Fossil Fuel-Fired Electric Generating Units; and Repeal of the Affordable Clean Energy Rule, 88 FR 33240; May 23, 2023. Available at: https://www.federalregister.gov/documents/2023/05/23/2023-10141/new-source-performance-standards-for-greenhouse-gas-emissions-from-new-modified-and-reconstructed (accessed July 2, 2023).

3 Executive Order 12866, Regulatory Planning and Review, 58 FR 51735; October 4, 1993. Available at: https://www.archives.gov/files/federal-register/executive-orders/pdf/12866.pdf (accessed July 2, 2023).

1. Violates section 202 of the Clean Air Act by failing to adequately consider:

A. Impaired bulk power system reliability and

B. Increased retail electricity prices;

2. Does not comply with Executive Order 12866; and

3. Violates the Unfunded Mandates Reform Act. [EPA-HQ-OAR-2022-0829-0655, p. 1]

A. THE PROPOSED RULE FAILS TO ADEQUATELY CONSIDER IMPAIRED BULK POWER SYSTEM RELIABILITY

The reliability of the electric grid is a matter of public health and safety. The connection between access to reliable electric power and public health and safety is well established: blackouts are a safety hazard worthy of the Administrator's consideration.5 As one recent example, hundreds of lives were lost during Winter Storm Uri in February 2021 due to a lack of reliable electricity supplies during a long-lasting extreme cold weather event.6 EPA should avoid contributing to such losses in the future. Unfortunately, because EPA unreasonably assumed the Proposed Rule will have no reliability impacts, it failed to consider the risks to human health stemming from unreliable electricity among the many issues discussed in Chapter 7 of the DRIA (Health and welfare impacts). [EPA-HQ-OAR-2022-0829-0655, p. 2]

5 Power Outages and Community Health: A Narrative Review, available at: https://www.ncbi.nlm.nih.gov/pmc/articles/PMC7749027/ ("The existing literature suggests that power outages have important health consequences ranging from carbon monoxide poisoning, temperature-related illness, gastrointestinal illness, and mortality to all-cause, cardiovascular, respiratory, and renal disease hospitalizations, especially for individuals relying on electricity-dependent medical equipment.")

6 See: https://comptroller.texas.gov/economy/fiscal-notes/2021/oct/winter-storm-impact.php (accessed July 2, 2023).

The Proposed Rule was issued after many serious warnings of supply shortfalls in the U.S. electricity system. PJM Interconnection, Inc. (PJM), the largest regional transmission organization in the U.S., has warned federal policymakers about the rapid retirement of generation resources. PJM notes: [EPA-HQ-OAR-2022-0829-0655, pp. 2-3]

Historically, thermal resources have provided the majority of the reliability services in PJM. Today, a confluence of conditions, including state and federal policy requirements, industry and corporate goals requiring clean energy, reduced costs and/or subsidies for clean resources, stringent environmental standards, age-related maintenance costs, and diminished energy revenues are hastening the decline in thermal resources.7 [EPA-HQ-OAR-2022-0829-0655, pp. 2-3]

7 Energy Transition in PJM: Resource Retirements, Replacements & Risks. February 24, 2023. Available at: https://www.pjm.com/-/media/library/reports-notices/special-reports/2023/energy-transition-in-pjm-resource-retirements-replacements-and-risks.ashx (accessed July 2, 2023) (emphases added).

The following figure illustrates forecast retirements in PJM, of which policy-driven retirements comprise the majority. The total expected closures—40 GW—represent 21 percent of PJM's installed generating capacity. Taken together, the suite of EPA regulations already impacting the supply side of the electricity sector poses a significant threat to the reliable operation of the nation's bulk power system. [EPA-HQ-OAR-2022-0829-0655, pp. 2-3]

[See original for graph titled "Retirement Capacity (GW ICAP)] [EPA-HQ-OAR-2022-0829-0655, pp. 2-3]

The North American Electric Reliability Corporation (NERC), which is the organization responsible for establishing mandatory reliability standards, is also sounding alarms. In its most recent Long Term Reliability Assessment (LTRA), NERC highlighted the significant grid reliability problems facing the United States in the near term. The LTRA states that "[w]ithin the 10-year horizon, over 88 GW of generating capacity is confirmed for retirement."8 Speaking to the press about the report, John Moura, NERC's director of reliability assessment and performance analysis, said "[w]e are living in extraordinary times, from an electric industry perspective. There are extraordinary reliability challenges and opportunities in front of us."9 [EPA-HQ-OAR-2022-0829-0655, p. 3]

8 2022 Long-Term Reliability Assessment. NERC. December 2022. Available at https://www.nerc.com/pa/RAPA/ra/Reliability%20Assessments%20DL/NERC_LTRA_2022.pdf (accessed July 2, 2023).

9 Most of US electric grid faces risk of resource shortfall through 2027, NERC finds. Utility Dive. December 16, 2022. Available at: https://www.utilitydive.com/news/nerc-grid-resource-adequacy-shortfall-reliability-assessment/638949/ (accessed July 2, 2023).

In May of this year, NERC released its Summer Reliability Assessment, which warned that "two-thirds of North America is at risk of energy shortfalls this summer during periods of extreme demand." Figure 1 from NERC's 2023 Summer Reliability Assessment shows the regions of the country that face an elevated risk of supply shortfalls this year.10 [EPA-HQ-OAR-2022-0829-0655, pp. 3-5]

10 2023 Summer Reliability Assessment, page 6. NERC. May 2023. Available at: https://www.nerc.com/pa/RAPA/ra/Reliability%20Assessments%20DL/NERC_SRA_2023.pdf.

[See original for graphic titled "Figure 1: Summer Reliability Risk Area Summary"]

These risks are well known. NERC has been warning about the speed of the energy transition for years, largely from the perspective of the changing supply resource mix. However, more recently, NERC has set up working groups to help maintain the reliability of the bulk power system under increased penetration of plug-in electric vehicles (PEVs). Earlier this year, NERC CEO Jim Robb said "As the electrification of the transportation sector continues to grow, the North American grid must be prepared. … Collaboration, innovation, and information sharing are critical if we are to be able to meet future demands successfully."11 [EPA-HQ-OAR-2022-0829-0655, pp. 3-5]

11 Cross-Sector Collaboration: Addressing the Potential Challenges from Electric Vehicle Grid Impacts, available at: https://www.nerc.com/news/Headlines%20DL/CMC%20EV%20Grid%20Reliability%20Working%20Group%20Re port%20Press%20Release_11APRIL23.pdf.

EPA should be involved in NERC working groups in order to base its rulemakings in sound science and to fully consider the safety impacts of its rules. Given the requirement in section 202 of the Clean Air Act that the Administrator consider safety factors, EPA should not move forward with a final rule (or a new proposed rule) until it reaches a better understanding of

NERC's warnings, including NERC's concerns about distribution-connected inverter-based resources like PEVs.12 [EPA-HQ-OAR-2022-0829-0655, pp. 3-5]

12 White Paper: BPS-Connected Inverter-Based Resource Priorities. NERC Task Force on Inverter-Based Resources. June 2020. Available at: https://www.nerc.com/comm/PC/InverterBased%20Resource%20Performance%20Task%20Force%20IRPT/IRPTF_Priorities_June_2020.pdf

NERC's elevated risk scenario is for this summer, meaning reliability challenges are already here. Hence any EPA proposal—including the Proposed Rule—to force an increase in demand or a decrease in supply will further weaken an already fragile state of grid reliability. The Proposed Rule creates a new safety hazard by forcing a rapid increase in electricity demand from PEVs amid an extraordinary and worsening supply crisis. The DRIA notes this tension but ultimately makes no adverse finding in Chapter 11 (Energy Security Impacts): [EPA-HQ-OAR-2022-0829-0655, p. 5]

It is difficult to assess the combined effects of higher demand for electricity from PEVs, increasing extreme weather events in the context of climate change, and the greater use of variable supply technologies, such as wind/solar power, on electricity grid reliability and resiliency issues in the U.S. In part, this is because there is little experience to assess the impacts of significant PEV use on U.S. electric grid reliability and resiliency.13 [EPA-HQ-OAR-2022-0829-0655, p. 5]

13 DRIA at 11-14 (PDF page 603).

Although it is true that EPA has little experience in assessing the impacts of increased PEV penetration, that is precisely why EPA should work more closely with grid experts before moving forward in this docket. [EPA-HQ-OAR-2022-0829-0655, p. 5]

Chapter 5 (Electric Infrastructure Impacts) of the DRIA makes similar findings regarding a lack of impact, but, in doing so, reveals a fundamental misunderstanding of the role of the Federal Energy Regulatory Commission (FERC). FERC is the federal agency responsible for ensuring the reliability of the bulk power system (and approving the mandatory standards drafted by NERC), and its authority lies at the transmission level. However, the DRIA states that EPA staff "consulted with FERC staff on distribution system reliability and related issues."14 If that is true, EPA staff talked to the wrong agency about the distribution system. Further, it is alarming that EPA staff seem unaware that FERC has no jurisdiction over the reliability of the distribution system. [EPA-HQ-OAR-2022-0829-0655, p. 5]

14 DRIA at 5-38 (PDF page 380).

The DRIA also misidentifies NERC as the "National Electricity Reliability Corporation." (As defined above, NERC is short for the North American Electric Reliability Corporation.) These mistakes in the DRIA indicate a lack of familiarity with the topic area and a fundamental misunderstanding of the role of FERC and NERC in overseeing the reliability of the bulk power system. If EPA moves forward with a final rule, it should explain the extent to which EPA staff have consulted with FERC and NERC regarding the Proposed Rule's impact to the reliability of the bulk power system. Absent better coordination and information sharing, it is impossible for the EPA Administrator to give "appropriate consideration" to the electric reliability impacts of the Proposed Rule as he is required to do under section 202 of the Clean Air Act. [EPA-HQ-OAR-2022-0829-0655, p. 5]

B. THE PROPOSED RULE FAILS TO ADEQUATELY CONSIDER INCREASED RETAIL ELECTRICITY PRICES

The Retail Price Model (RPM) and Integrated Planning Model (IPM) cited in the DRIA contain fundamental errors that allow EPA to claim the rule will not increase retail electricity prices. EPA's modeling is opaque, but upon close inspection it appears to selectively rely on business-as-usual scenarios for some inputs and altered assumptions in others. Taken together, EPA's electricity price modeling in the DRIA yields significantly flawed results and does not enable reasoned decision-making by the Administrator. [EPA-HQ-OAR-2022-0829-0655, p. 6]

First, the DRIA violates the law of supply. An outward shift in the demand curve for electricity will increase prices because the new, higher demand intersects the supply curve at a higher price point. This phenomenon is well established in the economics literature, and a specific application of the impact of increasing demand on wholesale electricity prices is outlined in detail in a tutorial by the New England Independent System Operator (see figure below).15 This effect holds regardless of the time of day a PEV user decides to charge the vehicle. [EPA-HQ-OAR-2022-0829-0655, p. 6]

15 See https://www.iso-ne.com/about/what-we-do/in-depth/how-resources-are-selected-and-prices-are-set (accessed July 2, 2023).

[See original for graph titled "Supply Stack"] [EPA-HQ-OAR-2022-0829-0655, p. 6]

Astonishingly, the DRIA states that "[r]egional average retail electricity price differences showed small increases or decreases (less than approximately 1 to 2 percent),"16 meaning that EPA's model violates the law of supply. In no case should a rule that forces the rapid electrification of the transportation fleet—which represents a large increase in the demand for electricity—cause a reduction in prices. This observation alone is enough to require EPA to rework its modeling. [EPA-HQ-OAR-2022-0829-0655, p. 6]

16 DRIA at 5-15 (PDF page 357) (emphasis added).

Second, the RPM states that the "models use generation-related outputs from an IPM-modeled scenario together with T&D and other cost projections and assumptions from EIA's AEO Reference Case to estimate the retail price of electricity."17 This is unreasonable because the increased T&D (transmission and distribution) costs of the Proposed Rule are not captured in the Energy Information Administration's Annual Energy Outlook Reference Case. That case is used as a baseline and should apply only to the "no-action" case analyzed in the DRIA. The Proposed Rule would certainly cause distribution costs to increase because PEVs require substantial and costly upgrades. For example, a recent report prepared for the California Public Utilities Commission "estimates up to $50 billion in traditional electricity distribution grid infrastructure investments by 2035."18 The Proposed Rule could also cause an increase in transmission costs if the demand increased triggered by the Proposed Rule necessitates an expansion of the transmission system. [EPA-HQ-OAR-2022-0829-0655, p. 7]

17 Documentation of the Retail Price Model, page 1. Available at: https://www.epa.gov/sites/default/files/2019-06/documents/rpm_documentation_june2019.pdf.

18 Electrification Impacts Study Part 1: Bottom-Up Load Forecasting and System-Level Electrification Impacts Cost Estimates. May 2023. Available at: https://docs.cpuc.ca.gov/PublishedDocs/Efile/G000/M508/K423/508423247.PDF

Finally, EPA's retail price estimates do not account for the loss in electricity supply resources caused by EPA rules. The DRIA should cross-reference the EPA rules impacting generating resources and rework the electricity price estimates after taking into account the reasonably foreseeable power plant closures caused by its own rules (see Section 1.A of this comment). [EPA-HQ-OAR-2022-0829-0655, p. 7]

Principle 6 states:

"Each agency shall assess both the costs and the benefits of the intended regulation and, recognizing that some costs and benefits are difficult to quantify, propose or adopt a regulation only upon a reasoned determination that the benefits of the intended regulation justify its costs." [EPA-HQ-OAR-2022-0829-0655, pp. 7-8]

EPA fails to comply with Principle 6 because it has not undertaken a reasonable assessment of the cost of the Proposed Rule. As discussed above, EPA does not fully account for the Proposed Rule's impacts on the electricity system, which include increasing the cost of electricity and harming electric grid reliability. [EPA-HQ-OAR-2022-0829-0655, pp. 7-8]

Principle 7 states:

"Each agency shall base its decisions on the best reasonably obtainable scientific, technical, economic, and other information concerning the need for, and consequences of, the intended regulation." [EPA-HQ-OAR-2022-0829-0655, p. 8]

EPA fails to comply with Principle 7 because, as detailed above, it has not availed itself of the ample scientific and technical information—well known and published by leading sources such as NERC, FERC, and PJM—regarding the consequences of EPA regulations on the cost and reliability of the electricity system. [EPA-HQ-OAR-2022-0829-0655, p. 8]

Principle 8 states:

"Each agency shall identify and assess alternative forms of regulation and shall, to the extent feasible, specify performance objectives, rather than specifying the behavior or manner of compliance that regulated entities must adopt." [EPA-HQ-OAR-2022-0829-0655, p. 8]

EPA fails to comply with Principle 8 because the Proposed Rule is a de facto mandate for PEVs. Much like the unlawful Clean Power Plan,23 the thrust of the Proposed Rule is to force a shift away from internal combustion engine vehicles and toward PEVs. Indeed, the performance objectives outlined in the Proposed Rule are only viable if the regulated entities—drivers in the U.S.—behave as specified by EPA. [EPA-HQ-OAR-2022-0829-0655, p. 8]

23 See https://archive.epa.gov/epa/cleanpowerplan/clean-power-plan-existing-power-plants-regulatory-actions.html (accessed July 2, 2023).

Principle 10 states:

"Each agency shall avoid regulations that are inconsistent, incompatible, or duplicative with its other regulations or those of other Federal agencies." [EPA-HQ-OAR-2022-0829-0655, p. 9]

EPA fails to comply with principle 10 because, as outlined in the section on electric grid reliability above, the Proposed Rule is incompatible with the suite of existing and new EPA regulations that are forcing a large reduction in electricity supply. Although a minor conflict with an obscure rule from a different agency might be forgivable, EPA's Proposed Rule unreasonably conflicts with a concurrent proposed rule issued by EPA—the Greenhouse Gas Standards and Guidelines for Fossil Fuel-Fired Power Plants, issued in May of 2023.24 In fact, it appears that the DRIA fails to reference or otherwise acknowledge the power plant rule. [EPA-HQ-OAR-2022-0829-0655, p. 9]

> 24 New Source Performance Standards for Greenhouse Gas Emissions From New, Modified, and Reconstructed Fossil Fuel-Fired Electric Generating Units; Emission Guidelines for Greenhouse Gas Emissions From Existing Fossil Fuel-Fired Electric Generating Units; and Repeal of the Affordable Clean Energy Rule, 88 FR 33240; May 23, 2023. Available at: https://www.federalregister.gov/documents/2023/05/23/2023-10141/new-source-performance-standards-for-greenhouse-gas-emissions-from-new-modified-and-reconstructed (accessed July 2, 2023).

If the EPA moves forward with a final rule, it should explain why it finds that the federal mandates included in the Proposed Rule would not significantly affect State, local, or Tribal governments. As drafted, the Proposed Rule does not detail how it has satisfied the above procedural requirements of the UMRA and does not indicate that the EPA has undertaken the required analysis of the impacts on states and local governments and tribes of compliance with the Proposed Rule. For example, some electric utilities are owned and operated by State, local or Tribal governments.27 The Proposed Rule will significantly impact the cost of the distribution systems of those publicly owned utilities, and the DRIA should be amended to evaluate the extent of the cost increases and the impact of the Proposed Rule on the budgets of State, local or Tribal governments. [EPA-HQ-OAR-2022-0829-0655, pp. 9-10]

Organization: U.S. Chamber of Commerce

-Impacts on grid reliability and resiliency. The electric grid will be called upon to handle increased demand during its own period of transition. By EPA's own estimates, deployment of EVs as envisioned by the proposed rule would increase power demand by 114 terawatt-hours (2.25 percent) nationwide by 2035. Some geographic regions and subregions will experience higher changes on a percentage basis, and as EPA notes in the proposed rule, EV charging will result in "large and abrupt electricity demand peaks" during certain periods of the day. This presents a major challenge for an electricity system that is now facing its most difficult reliability challenges in decades, and in which an already accelerated loss of existing dispatchable generating capacity could be exacerbated by EPA's concurrently proposed rule targeting these same types of electric generating facilities. The Chamber urges EPA to undertake thorough analysis of the impact of recent and forthcoming regulations and other policies on the cost and feasibility of this proposal. [EPA-HQ-OAR-2022-0829-0604, p. 3]

Organization: United Steelworkers (USW)

EPA only models for BEVs, even though our nation's electric grid is far from ready for the energy transition.8 America's electric grid will be sorely challenged by the need to deliver clean power to BEVs. Even today, the electric grid barely functions in times of ordinary stress, and fails altogether too often for comfort, as widespread blackouts in California, Texas, Louisiana, and other states have shown.9 Problems ranging from grid congestion to age of transmissions to demand for electric cannot be addressed overnight even with investments from the IRA and IIJA. EPA must work with DOE and other relevant departments and agencies to understand current bottlenecks, and the additional strain that a high percentage of BEVs would have on our electric grid. [EPA-HQ-OAR-2022-0829-0587, p. 5]

8 The New York Times, (Link: https://www.nytimes.com/interactive/2023/06/12/climate/us-electric-grid-energy-transition.html) "Why the U.S. Electric Grid Isn't Ready for the Energy Transition", June 12, 2023.

9 The Washington Post, (Link: https://www.washingtonpost.com/business/2021/10/13/electric-vehicles-grid-upgrade/) "Plug-in cars are the future. The grid isn't ready", October 16, 2021.

Organization: Valero Energy Corporation

Although EPA acknowledges that upgrades to electricity distribution systems may be required to meet the charging loads associated with EVSE, it immediately dismisses the costs, explaining that [EPA-HQ-OAR-2022-0829-0707, pp. 1-3]

"EPA acknowledges that there may be additional infrastructure needs and costs beyond those associated with charging equipment itself. While planning for additional electricity demand is a standard practice for utilities and not specific to PEV charging, the buildout of public and private charging stations (particularly those with multiple high-powered DC fast charging units) could in some cases require upgrades to local distribution systems. For example, a recent study found power needs as low as 200 kW could trigger the need to install a distribution transformer while a load of 5 MW or more could require upgrades to feeder circuits or the addition of a feeder breaker."9 [EPA-HQ-OAR-2022-0829-0707, pp. 1-3]

9 DRIA at 5-34 to 5-35.

"There is considerable uncertainty associated with future distribution upgrade needs as well as with the uptake of the technologies and approaches discussed above that could reduce upgrade costs, and we do not model them directly as part of our infrastructure cost analysis."10 [EPA-HQ-OAR-2022-0829-0707, pp. 1-3]

10 DRIA at 5-36.

Regardless of who is paying, upgrades to electrical infrastructure are real impacts associated with EVSE installation and come with real costs. In their EV Infrastructure Deployment Plans, several states quantify the cost of electrical system upgrades needed to accommodate EVSE, including: [EPA-HQ-OAR-2022-0829-0707, pp. 1-3]

- Idaho cites that "charging stations installed with NEVI formula funds must be able to provide a power output of at least 600kW. In Idaho, most NEVI sites will require transformer upgrades. Additional improvements such as installing new feeder lines and completing substation upgrades also may be needed. At the very least, new electrical upgrades for a new transformer cost approximately $20-30,000."11 [EPA-HQ-OAR-2022-0829-0707, pp. 1-3]

11 Idaho Transportation Department, "2022 State of Idaho Electric Vehicle Infrastructure Baseline Plan" at 38 (August 1, 2022), https://www.fhwa.dot.gov/environment/nevi/ev_deployment_plans/id_nevi_plan.pdf.

- Indiana cites that "Utilities estimated investment between $50,000 to $125,000 to serve 600kW per station with locations requiring significant system upgrades totaling greater than $1 million. Upgrades could include new transformers, trenching, concrete/asphalt work, conduit, underground vaults, new conductor, and other miscellaneous equipment to serve the DCFC. Respondents expressed they would not deny an installation from proceeding. However, as expressed above, costs may be prohibitive for the prospective customer at certain locations."12 [EPA-HQ-OAR-2022-0829-0707, pp. 1-3]

12 Indiana Department of Transportation, "Indiana Electric Vehicle Infrastructure Deployment Plan" at 37 (July 29, 2022), https://www.fhwa.dot.gov/environment/nevi/ev_deployment_plans/in_nevi_plan.pdf.

These utility costs may not be borne solely by individual customers; in some cases, these costs will ultimately be passed on to ratepayers. EPA fails to acknowledge these costs and fails to assess the cumulative cost burden resulting from the concurrent increase in electrical demand resulting from implementing the proposed LMD vehicle rule in the same time frame it seeks to force electrification of the heavy-duty vehicle fleet. [EPA-HQ-OAR-2022-0829-0707, pp. 1-3]

E. EPA does not adequately consider potential grid reliability impacts.

As part of its evaluation of potential economic impacts to the welfare of Americans and businesses, EPA must assess grid reliability impacts stemming from the proposed rule's forced electrification of the LD and MD transportation sector. Reliance on BEVs may have unintended, negative consequences, especially in relation to the electricity generation sector. In addition, EPA needs to accurately predict the number of additional chargers that will be needed to support the anticipated BEV population. At present, charging infrastructure is inadequate to meet the country's transportation needs.227 [EPA-HQ-OAR-2022-0829-0707, pp. 41-42]

227 See JD Power, "2023 U.S. Electric Vehicle Consideration (EVC) Study," June 15, 2023, and JD Power, "2023 U.S. Electric Vehicle Experience (EVX) Home Charging Study," March 16, 2023.

1. EPA's analysis of grid impacts and electrical reliability is unrealistic.

ZEV mandates like the proposed rule also present significant risks to grid reliability and the stability of the transportation sector, yet EPA's analysis of electrical grid impacts is weak. [EPA-HQ-OAR-2022-0829-0707, pp. 42-44]

- EPA expects that the proposed standards will drive an increase in electricity demand and generation across the U.S.228 [EPA-HQ-OAR-2022-0829-0707, pp. 42-44]

- EPA estimates an increase in electricity consumption in response to this proposal of 2 Terawatt-hours (TWh) in 2028 (a 0.04 percent increase), 18 TWh in 2030 (a 0.39 percent increase), 114 TWh in 2035 (a 2.25 percent increase), 195 TWh in 2040 (a 3.52 percent increase) and 252 TWh in 2050 (a 3.92 percent increase)."229 [EPA-HQ-OAR-2022-0829-0707, pp. 42-44]

- EPA does not expect grid reliability to be adversely affected by this increase in electricity demand and generation, as long as charging behavior is carefully managed.230 This begs the question who would manage charging behavior, by what authority, and based on what standards or criteria. In the absence of any specific and credible information about how charging behavior will be managed, it is unreasonable for EPA to assume that it will be. [EPA-HQ-OAR-2022-0829-0707, pp. 42-44]

- In its analysis of electric grid reliability, EPA refers to a 25% increase in electrical demand that occurred over 1992 to 2021 and concludes that since the increase in demand occurred “without any adverse effects on electric grid reliability or electricity generation capacity shortages,” “grid reliability is not expected to be adversely affected by the modest increase in electricity demand associated with electric vehicle charging.”231 However, this glib assessment overlooks the vast increase in inexpensive natural gas occurring during this period which made it possible to meet the increased demand without compromising reliability. It also overlooks the potential impacts to electrical grid costs and reliability from EPA’s recently proposed New Source Performance Standards for GHG emissions from power plants.232 [EPA-HQ-OAR-2022-0829-0707, pp. 42-44]

228 EPA’s Multi-Pollutant LMDV Proposal at 29311.

229 DRIA at 11-14.

230 DRIA at 11-14 to 11-17.

231 EPA’s Multi-Pollutant LMDV Proposal at 29311.

232 88 Fed. Reg. 33240 (May 23, 2023).

Considering the regional and temporal nature of the PEV charging load, the recent trends of seasonal strain on grid reliability, and the increasing replacement of baseload generation with intermittent renewable sources, EPA’s comparison to a national trend occurring over the past three decades is not relevant or meaningful. [EPA-HQ-OAR-2022-0829-0707, pp. 42-44]

EPA also acknowledges that “PEVs can pose challenges for electricity supply reliability if PEV charging is not coordinated.”233 EPA references efforts by California, public and private electrical utilities, major automakers, EV charging companies, and other organizations to demonstrate “the ability of U.S. electric utilities to reschedule up to 20 percent of electric vehicle charging loads occurring at any hour of the day to any other hour of the day,”234 and concludes that since the expected increase in electric power demand from PEV charging is less than 20%, “we do not anticipate it to pose grid reliability issues.”235 With this statement, EPA blithely disregards the regional variations in expected PEV uptake, electricity generation, electricity demand, and grid reliability. [EPA-HQ-OAR-2022-0829-0707, pp. 42-44]

233 DRIA at 11-16.

234 DRIA at 11-14 to 11-17.

234 EPA’s Multi-Pollutant LMDV Proposal at 29312.

235 EPA’s Multi-Pollutant LMDV Proposal at 29312.

In seeming contradiction to the confidence of its earlier statements on impacts to grid reliability, EPA acknowledges the difficulty and lack of experience in assessing the combined effects of higher PEV electricity demand with other variables that could affect the electrical grid: “Projections of PEV uptake will need to be accounted for by U.S. electric utilities and transmission system operators in their resource planning processes. It is difficult to assess the combined effects of higher demand for electricity from PEVs, increasing extreme weather events in the context of climate change, and the greater use of variable supply technologies, such as wind/solar power, on electricity grid reliability and resiliency issues in the U.S. In part, this is because there is little experience to assess the impacts of significant PEV use on U.S. electric grid reliability and resiliency.”236 [EPA-HQ-OAR-2022-0829-0707, pp. 42-44]

236 DRIA at 11-14.

EPA explains that most of the electric power grid is owned and operated by the private industry, with Federal, state, local, Tribal and territorial governments playing significant role in enhancing the reliability of the electric power grid.237 While EPA is neither the expert in nor holds responsibility for the reliability of the electrical power grid, the agency offers suggestions for accommodating the increased electricity demand, such as: [EPA-HQ-OAR-2022-0829-0707, pp. 42-44]

237 EPA's Multi-Pollutant LMDV Proposal at 29311.

- Grid operators incorporating vehicle-grid integration (VGI) technology to manage vehicle charging time and rate;238 [EPA-HQ-OAR-2022-0829-0707, pp. 42-44]

238 EPA's Multi-Pollutant LMDV Proposal at 29312.

- Utilities developing new electric utility tariffs, including submetering for PEVs;239 and [EPA-HQ-OAR-2022-0829-0707, pp. 42-44]

239 EPA's Multi-Pollutant LMDV Proposal at 29312.

- Encouraging the adoption of vehicle-to-grid (V2G) technology, "which allows electricity to be drawn from vehicles when not in use."240 [EPA-HQ-OAR-2022-0829-0707, pp. 42-44]

240 DRIA at 5-37, 11-16.

EPA does not account for the costs of these suggestions in its DRIA nor for any other safeguards to protect grid reliability. [EPA-HQ-OAR-2022-0829-0707, pp. 42-44]

EPA asserts that it has statutory authority to adopt technology-forcing standards for reducing emissions from motor vehicle tailpipes. CAA Section 202(a) does not authorize the agency to force grid operators to manage electrical loads in completely new ways, or to dictate vehicle charging behavior. Yet EPA must account for the costs and impacts on the grid in the RIA for the rule and consider such costs and impacts and the availability and reliability of the grid. [EPA-HQ-OAR-2022-0829-0707, pp. 42-44]

2. EPA fails to adequately account for the regionality of the increased electrical demand.

EPA explains in the Preamble that "the anticipation of a highly regionalized initial rollout of electric vehicles under the California ZEV program necessitated modeling of the regionalization of PEV charge demand in order to fully capture emissions and other impacts on the electric power sector."241 [EPA-HQ-OAR-2022-0829-0707, pp. 44-47]

241 EPA's Multi-Pollutant LMDV Proposal at 29303.

EPA discusses the integration of several models that it used to project and regionally disaggregate the electricity demand for PEV charging, as shown in Figure 5-1 of the Draft RIA.242 [EPA-HQ-OAR-2022-0829-0707, pp. 44-47]

242 DRIA at 5-2.

- First, for each compliance scenario considered by EPA, the OMEGA Compliance Model solves for the lowest cost compliance solution, thereby generating projections of national vehicles sales, stock, energy consumption, and tailpipe emissions. However, EPA acknowledges that "to produce estimates of the spatiotemporal charging loads needed for power sector emissions modeling, the national PEV stock from OMEGA must first be disaggregated regionally."243 [EPA-HQ-OAR-2022-0829-0707, pp. 44-47]

243 DRIA at 5-2.

- To regionally disaggregate the national PEV stocks, EPA indicates that it leverages NREL's "likely adopter model" (LAM).244 [EPA-HQ-OAR-2022-0829-0707, pp. 44-47]

244 DRIA at 5-2.

- NREL is actively engaged in transportation and mobility research and offers dozens of integrated modeling and analysis tools designed to "overcome technical barriers and accelerate the development of advanced technologies and systems" 245 – the LAM upon which EPA relies is not amongst these NREL tools. [EPA-HQ-OAR-2022-0829-0707, pp. 44-47]

- Rather, the LAM makes an appearance in an NREL report246 that predicts the relative likelihood of a household to purchase a PEV based on access to charging. This LAM is developed from 3,772 survey responses, calibrating likelihood to purchase a PEV with household income, state of residence (i.e., whether or not the state has ZEV initiatives), housing type and tenure, and population density of the residential location.247 The NREL study is nice work, but EPA's reliance on the study for this application is wholly unsuitable. [EPA-HQ-OAR-2022-0829-0707, pp. 44-47]

- Figure 3 of the NREL report shows the geographical distribution of survey respondents used to develop the LAM, almost none of which are located in the Midwest states or other areas of low population density.248 Based on the geographical distribution of survey respondents, the LAM offers EPA no insight into or basis for estimating the PEV update and grid reliability impacts for most of the United States. [EPA-HQ-OAR-2022-0829-0707, pp. 44-47]

245 https://www.nrel.gov/transportation/adopt.html.

246 Ge, et al, "There's No Place Like Home: Residential Parking, Electrical Access, and Implications for the Future of Electrical Vehicle Charging Infrastructure," 2021.

247 Ge, et al at 3-4.

248 Ge, et al at 5.

[See original for graphic titled "Figure 3. Geographic Distribution of the survey respondents overlaid on a population density map] [EPA-HQ-OAR-2022-0829-0707, pp. 44-47]

- Ge, et al thoroughly acknowledge the limitations of the survey and the resulting LAM, none of which are acknowledged by EPA in its adoption of the LAM: [EPA-HQ-OAR-2022-0829-0707, pp. 44-47]

- "Our final respondent sample underrepresents the highest income bracket, overrepresents those with higher levels of education (e.g., those with bachelor's degrees), underrepresents those with lower levels of education, underrepresents single-family detached housing, and overrepresents single-family attached housing and high-capacity apartments."249 [EPA-HQ-OAR-2022-0829-0707, pp. 44-47]

- “Admittedly, the likely adopter model estimated in this study is not able to account for PEV owners’ preference that could cause this result to vary. For example, some PEV owners might prefer to have a traditional gasoline vehicle in the household to cover long-distance travel. Therefore, the accuracy of the results on the vehicle ranking is subject to further scrutiny once a more accurate PEV likely adopter model is available. “250 [EPA-HQ-OAR-2022-0829-0707, pp. 44-47]

- “There are several limitations to this analysis, and some require future research to improve accuracy. Sampling error associated with a small sample size compared to the reference population is a concern. Because the U.S. population is so large, and the PEV market is still in its infancy, a large sample is necessary to reach enough vehicle (PEV and non-PEV) owners to guarantee an adoption model with results at a high confidence interval.”251 [EPA-HQ-OAR-2022-0829-0707, pp. 44-47]

- “The adoption model suffers from data limitations, such as low goodness of fit and predictive power, due to the omission of psychological variables.” “The survey also relied on the respondents’ non-technical judgement about the ability to extend electrical access to their home parking option. It is unclear if this subjective assessment over-or underestimates the true potential of enhanced electrical access scenarios.”252 [EPA-HQ-OAR-2022-0829-0707, pp. 44-47]

- “This analysis assumes ceteris paribus conditions. Specifically, we project future results based on historic data. However, due to the early stage of PEV adoption, an adoption model calibrated on the current PEV owners is not ideal for projecting adoption likelihood in the future.”253 [EPA-HQ-OAR-2022-0829-0707, pp. 44-47]

- “The analysis herein was conducted without a specific time scale in mind. In particular, we did not incorporate a specific timeline associated with achieving different PEV penetration levels. Time-specific factors, such as vehicle replacement, turnover, and scrappage rates, were likewise not incorporated.” “The national-level results shown here may not be representative of the residential charging accessibility of smaller regions as it does not distinguish location-specific characteristics other than density class.”254 [EPA-HQ-OAR-2022-0829-0707, pp. 44-47]

- “The framework established in this study can be adapted and improved with higher accuracy PEV adoption modeling and with further increased PEV market penetration.”255 [EPA-HQ-OAR-2022-0829-0707, pp. 44-47]

249 Ge, et al at 6.

253 Ge, et al at 25.

254 Ge, et al at 25-26.

255 Ge, et al at 26.

• EPA then purports to have developed four chassis-specific LAMs – a LAM each for PEV sedans, PEV S/CUVs, PEV pickups, and PEV vans,256 but neither the basis nor the results are provided for review by stakeholders. How did EPA go about establishing chassis-specific LAMs when the original NREL report mentioned nothing about vehicle classifications? Did EPA resurvey the 3,772 respondents with new questions relating to vehicle classification? Did EPA conduct a separate survey for commercial vehicle use to support its truck and van LAMs? Why is none of this provided in the docket? [EPA-HQ-OAR-2022-0829-0707, pp. 44-47]

256 DRIA at 5-3.

• The only results that EPA shares from its chassis-specific LAMs fit into a roughly 1-square inch corner of DRIA Figure 5-2.257 Despite the lack of LAM survey respondents in the Midwest and Alaska, EPA inexplicably projects these regions to have the highest PEV pickup stocks of the entire United States. [EPA-HQ-OAR-2022-0829-0707, pp. 44-47]

257 DRIA at 5-3. "PEV adoption (IPM region-level)" image within Figure 5-2.

• Without an adequate understanding or representation of the regional PEV adoption that its proposed standards would drive, EPA uses the results of its chassis-specific LAMs to feed into NREL's EVI-X modelling suite, which simulates PEV charging infrastructure requirements and spaciotemporal electricity loads.258 [EPA-HQ-OAR-2022-0829-0707, pp. 44-47]

258 DRIA at 5-2.

• Finally, EPA aggregates county-level load profiles into its Integrated Planning Model (IPM), which provides projections of least-cost capacity expansion, electricity dispatch, and emission control strategies for meeting energy demand and environmental, transmission, dispatch, and reliability constraints.259 [EPA-HQ-OAR-2022-0829-0707, pp. 44-47]

259 DRIA at 5-2.

EPA's assessment of local and temporal impacts to the electrical grid is entirely discredited by its failure to reasonably disaggregate national PEV adoption. [EPA-HQ-OAR-2022-0829-0707, pp. 44-47]

3. EPA fails to recognize existing grid reliability concerns.

EPA's analysis of impacts to the electrical power grid overlooks existing grid reliability issues such as the following: [EPA-HQ-OAR-2022-0829-0707, pp. 47-48]

• The North American Electric Reliability Corporation's (NERC's) "2023 Summer Reliability Assessment" warns that two-thirds of North America is at risk of energy shortfalls this summer during periods of extreme demand. While there are no high-risk areas in this year's assessment, the number of areas identified as being at elevated risk has increased. The assessment finds that, while resources are adequate for normal summer peak demand, if summer temperatures spike, seven areas — the U.S. West, SPP and MISO, ERCOT, SERC Central, New England and Ontario — may face supply shortages during higher demand levels.260 [EPA-HQ-OAR-2022-0829-0707, pp. 47-48]

260 NERC, "2023 Summer Reliability Assessment" (May 17, 2023), https://www.nerc.com/news/Headlines%20DL/Summer%20Reliability%20Assessment%20Announcement%20May%202023.pdf.

• NERC's "2022-2023 Winter Reliability Assessment" warned that a large portion of the North America BPS was at risk of insufficient electricity supplies during peak winter conditions, including Texas RE-ERCOT, MISO, SERC-East, WECC-Alberta, NPCC-Maritimes, NPCC-New England.261 [EPA-HQ-OAR-2022-0829-0707, pp. 47-48]

261 NERC, "2022-2023 Winter Reliability Assessment" (November 2022), https://www.nerc.com/pa/RAPA/ra/Reliability%20Assessments%20DL/NERC_WRA_2022.pdf.

• NERC's "2022 Long Term Reliability Assessment" identifies three high risk areas – MISO, NPCC-Ontario, and the California/Mexico part of WECC – that are projected to not have adequate electricity supply to meet demand forecasts associated with normal weather over the 10-year assessment period. Several other areas are identified as having elevated risk, i.e., meeting the resource adequacy criteria for normal forecasted conditions but at risk of shortfall in extreme conditions. These areas include the U.S. West—CA/MX, Western Power Pool (WPP), and the Southwest Reserve Sharing Group (SRSG), Texas RE-ERCOT, SPP and New England. Specific recommendations from NERC to manage the risks include considering "the impact that the electrification of transportation, space heating, and other sectors may have on future electricity demand and infrastructure."262 [EPA-HQ-OAR-2022-0829-0707, pp. 47-48]

262 NERC, "2022 Long-Term Reliability Assessment" (December 2022), https://www.nerc.com/pa/RAPA/ra/Reliability%20Assessments%20DL/NERC_LTRA_2022.pdf.

• As California has faced rolling blackouts and historic energy prices, Governor Newsom in his May 2022 state budget proposal, has pivoted to the use of traditional fuel infrastructure to ensure system reliability to protect against outages. Approximately one week after the California Air Resources Board approved its "Advanced Clean Cars II" rule prohibiting sales of new ICEV passenger cars in California by 2035, Governor Gavin Newsom issued a statewide request for electric vehicle owners to refrain from charging their vehicles in order to prevent blackouts.263 [EPA-HQ-OAR-2022-0829-0707, pp. 47-48]

263 https://www.nytimes.com/2022/09/01/us/california-heat-wave-flex-alert-ac-ev-charging.html.

• Twelve states expressed concerns regarding electrical grid and utility impacts in their DOT-approved state EV Infrastructure Deployment Plans, as summarized below. EPA has not accounted for these concerns in its analysis. [EPA-HQ-OAR-2022-0829-0707, pp. 47-48]

State: Hawaii

Concern: HDOT submits requests for discretionary exceptions based on grid capacity, "as there is insufficient power availability in areas where charging stations must be installed" and "delivering sufficient power requires significant upgrades to existing infrastructure. In evaluating the grid capacity, HDOT considered renewable energy sources, like photovoltaic panels, and has determined that this approach is also infeasible in supporting these charging facilities."264 [EPA-HQ-OAR-2022-0829-0707, pp. 47-48]

264 "National Electric Vehicle Infrastructure (NEVI) Hawai'i State Plan" at 39 (July 2022), https://www.fhwa.dot.gov/environment/nevi/ev_deployment_plans/hi_nevi_plan.pdf.

State: Idaho

Concern: "Idaho's utilities will need to assess grid capacity and plan for increased demand as EV adoption grows in Idaho. Today, most challenges relating to EV charging occur at the distribution system level." "In most, if not all, areas, transformer upgrades will be needed. Additional improvements such as installing new feeder lines and completing substation upgrades may also be required at some sites."265 [EPA-HQ-OAR-2022-0829-0707, pp. 47-48]

265 Idaho Transportation Department, "2022 State of Idaho Electric Vehicle Infrastructure Baseline Plan" at 31 (August 1, 2022), https://www.fhwa.dot.gov/environment/nevi/ev_deployment_plans/id_nevi_plan.pdf.

State: Illinois

Concern: "Illinois may run into challenges related to sufficient electric grid capacity, particularly in rural areas of the state. Acceptable locations for charging stations may be limited or may require additional make-ready investments either by site hosts or utilities. This could increase the cost of these stations or delay the timeline for implementation."266 [EPA-HQ-OAR-2022-0829-0707, pp. 47-48]

266 Illinois Department of Transportation, "Illinois Electric Vehicle Infrastructure Deployment Plan" at 23 (August 1, 2022), https://www.fhwa.dot.gov/environment/nevi/ev_deployment_plans/il_nevi_plan.pdf.

State: Maine

Concern: "The Roadmap already recognizes electric grid issues as a challenge. In the short term, demand charges increase the operating costs for DCFC. In the longer term, as EV adoption rates increase, particularly when combined with other electrification, there will be a need for new grid capacity in certain areas."267 [EPA-HQ-OAR-2022-0829-0707, pp. 48-50]

267 Maine DOT, "Maine Plan for Electric Vehicle Infrastructure Deployment" at 31 (July 2022), https://www.fhwa.dot.gov/environment/nevi/ev_deployment_plans/me_nevi_plan.pdf.

State: Maryland

Concern: "Electrification of the transportation sector will lead to an increase in electrical demand on the grid. Existing infrastructure may not be able to support the increase and require upgrades to ensure the grid can reliably support the increase in electrical load."268 [EPA-HQ-OAR-2022-0829-0707, pp. 48-50]

268 Maryland Department of Transportation, "Maryland State Plan for National Electric Vehicle Infrastructure (NEVI) Formula Funding Deployment" at 19 (July 15, 2022), https://www.fhwa.dot.gov/environment/nevi/ev_deployment_plans/md_nevi_plan.pdf.

State: Montana

Concern: "NorthWestern Energy, Montana's largest utility provider, anticipates about an 800-megawatt (MW) peaking capacity deficit by 2030 without the addition of new peaking capacity resources (peaking capacity is the amount of power that can be delivered during times of maximum electricity demand)."269 [EPA-HQ-OAR-2022-0829-0707, pp. 48-50]

269 "Montana Electric Vehicle Infrastructure Deployment Plan" at 10 (July 28, 2022), https://www.fhwa.dot.gov/environment/nevi/ev_deployment_plans/mt_nevi_plan.pdf.

State: New Jersey

Concern: "There are areas with little to no existing capacity to accommodate the minimum 600 kW required. In addition, based on the dense population of the State there are certain locations along AFCs where there may not be grid capacity or site hosts within 1 mile from the exit ramp."270 [EPA-HQ-OAR-2022-0829-0707, pp. 48-50]

270 "New Jersey's National Electric Vehicle Infrastructure (NEVI) Deployment Plan" at 25 (August 1, 2022), https://www.fhwa.dot.gov/environment/nevi/ev_deployment_plans/nj_nevi_plan.pdf.

State: New Mexico

Concern: "While grid capacity may be a concern in the future, it is not the primary issue in most areas. Utilities are predominately concerned with significant transformer upgrades and the long lead times the industry is experiencing in the supply chain. Utilities may not be able to obtain the equipment necessary to begin upgrades and construction in a timely manner."271 [EPA-HQ-OAR-2022-0829-0707, pp. 48-50]

271 New Mexico Department of Transportation, "New Mexico EV Infrastructure Deployment Plan" at 7 (July 13, 2022), https://www.fhwa.dot.gov/environment/nevi/ev_deployment_plans/nm_nevi_plan.pdf.

State: North Dakota

Concern: "In addition, stakeholders that represented utility agencies were concerned about the demand on the power grid, especially during peak demand."272 [EPA-HQ-OAR-2022-0829-0707, pp. 48-50]

272 North Dakota Transportation, "Electric Vehicle Infrastructure Plan" at 17 (2022), https://www.fhwa.dot.gov/environment/nevi/ev_deployment_plans/nd_nevi_plan.pdf.

State: Pennsylvania

Concern: "PennDOT has also heard through stakeholder outreach that utility demand charges continue to be a barrier for the more rapid deployment of economically self-sustaining DCFC stations."273 [EPA-HQ-OAR-2022-0829-0707, pp. 48-50]

273 Pennsylvania Department of Transportation, "Pennsylvania State Plan for Electric Vehicle Infrastructure Deployment" at 49 (July 21, 2022), https://www.fhwa.dot.gov/environment/nevi/ev_deployment_plans/pa_nevi_plan.pdf.

State: Utah

Concern: "Lack of grid availability: Some rural and remote areas do not have any existing power infrastructure. In UDOT's previous VW/DEQ grant project, three-phase power did not exist at two sites. The estimated cost to bring three-phase power to two of the sites was quoted at double the entire project budget."274[EPA-HQ-OAR-2022-0829-0707, pp. 48-50]

274 UTDOT, "Utah Plan for Electrical Vehicle Infrastructure Deployment" at 34 (July 2022), https://www.fhwa.dot.gov/environment/nevi/ev_deployment_plans/ut_nevi_plan.pdf.

State: Washington

Concern: "Grid challenges are another known risk and challenge. Washington's electric power system requires substantial alteration. New or expanded transmission capacity is required for access to the best renewable resources and to take full advantage of coordination opportunities across the West."275 [EPA-HQ-OAR-2022-0829-0707, pp. 48-50]

275 "Washington State Plan for Electric Vehicle Infrastructure Deployment" at 27 (July 2022), https://www.fhwa.dot.gov/environment/nevi/ev_deployment_plans/wa_nevi_plan.pdf.

B. EPA has inappropriately made the 0 g/mile upstream incentive permanent in the proposed rule.

EPA has proposed to "indefinitely exclude upstream emissions from BEV compliance calculations."332 EPA has long maintained that its decision to not count upstream emissions from BEVs was to provide a "temporary regulatory incentive."333 A temporary incentive was appropriate because while EVs do not have a tailpipe, the incentive did not "reflect the increase in upstream GHG emissions associated with electricity used by EVs."334 As EPA explained, in 2010 a midsize EV caused a net upstream GHG emissions increase of about 120 grams/mile compared to a midsize gasoline car.335 EPA's proposal to permanently extend this incentive is entirely unmerited. [EPA-HQ-OAR-2022-0829-0707, pp. 62-64]

332 Proposed Rule at 29247.

333 See Light-Duty Vehicle Greenhouse Gas Emission Standards and Corporate Average Fuel Economy Standards; Final Rule, 75 Fed. Reg. 25324, 25434–5 (May 7, 2010) (hereinafter 2010 rule); 2017 and Later model Year Light-Duty Vehicle Greenhouse Gas Emissions and Corporate Average Fuel Economy Standards, 77 Fed. Reg. 62624, 62650–1 (Oct. 15, 2012) ("In order to provide temporary regulatory incentives . . . EPA is [] finalizing. . . a value of 0 g/mile."); see also, Proposed Rule at 185 ("[T]he 0 g/mile accounting was temporary.").

334 2010 Rule at 25435.

335 Id.

EV charging necessarily affects the grid, one such effect is a contribution to greater electricity demand during peak demand hours.336 While today's grid has seen some emissions reductions in annual total output emission rates since 2010,337 based on EPA's own prior analysis, upstream greenhouse gas emissions would have needed to fall by two-thirds (or ~66%) from 2010 to the present day before the upstream emissions increase caused by EVs is equivalent to the ICE's upstream emissions.338 But greenhouse emissions, from a pure generation-basis perspective, have not fallen by nearly the required amount based on EPA's most recently available data.339 [EPA-HQ-OAR-2022-0829-0707, pp. 62-64]

336 See Siobhan Powell et al., Charging infrastructure access and operation to reduce the grid impacts of deep electric vehicle adoption, NATURE ENERGY 7, at 932 (Jan. 1, 2022).

337 Cf. eGRID 9th edition Version 1.0 Year 2010 GHG Annual Output Emission Rates, EPA (Feb. 2015), https://www.epa.gov/sites/default/files/2015-02/documents/egrid_9th_edition_v1-0_year_2010_ghg_rates.pdf , with eGRID Summary Tables 2021, EPA (Jan. 30, 2023), https://www.epa.gov/system/files/documents/2023-01/eGRID2021_summary_tables.pdf

338 See 2010 Rule, 75 Fed. Reg. 25435.

339 In 2010, the U.S. average GHG emissions rate for electricity was 1,238.52 lbs/MWh CO2e (eGRID 9th edition Version 1.0 year 2010 GHG Annual Output Emission Rates, supra). But in 2021, the U.S. average GHG emissions rate was 857.0 lbs/MWh CO2e (eGRID Summary Tables 2021, supra , at 2), that means U.S. average GHG emissions have only fallen by approximately one-third.

Even worse, the emissions associated with power plants called upon to supply the grid at peak hours generally have higher emissions per generated MWh.340 A fact borne out in EPA's data that shows that non-baseload power, which reflects the power dispatched to the grid during peak demand,341 has not seen any major declines in CO2 emissions since 2010, and is worse than the emissions associated with baseload power in 2010.342 This data suggests that the impact of EVs on CO_2 emissions might be, at best, nearly identical to the upstream emissions increase in 2010. Regardless of which emissions source is used to calculate an EV's true footprint. Indeed, the table below illustrates just how arbitrary and inappropriate it is for EPA's proposal to ignore the upstream emissions increase caused by electric vehicle in light of this reality. [EPA-HQ-OAR-2022-0829-0707, pp. 62-64]

340 See DOE, Emission Reduction Calculation Roadmap (Jan. 2019), https://www.energy.gov/sites/default/files/2019/01/f58/Emission_Roadmap_FINAL.pdf

341 Susy S. Rothschild & Art Diem, Total, Non-baseload, EGRID Subregion, State? Guidance on the Use of eGRID Output Emission Rate, at 5 (last accessed May 2023), https://www3.epa.gov/ttn/chief/conference/ei18/session5/rothschild.pdf

342 In 2010, baseload power GHG emissions rate was 1,238.52 lbs/MWh CO_2e (eGRID 9th edition Version 1.0 year 2010 GHG Annual Output Emission Rates, supra). In 2021, non-baseload GHG emissions rate was 1,417.3 lbs/MWh CO_2e (eGRID Summary Tables 2021, supra , at 2). Despite the fact that "non-baseload values should not be used for assigning an emissions value for electricity," (Rothschild & Diem, supra) the non-baseload emissions rate reflects emissions for plants "that operate coincident with peak demand for electricity." (id.) Because EVs are expected to increase demand at peak hours (See Powell et al., supra) this may be the proper emissions rate to use when evaluating the upstream emissions associated with EVs.

eGRID CO_2e Emissions [EPA-HQ-OAR-2022-0829-0707, pp. 62-64]		EV Upstream CO_2e Emissions[343]	ICEV Upstream CO_2e Emissions[344]	Net Increase[345]
2010	1,238.52 lbs/MWh[346]	173.6 g/mile	60 g/mile	113.6 g/mile
2021	857.0 lbs/MWh[347]	120.1 g/mile	60 g/mile	60.1 g/mile
2021	1,417.3 lbs/MWh[348]	198.6 g/mile	60 g/mile	138.6 g/mile

[EPA-HQ-OAR-2022-0829-0707, pp. 62-64]

343 Calculated based on 2022 Tesla Model 3 Long Range AWD with an efficiency of 0.26 kWh/mi (see https://www.fueleconomy.gov/feg/Find.do?action=sbs&id=45011). Calculation uses an EV charging efficiency of 90% and a transmission efficiency of 93.5% (EPA LMDV OMEGA GHG Compliance Modeling Runs, "onroad_fuels_20220325.csv," supra).

344 See 2010 Rule, 75 Fed. Reg. 25435. Refers to a "typical midsize gasoline car."

345 Calculated as (EV upstream CO_2e emissions) – (ICEV upstream CO_2e emissions).

346 EPA eGRID 9th edition Version 1.0 year 2010 GHG Annual Output Emission Rates.

347 EPA eGRID Summary Tables 2021.

348 Reflects non-baseload power emissions. (See eGRID Summary Tables 2021, supra , at 2.)

Organization: Western Energy Alliance

it is hard to fathom how EPA comes to that conclusion. The electric grid is in no way capable of handling the huge increase in electricity demand that the rule would require, the United States does not have access to the critical minerals required for such a high market penetration of EVs, nor is the increased wind and solar energy generation available now nor in the foreseeable future to make supposedly ZEVs actually ZEVs. EPA has failed to adequately consider the impact of this rule on grid reliability. EPA should analyze grid reliability in this rulemaking and reference the large body of work raising concerns about how increased EVs will destabilize the grid.1 Without the grid capability and the critical minerals, EPA's EPA Proposed Rule on Light-Duty Vehicle Emissions Standards July 5, 2023 statement on technical feasibility is logically flawed, as current and projected grid infrastructure cannot support the goal of the proposed rule. [EPA-HQ-OAR-2022-0829-0679, pp. 2-3]

1 For example see E lectric Vehicle Dynamic Charging Performance Characteristics during Bulk Power System D isturbances, North American Electric Grid Reliability Corp. et al., April 2023; T estimony of Federal Energy Regulatory Commissioners Willie Phillips, Mark Christie, and James Danly before the Senate Energy & Natural Resources Committee, May 4, 2023, warning: "We face unprecedented challenges to the reliability of our nation's electric system."…the U.S. electric grid is "heading for a very catastrophic situation in terms of reliability…" and there is a "looming reliability crisis in our electricity markets."

EPA must reconsider its analysis on technical feasibility by considering a full range of data on grid reliability. The Rapid Energy Policy Evaluation and Analysis Toolkit Domestic, a project of Princeton University, projects electricity demand would need to increase 18% by 2030 and 38% by 2035 to meet the president's EV goals.2 Many are warning of the lack of infrastructure to support the EV goals. The nation would need to spend $20 billion to $30 billion annually on new transmission lines for the increased demand, but is spending next to nothing.3 [EPA-HQ-OAR-2022-0829-0679, p. 3]

2 Preview: Final REPEAT Project Findings on the Emissions Impacts of the Inflation Reduction Act and Infrastructure Investment and Jobs Act, Rapid Energy Policy Evaluation and Analysis Toolkit, Princeton University, April 2023.

3 Rob Gramlich, founder and president of Grid Strategies, a transmission policy group, as quoted in "Why the electric vehicle boom could put a major strain on the U.S. power grid," CNBC, July 1, 2023.

Further, it is not at all clear that the proposed rule will reduce GHGs as planned. Pure plug-in battery-powered vehicles can create more emissions than hybrid EVs (HEV) and even more than some traditional ICEVs for a variety of reasons including the fuel mix of the electrical grid where the EV is being charged and the large GHG footprint for producing the battery. The manufacture of a battery can produce GHGs equivalent to driving 24,000 miles, in the case of a Nissan Leaf up to 60,000 miles in the case of a Tesla Model S.4 Those numbers are before a single mile is driven by the supposed ZEV with its associated GHGs from the electricity used. When CO2 emissions linked to the production of batteries and the energy mix are considered, a study in Germany found EVs emit 11% to 28% more than their diesel counterparts.5 Volvo reports that in comparing a gas-burning model with its fully electric equivalent, with both vehicles built in the same factory, on the same assembly line, and sharing a large number of components, it found the electric version results in 70% more emissions.6 [EPA-HQ-OAR-2022-0829-0679, p. 3]

4 "A Data-Driven Greenhouse Gas Emission Rate Analysis for Vehicle Comparisons," SAE International, Journal of Electrified Vehicles, V132-14EJ, April 13, 2022.

5 Kohlemotoren, Windmotoren und Dieselmotoren: Was zeigt die CO2-Bilanz?, Crhristoph Buchal et al., Ifo Institut, 2019.

6 “Building An EV Produces 70% More Emissions Than ICE, Says Volvo,” InsideEVs, Andrei Nedelea, November 20, 2021.

EPA needs better analysis of the GHG reductions by EVs. The assumption that they are “zero emission” must be tested using a more comprehensive analysis of full lifecycle emissions sources from EVs. [EPA-HQ-OAR-2022-0829-0679, p. 3]

Arbitrary and Capricious

The proposed rule is arbitrary and capricious because EPA relies on incomplete facts, biased studies, and mistaken assumptions in an attempt to restructure the entire vehicle market. The rule exposes the country to severe grid instability and increases the chances for electricity blackouts and brownouts. EPA’s reasoning and justification for the rule are similarly flawed, based on a market assessment that is faulty. [EPA-HQ-OAR-2022-0829-0679, p. 8]

EPA relies on rosy market projections, citing a Bloomberg New Energy Finance analysis suggesting that, “under current policy and market conditions, and prior to the IRA, the U.S. was on pace to reach 40 to 50 percent PEVs by 2030. When adjusted for the effects of the Inflation Reduction Act, this estimate increases to 52 percent.” (p. 29189) EPA also cites the International Council on Clean Transportation as projecting an increase in new car sales of 67%. EPA should conduct a more robust market analysis with less biased sources if it is to avoid the charge of being arbitrary and capricious. [EPA-HQ-OAR-2022-0829-0679, p. 8]

However, with the generous assumption that the market penetration numbers are correct, then why does EPA need to move forward with this rule at all? If EPA is right and EV sales will increase to 67% by 2032 anyway, why is the rule necessary? We are inclined to think that a more robust market analysis would reach another conclusion, especially as market penetration increases and the effects from the strain on the electrical grid would become apparent. Given the fundamental lack of authority to force this transition, EPA’s own analysis of market penetration by 2032 suggests the rule is unwise. [EPA-HQ-OAR-2022-0829-0679, p. 8]

Organization: World Resources Institute (WRI)

Thus, we urge EPA to strengthen and finalize the strongest rule possible as [EPA-HQ-OAR-2022-0829-0544, pp. 1-3]

1. Complementary policies provide incentives for vehicle manufacturers and consumers in the transition; and
2. Strong private investments are rapidly expanding supply chains and manufacturing, helping to accelerate the transition to cleaner, electric vehicles.[EPA-HQ-OAR-2022-0829-0544, pp. 1-3]

Organization: Zero Emission Transportation Association (ZETA)

Expanded EV deployment will lead to significant changes to the 24-hour electricity demand cycle. By incorporating emerging technologies such as power storage and grid-scale battery technology, using smart software to optimize charging schedules, capitalizing on time-of-use rates, and ensuring strategic charging buildout, transportation electrification has the potential to become a mechanism for reinforcing and stabilizing U.S. electricity infrastructure. [EPA-HQ-OAR-2022-0829-0638, p. 2]

c. Electricity Generation and Grid Readiness

Transitioning to zero-emission transportation offers a unique challenge to the energy companies that will need to ensure they have ample electricity supply to match EV-driven demand. At minimum, this will require investments in the electricity distribution system to enable the deployment of electric vehicle charging equipment. In some instances, this may also require investing in new energy generation sources and associated distribution system infrastructure to accommodate high-use EV charging centers. [EPA-HQ-OAR-2022-0829-0638, pp. 45-46]

However, this is not the first time electricity providers have navigated increases in electricity demand brought on by new technologies: similar spikes accompanied the mass adoption of now-standard appliances like refrigerators and in-home air conditioners. Still, it will be important to ensure that providers and government agencies can work within their regulatory frameworks to test solutions and upgrade the grid to prepare for future demand increases accompanying greater EV adoption. [EPA-HQ-OAR-2022-0829-0638, pp. 45-46]

This section will discuss the growing energy demands of widespread EV adoption and new potential hotspots for energy demand. It will also use case studies to highlight how electricity providers are preparing for this transition. These case studies showcase solutions that have the potential to revolutionize energy consumption and highlight how electricity providers support customer EV adoption through incentive programs, building infrastructure, and other initiatives. [EPA-HQ-OAR-2022-0829-0638, pp. 45-46]

The grid's ability to handle millions of additional EVs hinges on utilities' proactive planning capacity. Granting utilities the flexibility to make proactive upgrades to the electrical grid and facilitate transportation electrification will require careful planning and coordination between regulators and stakeholders. [EPA-HQ-OAR-2022-0829-0638, pp. 45-46]

Regulatory certainty will allow utilities to make the investments necessary to facilitate a smooth EV transition. To invest proactively, rather than in response to firm load, energy providers will need clear insight into multi-year schedules for customer electrification, approval from regulators to recover costs, and/or flexibility to serve loads with non-wire alternatives. [EPA-HQ-OAR-2022-0829-0638, pp. 45-46]

Stringent EPA emissions standards will provide the regulatory certainty needed to not only ensure vehicle manufacturers continue to invest in EV technologies, but that the entire supply chain supporting the transition to electrification will have a clearer picture of how to plan capital expenditures today to meet the increased demand over the coming years. [EPA-HQ-OAR-2022-0829-0638, pp. 45-46]

i. Anticipated Impacts to the Electrical Grid from Increased EV Deployment

In 2021, the U.S. fleet of electric vehicles used 6.1 TWhs of electricity to travel 19.1 billion miles.205 That accounted for just 0.15% of the total national energy generation that year.206 In 2022, the United States produced 4,243 TWhs of electricity.207 To meet the demand of transportation electrification, more generation will be needed to service EVs and electrified vehicle technologies. One estimate suggests it would take roughly 800 to 1,900 TWh of electricity to power all vehicles if they were electric.208 It is important to remember, however, that this new demand will not occur all at once but rather more gradually as EVs continue to displace ICEVs. While achievable, meeting this increase in electricity demand will require significant strategy as electric providers transition to renewable, carbon free resources. [EPA-HQ-OAR-2022-0829-0638, p. 46]

205 “Assessment of Light-Duty Plug-in Electric Vehicles in the United States, 2010–2021,” Argonne National Laboratory, (November 2022) https://publications.anl.gov/anlpubs/2022/11/178584.pdf

206 “Monthly Energy Review May 2023,” EIA, https://www.eia.gov/totalenergy/data/monthly/pdf/sec7_3.pdf

207 Id. at footnote 206

208 “How much electricity would it take to power all cars if they were electric?,” USAFacts, (May 15, 2023) https://usafacts.org/articles/how-much-electricity-would-it-take-to-power-all-cars-if-they-were-electric/

The key to meeting these energy requirements will be the expansion of renewable energy resources but also the addition of new, zero-emission and low-emission load-following resources like advanced nuclear, carbon capture, long-term energy storage, and green hydrogen. In 2022, electricity generated from renewable sources surpassed coal for the first time in U.S. history.209 At the same time, electricity providers are looking at ways to add low-cost energy storage to increase the availability of non-dispatchable renewable generation such as solar and wind. [EPA-HQ-OAR-2022-0829-0638, pp. 46-47]

Currently, renewable energy generates about 20% of all electricity production in the U.S, and renewable sources like solar and wind are expected to account for the majority of new utility-scale electricity generation going forward.210,211 Already, available renewable energy resources in the U.S. are estimated to amount to more than 100 times the nation’s current electricity needs.212 [EPA-HQ-OAR-2022-0829-0638, pp. 46-47]

209 “U.S. renewable electricity surpassed coal in 2022,” Associated Press, (March 28, 2023) https://apnews.com/article/renewable-energy-coal-nuclear-climate-change-dd4a0b168fe057f430e37398615155a0

211 “Solar power will account for nearly half of new U.S. electric generating capacity in 2022,” EIA, (January 10, 2022) https://www.eia.gov/todayinenergy/detail.php?id=50818

212 “Renewable Energy Resource Assessment Information for the United States,” U.S. Department of Energy, accessed June 4, 2023 https://www.energy.gov/eere/analysis/renewable-energy-resource-assessment-information-united-states

Power generation is only one of the considerations when preparing for 100% transportation electrification. In particular, the industry needs to develop its ability to precisely manage demand in real time, including by accurately predicting when and where increases in demand will occur. [EPA-HQ-OAR-2022-0829-0638, p. 47]

It is important to note that energy demand is not constant. Instead, it consists of relatively predictable peaks and troughs throughout the day. High demand consistently occurs between 5:00 PM and 8:00 PM each day, as customers return home, turn up their climate control systems, begin cooking dinner, and turn on other devices.213 System demand peak is typically between 5:00-6:00 PM during the summer, and 7:00-8:00 AM in the winter. As such, EV charging poses minimal impacts to the winter peak hours but could increase summer peaks without managed charging. As discussed further below, electricity providers are looking at ways to reduce the impact of EV charging on these spikes in energy demand by studying the energy needs of their customers. [EPA-HQ-OAR-2022-0829-0638, p. 47]

213 “Yes, the grid can handle EV charging, even when demand spikes,” Yale Climate Connections, (March 23, 2023) https://yaleclimateconnections.org/2023/03/yes-the-grid-can-handle-ev-charging-even-when-demand-spikes/

ii. Utility-Specific Planning Underway

The following collection of case studies demonstrates how electricity providers in ZETA’s membership are preparing for the EV transition and highlights some of their groundbreaking initiatives to support EV adoption in the United States. It should be noted that each provider operates within a regulatory framework that is unique to the state in which it serves. The cases outlined below do not represent the entire portfolio of EV-related products and services offered by these providers. [EPA-HQ-OAR-2022-0829-0638, pp. 47-48]

These examples include programs that exist across the EV supply chain, with earlier examples covering infrastructure planning programs and later examples focusing on programs to engage with EV drivers on their charging needs. [EPA-HQ-OAR-2022-0829-0638, pp. 47-48]

1. Pacific Gas & Electric

As California’s largest electric provider, PG&E continues to play an important role in advancing electric vehicle adoption in support of the state’s broad climate goals. PG&E works in collaboration with the California Energy Commission and California Public Utilities Commission to plan and approve grid infrastructure upgrades to support this shift to zero-emission transportation. [EPA-HQ-OAR-2022-0829-0638, pp. 47-48]

With nearly 500,000 EVs sold in its service area—one in every seven of all EVs on the road throughout the nation—expansion of PG&E’s EV charging network in Northern and Central California is critical to support the State’s transition to a clean transportation future. Over the last half-decade, the provider has deployed more than 5,000 EV charging ports across its service area. Additionally, it offers a variety of resources to help accelerate EV adoption among customers, and PG&E is working collaboratively with vehicle manufacturers to develop vehicle grid-integration technologies. [EPA-HQ-OAR-2022-0829-0638, pp. 47-48]

Grid planning requires precise forecasts to ensure electric infrastructure is available to support future demand. Pre-existing electricity demand (load) forecasts did not provide the geographical granularity needed to best plan for grid investments. PG&E could allocate the load to residential charging locations; however, larger charging loads that are often not associated with existing service points—such as public charging systems—lacked a methodology to be accounted for in long-term forecasting efforts. Without the ability to identify future EV demand with geographic and temporal accuracy, PG&E was limited in its ability to plan future grid capacity. [EPA-HQ-OAR-2022-0829-0638, pp. 47-48]

Lacking a long-term geospatial forecasting methodology, PG&E was primarily dependent on customer requests for service to inform where EV load would materialize. This reliance on customer requests led PG&E to reactively develop capacity solutions to serve load requests. Given the long lead times often associated with capacity projects and the relatively fast pace at which customers wish to build EV charging infrastructure, there would be instances where energization timelines exceeded the requested energization date from customers. This can occur with large load applications associated with public DCFC charging stations or large fleets, which have the potential to exceed the maximum capacity of existing electrical infrastructure in those areas. [EPA-HQ-OAR-2022-0829-0638, pp. 47-48]

Identifying a need for a more proactive approach, PG&E set out to improve its forecasting abilities to increase the clarity of where and when EV loading is most likely to materialize. This enables PG&E to build capacity in advance of service applications being received. Although research indicates that customer preference for EVs is increasing, and there are many regulations and incentives which further support the transition to EVs, there are still uncertainties around the pace of adoption. This impacts how the EV load will manifest on the electric grid. For this reason, a solution capable of supporting a variety of forecast scenarios was necessary for success. PG&E commissioned a multi-faceted project focused on three common categories of EV charging load: 1) public DCFC & Level 2 charging stations, 2) residential EV charging, and 3) fleet charging. [EPA-HQ-OAR-2022-0829-0638, pp. 48-49]

Detailed analysis and machine learning modeling and testing were applied to each of these focus areas to predict where EV charging is most likely to occur. These analyses were performed at the premise level and resulted in over 5 million potential growth points across PG&E's service territory that were integrated into existing distribution planning software. This created a dynamic tool that can adapt to a variety of forecast inputs, such as system-level adoption forecasts, EV charging behaviors, and charging infrastructure assumptions. These scenarios can be integrated into PG&E's distribution planning processes. [EPA-HQ-OAR-2022-0829-0638, pp. 48-49]

Developing a solution that was easily integrated into existing distribution planning processes and software was critical for successful implementation. Involving PG&E forecasting and asset planning teams in the development of the EV forecasting tool, as well as reviewing and approval of the major inputs and assumptions used to develop forecast scenarios, ensured alignment in the scenarios generated. [EPA-HQ-OAR-2022-0829-0638, pp. 48-49]

Using varying EV forecast scenarios, PG&E was able to assess the localized grid impacts from high EV adoption scenarios that are better aligned with state transportation electrification goals and policies. PG&E assessed how various levels of EV adoption, as well as the impacts that changing charging behaviors (such as on vs. off-peak charging), can have on grid needs. Early analysis has indicated that off-peak charging can reduce near-term grid constraints. In the future, this may lead to new circuit peaks and capacity constraints that must be addressed. [EPA-HQ-OAR-2022-0829-0638, pp. 48-49]

Results from these analyses were helpful in advocating for approval of higher transportation electrification forecasts with regulators and the state energy commission, which are ultimately used for electric grid planning. PG&E has also used these forecasts to produce directional assessments of the resources needed to support capacity investments included in their long-term capital planning. PG&E continues to work to improve its forecasting and planning capabilities. Still, the solutions implemented to date have enabled a more robust approach that will allow PG&E to continue to support its customers' electrification transition. PG&E's plan for a high electrification future also includes the following measures:214 [EPA-HQ-OAR-2022-0829-0638, pp. 49-50]

214 “Answers to Administrative Law Judge’s Ruling Seeking Additional Information on the Distribution Planning Process by Pacific Gas and Electric Company,” PG&E, (April 10, 2023) https://docs.cpuc.ca.gov/PublishedDocs/Efile/G000/M505/K839/505839889.PDF

-Working diligently to plan and develop capacity infrastructure to ensure electricity is available where peak demand is expected to increase as zero-emission vehicle adoption continues to grow. Efforts include close collaboration with state agencies, technology partnerships, EV charging developers, vehicle original equipment manufacturers, and adopters of zero-emission vehicles to proactively prepare electric capacity in high demand areas in ways that consider economic development and customer electricity rates. [EPA-HQ-OAR-2022-0829-0638, pp. 49-50]

-Proactive discussions with customers and municipalities to understand their individual plans for electrification load growth to better include them in PG&E forecasting and planning. [EPA-HQ-OAR-2022-0829-0638, pp. 49-50]

-In addition to using customer TE plans to inform longer-term load forecasts and planning, PG&E is also using these customer plans to inform our near-term priority proactive upgrades. [EPA-HQ-OAR-2022-0829-0638, pp. 49-50]

-Working with state agencies and regulators to increase the load forecasts that are used for utility planning, enabling a faster build out of additional capacity infrastructure (as described earlier). [EPA-HQ-OAR-2022-0829-0638, pp. 49-50]

2. Vistra

Electricity generators are making the transition to low-and no-carbon-emitting sources of energy as quickly as possible in response to investor, regulator, policymaker, and customer expectations. This transition is backed by a strong business case for doing so, as renewables and battery storage systems are able to compete effectively with fossil fuel generation and provide benefits to the power grid. The International Energy Agency expects renewable energy resources to provide 18% of the world’s power by 2030, up from 11.2% in 2019.215 However, certain renewable energy sources—such as solar and offshore/onshore wind—are dependent on weather conditions and the time of day. This means deploying these resources at scale will require accompanying battery technology to ensure electric grid reliability. [EPA-HQ-OAR-2022-0829-0638, p. 50]

215 “Modern renewables,” IEA, accessed June 4, 2023 https://www.iea.org/reports/sdg7-data-and-projections/modern-renewables

Energy storage allows for the integration of more intermittent resources by storing electricity until it is needed. It also augments existing energy generation by allowing excess energy to be produced when low demand is stored until demand peaks. Energy storage can provide benefits beyond emissions reduction, including cost-savings for consumers, reliability, and backup and startup power during extreme events. [EPA-HQ-OAR-2022-0829-0638, p. 50]

Vistra operates the Moss Landing Energy Storage Facility in California, the largest of its kind in the world, and is pursuing an expansion that will bring 750 MW online in the second quarter of 2023.216 This facility is particularly valuable in California, where the swift transition to renewable energy, paired with a constantly growing demand for electricity, illustrates the need for reliability in the electric grid and the role energy storage can play. As of 2021, non-hydroelectric renewables provide approximately 35% of California's electricity, and electricity demand has increased due to a variety of factors, including severe weather events, widespread electrification, and electric vehicle deployment.217 This combination was put to the test in September 2022, when the state faced its most extreme September heat event in recorded history. This weather event put unprecedented strain on the electric grid and set records for electricity demand. To the surprise of many, the lights stayed on. During that event, batteries, including Vistra's Moss Landing facility, provided about 4% of supply—over 3,360 MW, more than the Diablo Canyon nuclear power plant (the state's largest electricity generator)—during the peak demand, averting rolling blackouts. A report from the California Independent System Operation (CAISO) following the September 2022 event specifically highlighted the increase in energy storage resources as a key factor that supported the grid's reliability.218 As a comparison, the August 2020 heat wave, which occurred when California's energy storage resources were few and far between, resulted in rolling blackouts over multiple days. [EPA-HQ-OAR-2022-0829-0638, pp. 50-51]

216 "Vistra Announces Expansion of World's Largest Battery Energy Storage Facility," Vistra, (January 24, 2022) https://investor.vistracorp.com/2022-01-24-Vistra-Announces-Expansion-of-Worlds-Largest-Battery-Energy-Storage-Facility

217 "2021 Total System Electric Generation," California Energy Commission, accessed June 5, 2023 https://www.energy.ca.gov/data-reports/energy-almanac/california-electricity-data/2021-total-system-electric-genera tion

218 "California ISO posts analysis of September heat wave," California ISO, accessed June 5, 2023 http://www.caiso.com/Documents/california-iso-posts-analysis-of-september-heat-wave.pdf

Recognizing that the replacement of fossil fuel-powered assets with zero-carbon resources is not a one-to-one exchange, Vistra is working to maintain reliability by using energy storage and installing zero-carbon investments on the sites of retired or soon-to-be-retired fossil fuel plants. This also ensures that communities do not lose key energy supplies or ongoing tax revenue. [EPA-HQ-OAR-2022-0829-0638, pp. 51-52]

Vistra is also focused on ensuring that existing zero-carbon generation remains online, such as the Comanche Peak Nuclear Power Plant in Texas, which is currently going through the Nuclear Regulatory Commission's relicensing process to continue operations through 2053. This high-performing plant is able to produce power—rain, snow, or shine—increasing grid reliability for Texans and making it a keystone generator for the Electric Reliability Council of Texas (ERCOT) grid. Alongside the transition to cleaner generation resources, Vistra has been able to maintain reliability for its consumers and ensure that individuals and businesses are able to keep their lights on, even during extreme weather events. During Winter Storm Uri in Texas in 2021, Vistra's plants produced between 25-30% of the power on the grid during the storm, far beyond its ~18% market share. [EPA-HQ-OAR-2022-0829-0638, pp. 51-52]

As the energy supply mix shifts toward low-and zero-carbon resources, energy storage will fill the reliability gap and allow that mix to evolve more reliably and flexibly. The Inflation Reduction Act provides new tax incentives for investment in energy storage technologies and resources to support the R&D of advanced and long-duration energy storage technologies. These investments will enable the deployment of utility-scale energy storage and add reliability to the grid, no matter what the future energy generation mix looks like. It is crucial that the United States continues to make the transition to a carbon-neutral economy and electric grid in a way that ensures the continued reliability of the grid at a reasonable cost to consumers. [EPA-HQ-OAR-2022-0829-0638, pp. 51-52]

3. Southern California Edison

About 40% of the nation's electric vehicles, more than 1.3 million, have been sold in the state of California. More than 430,000 of those are in SCE's service area alone. Many have expressed doubts that the grid is ready for the energy demand created by the need to charge so many EVs, but electric power companies, including SCE, are keeping up with increasing levels of adoption. In anticipation of growing EV demand in Southern California, SCE is continuously taking the steps to upgrade the grid and promote customers' transition to electric transportation and proactively solve near-term issues, while also undertaking long-term investments to ensure the grid is ready for all levels of anticipated electrification adoption. [EPA-HQ-OAR-2022-0829-0638, pp. 52-53]

Solving near-term challenges

One way SCE is addressing the near-term issues is its Power Service Availability (PSA) initiative for Transportation Electric service. [EPA-HQ-OAR-2022-0829-0638, pp. 52-53]

-SCE is focusing on (1) improving its internal processes to streamline interconnection, (2) engaging fleet operators to better understand their plans for electrification, (3) improving its ability to forecast and assess the impacts of transportation electrification (TE) growth, and (4) leveraging new technologies as grid infrastructure solutions [EPA-HQ-OAR-2022-0829-0638, pp. 52-53]

-Because some projects require more time than others to build, SCE is encouraging fleet owners to engage with the utility early in the process so that SCE can better understand and plan for the fleets' needs. [EPA-HQ-OAR-2022-0829-0638, pp. 52-53]

SCE is also improving how we partner with customers to meet their needs. [EPA-HQ-OAR-2022-0829-0638, pp. 52-53]

-This includes streamlining buildout, developing deeper customer engagements that include rate planning and load management education, and right-sizing grid solutions to meet the expected charging demand growth in both the near and long term. These efforts will provide more innovative and customer-focused solutions. [EPA-HQ-OAR-2022-0829-0638, pp. 52-53]

In addition to customer project deployment, SCE has also pushed to accelerate EV adoption through customer-side infrastructure programs such as Charge Ready for light-duty vehicles. [EPA-HQ-OAR-2022-0829-0638, pp. 52-53]

-Through its Charge Ready program, SCE installs, maintains, and covers installation costs for charging infrastructure while participants own, operate, and maintain the charging stations. For those ready to invest in EV charging for medium-and heavy-duty vehicles, SCE's Charge Ready Transport program similarly offers low-to no-cost site upgrades to support the installation. The program provides funding to help electrify semi-trucks, buses, and delivery vehicles, among others. Through its Charge Ready programs, SCE has installed more than 3,000 charging ports throughout its service area and is targeting 30,000 charging ports by 2026. [EPA-HQ-OAR-2022-0829-0638, pp. 52-53]

SCE's Transportation Electrification Advisory Services program is also available for commercial customers considering electric transportation options. [EPA-HQ-OAR-2022-0829-0638, pp. 52-53]

-On top of offering educational webinars and workshops, the program also offers to develop site-specific EV-readiness studies to help determine the feasibility of proposed projects and grant writing assistance to help customers secure zero-emission vehicle grants. [EPA-HQ-OAR-2022-0829-0638, pp. 52-53]

Long-term Planning and investing in the grid for TE

SCE is improving the value of EV adoption forecasts used for grid planning by assessing where, when, and how much EVs are likely to charge. [EPA-HQ-OAR-2022-0829-0638, pp. 53-54]

-SCE led the West Coast Clean Transit Corridor Initiative, composed of nine other electric utilities and two agencies representing more than two dozen municipal utilities, to conduct a multi-phase and multi-year research study to forecast EV truck populations and determine the proper number and size of highway charging sites. Subsequent phases of this initiative are supporting internal planning operations across the participating utilities. [EPA-HQ-OAR-2022-0829-0638, pp. 53-54]

-SCE developed an augmented forecasting approach to capture accelerated load growth due to Medium-Duty / Heavy Duty (MDHD) vehicles as well as the direct current fast charging (DCFC) for Light-Duty vehicles and port electrification for the recent General Rate Case (GRC) Application. [EPA-HQ-OAR-2022-0829-0638, pp. 53-54]

-Because MDHD electrification is still nascent, current forecasting methodologies that are based (in part) on historical adoption are insufficient [EPA-HQ-OAR-2022-0829-0638, pp. 53-54]

-For the GRC, SCE's augmented forecasting methodology leverages MDHD fleet industry data to more accurately predict MDHD electrification adoption and corresponding grid needs [EPA-HQ-OAR-2022-0829-0638, pp. 53-54]

-The augmented forecasting approach also included added load from DCFC charging plazas for Light-Duty vehicles. [EPA-HQ-OAR-2022-0829-0638, pp. 53-54]

-SCE (and the IOUs) are collaborating with CPUC on a new "Freight Infrastructure Planning" (FIP) Framework to further address planning for MDHD [EPA-HQ-OAR-2022-0829-0638, pp. 53-54]

-SCE is working to expand the current distribution planning forecast window from 10 years to 20 years. Developing and implementing an interagency-sponsored forecast that spans 20 years for distribution will bring benefits, such as: [EPA-HQ-OAR-2022-0829-0638, pp. 53-54]

-Identifying long lead time projects that are needed beyond the 10-year horizon

-Identifying important land acquisition needs

-Informing how the development of infrastructure may need to be levelized to practically achieve the scale of development required by achieving state ZEV policies and GHG targets. [EPA-HQ-OAR-2022-0829-0638, pp. 53-54]

-SCE has proposed robust investments in its GRC application to support TE adoption and load growth. [EPA-HQ-OAR-2022-0829-0638, pp. 53-54]

-The investments proposed are designed to ensure long-lead infrastructure projects (such as substation expansion or new substations) will be completed when load growth arrives. The plan especially focuses on high TE locations: freight corridors, fleet hubs, Port of Long Beach, etc. [EPA-HQ-OAR-2022-0829-0638, pp. 53-54]

-Specific TE-focused projects include: [See original comment for project types table] [EPA-HQ-OAR-2022-0829-0638, pp. 53-54]

4. Con Edison

Con Edison is helping to accelerate New York State's transition to clean transportation and EV adoption through grid and customer investments that support buildout of a widespread charging network. The Company's PowerReady Program provides incentives to connect thousands of new public and private charging stations to the electric grid. Authorized by the New York State Public Service Commission's July 2020 Order Establishing Electric Vehicle Infrastructure Make-Ready Program and Other Programs, the program offsets the electric infrastructure costs associated with installing chargers for light-duty EVs, including cars and small vans. To date, nearly 4,000 Level 2 and 175 DCFC chargers have been installed under the program, with the goal of installing 18,539 Level 2 and 457 DCFC chargers by 2025, with the potential for significant expansion of the program budget and goals as recently recommended by the New York State Department of Public Service Staff. The Company provides a similar pilot program for medium-and heavy-duty (MHD) vehicles, and a full-scale program is being considered in the recently launched New York State proceeding to address barriers to MHD charging infrastructure (MHD Proceeding). [EPA-HQ-OAR-2022-0829-0638, pp. 54-55]

Along with these infrastructure incentive programs, Con Edison also offers the SmartCharge New York managed charging program that provides incentives for personal drivers to charge outside of grid peak periods and the Company is launching a commercial managed charging program later this year including eligibility for all fleets, public stations, and multi-unit dwellings. SmartCharge New York is discussed below as an example of how managed charging can help mitigate the impact of EV charging on the grid. [EPA-HQ-OAR-2022-0829-0638, pp. 54-55]

An essential step in EV charger buildout is interconnection with the grid. Con Edison has developed dedicated teams that support the growing number of EV charging interconnections, including those that provide load evaluation, engineering review, project queue management, and incentive deployments. The Company is implementing multiple efforts to improve the customer experience and speed interconnection timelines and will continue to identify and implement efficiencies and improvements. For example, the Company provides pre-application advisory services for fleets and other customers to evaluate site feasibility and understand electric fueling costs, automates internal processes such as service rulings for smaller stations, and is coordinating with permitting agencies to identify and resolve challenges. Con Edison provides load-serving capacity maps to help those seeking to install EV charging infrastructure identify suitable sites with adequate grid capacity. [EPA-HQ-OAR-2022-0829-0638, pp. 54-55]

While Con Edison is supporting installation of increasing numbers of EV chargers under its programs today, the Company is also working to evolve its robust planning processes to prepare for the ramp in clean transportation loads. These loads are expected to drive significant grid impacts in New York State and ambitious emissions regulations will further accelerate an already rapidly growing EV market, with the exact timing in the inflection point unknown. The timeline to install EV chargers is relatively short compared to that of other new customer infrastructure, such as a new building, while the buildout of utility-side grid infrastructure to meet the significant increase in demand from EV chargers requires longer timelines, sometimes of 5 to 7 years. A proactive grid planning process to meet near-term needs and build out the grid in advance to support long-term growth in the deployment of EVs is being considered in the New York State MHD Proceeding. Con Edison, along with other NY State Utilities, filed comments proposing a proactive utility infrastructure planning framework to prepare the grid in advance of future transportation electrification needs. [EPA-HQ-OAR-2022-0829-0638, pp. 54-55]

SmartCharge New York Managed Charging Case Study

In 2017, Con Edison launched SmartCharge New York program with the goal of instilling grid-beneficial charging behavior in parallel with the upswing in electric vehicle adoption. The goal was to influence driver behavior at the inflection point of transitioning from combustion-engine fueling to electric battery charging and have drivers default to grid-optimizing charging activity. Program participants received a free cellular-enabled device that plugs into the vehicle's diagnostic port that allowed Con Edison to track time, energy, and power consumed when charging in the utility's service territory. Incentives encourage drivers to 1) avoid charging during the system peak (2 PM to 6 PM) during summer weekdays from June to September, and 2) charge overnight from 12 AM to 8 AM. Incentives were initially paid off-bill through gift cards to the customer's business of choice, such as Amazon, Starbucks, or Home Depot. [EPA-HQ-OAR-2022-0829-0638, p. 56]

As electric vehicle adoption continues to rise, managing charging behavior will grow increasingly important in maintaining a healthy and reliable grid. Since its inception, the SmartCharge New York program has evolved to meet customer needs and program objectives. Starting in 2023 for example, the program was overhauled to allow participation through a mobile application and payments are now issued through Venmo or Paypal, in line with participant feedback. This shift also changed the way the program collects data, favoring more cost-effective vehicle onboard telematics or networked electric vehicle supply equipment such as a Wi-Fi-enabled charger or charging cable. This enables the program to scale efficiently with the market and give a greater number of drivers insight into their behavior and how that activity translates to incentive earnings. [EPA-HQ-OAR-2022-0829-0638, p. 56]

In light of the EPA announcement of its heavy-duty and light/medium-duty proposed emissions standards, Con Edison released the following statement: [EPA-HQ-OAR-2022-0829-0638, pp. 56-57]

"Con Edison applauds the Environmental Protection Agency's efforts to rev up the market for electric vehicles, which will improve the air in the communities we serve and help in the fight against climate change. [EPA-HQ-OAR-2022-0829-0638, pp. 56-57]

A rapid shift to mass EV adoption looks more achievable all the time, with vehicle options expanding and new charging stations being built across New York City and Westchester County, including locations that serve the needs of disadvantaged communities. [EPA-HQ-OAR-2022-0829-0638, pp. 56-57]

Con Edison will continue to support the EV market's development through investment in the grid and by offering a range of programs, from incenting new chargers to managing the grid impact by rewarding drivers for charging overnight."219 [EPA-HQ-OAR-2022-0829-0638, pp. 56-57]

219 "Con Edison Supports Effort to Encourage Electric Vehicle Adoption," Con Edison Media Relations, (April 12, 2023) https://www.coned.com/en/about-us/media-center/news/2023/04-12/con-edison-supports-effort-to-encourage-electri c-vehicle-adoption

5. SRP

When EVs were still in the early stages of adoption, SRP recognized the importance of exploring ways to identify EV households and analyze their charging behavior in order to help prepare for greater EV uptake in the future. It was also important to begin engaging customers who were EV drivers in order to understand their interests and their charging patterns and assess ways to influence charging behaviors. [EPA-HQ-OAR-2022-0829-0638, pp. 57-58]

In 2014, SRP launched "EV Community" (EVC)—a program that offers customers a $50 bill credit for each EV they register (up to two vehicles per household)—as a means to incentivize EV drivers to identify themselves and engage with SRP. Participants provide basic information about the electric vehicle and the type of charger they use. This provides a way for SRP to learn more about EV customers and their charging behavior and needs while offering them an incentive to help support EV growth in the region. There are currently more than 7,500 customers enrolled in the program. [EPA-HQ-OAR-2022-0829-0638, pp. 57-58]

While EVC members only account for a small number of total EV households, they are a fair overall representation of the EV customer base since all price plans are included, as well as households with one vs. two EVs. The program offers SRP a good platform for analysis, including the type of cars they drive (PHEV, BEV, brand, etc.) and the charge levels they use. In addition, SRP found that EVC members are willing to share information and are eager to participate in future pilot programs. [EPA-HQ-OAR-2022-0829-0638, pp. 57-58]

The EVC program also provides SRP with a method and channel to promote their Electric Vehicle Price Plan, a special time-of-use pricing plan which offers EV drivers the most opportunity to save on EV charging costs by charging during super off-peak times (between 11 PM and 5 AM). Load research has shown that this program has been highly effective at shifting EV charging loads away from peak periods. [EPA-HQ-OAR-2022-0829-0638, pp. 57-58]

The EVC program has helped SRP plan and prepare the grid for widespread EV adoption by enabling them to: [EPA-HQ-OAR-2022-0829-0638, pp. 57-58]

-Anticipate load growth. A pilot study with EVC members that monitors their EV driving and charging behavior through data telematics devices enables SRP to estimate typical consumption and charging load profiles per EV. [EPA-HQ-OAR-2022-0829-0638, pp. 57-58]

-Understand the impacts of EV charging on the grid. EVC data is used to model the impacts of EV charging on the electric grid, identify when transformers and wires may need to be upgraded, and understand when and how customers need to charge. [EPA-HQ-OAR-2022-0829-0638, pp. 57-58]

-Recruit for Managed Charging pilot programs. The EVC program and channel have enabled SRP to recruit participants for additional Managed Charging pilot programs to test other active control technologies to control EV charging load on the grid. [EPA-HQ-OAR-2022-0829-0638, pp. 57-58]

-Survey participants for insights. EVC members are surveyed regularly to get more data on their charging behaviors, including their use of home, workplace, and public charging and their satisfaction with EVs overall. [EPA-HQ-OAR-2022-0829-0638, pp. 57-58]

-Engagement. EVC participants receive regular newsletters and other communications with EV-related information. [EPA-HQ-OAR-2022-0829-0638, pp. 57-58]

6. Duke Energy

Electric fleet commitments are increasing as companies with ambitious sustainability goals work to decarbonize operations. Fleet owners are also seeking ways to take advantage of the cost savings available by transitioning to EVs. However, programs for fleet electrification and managed charging options are still limited to date. [EPA-HQ-OAR-2022-0829-0638, pp. 58-59]

When transitioning to an electric fleet, it is important that fleet managers understand the full scope of charging multiple vehicles while maintaining fleet operations and that larger MHDVs bring with them additional factors to consider. Fleet owners who have electrified fleets without consulting experts or an electric provider have likely been experiencing avoidable operational and technological issues. Long-term energy cost and performance risk are also potential issues for fleets and can hinder mainstream fleet electrification technology development if not managed correctly. [EPA-HQ-OAR-2022-0829-0638, pp. 58-59]

Duke Energy's significant experience and large customer base make it well-positioned to design and implement fleet electrification and charging programs. Duke Energy is building a first-of-its-kind performance center that will model and accelerate the development, testing, and deployment of zero-emission light-, medium-, and heavy-duty commercial electric vehicle EV fleets. The site will be located in North Carolina at Duke Energy's Mount Holly Technology and Innovation Center and incorporate microgrid integration. [EPA-HQ-OAR-2022-0829-0638, pp. 58-59]

The fleet electrification center will provide a commercial-grade charging experience for fleet customers evaluating or launching electrification strategies—reinforcing reliability, clean power, and optimization by integrating solar, storage, and microgrid controls software applications. The center will be connected to both the Duke Energy grid—charging from the bulk electric system—and to 100% carbon-free resources through the microgrid located at Mount Holly. This project is the first electric fleet depot to offer a microgrid charging option. [EPA-HQ-OAR-2022-0829-0638, pp. 58-59]

In addition to fleet charging, the site will also function as an innovation hub, allowing Duke Energy to collect data around charger use, performance, management, and energy integration with various generation resources. It will also allow for the development of managed charging algorithms for fleets connected to the bulk power system or integrated with renewables and storage—which can be utilized to minimize the upgrades needed to the distribution system, easing the transition to electrifying fleets. Identifying EV charging technologies and how they may be used to power any type of fleet with vehicles (ranging from class 1) will help develop a model to show the industry a clear, integrated, and cost-effective path to fleet electrification. [EPA-HQ-OAR-2022-0829-0638, p. 59]

Duke Energy is teaming up with Daimler Truck North America and Electrada on this important work. Electrada, an electric fuel solutions company, is providing funding for research and demonstration efforts. For fleets seeking to electrify, Electrada invests all required capital "behind the meter" and delivers reliable charging to the fleet's electric vehicles through a performance contract, eliminating the complexity and risk that fleets face in transitioning to this new source of fuel. Electrada's investment in the depot allows Duke Energy to focus on programs that simplify adoption for electric fleet customers and distribution system performance to support the predictable addition of electric load over time. [EPA-HQ-OAR-2022-0829-0638, p. 59]

By the end of 2023, fleet operators will be able to experience a best-in-class, commercial-grade fleet depot integrated with energy storage, solar, and optimization software. Moving to zero-emission vehicles in this sector allows North Carolina to seize the large economic potential of the transition and generate billions in net benefits for the state. Projects like Duke Energy's fleet performance center will be key for fleet owners across the state to take advantage of the cost savings of transitioning to electric vehicles. That said, fleet owners exploring electrification should engage their electricity provider early and often to identify and address site-specific considerations. As fleet electrification accelerates, it will be important for electricity providers and policymakers to identify best practices to proactively plan for fleet electrification, including readying the distribution grid. [EPA-HQ-OAR-2022-0829-0638, p. 59]

7. Xcel Energy

Xcel Energy is committed to electrifying all of its light-duty fleet and 30% of its medium-and heavy-duty fleet by 2030, equating to over 2,500 EVs. It's part of their vision to be a net-zero energy provider by 2050 and enable one out of five vehicles to be electric in the areas they serve by 2030. This will save customers $1 billion annually on fuel by 2030 and deliver cleaner air for everyone. [EPA-HQ-OAR-2022-0829-0638, pp. 59-60]

With a fleet that includes iconic bucket trucks, all-terrain service vehicles, and a host of pickup trucks and pool cars across eight states, achieving these goals will be no small feat, but an important one. There are notable hurdles, yet evolving technology presents solutions. [EPA-HQ-OAR-2022-0829-0638, pp. 59-60]

Electrifying the Marquee Fleet Vehicle

Xcel Energy is the first electric provider in the nation to add an all-electric bucket truck to its fleet. The truck features two electric sources: one for the drivetrain and one for the lift mechanism. It has a 135-mile driving range and can operate the bucket for an entire workday on a single charge. Crews are collecting data from real working conditions in Minnesota and

Colorado that will be used to inform further improvement to the vehicle's technology and operation. [EPA-HQ-OAR-2022-0829-0638, pp. 59-60]

Optimizing Charging to Minimize Grid Impacts

To support a growing electric fleet, over 1,200 EV chargers must be brought into service by 2030, which will result in an electric load increase of 71 megawatts. Charge management techniques enable low-cost charging for this growing electric fleet. It's a sophisticated approach to optimize charging times by using time-of-day and grid demand efficiencies and builds on the expertise Xcel Energy has developed through offering managed charging programs to customers in multiple states. [EPA-HQ-OAR-2022-0829-0638, pp. 59-60]

For fleets, overnight charging schedules make the most sense. Demand and rates are lower, and renewable wind sources are ample at that time. Yet, fast charging outside of these time periods may be required to help larger vehicles make it through a workday. This is when charging schedules need to be customized and highly specific. [EPA-HQ-OAR-2022-0829-0638, pp. 59-60]

Enabling Cleaner Service Calls Through Bucket Truck Technology

Xcel is also taking immediate action on other high-impact emission reduction opportunities, using technologies such as electric power take-off, idle mitigation, and solar systems to power jobsite tools. [EPA-HQ-OAR-2022-0829-0638, pp. 60-61]

-Electric power take-off (ePTO) -An ePTO system is a device that uses battery power. It's similar to an EV, but instead of moving the vehicle down the road, it powers equipment and tools to avoid engine idling at the job site. These devices are recharged by plugging into the same chargers that EVs use. [EPA-HQ-OAR-2022-0829-0638, pp. 60-61]

-Idle mitigation -An idling truck can consume 1.5 gallons of gas each hour. Idle mitigation on Xcel Energy's utility bucket trucks works by automatically shutting down the gas-powered engine when the vehicle is not in use or when the engine is idling for too long. This helps to reduce emissions and conserve fuel. [EPA-HQ-OAR-2022-0829-0638, pp. 60-61]

Fleet Electrification Solutions for Customers

Xcel Energy's experience and expertise with fleet electrification doesn't stop with their own fleet. They have developed a mix of customer programs across service areas to support fleet electrification for businesses and communities. These customer-centric solutions enable sophisticated planning, lower upfront costs with various rebates and incentives, and minimize impacts to the grid. [EPA-HQ-OAR-2022-0829-0638, p. 61]

Xcel's approach for commercial EV fleet development includes: [EPA-HQ-OAR-2022-0829-0638, p. 61]

-Advisory services: Xcel offers a "white-glove service" to meet customers where they are on their electrification journey by guiding them through customized planning for their infrastructure needs. For fleet operators, this includes a free assessment to help them determine the best path to electrify their fleet and advise them on future electric fleet considerations such as charging best practices. [EPA-HQ-OAR-2022-0829-0638, p. 61]

-Infrastructure installation: Xcel designs and builds EV supply infrastructure to support charging station installations at minimal to no cost to customers. [EPA-HQ-OAR-2022-0829-0638, p. 61]

-Equipment recommendations and rental options: Xcel also provides recommendations for charging equipment and offers customers the option to purchase their own qualifying vehicle chargers or rent them at a monthly fee that includes installation and maintenance. [EPA-HQ-OAR-2022-0829-0638, p. 61]

-Grid continuity: Xcel designs long-term clean energy resource and distribution plans to consider the future impact of new EV load to ensure ongoing grid stability, reliability and affordability. [EPA-HQ-OAR-2022-0829-0638, p. 61]

-Equitable opportunities: Xcel supports EV adoption in higher emissions communities and income-qualified neighborhoods through rebates and incentives. This includes facilitating the electrification of carshare, refuse trucks, school buses, paratransit vehicles, and other fleets operating in these disproportionately impacted communities. [EPA-HQ-OAR-2022-0829-0638, p. 61]

Fleet electrification is a key component of Xcel Energy's larger vision, which includes enabling zero-carbon transportation by 2050 across our eight-state service footprint. This long-term strategy balances affordability with sustainability across the entire grid. It's why Xcel is dedicated to assisting fleet managers across the ecosystem in providing fleet electrification solutions that empower and inspire a clean energy future while also leading by example. [EPA-HQ-OAR-2022-0829-0638, p. 61]

iii. Transmission

A critical part of ensuring a smooth transition to an electrified transportation sector will be a robust build out of high-voltage transmission lines. Doing so will also enable increased penetration of renewables into the grid mix, helping to further improve the environmental benefits of electric vehicles. While progress in this space has historically been slow and bogged down by procedural delays, there are some signs of progress. In April 2023, the U.S. Bureau of Land Management approved a 732-mile transmission line, which will carry wind energy from Wyoming through to Nevada.220 Also in April 2023, a Maine court granted approval to restart work on the 145-mile New England Clean Energy Connect project, which will carry hydropower from Canada to New England.221 The line is expected to carry up to 1,200 megawatts of power. [EPA-HQ-OAR-2022-0829-0638, p. 62]

220 "US approves $3bn Wyoming-Nevada power line," Power Technology, (April 12, 2023) https://www.power-technology.com/news/us-approves-3bn-wyoming-nevada-power-line

221 "Maine court greenlights embattled $1B transmission line," E&E News, (April 17, 2023) https://subscriber.politicopro.com/article/eenews/2023/04/21/maine-court-greenlights-embattled-1b-transmission-lin e-00093087

Electricity transmission is also a key focus of the Biden-Harris Administration. In May 2023, the administration published its plan to decrease permitting timelines for new transmission projects, among other key items.222 Also in May 2023, the U.S. Department of Energy proposed a rule on designating National Interest Electric Transmission Corridors.223 There will also be a role for Congress to play in improving transmission permitting times and this is a policy area where some bipartisan support exists. [EPA-HQ-OAR-2022-0829-0638, p. 62]

222 "FACT SHEET: Biden-Harris Administration Outlines Priorities for Building America's Energy Infrastructure Faster, Safer, and Cleaner," (May 2023) https://www.whitehouse.gov/briefing-room/statements-releases/2023/05/10/fact-sheet-biden-harris-administration-o utlines-priorities-for-building-americas-energy-infrastructure-faster-safer-and-cleaner/

223 See 88 FR 30956

ii. Impacts to EVSE Deployment from BIL and IRA Programs

With over $7.5 billion available across multiple programs, the Bipartisan Infrastructure Law represents the nation's largest ever investment in increasing Americans' access to EV chargers. Through the BIL's $5 billion National Electric Vehicle Infrastructure (NEVI) Formula Program, the federal government is partnering with private industry to build out a national charging network along key highway corridors. As of September 2022, the Federal Highway Administration approved formal plans submitted by all 50 States, the District of Columbia, and Puerto Rico and as of June 2023, multiple states had released requests for proposals from organizations seeking access to NEVI funds. The design of these state application processes through the NEVI Formula Program will help drive EVSE standardization, which will in turn improve reliability and consistency in the consumer-facing charging experience. Separately, the BIL's Charging and Fueling Infrastructure (CFI) Discretionary Grant Program allocates another $2.5 billion towards installing EV chargers in communities where people live and work. [EPA-HQ-OAR-2022-0829-0638, pp. 64-65]

As charging deployment continues to increase, the distribution of this network, not just its size, risks limiting electrification—especially in rural areas. In response, the Biden-Harris Administration has taken a comprehensive approach to EVSE build-out, recognizing the diverse demographics, landscapes, and types of communities throughout the United States. Ubitquity and visibility are important components of a national EVSE network deployment. The Department of Transportation has put together separate toolkits to guide EVSE deployment in both urban230 and rural231 areas. Both toolkits go through an explanation of electric mobility basics, as well as the benefits and challenges that are specific to individuals, communities, and transit operators in their respective region types. Both expand on public-private partnership opportunities, as well as best practices for early planning and financing. With respect to EVSE, DOT has identified three levels of EVSE planning: community, corridor, and site. These toolkits are intended to guide private, state, and local entities as they implement federal funding and engage in other equitable, thorough EVSE deployment strategies. [EPA-HQ-OAR-2022-0829-0638, pp. 64-65]

230 "Charging Forward: A Toolkit for Planning and Funding Urban Electric Mobility Infrastructure," U.S. Department of Transportation, (June 2023) https://www.transportation.gov/urban-e-mobility-toolkit

231 "Charging Forward: A Toolkit for Planning and Funding Rural Electric Mobility Infrastructure," U.S. Department of Transportation, (June 2023) https://www.transportation.gov/rural/ev/toolkit

<u>EPA Summary and Response</u>

We received many comments from the public related to the electric power sector, including generation capacity, transmission capacity, distribution capacity, electric power reliability and resiliency, air quality and emissions modeling, inventories, infrastructure upgrade costs, electricity rates, etc.

In those instances when complex comments span several subjects, the reply may appear in several related sections. For instance, if a hypothetical comment is submitted regarding "How local health effects may depend upon future natural gas prices and the likelihood that natural gas-fired electric generating units (EGU) will provide electricity to the surrounding community?" the response to the comment may appear in the economics section (as the comment touches upon the price of natural gas over time) or the response may appear in the air quality modeling section (as the comment touches upon health effects) or it may appear in this section (as the topic touches upon electric power sector modeling).

A summary of these comments as well as EPA's response appears below.

Summary:

Topic: Electric Power System: Generation Capacity

We received many comments related to generation capacity from the public. Some commenters expressed concern that the EPA did not adequately consider the generation system capacity, while other commenters stated that there would be sufficient generation system capacity to accommodate the modest increases in electricity demand due to additional PEV charging associated with the final rule.

Topic: Electric Power System: Transmission Capacity

We received many comments related to transmission capacity from the public. Some comments expressed concern that the EPA did not adequately consider the transmission system capacity, while other commenters stated that there would be sufficient transmission system capacity to accommodate the modest increases in electricity demand due to additional PEV charging associated with the final rule.

Topic: Electric Power System: Distribution Capacity

We received many comments related to distribution system from the public. Some comments expressed concern that the EPA did not adequately consider the distribution system capacity, while other commenters stated that the additional distribution needs associated with the rule could be addressed, including through additional distribution buildout, managed charging strategies, and other tools to mitigate distribution needs.

Topic: Electric Power System Reliability and Resilience

We received many comments related to the electric power sector reliability from the public. The comments expressed concern that the EPA did not adequately characterize possible improvements and/or degradation to the electric power system. Other commenters stated that the electric power system has historically been reliable and the rule would not adversely affect grid reliability.

Response:

Overview of Distribution Infrastructure Feasibility and Lead-Time

EPA has carefully considered the comments regarding the distribution infrastructure for charging light- and medium-duty PEVs, including issues of feasibility, lead-time, and costs. In this first response, we focus on the feasibility and lead-time of distribution infrastructure. The agency has conducted comprehensive analyses of distribution infrastructure needed to support light- and medium-duty PEV charging, including in close coordination with the Department of Energy and informed by the extensive public engagement on this issue. We find that there will be sufficient lead-time to develop the necessary distribution infrastructure associated with light- and medium-duty PEV uptake under the modeled potential compliance pathway for the final standards. We note that the final standards themselves provide significant additional lead-time relative to the proposal, which also means additional lead-time to build and connect distribution infrastructure. Our conclusion as to the sufficiency of distribution infrastructure is supported by numerous comments and analyses, including those from the stakeholders most intimately familiar with building and operating distribution infrastructure: the utility industry and state utility agencies. Below, we highlight several key lines of evidence.

Because the need for distribution infrastructure is associated with increases in electricity demand, EPA evaluated demand increases at the national, regional, and local levels. We found only modest increases in demand associated with this Rule at all of these levels. Assuming manufacturers follow the modeled potential compliance pathway—which focuses on increasing penetrations of light- and medium-duty PEVs—we project the additional generation needed to meet the projected demand of the light- and medium-duty PEVs under the final standards combined with our estimate of PEV demand from the Heavy-duty Phase 3 GHG proposed rule, to be relatively modest compared to a no action case, ranging from 0.93 percent in 2030 to approximately 12 percent in 2050 for both actions combined. Of that increased generation, approximately 84 percent in 2030 and approximately 66 percent in 2050 is due to light- and medium-duty PEVs, which are projected to represent approximately 0.78 percent and 7.6 percent of total U.S. generation in 2030 and 2050, respectively. These are modest increases and consistent with historical increases in demand, such as accompanying the introduction of refrigerators, air conditioners, and data centers, which the electric utilities have successfully managed.

At the local level, our analysis is informed by the recent Department of Energy Transportation Electrification Impact Study (TEIS) which found that only a small amount of new infrastructure would be needed. The TEIS evaluated five States susceptible to increased infrastructure needs, including due to high concentrations of freight corridors necessitating additional infrastructure, dense urban areas with less space for infrastructure buildout, and rural areas with relatively little existing infrastructure. The study evaluated the combined effects of both the Light- and Medium-Duty Multi-Pollutant Rule and the Phase 3 Rule. It found only minor incremental increases in peak demand associated with the vehicle rules in 2027 and 2032 (+0.1 to +3.0%) and that even those minor increases could be reduced, in some cases to below zero (i.e., decreases in peak demand relative to the baseline without the vehicle rules), through basic, easily implemented, demand management strategies (-1.8% to +0.5%). The study estimated that the peak demand increases could be accommodated by a small volume of additional infrastructure; for example, in 2027 with basic management strategies, it found the need for zero new substations, five new feeders, and 2,400 transformers. Based on our assessment of the time needed to build different kinds of infrastructure, EPA determined that the level of buildout identified by the TEIS could be achieved within the timeframe available. EPA regards these projected increases in infrastructure as modest. The projected increases in 2027, when there is the shortest lead time for buildout, are small. As expected, demand is projected to increase in 2032 but there is considerably more available lead time in which buildout can be accommodated.

We also carefully evaluated programs and funding to support charging infrastructure, including at the Federal, State, local, and utility levels, for both depot and public charging. The Federal government continues to provide significant funds for developing charging infrastructure, including through the Charging and Fueling Infrastructure Discretionary Grant Program. Many States have also developed programs to support such infrastructure. Many localities and utilities also are actively developing innovative strategies to build and support additional charging infrastructure; for example, Edison Electric Institute, the trade group for the nation's investor-owned utilities, identified numerous such strategies and concluded that needed infrastructure could be timely developed. The final rule provides beneficial regulatory certainty to support the development of these programs and of charging infrastructure generally.

Finally, we underscore the potential for numerous innovative strategies to mitigate distribution infrastructure demands. As noted regarding the TEIS study, even basic mitigation strategies for light- and medium-duty PEV charging can significantly ameliorate or even reduce peak demand. A panoply of potential strategies—including short-term load rebalancing, smart charging contracts, flexible interconnections, hosting capacity maps, managed charging software, vehicle-to-grid technologies, distributed energy generation, integrated battery storage, and more—provides many opportunities for mitigating the impacts of additional demand, and in some cases, for providing benefits back to the grid as the volume of BEV charging increases.

Transportation Electrification Impact Study ("TEIS")

To further respond to comments regarding the lead-time and feasibility of distribution infrastructure, we provide a more in-depth discussion of TEIS, which addresses these issues. TEIS also addresses the costs of distribution infrastructure buildout, which are discussed in preamble IV.C.5 and RIA 5.

The Department of Energy Study, "Transportation Electrification Impact Study" ("TEIS")[591] is a first-of-its-kind study which performs thermal capacity analysis (at the substation, feeder, and service transformer levels) compared to cumulative LMHD vehicle demand (i.e., demand from both the light- and heavy-duty sectors) enabling location-specific estimates of potential buildout capacity needs and costs. This is the first study to be bottom up, comparing parcel level LMHD demand to parcel supply by PV (photo voltaic) and grid capacity at each examined parcel.[592] Previous studies made estimates of how the new demand from BEV might align with the existing grid capacity or studied the parcel level grid needs for a smaller area (as compared to this 5 state analysis). The TEIS is especially valuable, in fact unique, in assessing both a large

[591] Eric Wood, Brennan Borlaug, Kilian McKenna, Jeremy Keen, Bo Liu, Dave Narang, Lawryn Kiboma, Bin Wang, Wanshi Hong, Julieta Giraldez, Chuck Moran, Margot Everett, Troy Hodges "DOE Multi-State Transportation Electrification Impact Study" (March 2024) ("TEIS").

[592] A "parcel", as used in TEIS, means "a real estate property or land and any associated structures that are the property of a person with identification for taxation purposes." TEIS at 16 n. 18.

area (5-State) coupled with parcel-level analysis.[593] The study focuses on five study States (California, Illinois, New York, Oklahoma, and Pennsylvania), and extrapolates those results nationwide. The five states were intentionally chosen to address geographic concerns such as freight corridors, crowded urban areas, and rural areas with widely distributed demand sources. These states represent 30-35% of the costs of the extrapolated results in the TEIS, and 20% of overall peak 2021 demand. [594] They also account for nearly 20% of 2021 nationwide utility noncoincident[595] peak demand and account for 28% of investor-owned utility national investment.[596] The study also incorporates public charging such that the corresponding high power needs are reflected, addressing a concern of many comments. The study estimates overload at the substation level (100% criteria)[597], feeder level (100% criteria), and at the residential service transformer per feeder level (125% criteria).[598] Scenarios examined are no action case (baseline without EPA light-duty or heavy-duty emission standards), and action case with EPA light and heavy duty rules), using as an Action case the same case EPA used for its national and regional estimates presented above.), Both action and no action cases are analyzed with and without mitigation resulting in four scenarios generated. The study examines the same four scenarios for both 2027 and 2032.[599] The TEIS unmanaged (without mitigation) case assumes BEVs charge as soon as they arrive at a charger. In contract, the managed case simply distributes the BEV demand over the vehicle dwell time available for charging so that charging can occur at a slower rate. The BEV charging is ignorant to non BEV loads. Charging could still occur on top of, and increasing, peak demand. As an example, if the peak load due to existing homes and business occurs at 7 pm and the BEV dwell time runs from 6 pm to 6 am, the unmanaged charging would apply peak power charging at 7 pm, exacerbating peak demand. The managed scenario assumes a lower power level and uses the available dwell time. The peak power demand increases but at a lower level.

The TEIS projects minimal increase in demand (energy consumption) and minimal increase in peak demand for the LMHD action case relative to no action for both 2027 and 2032, even without considering any management. In 2027, incremental energy consumption across the five states attributable to the light- and heavy-duty rules ranged from 0.1-0.3%.[600] In 2032, that incremental increase ranged from 1.6% to 2.7%.[601] Incremental impact on 5 state peak demand, again from the unmanaged case, was 0.1-0.2% in 2027 and 0.6-3.0% in 2032.[602]

[593] TEIS at 22-23.
[594] TEIS at 8, 99, 110. EPA agrees with the TEIS that these States' results are sufficiently representative to allow for national extrapolation. See TEIS App B for description of the extrapolation methodology in the Study.
[595] Noncoincident peak is the maximum power demand for a given time period occuring at different times than other peaks.
[596] TEIS at 111.
[597] Criteria level is showing if the peak loads are directly applicable to the design capacity of the system as is the case for the 100% criteria level. Criteria level of 125% for service transformer shows that many individual noncoincident peaks exist. See TEIS for additional detail.
[598] TEIS at 61 (substation), 62 (feeder), and 63 (transformer).
[599] TEIS at 18-19. The No Action case includes current state and federal policies and regulations as of April 2023. Id.
[600] TEIS at 70.
[601] TEIS at 71.
[602] TEIS at 76

If BEV users engage in non-optimized "conservative" management – spreading charging out over dwell times without consideration of actual extra grid capacity[603] – not only do these estimates of energy consumption and peak demand impacts decrease, but in some instances, peak demand is projected to decrease, that is, to be less than in the no action unmanaged case. Just by engaging in easy-to-implement time of day charging adjustments, overall demand to the grid is reduced (demand relative to the no action case), smoothing out overall demand and allowing for more efficient distribution. Thus, for 2027, incremental peak demand is reduced in four of the five states, and unchanged in the fifth.[604] For 2032, incremental peak demand is positive in two of the states but the increase is only 0.1% and 0.5%, and *reduced* in the other states by 0.5%-1.8% potentially obviating the need for any incremental buildout associated with the vehicle rules.[605]

These minor increases reflect low numbers of incremental transformers, feeders, and substations estimated to be needed (again, for the five states at issue, and for both light and heavy-duty rules together) relative to the no action case. In 2027, the TEIS projects need for only a single substation, and zero in the managed case. In 2032, the TEIS projects that only 8 substations would be needed in the unmanaged case, 4 if conservative mitigative measures are utilized.[606] Of these, all but one would be upgrades to an existing substation.[607] Projections for feeders are 9 in 2027 (5 in the managed case), and 125 in 2032 (75 if managed). In 2027, the TEIS projects 2800 transformers (2,400 if managed), and 30,000 in 2032 (21,000 in the managed case).[608] Compare this to the estimated 1 million transformers sold domestically each year, and the estimated 50 million transformers associated with the U.S. electric grid.[609] Industry is also responding with actions such as Prolec GE's $30 million expansion at its Shreveport, Louisiana transformer plant, their $85 million new plant in Monterrey, Mexico, and Siemens Energy investing $150 million to build their first transformer production facility in the US in Charlotte, North Carolina.[610]

EPA finds that this projected amount of buildout attributable to the rule can be accommodated in the rule's time frame. Realistic estimates for time needed to install infrastructure components have been studied and are shared here (and see also RIA Chapter 5 for further discussion):

		Time to Implement (months)	
Component	**Capacity per Borlaug**	**Borlaug et al. 2021[611]**	**EPRI[612]**
Substation New	3 – 10+ MW	24–48	36–60
Substation Upgrade	3 – 10+ MW	12–18	24–36
Feeder New	5+ MW		12–24
Feeder Upgrade	5+ MW	3–12	6–12
Transformer New	200+ kW	3 - 8	3 - 8

Although new substations are a significant undertaking that can take multiple years as shown in the Table above, as noted, the TEIS finds that, for the 5-state analysis, only 4 incremental substations are required for the managed scenario and 8 for unmanaged in 2032. In 2027, TEIS found that only a single upgraded substation (or none in the managed case). We note further that the estimates in the TEIS Study of the amount of distributive buildout needed are likely conservative with respect to this rule as the TEIS Study considered aggregate effects of the light/medium duty standards and the Phase 3 heavy duty emission standards together and did not disaggregate the results. Given the relatively low power requirements associated with light- and medium-duty electric vehicle charging, we expect the associated distribution system infrastructure upgrades to be less significant than that associated with heavy-duty charging. In addition as noted above, the "unmanaged" scenario presented above considers no mitigation efforts at all. In the managed scenarios with basic management practices, the estimated impacts decrease sharply. The action managed case is projected to *reduce* peak loads in all 5 States in 2027, and to reduce peak loads in 3 of the 5 States in 2032.

Additional Considerations Supporting Feasibility and Leadtime of Infrastructure

Commenters representing the utility sector also emphasized their ability to upgrade their systems as needed to accommodate the increases in electricity demand associated with PEV charging. EPA notes this assessment from the Energy Strategy Coalition:

> Members of this coalition are already engaging in long-term planning to meet the increased demand for electricity attributable to vehicle electrification, and the LMDV Proposal will provide a regulatory backstop supporting further investments in electrification and grid reliability. Demand for electricity will increase under both the LMDV Proposal and the recently-proposed Phase 3 Greenhouse Gas Emissions Standards for Heavy-Duty Vehicles ("HDV Proposed Rule"), but the electricity grid is capable of planning for and accommodating such demand growth and has previously experienced periods of significant and sustained growth. Moreover, historic growth in demand and generation resources does not reflect the investments that will be made under the Infrastructure Investment and Jobs Act ("IIJA") and the Inflation Reduction Act ("IRA") to support the deployment of new renewable and zero-carbon generation resources, energy storage and charging infrastructure.

We also note the following supportive comment from Edison Electric Institute:

> As EPA notes, the electric power sector has a long history of accommodating growth in electricity demand from the adoption of new technologies, including electric home appliances, residential and commercial air conditioning, and data centers. See id. At 25,983. Electricity use from EVs today is modest. Argonne National Lab estimates the approximately 2.3 million EVs on the road as of the end of 2021 consumed 6.1 terawatt-hours of electricity in that year, or about 0.16 percent of the total electric sales to U.S. customers in that year. As EPA also notes, the increase in electricity use resulting from the Proposed Rule also will be modest, increasing electricity end-use by less than 3 percent in 2055. See id. On a macro-level, meeting the increased energy usage from electric truck adoption as contemplated in the Proposed Rule will not be a significant challenge for the electric power sector. Meeting the location-specific power needs of large electric vehicle (EV) charging facilities can be a more pressing challenge. *** However, this is a challenge that can be addressed with deliberate effort and collaboration among electric companies, fleet operators, and stakeholders.

We have also observed States and localities taking appropriate action to support needed infrastructure. For example, as the Energy Strategy Coalition notes, “Expectations for electrification of the vehicle fleet are already being incorporated into long-term planning decisions of electric utilities, regional transmission organizations and independent system operators. For example, National Grid co-authored a November 2022 study to “support utility long-term capital planning,” which assumed that the two states in its service territory (New York and Massachusetts) reached 100% sales of zero-emission passenger vehicles by 2035 and complied with California’s Advanced Clean Trucks regulation.”[613] Numerous States and Cities also submitted supportive comments reflecting the support for charging infrastructure in their jurisdictions.[614]

Historical precedent also provides substantial support for the feasibility of the needed distribution buildout. As we noted at proposal, and as several commenters agreed, U.S. electric power utilities routinely upgrade the nation’s electric power system to improve grid reliability and to meet new electric power demands. For example, when confronted with rapid adoption of air conditioners in the 1960s and 1970s, U.S. electric power utilities maintained reliability and met the new demand for electricity by planning and building upgrades to the electric power distribution system. Likewise, U.S. electric power utilities planned and built distribution system upgrades required to service the rapid growth of power-intensive data centers and server farms over the past two decades. The U.S. electric power distribution system infrastructure has already successfully accommodated the addition of 1.4 million electric vehicles in 2023 alone.[615]

[614] See CA AG Comment at 21-25.

[615] U.S. DOE. Statement by U.S. Energy Secretary Jennifer M. Granholm on 2023 EV Sales. Accessed February 22, 2024. January 5, 2024. Available online: https://www.energy.gov/articles/statement-us-energy-secretary-jennifer-m-granholm-2023-ev-sales

We note further that the need for additional infrastructure buildout is not an unprecedented situation with CAA section 202 standards. For example, when EPA required the removal of lead from gasoline, an entire new parallel fuel distribution system was developed to dispense the new unleaded gasoline. Other examples where new distribution systems arose to ensure delivery of fuels necessary to vehicular pollution control include the infrastructure to supply diesel exhaust fluid (used to support selective catalytic reduction) and ultra-low sulfur diesel fuel (used to support diesel particulate filters). We thus see that there can be successful market responses to demand created by a section 202 standard, including successful responses from unregulated entities.

Consistent with this historical precedent, we expect that the final rule itself will serve as a strong signal to the utility industry to make proactive investments and otherwise proactively analyze and plan for potential buildout needs. Numerous commenters, including utilities, State and local governments, NGOs, and other experts, filed comments in agreement.

Putting this together, EPA finds that the increases in national electricity demand associated with the rule are very low in 2027 and increase to modest and manageable levels in later years of the program. At a regional and local level, we expect some areas to see small increases in peak demand, while other areas may see small decreases in peak demand associated with basic managed charging strategies. The resulting level of needed infrastructure buildout is small and manageable given the lead-time available.

Time for Interconnection

Certain commenters noted that even if no distributive buildout is needed, the time for interconnection can be significant. In response, EPA notes that the timeline for EVSE deployment—even without distribution upgrades—is very site specific and also has considerable variability based on the permitting jurisdiction, but we believe that where connection is required, that can be accomplished within the leadtime provided. Electrify America found that after site construction is completed, an additional 12 weeks was required on average for inspection, commissioning and other steps before a site was energized. In addition, permitting times can vary by region and site specifics. For example, Electrify America reported that the permitting process took an average of 13 weeks for its U.S. "ultra-fast" DCFC stations in 2021, but took over twice as long for stations in New Jersey.[616] Finally, we note FERC Order 2023, which relates to interconnection reforms. Order 2023 requires grid operators to adopt certain interconnection practices with the goal of reducing interconnection delays. These practices include a first-ready, first-served interconnection process that requires new generators to demonstrate commercial readiness to proceed, and a cluster study interconnection process that studies many new generators together.[617]

[617] See generally FERC Order 1023, 184 FERC ¶ 61,054 (July 28, 2023) (Docket No. RM22-14-000).

Additional Comments and Responses

When commenting on the methodology that we used to determine the effects and costs of generation, transmission, and distribution system impacts presented in the proposed rule, some commenters stated that "EPA does not include in its assessment a clear explanation on how this estimate was obtained."

EPA conducted extensive electric power sector modeling analyses in which it concluded that there is adequate generation and transmission capacity required to meet the electric load demands imposed by the final rule. Moreover, the modeling analyses confirmed that there is adequate generation and transmission capacity to meet North American Electric Reliability Corporation (NERC) reliability standards, including those for reserve capacity.

In this final rule, EPA demonstrates that the impacts of both this rule alone and this rule combined with other proposed EPA actions result in anticipated power grid changes that 1) are consistent with key National Electric Reliability Corporation (NERC) assumptions, 2) that are consistent with historical trends and empirical data, and 3) are consistent with goals, planning efforts and Integrated Resource Plans (IRPs) of industry itself.

For additional discussion of these topics, see RIA Chapter 5: Electric Power Sector and Infrastructure Impacts and the Technical Memorandum for Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles, and Greenhouse Gas Emissions Standards for Heavy-Duty Vehicles – Phase 3 Docket ID No Numbers. EPA-EPA–HQ–OAR–2022–0829 and EPA-HQ-OAR-2022-0985 (also referred to as "Resource Adequacy Technical Memorandum").

EPA also conducted extensive and first-ever, national-level distribution system modeling analyses in conjunction with the U.S. Department of Energy (DOE), the National Renewable Energy Laboratory (NREL), and the Lawrence Berkeley National Laboratory (LBNL) in support of this final rule. This analysis found that managed electric vehicle charging confers many benefits to the distribution system and its reliability and. For additional discussion For additional discussion, see RIA Chapter 5: Electric Power Sector and Infrastructure Impacts and the joint DOE-NREL-LBNL-EPA Technical Report for the Transportation Electrification Infrastructure Study (TEIS).

One commentor expressed concern that electric vehicles will require new EGUs that "rely heavily on carbon capture technologies to keep the emissions from these electricity-generating power plants out of the atmosphere. Current carbon capture technologies are experimental and may prove dangerous."

The final rule is not premised on the adoption of CCS technologies at EGUs. The electric power grid has been and continues to be in transition, from coal-fired to renewably-sourced generation. As such, we expect that the electric power generation capacity required to charge the electric vehicle fleet will be derived increasingly from renewable sources and less so from fossil fuel-fired sources. Variations of CCS have been in use safely for over 40 years for enhanced oil recovery, a process by which carbon dioxide is injected underground to increase oil production.

One commenter stated, "As indicated by a study conducted by the National Renewable Energy Laboratory (NREL), dramatically accelerating electrification of sectors such as transportation, may make it more difficult to decarbonize the electricity system due to the higher rate of generation and transmission capacity additions needed." However, the authors of the cited NREL report go on to state in the sentence following the one provided by the commentor that implementing such transportation electrification, when combined with the electrification of building end-uses "is likely a key part of the most cost-effective pathway to achieving largescale decarbonization across the economy." EPA's modeling of the emissions impacts of this rule, including the upstream impacts associated with increased electricity generation, concludes that the rule will create significant net reductions of GHGs and criteria pollutants and will lead to air quality improvements across the United States.

One commentor stated that the results of the final rule "leap-frog even President Biden's ambitious 2030 target… described in The U.S. National Blueprint for Transportation Decarbonization, authored by four cabinet level agencies."

As a "blueprint", the self-described U.S. National Blueprint for Transportation Decarbonization does not set enforceable targets but, rather, serves as a long-term guide for federal agencies tasked with writing climate change-related policies. While EPA is aware of the U.S. National Blueprint for Transportation Decarbonization, it is not part of EPA's rationale for this rulemaking. Rather, EPA promulgated this rulemaking under its own authority in the Clean Air Act and based on the Administrator's own judgments as to feasibility, costs, lead-time, and other factors.

Some commenters claim that the Integrated Planning Model (IPM), EPA's multi-regional, dynamic, deterministic linear programming model of the U.S. electric power sector that EPA used to develop this final rule, does not consider the cost of grid-scale electric power storage. EPA disagrees; IPM provides projections of least-cost capacity expansion, electricity dispatch, and emission control strategies for meeting energy demand and environmental, transmission, dispatch, and reliability constraints and does, in fact, consider the cost of grid-scale electric power storage.

As some commenters note, the Inflation Reduction Act does not include transmission system permitting reforms.

As an initial matter, the need for new transmission lines associated with the final rule and the HD Phase 3 Rule between now and 2050 is projected to be very small, approximately one percent or less of transmission. Nearly all of the projected new transmission builds appear to overlap with pre-existing transmission line right of ways (ROW), which makes the permitting process simpler. Approximately 41-percent of the potential new transmission line builds projected by IPM have already been independently publicly proposed by developers. The agency finds that the utility sector can reasonably manage this very limited need for additional transmission.[618] We do not believe transmission system permitting reforms are needed to accommodate the minimal increases in transmission infrastructure associated with this rule.

Further, several recent initiatives have been undertaken to improve the transmission system planning and permitting process. These initiatives have been undertaken by the Congress, DOE, and FERC. For example, FERC issued a Notice of Proposed Rulemaking (NOPR) in 2022, titled Building for the Future Through Electric Regional Transmission Planning and Cost Allocation and Generator Interconnection, that requires transmission operators to conduct long-term

[618] See RIA 5.2.7.

transmission planning as well as requiring transmission providers to work with states to develop a cost-allocation formula, among other changes. The primary goal of the NOPR is to improve the quality of transmission projects that get built and to align the projects with long-term capacity needs to insure that the new builds are will continue to foster grid reliability into the future.

DOE recently announced several programs and projects to accelerate transmission system permitting reforms. Examples of such programs and projects include DOE's Interconnection Innovation e-Xchange (i2X), which aims to increase data access and transparency, improve process and timing, promote economic efficiency, and maintaining grid reliability; DOE's Grid Resilience and Innovation Partnerships (GRIP) program, with $10.5 billion in Bipartisan Infrastructure Law funding to develop and deploy Grid Enhancing Technologies (GET), such as Dynamic Line Ratings (DLR) and Advanced Power Flow Controllers (APFC), which help to increase the load carrying ability of transmission lines. To facilitate upgrading and rebuilding transmission lines, DOE issued a Notice of Proposed Rulemaking to update its National Environmental Policy Act ("NEPA") implementing regulations. DOE also conducted the National Transmission Planning Study to designate areas experiencing electricity transmission constraints or congestion as National Interest Electric Transmission Corridors (NIETCs). In February 2024, DOE announced a Request for Proposals (RFP) for the second round of the Transmission Facilitation Program, a revolving fund supported by the Bipartisan Infrastructure Law to help overcome financial hurdles facing large-scale new and upgraded transmission lines.

To facilitate transmission interconnection reforms, FERC has initiated a rulemaking for Order 2023 (Improvements to Generator Interconnection Procedures and Agreements), which requires grid operators to adopt certain interconnection practices with the goal of reducing interconnection delays in the face of rapidly growing interconnection queues of new resources looking to connect to the transmission system. These practices include a first-ready, first-served interconnection process that requires new generators to demonstrate commercial readiness to proceed, and a cluster study interconnection process that studies many new generators together.

Citing perceived hurdles in the transmission line siting process, the Congressional Research Service (CRS) notes that transmission permitting reform has been a topic of debate in the 118th Congress and that Congress amended FERC's siting authority in the Infrastructure Investment and Jobs Act in 2021. The CRS also notes that "DOE and FERC are currently developing regulations to implement this revised authority. Some transmission permitting reform legislative proposals would further amend this authority, for example by granting siting authority for all large interstate transmission lines to FERC."[619]

Energy storage projects can also be used to help to increase transmission line capacity by reducing line congestion and are seen as alternatives to transmission line construction. These projects, known as Storage As Transmission Asset (SATA), can help to reduce transmission line congestion, have smaller footprints, have shorter development, permitting, and construction times, and can be added incrementally, as required. Examples of SATA projects include the ERCOT Presidio Project, a 4 MW battery system that improves power quality and reducing momentary outages due to voltage fluctuations, the APS Punkin Center, a 2 MW, 8 MWh battery system deployed in place of upgrading 20 miles of transmission and distribution lines, the

[619] Congressional Research Service, 2023. Electricity Transmission Permitting Reform Proposals (https://crsreports.congress.gov/product/pdf/R/R47627/3).

National Grid Nantucket Project, a 6 MW, 48 MWh battery system installed on Nantucket Island, MA, as a contingency to undersea electric supply cables, and the Oakland Clean Energy Initiative Projects, a 43.25 MW, 173 MWh energy storage project to replace fossil generation in the Bay area.

Through such efforts, the interconnection queues can be reduced in length, transmission capacity on existing transmission lines can be increased, additional generation assets can be brought online, and electricity generated by existing assets will be curtailed less often. These factors help to improve overall grid reliability.

This should not be considered a comprehensive list of transmission system initiatives or storage activities currently underway.

One commenter claimed that “The electrical grids are neither stable nor safe enough to handle EPA’s proposal” and that “The country will be more energy dependent and less secure because of it.” The commenter, however, fails to adduce any data, analysis, or other evidence in support of its view. Therefore, its comment is not raised with reasonable specificity as required. As we explain in preamble IV.C.5, EPA has performed comprehensive analysis of grid reliability and projects that this rule will not adverse affect grid reliability. Further, EPA’s analysis of energy security shows that this rule will create significant positive energy security benefits. See IV.C.7.iii of this preamble for a discussion of energy security benefits.

One commenter claim that the electric power system is “already strained” by the uptick in renewable energy.”

Sources of renewable electricity generation currently comprise one-quarter of total generation by the U.S. power sector (EIA Monthly Energy Review (2/24). EPA also notes that this increase in renewable electric power generation coincides with an increase in grid reliability.(https://www.eia.gov/todayinenergy/detail.php?id=45796).

These indicators suggests that the U.S. electric power system is capable of safely and effectively delivering electricity from renewable sources. Studies from DOE show how the U.S. could accommodate between 70-79% of wind and solar generation by 2050 (Brinkman, Gregory, Dominique Bain, Grant Buster, Caroline Draxl, Paritosh Das, Jonathan Ho, Eduardo Ibanez, et al. 2021. The North American Renewable Integration Study: A U.S. Perspective. Golden, CO: National Renewable Energy Laboratory. NREL/TP-6A20-79224. https://www.nrel.gov/docs/fy21osti/79224.pdf).

EPA’s analysis in the Resource Adequacy Technical Memorandum further finds that this rule and the HD Phase 3 Rule (“Vehicle Rules”), whether alone or combined with other EPA rules affecting the power sector (“Power Sector Rules”), are associated with changes in grid composition that do not adversely affect resource adequacy, a key element of grid reliability. As part of this analysis, we show that significant increases in variable renewable penetrations can be achieved while respecting resource adequacy, as projected by multiple, highly respected peer-reviewed models.

Citing an article about indoor marijuana cultivation, one commenter claimed that the electric power system is “running on an antiquated delivery system established several decades ago.”

We overview the history of the electric power sector in preamble IV.C.5. While aspects of this claim may be correct, many articles, reports, and studies from sources such as Institute of Electrical and Electronics Engineers (IEEE), a “professional association for electronics engineering, electrical engineering, and other related disciplines,” find that electric vehicles can facilitate the integration of renewable resources. For instance, see “EVs Are Essential Grid-Scale Storage” (https://spectrum.ieee.org/electric-vehicle-grid-storage), which summarizes the results of the research of Xu et. al (Xu, C., Behrens, P., Gasper, P. et al. Electric vehicle batteries alone could satisfy short-term grid storage demand by as early as 2030. Nat Commun 14, 119 (2023). https://doi.org/10.1038/s41467-022-35393-0).

Citing a California news report, one commenter claimed that “EV owners asked to not charge vehicles during peak hours” during the 2022 heatwave that affected southern California. The article cited by the commentor cites an alert issued by the California Independent System Operator (ISO), which oversees the operation of California's bulk electric power system. In the alert, California ISO requested “voluntary electricity conservation” when temperatures in Northern California were 10-20 degrees warmer than normal and 10-18 degrees warmer than normal in Souther California. The California ISO’s request continued: “To minimize discomfort and help with grid stability, consumers are also encouraged to pre-cool their homes and use major appliances and charge electric vehicles and electronic devices before 4 p.m., when conservation begins to become most critical.”

The California ISO alert also provided a list of ten voluntary ways in which electricity consumers could help to reduce electricity consumption during the alert, of which postponing electric vehicle charging was one. A U.S. Department of Energy (DOE) report agrees with these actions as options for consumers to improve energy efficiency (https://www.energy.gov/energysaver/reducing-electricity-use-and-costs#:~:text=Incorporate%20passive%20solar%20design%20concepts,heater%20and%20operate%20it%20efficiently).

Generally, we find that scheduling electric vehicle charging during lower demand periods can significantly reduce the costs of charging as well as provide important services to the grid. We further discuss the benefits of managed charging practices in preamble IV.C.5.

Citing an article, a commenter claims that the cybersecurity concerns associated with electric vehicle charging are “without a solution.” However, the cited article presents “several patches for the existing (cybersecurity) vulnerabilities and discuss two methods aimed at detecting EV attacks.” Continuing, the commenter claims that “The grids not only lack the capacity to accommodate the Proposed Rule’s new demands on them, but are also nowhere near secure enough to take them on.”

The commenter makes two claims: that the grid lacks capacity and that the grid is not secure. Regarding the first claim, EPA conducted extensive electric power sector modeling analyses in support of this final rule in which it concluded that there is adequate generation and transmission capacity to meet the load demands imposed by the final rule. Moreover, the modeling analyses confirmed that there is adequate generation and transmission capacity to also meet North American Electric Reliability Corporation (NERC) reliability standards, including those for reserve capacity. Through such analyses, we project that the final rule will not have adversely affect resource adequacy and grid reliability. The managed charging of electric vehicle has also been shown to increase grid reliability and facilitate the deferral of electric power sector infrastructure.

For additional discussion of these topics, see RIA Chapter 5: Electric Power Sector and Infrastructure Impacts and the Technical Memorandum for Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles, and Greenhouse Gas Emissions Standards for Heavy-Duty Vehicles – Phase 3 Docket ID No Numbers. EPA-EPA–HQ–OAR–2022–0829 and EPA-HQ-OAR-2022-0985.

Regarding the second claim, Presidential Executive Order 13636: Improving Critical Infrastructure mandates that the Department of Homeland Security (DHS) establish a Cybersecurity Framework, which has been done in conjunction with the National Institute of Standards and Technology (NIST). As directed by DHS, NIST has undertaken several actions and activities, including the recently released NIST Cybersecurity Framework (CSF) 2.0, designed to contend with a range of threats and multiple attack vectors, both physical and cyber. In response to a National Security Memorandum, "Improving Cybersecurity for Critical Infrastructure Control Systems," DHS's Cybersecurity and Infrastructure Security Agency (CISA), in coordination with NIST, developed preliminary cybersecurity performance goals (https://www.govinfo.gov/content/pkg/DCPD-202100622/pdf/DCPD-202100622.pdf). In addition to collaborating with DHS, NIST works closely with the Department of Energy and several National Laboratories in securing EV charging stations, data flow networks, and utility power distributers.

We note, moreover, that cybersecurity concerns are not limited to PEV charging. The same true with respect to power outages more generally. Both of these concerns apply to infrastructure more generally, including the infrastructure used to fuel ICE vehicles. For example, as gasoline pumps are electric powered, power outages affect both owners of all vehicles. As we note in RIA 5.4.5:

The effect of power outages on electric vehicle owners is expected to be similar to that of non-electric vehicle drivers. Neither driver will be able to "fuel" during power outages, as gasoline pumps are electric powered. However, electric vehicles can provide their owners with residential power for a limited time. Moreover, electric vehicle chargers that are attached to distributed energy resources, such as homes or businesses with solar and/or stationary battery storage, would be unaffected by power outages and, thereby, can continue to provide charge for electric vehicles via its independent capacity. In fact, electric vehicles could be used to power gasoline pumps during electric power outages. Given that the physical extent of typical power outages tends to be relatively small, electric vehicle drivers, as well as conventional vehicle drivers, can be expected to drive out of the outage area and to unaffected charging or refueling stations, should it become necessary. Furthermore, we note that there are cybersecurity concerns uniquely associated with refueling of ICE vehicles, for example, cybersecurity attacks on petroleum pipelines. See The Attack on Colonial Pipeline: What We've Learned & What We've Done Over the Past Two Years, https://www.cisa.gov/news-events/news/attack-colonial-pipeline-what-weve-learned-what-weve-done-over-past-two-years

One commentor claims that "EPA fails to account for the rising cost of electricity over the regulatory period." Another commentor claims that "in some cases, these costs will ultimately be passed on to ratepayers" when discussing the cost of electrical infrastructure upgrades associated with this final rule. EPA discusses the impacts on retail electricity prices in preamble IV.C.5 and RIA 5.

When discussing possible costs associated with National Electric Vehicle Infrastructure (NEVI) program, a formula program administered by the Federal Highway Administration (FHWA) and the Joint Office of Energy and Transportation and funded through the Bipartisan Infrastructure Law, as enacted in the Infrastructure Investment and Jobs Act, one commentor cited infrastructure costs from the Electric Vehicle Infrastructure Deployment Plans from Idaho and Indiana.

EPA notes that NEVI funds can be used to offset certain increases in EVSE and distribution costs due to increased PEV charging associated with the final rule. The existence of NEVI funds, along other funding opportunities, further supports that the needed charging infrastructure can be developed. We further discuss funding opportunities for EVSEs in RTC 17.

NEVI is a federally-funded voluntary program to which state apply. As such, it is presumed that the states of Idaho and Indiana voluntarily sought NEVI funding and, conversely, that if these states did not desire electric vehicle infrastructure funding from this voluntary program, they would not have applied. The NEVI program has funded a total in $615 million in 2022, an estimated $885 million in 2023, and $885 million in each successive year until the end of fiscal year 2026.

NEVI Formula Program funds can be used for electric grid equipment and upgrades. The costs to acquire and install on-site electric service equipment (e.g., power meter, transformer, switch gear) are eligible. Costs for minor grid upgrades are also eligible, provided the work is necessitated solely by the construction or upgrading of the EV charging station and participation in the upgrade does not exceed the allocable cost of the minimum upgrades needed to match the planned power requirements of the EV charging station. A minor grid upgrade is defined as the work necessary to connect a charging station to the electric grid distribution network; for example, extending power lines or upgrading existing power lines several miles. Finally, major grid upgrades, such as longer line extensions or upgrades, improvements to offsite power generation, bulk power transmission, or substations are ineligible.

State DOTs are encouraged to consider the magnitude of these costs and explore whether they could be covered by the electric utility or programs other than the NEVI Formula Program so as to minimize use of NEVI Formula funds for grid upgrades where possible. See the Utility Planning section below for additional information.

States are also encouraged to consult with the FHWA and the Joint Office of Energy and Transportation to determine if an exception to charging station siting requirements may be warranted or if there are additional viable alternatives.

One commentor claims that “EPA fails to account for the impacts of mass electrification (increased electricity demand), the transmission infrastructure upgrades and battery storage that will be needed to support a transition to renewable generation sources, and the potential impacts to electrical grid costs and reliability” in its projection of future electricity prices.

As noted earlier, EPA conducted extensive electric power sector modeling analyses in support of this final rule in which it accounted for the impacts of mass electrification (increased electricity demand), the transmission infrastructure upgrades and battery storage that will be needed to support a transition to renewable generation sources and the potential impacts to electrical grid costs. In conducting the modeling analysis, EPA demonstrated that there is adequate generation and transmission capacity to meet the load demands imposed by the final rule. Moreover, the modeling analyses confirmed that there is adequate generation and transmission capacity to also meet North American Electric Reliability Corporation (NERC) reliability standards, including those for reserve capacity.

For additional discussion of these topics, see RIA Chapter 5: Electric Power Sector and Infrastructure Impacts and the Technical Memorandum for Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles, and Greenhouse Gas Emissions Standards for Heavy-Duty Vehicles – Phase 3 Docket ID No Numbers. EPA-EPA–HQ–OAR–2022–0829 and EPA-HQ-OAR-2022-0985.

One commentor claims that "EPA does not adequately consider potential grid reliability impacts."

As noted earlier, EPA conducted extensive electric power sector modeling analyses in support of this final rule in which it considered potential grid reliability impacts. In this modeling analyses, EPA demonstrated that there is adequate generation and transmission capacity to meet the load demands imposed by the final rule. Moreover, the modeling analyses confirmed that there is adequate generation and transmission capacity to also meet North American Electric Reliability Corporation (NERC) reliability standards, including those for reserve capacity for the Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles, and Greenhouse Gas Emissions Standards for Heavy-Duty Vehicles – Phase 3.

For additional discussion of these topics, see RIA Chapter 5: Electric Power Sector and Infrastructure Impacts and the Technical Memorandum for Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles, and Greenhouse Gas Emissions Standards for Heavy-Duty Vehicles – Phase 3 Docket ID No Numbers. EPA-EPA–HQ–OAR–2022–0829 and EPA-HQ-OAR-2022-0985.

One commentor alleges that "Reliance on BEVs may have unintended, negative consequences, especially in relation to the electricity generation sector." The commenter, however, fails to adduce any data, analysis, or other evidence in support of its claim. Therefore, its comment is not raised with reasonable specificity as required.

Notwithstanding the commenter's failure to provide any data or analysis in support of its contentions, EPA conducted extensive electric power sector modeling analyses in support of this final rule in which it considered potential grid reliability impacts. In this modeling analyses, EPA demonstrated that there is adequate generation and transmission capacity to meet the load demands imposed by the final rule. Moreover, the modeling analyses confirmed that there is adequate generation and transmission capacity to also meet North American Electric Reliability Corporation (NERC) reliability standards, including those for reserve capacity for the Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles, and Greenhouse Gas Emissions Standards for Heavy-Duty Vehicles – Phase 3.

For additional discussion of these topics, see RIA Chapter 5: Electric Power Sector and Infrastructure Impacts and the Technical Memorandum for Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles, and Greenhouse Gas

Emissions Standards for Heavy-Duty Vehicles – Phase 3 Docket ID No Numbers. EPA-EPA–HQ–OAR–2022–0829 and EPA-HQ-OAR-2022-0985.

One commentor claims that "charging infrastructure is inadequate to meet the country's transportation needs."

This study cited by the commentor discusses shoppers' interest in purchasing electric vehicles. The study cited by the commentator finds that "26% of shoppers say they are "very likely" to consider purchasing an EV, up from 24% a year ago, while the percentage of shoppers who say they are "overall likely" to consider purchasing an EV increases to 61% from 59% in 2022." The study also finds that "Most EV owners will say charging is one of the greatest benefits of ownership, because 85% of it is done at home, But it's the exceptional use case—like a vacation road trip—that's holding shoppers back." While the study also reveals dissatisfaction with public charging, the study makes no claims about the adequacy of the U.S. charging infrastructure. We further respond to comments about EVSEs, including public charging stations, in RTC 17.

The second reference cited by the commentator considers "home charging behaviors and attitudes", rather than the adequacy of the U.S. charging infrastructure. Moreover, the second reference cited by the commentator is scheduled to be published after this rule is finalized. As the study has not yet been released to the public, EPA cannot comment on the merits of the claims made therein.

One commentor claims that "EPA's analysis of grid impacts and electrical reliability is unrealistic" and that "ZEV mandates like the proposed rule also present significant risks to grid reliability and the stability of the transportation sector, yet EPA's analysis of electrical grid impacts is weak." EPA disagrees. EPA conducted extensive electric power sector modeling analyses in support of this final rule in which it considered potential grid reliability impacts. In this modeling analyses, EPA demonstrated that there is adequate generation and transmission capacity to meet the load demands imposed by the final rule. Moreover, the modeling analyses confirmed that there is adequate generation and transmission capacity to also meet North American Electric Reliability Corporation (NERC) reliability standards, including those for reserve capacity for the Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles, and Greenhouse Gas Emissions Standards for Heavy-Duty Vehicles – Phase 3.

For additional discussion of these topics, see RIA Chapter 5: Electric Power Sector and Infrastructure Impacts and the Technical Memorandum for Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles, and Greenhouse Gas Emissions Standards for Heavy-Duty Vehicles – Phase 3 Docket ID No Numbers. EPA-EPA–HQ–OAR–2022–0829 and EPA-HQ-OAR-2022-0985.

Moreover, as we explain in RTC 2, this rule is not a "ZEV mandate." Manufacturers may comply with this rule in many ways, including by producing no additional BEVs above the no-action baseline. See preamble IV.

Some commentors expressed a need to be better-integrated into the planning processes. The National Association of Regulatory Utility Commissioners (NARUC) has undertaken several key initiatives that help to facilitate outreach and communications between Public Service

Commissions and Public Utilities Commissions and the investor-owned utilities, publicly owned utilities, and member-owned or cooperative utilities that they regulate.

Some commentors expressed concerns about supply chain shortfalls related to electric power sector components. The Department of Energy is undertaking several programs to reduce supply chain lead times for electric power sector components. These programs range from addressing the ongoing shortage of grain-oriented electrical steel (GOES) to developing and approving approaches to speed the development of EV charging infrastructure and include a Siemens transformer manufacturing facility (Expanding U.S. transformer manufacturing and service footprint (siemens-energy.com)), a DOE award to CorePower Magnetics to build a manufacturing facility for magnetic components and advanced metals (CorePower Magnetics Awarded $20M from DOE to Establish Domestic Manufacturing Facility in Pittsburgh), a DOE funding announcement for Flexible and Innovative Transformer Technologies (U.S. Department of Energy Announces $18 Million for Flexible, Innovative Transformers | Department of Energy), and a late 2022 announcement from Hitachi Energy of a $37 million investment in its transformer manufacturing facility in Virginia (Hitachi Energy invests US$37 million to expand transformer manufacturing facility in South Boston, Virginia).

Significant investment is going toward improving grid component supply chains and many innovative charging solutions are available to minimize the need for grid upgrades. BIL and IRA incentives have led to significant new investments in grid component supply chains in the U.S. that will reduce lead times and costs for needed utility upgrades. In February 2024, Siemens announced that it will invest $150 million in a transformer manufacturing facility in North Carolina that will build and refurbish large power transformers.[620] CorePower Magnetics received a $20 million DOE award to build a manufacturing facility for amorphous metals and magnetic components that are used in transformers, among other applications. The facility will increase U.S. production by 20%.[621] DOE also announced a funding opportunity in February 2024 for $18 million to advance research, deployment, and demonstration of transformer technologies that can alleviate supply chain constraints.[622] In addition, numerous tools are available to accelerate connection of new EV charging loads to the utility grid. As discussed in Section IV.C.5 of the Preamble, flexible interconnection using power control systems can allow new fast charging loads to connect to the grid while utility upgrades are still in progress. Battery-integrated charging, which reduces charging stations' maximum power draw from the grid, can accelerate deployment by mitigating the need for utility system upgrades and can also potentially lower levelized costs of charging.[623] One company, Freewire, sells DC fast chargers with built-in battery storage.[624] Other types of distributed generation (including solar, linear generators, and fuel cells) can similarly be used to reduce the dependence of charging infrastructure on the grid. Utilities also have opportunities to smooth deployment of charging infrastructure, and can help their customers find locations where fewer grid upgrades would be needed. Utility hosting

624 https://freewiretech.com/dc-boost-charger/

capacity maps are available in at least 24 states and the District of Columbia, and maps that show capacity for additional load can direct charging infrastructure developers toward sites where installations can be completed more quickly.[625] New software platforms like the Energy Services eXchange (ESX), developed by Evoke and Argonne National Laboratory with funding from DOE, can help utilities manage EV loads on their distribution systems to further limit required upgrades.[626] Other potential solutions to accelerate EVSE deployment include mobile charging, sharing private chargers, and battery swapping.[627,628,629]

When inquiring about managed charging, one commentor asks "who would manage charging behavior, by what authority, and based on what standards or criteria."

The standards and criteria by which managed charging will occur are being addressed by the relevant state agencies, electric utilities, national associations representing these state agencies, standard-setting organizations, and the public. The motivation to address such issues is primarily economic self-interest. Electric utilities benefit from managed charging. The shareholders of electric utilities benefit from managed charging. Electric vehicle users benefit from managed charging. And electricity ratepayers – including those who are not electric vehicle users – benefit from managed charging.

The commenter alleges that "EPA does not account for the costs of these suggestions in its DRIA nor for any other safeguards to protect grid reliability." The commenter, however, fails to adduce any data, analysis, or other evidence in support of its claim. Therefore, its comment is not raised with reasonable specificity as required.

Notwithstanding the commenter's failure to provide any data or analysis in support of its contentions, EPA conducted extensive electric power sector modeling analyses in support of this final rule in which it concluded that there is adequate generation and transmission capacity to meet the load demands imposed by the final rule. Moreover, the modeling analyses confirmed that there is adequate generation and transmission capacity to also meet North American Electric Reliability Corporation (NERC) reliability standards, including those for reserve capacity.

Our examination of the record, informed by our consultations with DOE, FERC, and other power sector stakeholders, is that the final standards of this rule, whether considered separately or in combination with the Phase 3 HD vehicle standards and upcoming power sector rules, are unlikely to adversely affect the reliability of the electric grid, and widespread adoption of PEVs could have significant benefits for the electric power system. For additional discussion of these topics, see RIA Chapter 5: Electric Power Sector and Infrastructure Impacts and the Technical Memorandum for Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles, and Greenhouse Gas Emissions Standards for Heavy-Duty Vehicles – Phase 3 Docket ID No Numbers. EPA-EPA–HQ–OAR–2022–0829 and EPA-HQ-OAR-2022-0985.

One commentor asks about the role of natural gas in helping to secure grid reliability between 1992 and 2021.

According to the Energy Information Administration, four times as much coal was used to generate electricity in the U.S. in 1992 than natural gas. In 2001, three times as much coal was used to generate electricity in the U.S. than natural gas. In 2009, two times as much coal was used to generate electricity in the U.S. than natural gas. It was only in 2015 that the amount of coal used to generate electricity in the U.S. was roughly equal to the amount of natural gas used to generate electricity. EPA projects that significant natural gas capacity will remain online to support grid reliability. We further discuss our projections of generation capacity in RIA 5.2.5.

Renewable sources of electricity have recently supplanted coal-fired sources of electricity and the increasingly successful integration of the renewable sources into the electric power sector will continue to help secure grid reliability.

One commentor suggests that EPA "disregards the regional variations in expected PEV uptake, electricity generation, electricity demand, and grid reliability."

EPA disagrees with this comment. Regional variations in expected PEV uptake are addressed in the Likely Adopter Model (LAM). Regional variations in electricity generation and demand are also addressed in the electric power sector modeling, and resource adequacy related issues are addressed in the Resource Adequacy Technical Memorandum.

As noted earlier, EPA conducted extensive electric power sector modeling analyses in support of this final rule in which it accounted for the impacts of mass electrification (increased electricity demand), the transmission infrastructure upgrades and battery storage that will be needed to support a transition to renewable generation sources and the potential impacts to electrical grid costs. In conducting the modeling analysis, EPA demonstrated that there is adequate generation and transmission capacity to meet the load demands imposed by the final rule. Moreover, the modeling analyses confirmed that there is adequate generation and transmission capacity to also meet North American Electric Reliability Corporation (NERC) reliability standards, including those for reserve capacity.

For additional discussion of these topics, see RIA Chapter 5: Electric Power Sector and Infrastructure Impacts and the Technical Memorandum for Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles, and Greenhouse Gas Emissions Standards for Heavy-Duty Vehicles – Phase 3 Docket ID No Numbers. EPA-EPA–HQ–OAR–2022–0829 and EPA-HQ-OAR-2022-0985.

One commentor claims that "CAA Section 202(a) does not authorize the agency to force grid operators to manage electrical loads in completely new ways, or to dictate vehicle charging behavior."

EPA expects those agencies and organizations whose responsibility it is to manage electrical loads and/or affect charging behavior to fulfill their obligations. Contrary to the commentor's claim, this final rule does not compel or dictate actions beyond which the CAA Section 202(a) currently authorizes the agency to do in carrying out its environmental protection mission. EPA has assessed how grid operators and vehicle drivers may respond to the increased PEV adoption associated with the rule, but the final rule does not require grid operators to manage electrical loads in any specific way or dictate the vehicle charging behavior of EV drivers. Citing North

American Electric Reliability Corporation's (NERC's) reliability assessments, some commentors suggest that the final rule "fails to recognize existing grid reliability concerns."

EPA conducted extensive electric power sector modeling analyses in which it concluded that there is adequate generation and transmission capacity required to meet the electric load demands imposed by the final rule. Moreover, the modeling analyses confirmed that there is adequate generation and transmission capacity to meet North American Electric Reliability Corporation (NERC) reliability standards, including those for reserve capacity.

In this final rule, EPA demonstrates that the impacts of both this rule alone and this rule combined with other proposed EPA actions result in anticipated power grid changes that 1) are consistent with key National Electric Reliability Corporation (NERC) assumptions, 2) that are consistent with historical trends and empirical data, and 3) are consistent with goals, planning efforts and Integrated Resource Plans (IRPs) of industry itself.

For additional discussion of these topics, see RIA Chapter 5: Electric Power Sector and Infrastructure Impacts and the Technical Memorandum for Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles, and Greenhouse Gas Emissions Standards for Heavy-Duty Vehicles – Phase 3 Docket ID No Numbers. EPA-EPA–HQ–OAR–2022–0829 and EPA-HQ-OAR-2022-0985.

Moreover, as we note in preamble IV.C.5, power interruptions caused by extreme weather are the most-commonly reported, naturally- occurring factors affecting grid reliability, with the frequency of these severe weather events increasing significantly over the past twenty years due to climate change. Decreasing emissions of greenhouse gases can be expected to help reduce future extreme weather events, which would serve to reduce the risks for electric power sector reliability. By requiring significant reductions in GHGs from new motor vehicles, this rule mitigates the harmful impacts of climate change, including the increased incidence of extreme weather events that affect grid reliability.

Citing a suite of integrated modeling and analysis tools created by the Department of Energy's National Renewable Energy Laboratory (NREL) – which are designed to "overcome technical barriers and accelerate the development of advanced technologies and systems" – and were used to develop this final rule, one commentor claims that the model in question is "not amongst these NREL tools."

This claim is incorrect: The model in question is featured prominently as a "Transportation & Mobility Research" tool on the NREL website" (https://www.nrel.gov/transportation/evi-x.html). Further, the model in question serves as the analytic basis for NREL's "seminal" 2030 National Charging Network study, which can be found on NREL's website at: https://www.nrel.gov/docs/fy23osti/85970.pdf. Other NREL studies using the model in question can be found on NREL's website. For instance, Ge et al (2021) was a component of the 2030 study, which can be found on NREL's website at: https://www.nrel.gov/docs/fy23osti/85654.pdf.

Citing the above-referenced suite of integrated modeling and analysis tools created by the Department of Energy's National Renewable Energy Laboratory (NREL) – which are designed to "overcome technical barriers and accelerate the development of advanced technologies and systems" – and were used to develop this final rule, the commentor alleges that "The NREL study is nice work, but EPA's reliance on the study for this application is wholly unsuitable."

EPA appreciates the commentor's candor regarding NREL's technical and scientific competence; the development of this final rule benefited from the technical and scientific competence as well as the professionalism of NREL and the Department of Energy. The commenter, however, fails to adduce any data, analysis, or other evidence in support of its view. Therefore, its comment is not raised with reasonable specificity as required.

The commentor claims that the model in question "offers EPA no insight into or basis for estimating the PEV update and grid reliability impacts for most of the United States."

This claim is incorrect: "The geographic distribution of responses is representative of the population distribution in the United States..." which is supported by comparative distributions of spatial and demographic variables shown in Figures 3-6 of Ge et. al. (2021), as referenced above.

A commentor cited examples in which the authors of scientific research used in support of this final rule discussed limitations associated with the methodology used.

As is standard practice in scientific research publications, study limitations are discussed freely as a measure of transparency and in the name of scientific integrity. However, the examples of limitations cited by the commentor do not invalidate the subsequent analysis.

When discussing the suite of integrated modeling and analysis tools created by the Department of Energy's National Renewable Energy Laboratory (NREL) and used to develop this final rule, a commentor asks: "How did EPA go about establishing chassis-specific LAMs when the original NREL report mentioned nothing about vehicle classifications?" A "LAM" (Likely Adopter Model) is a type of model used by NREL, which provides a relative ranking of the likelihood of electric vehicle adoption across the general population.

Rather than develop four LAMs specific to each chassis type, the same LAM was applied to each of the four cited chassis types. The vehicle population for each chassis type features a unique spatial distribution (as reflected in registration data across all fuel types). The LAM was applied to the national population of each chassis type independently, providing regionalized adoption scenarios for each chassis type that reflect a combination of relative preference for chassis type and PEV likely adopters.

A commentor asks "Despite the lack of LAM survey respondents in the Midwest and Alaska, EPA inexplicably projects these regions to have the highest PEV pickup stocks of the entire United States."

We believe the commentor misinterpreted the data provided by EPA. Among the top five states for simulated adoption of PEV pickup trucks in 2032, the state of Ohio is ranked fifth. The state of Alaska is ranked 44th.

One commenter asserts that the EPA rule will require $1-2.4 trillion to update through 2050.

The high costs specified in the comment are not related to EPA's rules; rather, the comments refer to the costs of upgrading the entire aging transmission system (independent of EPA's rules) as well as the costs of capturing benefits associated with the renewable energy provisions of the IRA. This commentor cites a Reuters article from May 2022, which, in turn, refers to other two reports as sources of the article's information.

The first source appears to be an article from PUF (Public Utilities Fortnightly) in May 2020, entitled Modernizing Aging Transmission – A Golden Opportunity. This article states that the aging U.S. electrical transmission system – without potential EV load – will require $700 billion to upgrade its 140,000 miles of transmission lines by 2050. The article then goes on to claim that the costs of upgrading the transmission system to allow for vehicle electrification will increase this cost to more than $1 trillion by 2050. The article assumes an electric load growth associated with EVs of 45%. The article does not include technical details, so it is not possible to comment on them. However, the load growth associated with vehicle electrification from EPA's rule are more on the order of 11% by 2050, and not 45%, as claimed in the article.

The second source cited in the Reuters piece is from a Princeton Report on transmission general system upgrades the report authors believed were necessary in order to capture renewable energy provisions of the Inflation Reduction Act (IRA). Note that the study pertains to the IRA, not EPA's rules. This is a preliminary report and its conclusions are subject to change.

As EPA explains in the RIA, the regulatory analysis for this rulemaking evaluates the impacts of this rule relative to the regulatory baseline. This is consistent with OMB Circular A-4's guidance on regulatory analysis. For our analysis of electric sector impacts, EPA took the extra step of evaluating the combined impacts of this rule and the HD Phase 3 Rule, and in some cases, also evaluating the additional impacts of the Power Sector Rules, in order to better understand the context for this rule and the cumulative impacts of our rules, and to respond to comments regarding those cumulative impacts. Our analysis, including the IPM, also considers the impacts of the IRA and BIL, which provides important context for the final rule, including by significantly reducing the costs to purchase PEVs. We disagree with the commenter's suggestion, however, that the impacts of actions beyond this rule should be attributed to this rule for purposes of assessing costs. For example, even were EPA to accept as true the $1-2.4 trillion price tag for a complete overhaul of the electric grid, those costs are not attributable to this rule, and those numbers are therefore irrelevant. In the same way, although we project that manufacturers may use advanced gasoline vehicle technologies to comply with this rule, it would not be appropriate to consider the considerable costs associated with US petroleum infrastructure development as attributable to this rule. In any event, we have fully considered the costs of increasing electricity demand due to increased PEV adoption associated with this rule and found that those costs are modest and reasonable, as explained in RIA 5 and preamble IV.C.5.

A commentor claims that states have "expressed concerns regarding electrical grid and utility impacts in their DOT-approved state EV Infrastructure Deployment Plans".

The "DOT-approved state EV Infrastructure Deployment Plans" to which the commentor refers to is known collectively as the National Electric Vehicle Infrastructure (NEVI) program, a voluntary program administered by the Federal Highway Administration (FHWA) and the Joint Office of Energy and Transportation and funded through the Bipartisan Infrastructure Law, as enacted in the Infrastructure Investment and Jobs Act.

NEVI is a federally-funded program to which states may voluntarily choose to apply. As such, it is presumed that the states cited by the commenter have voluntarily sought NEVI funding. By extension, it seems reasonable to conclude that if the states cited by the commentor did not desire electric vehicle infrastructure funding from this voluntary program, they would not have applied. The NEVI program has funded a total in $615 million in 2022, an estimated $885 million in 2023, and $885 million in each successive year until the end of fiscal year 2026.

NEVI Formula Program funds can be used for electric grid equipment and upgrades. The costs to acquire and install on-site electric service equipment (e.g., power meter, transformer, switch gear) are eligible. Costs for minor grid upgrades are also eligible, provided the work is necessitated solely by the construction or upgrading of the EV charging station and participation in the upgrade does not exceed the allocable cost of the minimum upgrades needed to match the planned power requirements of the EV charging station. A minor grid upgrade is defined as the work necessary to connect a charging station to the electric grid distribution network; for example, extending power lines or upgrading existing power lines several miles. Finally, major grid upgrades, such as longer line extensions or upgrades, improvements to offsite power generation, bulk power transmission, or substations are ineligible.

State DOTs are encouraged to consider the magnitude of these costs and explore whether they could be covered by the electric utility or programs other than the NEVI Formula Program so as to minimize use of NEVI Formula funds for grid upgrades where possible.

States are also encouraged to consult with the FHWA and the Joint Office of Energy and Transportation to determine if an exception to charging station siting requirements may be warranted or if there are additional viable alternatives.

This commentor continues, claiming that "EPA has not accounted for these concerns in its analysis."

Overall, the identification of potential infrastructure issues (along with other challenges) in State NEVI plans indicates that State governments are well aware of these issues and giving due consideration to them as they plan to install new charging infrastructure with NEVI funds. Given the important role of State agencies in electricity infrastructure, we think this awareness and consideration by State agencies is a positive factor supporting the development of charging infrastructure. As we explain in preamble IV.C.5, we do also agree that additional infrastructure buildout is likely to support increased PEV adoption, and based on our analysis, we find that the scope and costs of that buildout is modest and reasonable.

To the extent the commenter is concerned with how the NEVI funds themselves are administered by FHWA and JOET, that issue is beyond the scope of this rulemaking.

A commentor correctly points out that electricity demand varies by time of day. To capture the time-varying nature of electricity demand, we used the Integrated Planning Model (IPM), EPA's multi-regional, dynamic, deterministic linear programming model of the U.S. electric power sector, to estimate electric power plant emissions that were used to develop this final rule.

However, the source of the data cited by the commentor is eGRID, a static database which does not vary with time. As such, eGRID is incapable of capturing the time-varying nature of electricity demand, as required, and, therefore, fails to capture actual electric power plant emissions.

One commentor claims that the cost of charging an electric vehicle at home "could raise the annual electricity bill for the average family by 50 percent or more", but fails to note that the reduction of gasoline costs *not* paid by the family are approximately three-times greater.

In other words, the cost of electricity paid for electric vehicle charging by the average hypothetical family would be approximately $675 per year, whereas the cost of gasoline paid for by the aforementioned family would be approximately $1,900 per year, given the assumptions provided by the commenter. As such, the cost of driving an electric vehicle is three-times less-expensive than driving a gasoline-powered vehicle. EPA's own analysis also demonstrates that purchasers of PEVs will incur significant operating savings over the lifetime of the vehicle.

This same commentor alleges that EPA pretends its "rules will not put a colossal additional strain on our already vulnerable national power grid."

As noted earlier, EPA conducted extensive electric power sector modeling analyses in which it concluded that there is adequate generation and transmission capacity required to meet the electric load demands imposed by the final rule. Moreover, the modeling analyses confirmed that there is adequate generation and transmission capacity to meet North American Electric Reliability Corporation (NERC) reliability standards, including those for reserve capacity.

In this final rule, EPA demonstrates that the impacts of both this rule alone and this rule combined with other proposed EPA actions result in anticipated power grid changes that 1) are consistent with key National Electric Reliability Corporation (NERC) assumptions, 2) that are consistent with historical trends and empirical data, and 3) are consistent with goals, planning efforts and Integrated Resource Plans (IRPs) of industry itself.

For additional discussion of these topics, see RIA Chapter 5: Electric Power Sector and Infrastructure Impacts and the Technical Memorandum for Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles, and Greenhouse Gas Emissions Standards for Heavy-Duty Vehicles – Phase 3 Docket ID No Numbers. EPA-EPA–HQ–OAR–2022–0829 and EPA-HQ-OAR-2022-0985.

Continuing, this commentor alleges that "To accommodate EPA's future fleet of EVs, our national electric grid capacity would need to grow 60 percent or so by 2030."

Based upon the extensive electric power sector modeling conducted in support of this final rule, the expected increase in electric power demand in 2030 will be less than one-percent of the overall expected electricity consumption for that year. In other words, the expected impact on the electric power system is expected to be approximately 60 times less than alleged by the commentor.

Continuing the discussion of the expected electricity demand made by this final rule in 2030, the commentor suggests that the "This buildout is simply not practicable in the timeframe EPA is contemplating."

As noted above, the increase in electricity demand is expected to be less than one-percent by 2030. The increase in expected electricity demand between the kick-off of the Super Bowl and the end of the Super Bowl will be approximately 4.2%, according to PJM Interconnection, a regional transmission organization (RTO) operating the electric transmission system serving all or parts of Delaware, Illinois, Indiana, Kentucky, Maryland, Michigan, New Jersey, North Carolina, Ohio, Pennsylvania, Tennessee, Virginia, West Virginia, and the District of Columbia that serves 65 million people, or about 20 percent of the U.S. population.

One commenter cited the average retail electricity rates from a 2015 EIA study of the proposed Clean Power Plan. The commenter subsequently used the average retail electricity rates to extrapolate electricity expenditures associated with this final rule and claimed that there "is a nearly $1 trillion difference" between the costs cited in this final rule and those extrapolated by the commentor.

We disagree with the commenter's analysis. We do not think a nearly decade old EIA study of a different rule—indeed a different *proposed* rule regulating an entirely different industry sector—has persuasive value. By contrast, EPA conducted extensive electric power sector modeling analyses in support of this final rule based on the most up to date information. For additional discussion of these topics, see RIA Chapter 5: Electric Power Sector and Infrastructure Impacts.

Further, as noted in the EIA study, the model used to develop the analysis is not a comprehensive macroeconomic model of the economy; rather, it is an energy model, which does not contain a power flow model or assess the reliability of bulk power transmission systems in detail. The EIA model also excludes health effects and was also criticized in congressional hearings for overstating in its base case the emissions from coal plants and understating the power generation contributions from natural gas, nuclear and renewable energy.

Citing a document entitled "Grid-Friendly EV Charging Dynamic Behavior", one commentor referenced concerns regarding potential grid reliability issues associated with residential air conditioning units in the western U.S. and linked these concerns to electric vehicle charging. There have been no documented instances of electric vehicle charging that have led to the similar grid reliability issues. The document in question focused on infrequent grid disturbances that originate on the Bulk-Power System (BPS) that, in 2010, caused residential air conditioning units to stall. There was concern at the time of the incidents, if left unchecked, might lead to blackouts, but the matter was quickly diagnosed by a consortium of electric power sector researchers. Many of these researchers helped author the cited document, which provides recommendations and describes EV charging behavior.

Some commenters claim that natural gas prices have "risen significantly due to the Russian invasion of Ukraine." The claims are incorrect. U.S. natural gas prices have decreased steadily since the start of the Ukrainian war. For instance, the U.S. benchmark Henry Hub natural gas price in 2023 was about a 62% lower than in 2022 due, in part, to record-high natural gas production, flat consumption, and rising natural gas inventories, according to the EIA.

Some commentors claim that "If the conflict ends in the next 5-10 years, natural gas prices in the U.S. could return to pre-invasion levels, which would complicate the accelerated deployment of renewables that the agency is forecasting." The commenter, however, fails to adduce any data, analysis, or other evidence in support of its view. Therefore, its comment is not raised with reasonable specificity as required.

This failure notwithstanding, natural gas prices have decreased, on average, since the start of Russia's invasion of the Ukraine. Further, a return to relatively higher pre-invasion natural gas prices would seem to further accelerate the transition from natural gas-fired EGUs to renewable electric power generation.

Some commenters claim that "dramatic expansion in wind and solar can occur only with breakthroughs in the economics of grid-scale energy storage technologies." According to the EIA Monthly Energy Review, wind and solar-powered electricity generation in the U.S. increased by a factor of 82.5 times – an increase of 2,300% – since 2000 without the need for “breakthroughs in the economics of grid-scale energy storage technologies.” While we are unaware of a strict statistical definition of “dramatic”, we do believe that the 82.5 times increase in renewable energy penetration in the U.S. since 2000 does constitute, if nothing else, a “significant” expansion of wind and solar. In short, the dramatic expansion of wind and solar penetration has already occurred.

Some commentors claim, in part, that EPA “ignores the need for more natural gas peaking capacity and massive transmission, substation, and transformer investment to integrate these technologies into the power grid. Those emissions are significant and may offset or eliminate the benefits that EPA calculates.” This claim is inaccurate. EPA conducted extensive electric power sector modeling analyses in which it concluded that there is adequate generation and transmission capacity required to meet the electric load demands imposed by the final rule. The analysis included the anticipated need for electric power generation, which includes natural gas-fired peaking units. These costs are included in the retail electricity process. We also modeled emissions, including upstream emissions associated with electricity generation, and found that on net, this rule results in significant reductions of GHGs and criteria pollutants, with widespread benefits for air quality.

One commentor expressed their dissatisfaction with this rule and wondered “How are we powering the chargers for these electric vehicles?” EPA conducted extensive electric power sector modeling analyses in which it concluded that there is adequate generation and transmission capacity required to meet the electric load demands imposed by the final rule. The analysis presumes that electric vehicles will be charged with electricity generated at electric generation units (EGU).

When discussing EPA’s analysis of the potential impacts of vehicle electrification, some commentors claim that the EPA violates the “law of supply”. These claims might stand to reason if the economic system described by the commentor was static and unchanging or, as economists might say, “ceteris paribus”.

However, the system, as described by the commentor, is neither.

And the commentor’s reasoning neglects to consider these other factors – factors that may affect electricity prices include location, time, and fluctuations in other inputs (e.g., the effects of lower cost electricity available from distributed energy resources (DER) or vehicle to grid (V2G) technologies, which are available at the periphery of the distribution system, as well as other factors which serve to alter the supply and demand curves). It is through the consumer’s shift to the new, lower-price supply curve that consistency with the “law of supply” is maintained; this is an example of fluctuations in inputs. The commentor’s reasoning also neglects to consider managed charging, which has the effect of shifting electric vehicle charging to times when electricity is less expensive; this is an example of the time sensitivity of electric vehicle charging. Managed charging and related approaches to mitigating distribution system impacts confer additional benefits that are not captured by the commentor, such as those associated with the deferral of capital expenditures for distribution system upgrades.

To lend credence to this claim, the commentor cites a tutorial by the New England Independent System Operator (ISO-NE), an independent, non-profit, regional transmission organization (RTO) that serves approximately 6.5 million people in the states of Connecticut, Maine, New Hampshire, Rhode Island, and Vermont as well as the Commonwealth of

Massachusetts. EPA notes that in the final section of this tutorial, entitled "Reality Is Much More Complicated", ISO-NE states that "The examples above provide a simplified way to understand how the markets work. In reality, the ISO manages market clearing and settlement for hundreds of market participants at hundreds of distinct clearing prices every day of the year". The tutorial then goes on to cite the reasons why electricity prices may vary, which includes location, time, and fluctuation in other inputs, all of which was considered in EPA analysis.

One commentor suggests that the Inflation Reduction Act is "required for the large new transmission lines necessary to bring renewable energy to the markets where they are needed." While constraints in the U.S. electricity transmission system exist, DOE, FERC, and others have taken extensive steps to help reduce the constraints. These are discussed elsewhere in this document. It is also worth noting that the U.S. electric power system has already successfully and reliably integrated enough renewable electricity to surpass, for the first time, nuclear generation in 2021, and coal-fired generation in 2022. In support of the commentor's claim, the commentor cites various reports and testimony. The first cited report states that "to achieve its climate ambitions and fully implement transformative legislation like the Inflation Reduction Act, Congress will also have to enable a massively accelerated build-out of clean energy infrastructure." The report then goes on to discuss possible approaches that may help to facilitate transmission line development. These approaches are laid out in the report as "Actionable Policy Options" and include: a significant expansion of federal planning, general permitting, and programmatic review; siting authority for all interstate transmission lines could be federalized; the administration could conduct a staff capacity, funding, and technology needs assessment across agencies involved with critical permitting for clean energy Congress could support multi-agency coordination by allocating additional funding to the Federal Permitting Improvement Steering Council (FPISC); Congress could transfer initial authority for Clean Air Act permitting for offshore wind from the Environmental Protection Agency (EPA) to the Bureau of Ocean Energy Management (BOEM); Congress could support multi-agency coordination by allocating additional funding to the Federal Permitting Improvement Steering Council (FPISC); and Congress could proceed with narrow reforms to the National Environmental Policy Act (NEPA).

The second report cited by the commentor states that "The IRA may significantly reduce emissions from coal owing to the large volume of subsidy directed for low-carbon electricity generation". However, the report authors then go on to note that the potential effects associated with the IRA on transmission system development were not considered on their report. Acknowledging such, the report authors write that "This analysis did not assess (IRA) provisions for energy efficiency, transmission or permitting." The report authors continue, noting that "This analysis did not assess provisions for energy efficiency, transmission or permitting." As for the reasoning behind why the report authors elected to not consider the potential effects of the IRA on transmission system development in the report cited by the commentors, the report authors write that "…the IRA spends over $2 billion on transmission facilities. As the impact of this spending can be highly variable depending on where it is distributed, we do not assume its effects". The final reference cited by the commentor that electric power transmission may affect the potential benefits associated with the IRA. As noted above, DOE, FERC, and others have taken extensive steps to help reduce transmission constraints.

Continuing, the commentor states that "The IPM modeling also ignores the massive expansion of grid-scale energy storage that would be required to achieve reliability with renewables." EPA conducted extensive electric power sector modeling in support of the final rule, which includes grid-scale storage facilities, which were found to help integrate renewable electricity sources into the grid. See Chapter 5 of the RIA for a discussion on the electric power sector modeling. The commentor continues, "For these reasons, it is unrealistic to expect that the electricity currently provided by fossil fuels will be provided by renewables within the average lifetime of the model year 2032 vehicle." We do expect continuing use of fossil fuels, including coal and natural gas. However, we expect significant increases in renewable penetration over the coming decades. EPA notes that the grid transition referred to by the commentor has already occurred and continues, in part, with support from the IRA.

More generally, to the extent the commenter is requesting legislative action or permitting reforms by other Federal agencies or State agencies, the comments are beyond the scope of this rulemaking.

Some commentors suggested that electric power system upgrades might be needed to accommodate vehicle electrification in a more-timely manner. Should they be required, numerous tools are available to expedite the timely incorporation of electric vehicle charging infrastructure into existing electric power systems. These tools help to ensure that new charging stations can be connected to the grid as quickly as possible and without adversely affecting grid reliability. These tools include managed charging, time-of-use (TOU) electric rates, distributed energy resources (DERs), Power Control Systems (PCS), utility hosting capacity maps, Battery Energy Storage (BES), Advanced Distribution Management System (ADMS), Load Constraint Management System (LCMS), and others. For additional discussions of these topic, please see Chapter 5 of the RIA and preamble IV.C.5.

Some commentors point out that PEV charging can reduce utility bills for all customers. The EPA agrees with the commentor. Moreover, some commentors claim that the "electric system impacts associated with this final rule will be gradual and within the range of historical growth" and that the "projected growth in electricity demand are well within the range of past historical load growth." The EPA agrees with both comments.

Citing Southern California Edison (SCE), an electric utility based in Southern California, some commentors note the importance of time-of-use (TOU) electric rates in shifting charging times for electric vehicles: "The figures above represent real-world data collected from hundreds of thousands of households with PEVs. There is no need to test the proposition that simple TOU rates designed for PEVs work." The EPA agrees with the conclusions of commentor.

19 - Fuels and life cycle analysis (LCA)

19.1 - Fuels

Comments by Organizations

Organization: 25x'25 Alliance, et al.

The failings of the proposed rule follow almost entirely from EPA's decision to "bet the farm" on electric vehicles. The agency would be far better served by taking a more holistic approach. There are 281 million internal combustion engine vehicles on the road today and 100 million more will be built in the next two decades. All of these vehicles could be improved—and for far less than what EPA's proposal would cost—with an improvement in fuel quality. [EPA-HQ-OAR-2022-0829-0573, pp. 1-4]

SEE ORIGINAL COMMENT FOR PIE CHART of Role for Liquid Fuels [EPA-HQ-OAR-2022-0829-0573, pp. 1-4]

SEE ORIGINAL COMMENT FOR BAR GRAPH of EPA-Projected Cumulative U.S. Sales 2023-2032 [EPA-HQ-OAR-2022-0829-0573, pp. 1-4]

EPA is statutorily obligated to explore this approach. Section 202(a)(3)(A)(ii) requires that, "in establishing classes or categories of vehicles or engines for purposes of regulations under this paragraph, the Administrator may base such classes or categories on gross vehicle weight, horsepower, type of fuel used, or other appropriate factors." 42 U.S.C. § 7521(a)(3)(A)(ii) (emphasis added). There are many ways EPA could consider the type of fuel as a means of settings its regulations: through the consideration of life-cycle emissions under the agency's Section 202 powers, through increased volumes of low-carbon renewable fuels under the Renewable Fuel Standard, through alternative, low-carbon certification fuels, or through Section 211(c) rulemaking—as the proposal itself suggests. These options are not beyond the scope of this rulemaking but are obvious alternatives to EPA's current all-electric approach. And "the failure of an agency to consider obvious alternatives has led uniformly to reversal." Spirit Airlines, Inc. v. DOT, 997 F.3d 1247, 1255 (D.C. Cir. 2021). [EPA-HQ-OAR-2022-0829-0573, pp. 1-4]

EPA must consider these alternatives, and would be well served to issue a new proposed multipollutant rule that: [EPA-HQ-OAR-2022-0829-0573, pp. 1-4]

1) incorporates requirements to improve fuel quality by

- establishing a higher federal octane standard while allowing higher blends of ethanol; and

- "incenting the reduction of carbon and aromatic compounds via reformulation or alternatively increasing ethanol blending. [EPA-HQ-OAR-2022-0829-0573, pp. 1-4]

2) provides incentives for automakers to produce flex-fuel vehicles by

- creating alternative certification pathways for higher ethanol blends; and

- correcting the problems with R-Value and CO2 penalty that other commentors have identified and re-establishing the Volumetric Conversion Factor in the fuel economy calculation algorithm. [EPA-HQ-OAR-2022-0829-0573, pp. 1-4]

3) adopts a life-cycle analysis approach to calculating and comparing emissions from different technologies. [EPA-HQ-OAR-2022-0829-0573, pp. 1-4]

Embracing and enabling a pathway to improve fuel quality will increase and accelerate emission reductions, improve public health, help achieve environmental justice goals, provide greater versatility, and improve reliability all at less cost. This pathway is available to EPA and the consideration of it is demanded by the Clean Air Act. The best and most recent data suggests that the adoption of even mid-level ethanol blends would reduce pollution emissions at least as much as EPA's electrification approach, and at far less cost.i Even if EPA's electrification program could be successful—and as explained above, it cannot—a complimentary fuel improvement would double EPA's projected emissions reduction. The current rule takes this option off the table and leaves those pollutants in the air. EPA could do far better. [EPA-HQ-OAR-2022-0829-0573, pp. 1-4]

1 See "Higher Ethanol Blends Support the Transition to a Low-Carbon Future," Brian West, SAE Update, February 2023, pp2-6) National adoption of mid-level ethanol blends is available, feasible, and lower cost than current gasoline. https://www.nxtbook.com/smg/sae/23UPD02/index.php#/p/2

Organization: Alliance for Automotive Innovation

X. Fuels

Given the timespan over which internal combustion engine technology will continue to be available to new vehicle purchasers, and the years that those vehicles will remain in the field, improved liquid fuels are a critically important technology enabling pathway. Improved liquid fuels can facilitate increased fuel efficiency, and reduced GHG and non-GHG emissions as the EV market continues to grow. EPA has requested comments on potential future gasoline fuel property standards, and as such we offer the following.403 [EPA-HQ-OAR-2022-0829-0701, p. 260]

403 NPRM at 29197.

A. EPA Should Act Now to Improve Fuels

EPA should act now to: [EPA-HQ-OAR-2022-0829-0701, pp. 260-261]

- Implement a nationwide clean fuel standard to lower GHG emissions;

- Regulate the particulate forming tendency of market gasoline by eliminating the heavy aromatic fraction of gasoline, thereby reducing PM emissions from all ICE vehicles, equipment, and engines to improve air quality for all;

- Lower the sulfur cap of gasoline from 80 ppm to 10 ppm at the refinery gate to further reduce non-GHG emissions from ICE-equipped vehicles and engines to improve air quality;

- Adjust Tier 3 certification fuel specifications to align with current market fuel composition and to enable fuel suppliers to target a particulate matter index of 1.5 to 1.6;

- Cap summer vapor pressure of gasoline at 9.0 psi or less, regardless of ethanol content, to further reduce evaporative emissions as E10 fuel is ubiquitous in the market;

- Immediately eliminate sub-87 anti-knock index ("AKI") octane fuels from the market to increase fuel efficiency and reduce GHG emissions;

- Transition to a higher minimum-octane gasoline (i.e., minimum 95–98 research octane number) to facilitate higher engine efficiency; and

- Limit air toxics, e.g., olefins and aromatics, and their precursors from the fuel to improve air quality for all. [EPA-HQ-OAR-2022-0829-0701, pp. 260-261]

In addition to a comprehensive fuels rulemaking, Auto Innovators recommends that EPA also proceed with finalizing its eRINs proposal from the Renewable Fuel Standard Set Rule for Renewable Volume Obligations for 2023-2025 NPRM.404 This proposal provides a complementary approach to EPA's proposed multipollutant rule, including supporting and encouraging both EVs and renewable sources of energy, as well as to the overall goal of decarbonizing the transportation sector. [EPA-HQ-OAR-2022-0829-0701, pp. 260-261]

404 Renewable Fuel Standard Set Rule for Renewable Volume Obligations for 2023-2025, https://www.govinfo.gov/content/pkg/FR-2022-12-30/pdf/2022-26499.pdf

B. Legacy and New ICE-Equipped Vehicles Will Continue in the Fleet for a significant Time

Liquid fuels will continue to play a vital role in transportation for years to come, and there are important improvements that can be made to reduce carbon, increase vehicle fuel efficiency, and lower emissions supported directly by high octane, low carbon, and low emissions fuels. [EPA-HQ-OAR-2022-0829-0701, p. 261]

There are nearly 290 million light-duty cars and trucks in the United States,405 and nearly 98% of those vehicles operate on gasoline or diesel fuel.406 Even with the proposed GHG reductions in the NPRM, which as currently proposed would result in a projected BEV penetration of 67% of sales in 2032, it is clear that substantial numbers of liquid-fueled vehicles will be produced well through this decade and into the next. In addition, the average age of a vehicle in the U.S. has grown to over 12 years.407 The car parc will continue to rely on liquid fuels for years to come, and gasoline will continue to play a significant role in transportation and ultimately, air quality. [EPA-HQ-OAR-2022-0829-0701, p. 261]

405 U.S. Vehicle Registration Statistics, Hedges & Company, htps://hedgescompany.com/automotive-market- research-statistics/auto-mailing-lists-and-marketing/ (accessed May 23, 2023).

406 Figures compiled by Alliance for Automotive Innovation with registered vehicle data provided by IHS Markit, htps://www.autosinnovate.org/resources/electric-vehicle-sales-dashboard. (accessed May 23, 2023)

407 U.S. Vehicle Registration Statistics, Hedges & Company, htps://hedgescompany.com/automotive-market- research-statistics/auto-mailing-lists-and-marketing/ (accessed May 23, 2023).

Vehicles and fuels are a system and the role of liquid fuel improvements for gasoline vehicles can reduce emissions and improve air quality now and complement the GHG reduction from the EV fleet turnover. If EPA does not act as part of this rulemaking, or undertake a comprehensive fuels rulemaking in the near future, it is missing an important and crucial opportunity to implement a low-cost approach to improving fuel economy and reducing GHG and criteria pollutant emissions. [EPA-HQ-OAR-2022-0829-0701, p. 261]

C. EPA Has the Authority to Regulate Fuels to Improve GHG Emissions

The Clean Air Act provides statutory authority for the EPA to regulate GHG emissions, which can “cause, or contribute to, air pollution which may reasonably be anticipated to endanger the public health or welfare.”408 Section 211 of the Clean Air Act provides EPA with the authority to regulate motor vehicle fuels in furtherance of the Act’s goals. Specifically, Section 211(c) of the Act grants EPA the authority to set new national fuel standards, including octane rating, under the following circumstances: [EPA-HQ-OAR-2022-0829-0701, pp. 261-262]

408 Massachusetts v. EPA, 549 U.S. 497 (2007).

- (1)(A) “if in the judgment of the Administrator, any fuel or fuel additive or any emission product of such fuel or fuel additive causes or contributes to air pollution or water pollution… that may reasonably be anticipated to endanger the public health or welfare,” or

- (1)(B)“if emission products of such fuel or fuel additive will impair to a significant degree the performance of any emission control device or system which is in general use, or has been developed to a point where in a reasonable time it would be in general use were such regulations to be promulgated.” [EPA-HQ-OAR-2022-0829-0701, pp. 261-262]

It is important to note that the addition of GHGs to the list of Clean Air Act “pollutants” is changing how one thinks of emissions control. For purposes of considering EPA’s authority under 211(c)(1)(B), it is important to realize that the term “any emission control device or system” must be understood more broadly than it once was. With this realization, it is easy to see that engine efficiency improvements offer emission control benefits. However, low-octane fuel acts as a barrier to these efficiency benefits. EPA has the authority and must stand firmly on the side of removing these barriers and providing manufacturers with a full menu of options for striving to meet the future GHG standards. [EPA-HQ-OAR-2022-0829-0701, pp. 261-262]

In light of increasing GHG and CAFE requirements, it continues to be essential for vehicles and the fuels they operate on to be treated as a system and developed in tandem. Prospective fuels should enable greater vehicle efficiency and lower emissions, optimize the consumer experience, and fulfill societal values. Technology is in place to produce advanced engines. However, without a promulgated higher-octane fuel standard, the advanced engines cannot optimize their potential operational efficiency. It is now timely for EPA to undertake an accelerated process to implement and synchronize the market introduction of higher-octane gasoline that will enable the benefits of advanced technologies and support manufacturer investments. EPA has the authority to regulate national commercial gasoline octane specifications under the Clean Air Act. EPA should initiate a fast-track process to assure higher octane gasoline that meets the market and timing needs of new vehicle technologies for the U.S. commercial supply. [EPA-HQ-OAR-2022-0829-0701, pp. 261-262]

D. EPA Should Implement a Nationwide Clean Fuel Standard

Achieving ambitious climate goals requires regulators to recognize and incentivize all carbon reducing technologies. Fuels and vehicles should be treated as a holistic system, and as such, decarbonizing liquid fuels would yield immediate benefits for lowering the carbon intensity of transportation energy. Inclusion of low carbon fuels within a multi-pathway approach to emissions reductions would enhance the probability of meeting emissions goals. Low carbon fuels offer a hedge against uncertainties that could affect the pace of electrification. In addition, low carbon fuels would offer consumer choice on vehicles while still supporting decarbonization of transportation energy. The proposed regulations should factor for a range of consumers whose needs or budgets require different solutions, consistent with environmental justice objectives. Low carbon liquid fuels are an important part of enabling all vehicle owners to play a role in reducing emissions as fast as possible during the transition to an all-electric future. [EPA-HQ-OAR-2022-0829-0701, pp. 262-263]

EPA should take actions to support low or net-zero carbon liquid fuels. Although automobile manufacturers are focused on electrification, as noted above, actions on liquid fuels can provide benefits to legacy vehicles, would support even lower GHG emissions from PHEVs, and could provide much-needed GHG reduction pathways. EPA should leverage a new national Clean Fuel Standard (i.e., Low Carbon Fuel Standard or LCFS) and/or modified renewable fuel standard (RFS) to incentivize low carbon fuel use (e.g., renewable fuels and emerging carbon-neutral fuels, such as eFuels and synthetic fuels) in legacy and future ICE vehicles and engines. Upon introduction, this would have an immediate impact, reducing GHG emissions across the entire fleet of in use vehicles and engines. In addition, a properly structured nationwide Clean Fuel Standard, while providing GHG reductions, can also create new revenue sources to incentivize market adoption of EVs. [EPA-HQ-OAR-2022-0829-0701, pp. 262-263]

F. EPA Should Take Further Action on Fuels to Reduce Emissions and Improve Air Quality

Use of improved liquid fuels supports ongoing efforts to improve air quality and can provide an important bridge in reducing emissions during the transition to expanded vehicle electrification. [EPA-HQ-OAR-2022-0829-0701, p. 274]

In many cases gasoline improvements would improve emissions from virtually all of the 290 million vehicles on the road today, in addition to other liquid-fueled equipment. Given that these vehicles are on the road today and that benefits would accrue immediately upon introduction, we see no reason for EPA to delay in implementing a rulemaking. Auto Innovators has commented extensively in the past on the fuel improvements needed to address criteria pollutant and air toxics emissions. Several improvements to market fuels should be pursued: [EPA-HQ-OAR-2022-0829-0701, p. 274]

1. Reduce Refinery Gate and Downstream Sulfur Caps to 10 ppm

When EPA finalized the Tier 3 rules governing gasoline, it lowered the maximum average sulfur level from 30 ppm to 10 ppm. This change was essential to enable advance emissions control technology to achieve the lower tailpipe emissions standards that are part of the Tier 3 standards because, as EPA points out, "any amount of gasoline sulfur will deteriorate catalyst efficiency."446 However, EPA continues to allow gasoline with 80 ppm sulfur at the refinery gate and 95 ppm downstream. Auto Innovators continues to stand behind previous industry comments on sulfur as detailed in the Auto Alliance Tier 3 comments.447 Refiners and the distribution system have had many years to adjust to lower sulfur standards. [EPA-HQ-OAR-2022-0829-0701, p. 274]

446 Control of Air Pollution from Motor Vehicles: Tier 3 Motor Vehicle Emission and Fuel Standards, Proposed Rule, 78 Fed. Reg. 29816, 29821 (May 21, 2013).

447 Supplemental Comments of the Alliance of Automobile Manufacturers on Market Gasoline Sulfur, Alliance of Automobile Manufacturers (Oct. 31, 2013), Docket ID EPA-HQ-OAR-2011-0135-4950.

If EPA pursues lower Tier 4 emissions standards in the NPRM, we urge EPA to reduce the refinery gate cap to 10 ppm, perhaps with a phase-in period, and at the same time to develop a pathway toward a downstream retail cap of 10 ppm per gallon. The elimination of gasoline with greater than 10 ppm sulfur will enable advanced emissions control technology and will reduce the impact of sulfur on catalyst efficiency. This cap aligns with sulfur caps in the European Union and many parts of Asia, including China. The lower sulfur cap also aligns with the lower NMOG + NOx standards as proposed in the NPRM. [EPA-HQ-OAR-2022-0829-0701, p. 274]

2. Cap Summer Vapor Pressure at 9.0 psi or Less

EPA should cap summer gasoline vapor pressure at 9.0 psi or less regardless of ethanol level. From a vehicle operability perspective, there is no need for fuel vapor pressure to be even as high as 9.0 psi. California summer fuel is capped at 7 psi, and there have been no operability issues with on-specification fuel in California. Lower vapor pressure will reduce evaporative emissions across the fleet, particularly in older vehicles and off-road and handheld equipment. Since the beneficial effects of lower vapor pressure are enhanced by progressively lowering it and applying it to all gasoline fueled equipment from day one, there is no reason for EPA not to follow the California example for summer fuels and cap other seasons at ASTM D4814 maxima. [EPA-HQ-OAR-2022-0829-0701, pp. 274-275]

3. Eliminate sub-87 AKI Market Fuels

Vehicles sold in the U.S. require fuel octane of 87 AKI or higher. Tier 3 regular grade certification fuel has closely controlled octane and is specified at 87-88.4 AKI. In the majority of the U.S., the minimum market octane is 87 AKI by regulation or custom. However, in the Rocky Mountain states sub-octane fuel continues to be marketed. This was justified in the past by high altitude effects on engine knock. However, as ASTM D4814 section X1.6 points out: [EPA-HQ-OAR-2022-0829-0701, p. 275]

New vehicles have sensors to measure [sic] and engine management computers, which take into account such conditions as air charge temperature and barometric pressure. These vehicles are designed to have the same antiknock requirement at all altitudes and a reduced sensitivity to changes in ambient temperature. This more sophisticated control technology began to be used extensively in 1984. This technology, while constantly evolving and improving, is used on almost all new vehicles. This means that many vehicles in today's fleet require fuel having the same antiknock index regardless of changes in altitude or ambient temperatures.448 [EPA-HQ-OAR-2022-0829-0701, p. 275]

448 ASTM D4814, Standard Specification for Automotive Spark-Ignition Engine Fuel.

This text implies that the vehicles produced in the last 39 years require the same fuel as the rest of the country. More recently, automakers have produced increasing proportions of vehicles with turbocharged engines. These engines boost manifold pressure using turbochargers and are insensitive to altitude. [EPA-HQ-OAR-2022-0829-0701, p. 275]

The result of misfuelling these vehicles, whether they have sensors and engine management computers dating from 1984 or more advanced technologies, is that the vehicle will knock on the sub-octane fuel resulting in spark retard and enrichment to protect the engine from damage. Spark retard will reduce fuel economy and increase GHG emissions, while fuel enrichment will increase CO and HC emissions. The solution to these issues is easy: EPA must mandate that all market fuels meet or exceed the octane of Tier 3 certification fuel. [EPA-HQ-OAR-2022-0829-0701, p. 275]

4. EPA Should Adopt a High-Octane Fuel Standard

Higher-octane gasoline enables opportunities for the use of key energy-efficient technologies, including higher compression-ratio engines, lighter and smaller engines, improved turbocharging, and optimized engine combustion phasing and timing. All of these technologies, when paired with higher-octane gasoline, permit smaller engines to meet the demands of the consumer while at the same time providing higher efficiencies and thus reducing GHG emissions during vehicle use. Furthermore, depending on its composition, high-octane fuel is safe to use in many existing vehicles. [EPA-HQ-OAR-2022-0829-0701, pp. 275-277]

The relative efficiency gain enabled by higher octane rated gasoline is well documented. A literature review published by Leone et al. shows that increasing fuel octane rating from 91 RON to 95 RON facilitates an increase in efficiency by 3 to 5%.449 Figure 95 shows the correlation of efficiency gain enabled by higher octane rated fuels with higher compression ratio engines. [EPA-HQ-OAR-2022-0829-0701, pp. 275-277]

449 Thomas Leone et al., "The Effect of Compression Ratio, Fuel Octane Rating, and Ethanol Content on Spark- Ignition Engine efficiency." Environ. Sci. Technol. (2015) 49 (18), 10778-10789, htps://pubs.acs.org/doi/10.1021/acs.est.5b01420 (accessed Sep. 24, 2021).

[See original for graph titled "Figure 95: Relative efficiency gain with higher octane fuel rating. Raising octane enables engine compression ratio increases, resulting in improved engine efficiency."] [EPA-HQ-OAR-2022-0829-0701, pp. 275-277]

Auto Innovators (and its predecessor associations) has long advocated that EPA should require a transition to a higher minimum-octane gasoline (minimum 95–98 RON). There are several ways to produce higher octane-grade gasoline. Increasing the ethanol content of gasoline is one approach. Hydrocarbon composition changes are another. Reducing the proportion of low octane naphtha or increasing the proportion of higher-octane streams such as alkylate or reformate will result in higher octane fuels. Ethanol blends higher than E10, with misfuelling mitigation measures in place, have been suggested by some to provide better value to consumers to achieve higher octane numbers and reduce carbon emissions. Auto Innovators does not promote any sole or particular pathway. [EPA-HQ-OAR-2022-0829-0701, pp. 275-277]

Producing higher octane fuel for the future ICE fleet will not impose any significant burdens on the refining and retail sectors. Hirshfeld et al. analyzed the refining economics of raising the average octane rating of the U.S. gasoline pool by increasing the octane rating of refinery produced blendstocks for oxygenated blending and/or the ethanol content of the finished gasoline.450,451 These studies found a transition to higher-octane (95 RON, E10) gasoline was technically feasible and could be made without considerable increases in cost or CO2 emissions for refineries.452 The implementation of higher octane-rated gasoline in the marketplace would be a cost-effective means of improving fuel economy and therefore should be encouraged as soon as possible to maximize environmental benefits across the new car fleet. [EPA-HQ-OAR-2022-0829-0701, pp. 275-277]

451 David S. Hirshfeld et al., "Refining Economics of Higher Octane Sensitivity, Research Octane Number and Ethanol Content for U.S. Gasoline," Energy Fuels 2021, Publication Date: September 1, 2021, htps://doi.org/10.1021/acs.energyfuels.1c00247 (accessed Sep. 24, 2021).

Footnote 452: Id.

EPA has the ability to enable the ICE to achieve increased fuel efficiency by requiring higher minimum octane rated gasoline in the marketplace. Research, data, and evidence confirms the ability to increase ICE efficiencies as the octane rating of gasoline increases. EPA, in the past, has recognized its authority to alter fuel quality to increase efficiencies. Specifically, as the criteria emission standards have increased in stringency, the allowable sulfur concentration decreased in recognition of sulfur's deleterious effects on emission control systems. Today, the

GHG regulation has achieved such levels that the minimum market gasoline octane rating is limiting the ability to advance ICE technology. It is now necessary to adjust the gasoline octane rating (higher) commensurate with required decreases in GHG emissions. The new minimum octane rating needs to be set immediately to 95 RON and then increased to 98 RON as new GHG standards are implemented. The new gasoline octane levels are backwards compatible, and a subset of the vehicles in the legacy fleet have the ability to also increase efficiency in response to higher octane. Being able to leverage the legacy fleet in assisting in the reduction in transportation carbon emissions can significantly benefit the portfolio of technology solutions in achieving the collective goals associated with the climate. [EPA-HQ-OAR-2022-0829-0701, pp. 275-277]

The implementation of higher octane-rated gasoline in new vehicles would be a cost-effective means of improving fuel economy and reducing GHG emissions for the light-duty vehicle fleet. [EPA-HQ-OAR-2022-0829-0701, pp. 275-277]

Organization: Alliance for Vehicle Efficiency (AVE)

AVE seeks stronger support for hydrogen engine and fuel cell platforms as a means for the U.S. to meet its environmental goals.

AVE seeks stronger support from EPA for hydrogen fuel cells (H2FC) and hydrogen engine (H2ICE) vehicles, especially at MD levels. Although the Proposal acknowledges the benefits of fuel cell electric vehicles, ending the credit multipliers will hamper market penetration. Incentives could also help accelerate and encourage more hydrogen refueling infrastructure, which is desperately needed. [EPA-HQ-OAR-2022-0829-0631, p. 7]

AVE also asks EPA to consider H2ICE as a ZEV technology, as EPA did in its Phase 3 proposal. H2ICE could be an excellent opportunity to decarbonize the MD fleet faster with continued incentives. As the engine platform emits zero grams of CO2 at the tailpipe, H2ICE should be included as a compliance pathway. [EPA-HQ-OAR-2022-0829-0631, p. 7]

The IRA allocates billions of dollars towards the hydrogen marketplace, and President Biden has created a hydrogen policy roadmap. EPA can support these measures with compliance incentives for hydrogen-powered vehicles as they emit zero CO2 at the tailpipe and should qualify for the same incentives as all ZEV vehicles. [EPA-HQ-OAR-2022-0829-0631, p. 7]

AVE supports incentivizing renewable and low-carbon fuels as a compliance pathway.

AVE supports all efforts to help accelerate reaching the nation’s environmental goals. Although BEVs are expected to reach higher sales volumes, little attention is paid to the increased sales of larger SUVs. The International Energy Agency estimates that despite large gains in the future BEV market, the predominant vehicle technology sold in the U.S. will continue to be ICE vehicles. Moreover, the ICE vehicles will be bigger and have lower fuel economy than most passenger cars.21 [EPA-HQ-OAR-2022-0829-0631, pp. 8-9]

21 IEA - Global EV Outlook 2023 - Catching up with climate ambitions Page 10

Despite these market predictions, the Proposal does nothing to incentivize manufacturers to produce ICE vehicles that can operate on higher blends of renewable or low-carbon fuels. To fully appreciate the importance of incentivizing the use of low carbon fuels in ICE vehicles, EPA need not look any further than the analysis from the DOE's Energy Information Agency (EIA). EIA predicts fewer BEVs on U.S. roads than what EPA and others estimate over the next 27 years. [EPA-HQ-OAR-2022-0829-0631, pp. 8-9]

[See original for graphic titled "Light-duty vehicle sales by technology or fuel AEO2022 Reference case] [EPA-HQ-OAR-2022-0829-0631, pp. 8-9]

[See original for graphic titled "New vehicle sales of battery-powered vehicles AEO2022 Reference case] [EPA-HQ-OAR-2022-0829-0631, pp. 8-9]

Incentivizing renewable and low-carbon fuels will dramatically improve the emissions of the nation's existing fleet. The legacy LD fleet consists of approximately 280 million vehicles and consumers are now keeping vehicles for an average approaching 13-years. [EPA-HQ-OAR-2022-0829-0631, pp. 8-9]

Other regions of the world are investing in advanced biofuels and eFuels. In Europe, regulators have acknowledged the benefit of reducing the carbon footprint of liquid fuels and are supporting the expansion of eFuels.22 The EPA should support these efforts as well here in the U.S. Incentivizing the use of renewables and low-carbon fuels for compliance would accelerate and significantly increase CO2 reduction and bring greater environmental gains. [EPA-HQ-OAR-2022-0829-0631, pp. 8-9]

22 https://www.euronews.com/my-europe/2023/03/28/in-win-for-germany-eu-agrees-to-exempt-e-fuels-from-2035- ban-on-new-sales-of-combustion-en

Organization: American Coalition for Ethanol (ACE)

From the perspective of tailpipe-focused emissions, EPA's proposal represents the most ambitious standards ever for light-duty vehicles, effectively requiring 60% of all vehicle sales to be battery electric vehicles (BEVs) only by 2030, ramping up to BEVs representing 67% of all vehicle sales just two years later (2032). The Agency is seeking comment on alternative compliance scenarios; Alternative 1 would require BEVs to represent 69% of all vehicle sales by 2032 and Alternative 2, the "least stringent," would require BEVs to make up 64% of all vehicle sales by 2032. [EPA-HQ-OAR-2022-0829-0613, p. 1]

While ACE members share EPA's goal to significantly reduce lifecycle greenhouse gas (GHG) emissions from U.S. passenger vehicles, we know there is a better way than arbitrarily regulating a solution which merely focuses on the tailpipe and is practically unachievable. Therefore, ACE does not support the proposal nor either alternative. [EPA-HQ-OAR-2022-0829-0613, p. 1]

To be clear, ACE members recognize BEVs can play a meaningful role in decarbonizing the transportation sector. We also support technology-neutral policies which enable electric vehicles to compete on a level playing field with other low carbon technology solutions such as ethanol. We oppose policies which tilt the scale in favor of BEVs and ignore the lifecycle GHG emissions associated with them. [EPA-HQ-OAR-2022-0829-0613, p. 1]

Our comments will 1) discuss the practical, technical and legal problems associated with arbitrarily regulating BEVs as the only solution to reduce GHGs from the transportation sector, and 2) how EPA can fix its proposal to develop a practical and achievable technology-neutral final rule which achieves the goals we share to meaningfully reduce carbon pollution from transportation emissions. [EPA-HQ-OAR-2022-0829-0613, p. 1]

Another misnomer is the assertion BEVs have no emissions. BEVs are not zero emission vehicles. They are zero tailpipe emission vehicles. EPA's proposal conveniently ignores this reality by failing to account for the entirety of lifecycle GHG emissions associated with BEVs and the minerals/materials necessary to produce and power them. The Agency risks exposing itself to litigation regarding the potential arbitrary and capricious nature of a rule which ignores the lifecycle GHG emissions associated with BEVs in relation to how EPA assesses the emissions of biofuels. [EPA-HQ-OAR-2022-0829-0613, p. 3]

What's more, EPA lacks the authority to ignore upstream emissions for BEVs. The Agency has authority under 42 U.S.C. § 7521(a)(1) to prescribe "standards applicable to the emission of any air pollutant from any class or classes of new motor vehicles or new motor vehicle engines, which in its judgment cause, or contribute to, air pollution which may reasonably be anticipated to endanger public health or welfare." If BEVs are not "vehicles" "which cause, or contribute to, air pollution," then EPA may not set standards for them. If BEVs are "vehicles" "which cause, or contribute to, air pollution," then EPA must account for those emissions, which in the case of BEVs come from upstream electricity generating units. [EPA-HQ-OAR-2022-0829-0613, p. 3]

Recommended changes to ensure final rule achieves meaningful reductions in GHGs

EPA itself acknowledges millions of vehicles with internal combustion engines will continue to be sold well beyond 2032 and millions more of these vehicles will remain on U.S. roads for decades to come.7 Given this reality, we recommend the Agency develop a technology-neutral final rule which gives much more consideration to replacing the fossil fuel-based gasoline powering these vehicles with a lower carbon and higher-octane alternative, such as ethanol. President Biden himself has said we "simply cannot get to net-zero [emissions] by 2050 without biofuels."8 [EPA-HQ-OAR-2022-0829-0613, p. 4]

7 Fed. Register Page 29,397 of EPA's Proposed Rule.

8 U.S. President Joe Biden during an April 12, 2022 visit to Iowa announcing a temporary national emergency waiver for E15. https://www.whitehouse.gov/briefing-room/speeches-remarks/2022/04/12/remarks-by-president-biden-on-lowering-energy-costs-for-working-families/.

Many leading corn ethanol producers are on a trajectory to both net-zero and net-negative lifecycle emissions in the not-too-distant future. Compared to the massive supply chain disruptions and hurdles that must be cleared to achieve a transition to 67% BEVs by 2032, billions of gallons of low carbon and high-octane renewable liquid fuels such as ethanol are available right now to rapidly decarbonize transportation-related GHG emissions. Importantly, today's vehicle fleet and refueling infrastructure is mostly compatible with renewable fuels such as ethanol, biodiesel, and renewable diesel, making for a smoother, lower cost transition with the added benefit of not having to wait for immediate reductions in GHG emissions. If the overarching goal for the Biden Administration is net-zero emissions by mid- century, let's start making progress right now by taking full advantage of the 15 billion gallons of domestically produced ethanol available today as an affordable way to boost octane and meaningfully reduce GHG emissions from gasoline powered engines. [EPA-HQ-OAR-2022-0829-0613, p. 4]

EPA's final rule must address fuel quality and establish new certification fuel pathways to account for the tremendous benefits of high ethanol blends such as E15 and E85. This is the most effective way to rapidly reduce carbon pollution from light-duty vehicles. We strongly encourage the Agency to pay particularly close attention to the comprehensive comments submitted on July 2 by Pearson Fuels, the largest distributor of E85 in California, supplying more than 315 retail E85 stations. ACE specifically supports the recommendations Pearson Fuels makes with respect to establishing a GHG emissions factor or restoring a multiplier for E85 utilized in flexible fuel vehicles (FFVs) and developing an incentive to facilitate the development of hybrid FFVs such as the Toyota Hybrid Flex Corolla being pioneered in Brazil. [EPA-HQ-OAR-2022-0829-0613, p. 4]

We welcome EPA specifically identifying fuel and the opportunity to address particulate matter (PM) emission reductions from sources of liquid fuels in a separate future rulemaking. Given the inescapable link between vehicle emissions and the fuel used to power the engines in those vehicles, we strongly recommend the Agency not wait for a future rulemaking but rather address fuel quality and PM reductions as part of the final rule for 2027 and later model year vehicles. EPA's proposal explains the complications facing refiners with respect to reducing the content of high-boiling point compounds in gasoline given the need to meet market octane requirements (since removing aromatics from gasoline requires a method to replace the octane those aromatics contained). This presents another opportunity for the Agency to rely on greater concentrations of ethanol in gasoline because ethanol delivers the highest-octane rating for fuel at the lowest cost, allowing automakers to benefit by continuing to develop high-compression and fuel-efficient engine technologies to reduce vehicle GHG emissions. We believe high octane, low carbon blends comprised of 25 to 30 percent ethanol would enable more fuel-efficient vehicles, reduce GHG emissions, and reduce other pollutants. [EPA-HQ-OAR-2022-0829-0613, pp. 4-5]

There are approximately 25 million FFVs in the U.S. today. The ideal way to transition from today's legacy fleet of internal combustion engines to new vehicles with advanced engine technologies designed to run optimally on a high-octane fuel is to utilize FFVs as bridge vehicles that can provide immediate demand for midlevel ethanol blends. [EPA-HQ-OAR-2022-0829-0613, pp. 4-5]

As a matter of fact, the Department of Energy Oak Ridge National Lab has investigated the use of high- octane ethanol blends such as E25 and E30 in FFVs that are designed and compatible with ethanol blend levels from 0 to 85 percent and can therefore seamlessly and with OEM approval utilize midlevel ethanol blends.9 Key findings from Oak Ridge include: "Experiments were performed with four FFVs using an E10 (92 RON) and E30 (100 RON) fuel. The two direct-injection FFVs demonstrated performance improvements for E30 compared to E10 of 2.5 to 3 percent, based on the 15-80 wide- open throttle acceleration time. Three of the four FFVs showed performance improvement with high- octane E30 compared to regular E10. (…) Marketing E25 or E30 to FFV owners as a performance fuel may enable greater utilization of ethanol in the near term and could help establish the refueling infrastructure to enable manufacturers to build dedicated vehicles designed for a high-octane midlevel ethanol blend." [EPA-HQ-OAR-2022-0829-0613, pp. 4-5]

9 Effects of High-Octane Ethanol Blends on Four Legacy FFVs and a Turbocharged GDI Vehicle." Thomas, J, West, and Huff, S, U.S. DoE ORNL. March 2015.

Vehicle incentives/credits are not the only area in which EPA seems to penalize technologies designed to operate efficiently on ethanol-blended fuel, indeed another inequity exists with the Agency's outdated fuel economy formula. In previous statements, EPA has acknowledged part of the fuel economy formula (the R-factor) unfairly penalizes fuel containing ethanol. Consequently, EPA is discouraging automakers from developing efficient engines that require higher octane ratings and higher ethanol content. EPA has previously said the 0.6 R-factor is erroneous and fails to achieve the statutory purpose of evaluating the fuel economy of fuels containing ethanol. The auto industry has asked EPA for an R-factor of 1.0. In response, EPA has suggested the correct value may lie "between 0.8 and 0.9." ACE supports an R-factor of 1.0. [EPA-HQ-OAR-2022-0829-0613, p. 5]

Section 202(a)(3)(A)(ii) of the Clean Air Act authorizes EPA to look beyond the basic engine to set its engine or vehicle emission standards. Specifically, the statute says "in establishing classes or categories of vehicles or engines for purposes of regulations under this paragraph, the Administrator may base such classes or categories on gross vehicle weight, horsepower, type of fuel used, or other appropriate factors (emphasis added)." To account for the "type of fuel used" EPA needs to conduct a full lifecycle GHG emissions analysis. [EPA-HQ-OAR-2022-0829-0613, p. 5]

The full lifecycle GHG emissions analysis in the final rule must be based upon the latest version of the Greenhouse Gases, Regulated Emissions, and Energy Use in Technologies (GREET) model developed by U.S. Department of Energy's Argonne National Laboratory. GREET is considered the gold-standard for calculating energy use, GHGs, and other regulated emissions that occur during the full lifecycle production and combustion of all transportation fuels and sources. GREET is used by the California Low Carbon Fuel Standard program and the Oregon Clean Fuels program and has more than 40,000 registered users worldwide. Congress directed the Treasury Department to use GREET for the new 45Z clean fuel production tax credit in the Inflation Reduction Act (IRA). [EPA-HQ-OAR-2022-0829-0613, pp. 5-6]

While it may be an inconvenient truth for some to accept, corn ethanol is a proven and cost-effective low carbon fuel playing an important role in reducing GHG emissions and air pollution from the transportation sector. In fact, the RFS has cut GHG emissions by nearly 600 million metric tons since 2007, exceeding EPA's original expectation of 444 million metric tons.10 [EPA-HQ-OAR-2022-0829-0613, pp. 5-6]

10 Unnasch. S. (2019) GHG Reductions from the RFS2 – A 2018 Update. Life Cycle Associates Report LCA. LCA.6145.199.2019 Prepared for Renewable Fuels Association.

Ethanol and Agriculture are Part of the Solution

ACE members believe ethanol can and should be an even bigger part of the solution to climate change, and we are encouraged by statements from you and USDA Secretary Vilsack that biofuels and agriculture will have a seat at the table as the Biden administration determines how to achieve the ambitious yet important goal of reaching net-zero carbon emissions in the U.S. by midcentury. [EPA-HQ-OAR-2022-0829-0613, pp. 6-7]

The science is clear: agriculture is critical to reduce GHG emissions. In 2018, the Intergovernmental Panel on Climate Change (IPCC) found that 89% of the globe's capacity to mitigate carbon emissions comes from agricultural soil carbon sequestration.11 Farmers help mitigate climate change through practices such as conservation tillage which promotes soil carbon sequestration. It is estimated that U.S. farmers already store 20 million metric tons of carbon per year and scientists with EPA and USDA believe agricultural soil has the potential to sequester an additional 180 million metric tons per year.12 [EPA-HQ-OAR-2022-0829-0613, pp. 6-7]

11 Smith, P., D. Martino, Z. Cai, D. Gwary, H. Janzen, P. Kumar, B. McCarl, S. Ogle, F. O'Mara, C. Rice, B. Scholes, O. Sirotenko, 2007: Agriculture. In Climate Change 2007: Mitigation. Contribution of Working Group III to the Fourth Assessment Report of the Intergovernmental Panel on Climate Change [B. Metz, O.R. Davidson, P.R. Bosch, R. Dave, L.A. Meyer (eds)], Cambridge University Press, Cambridge, United Kingdom and New York, NY, USA, at p. 499 (emphasis in original), available at https://www.ipcc.ch/site/assets/uploads/2018/02/ar4-wg3-chapter8-1.pdf (last viewed July 16, 2020) (hereafter, 2018 IPCC Agriculture Chapter).

12 Greenhouse Gas Mitigation Potential in U.S. Forestry and Agriculture. EPA 430-R05-006.

We are particularly encouraged by new funding provided to USDA through the IRA to scale the deployment of climate-smart farming practices and demonstrate the link those practices have on reducing GHG emissions from products such as biofuels. [EPA-HQ-OAR-2022-0829-0613, pp. 6-7]

In 2018 ACE published a White Paper, titled "The Case for Properly Valuing the Low Carbon Benefits of Corn Ethanol," explaining if policymakers encouraged investment and adoption of more technology innovation, many ethanol plants would respond to the market signal to produce even cleaner fuel.13 A study published by MIT, Harvard, Tufts, and Environmental Health & Engineering Inc. scientists cites ACE's 2018 White Paper and reinforces the fact that the GHG reduction benefits of corn ethanol have been significantly undervalued because some regulatory bodies refuse to apply or use the latest lifecycle science. The MIT/Harvard/Tufts study found that average corn ethanol reduces GHGs by 46 percent compared to gasoline and given improvements occurring in corn farming and within ethanol facilities, corn ethanol's carbon footprint will continue to decline over time.14 [EPA-HQ-OAR-2022-0829-0613, pp. 6-7]

13 The Case for Properly Valuing the Low Carbon Benefits of Corn Ethanol. (2018) https://ethanol.org/ethanol-essentials/low- carbon-benefits-of-corn-ethanol.

14 https://ethanol.org/news/news/2021/01/26/new-study-showing-corn-ethanol-reduces-carbon-emissions-by-nearly-50- percent-cites-ace-low-carbon-white-paper/.

Understanding the need to more reliably validate how climate-smart agriculture reduces ethanol GHG emissions, ACE is proactively working to document the benefits climate smart practices have on the carbon intensity of corn ethanol in a scientifically irrefutable manner. We are leading a USDA funded Regional Conservation Partnership Program (RCPP) project, in partnership with top land-grant scientists and the U.S. Department of Energy's Sandia National Laboratory, to validate the current predictive model results of climate smart practice adoption showings significant GHG benefits of reduced tillage, cover crops, and nutrient management on corn ethanol's carbon footprint.15 [EPA-HQ-OAR-2022-0829-0613, pp. 6-7]

15 https://ethanol.org/carbon/usda-rcpp/.

The best way to unlock decarbonization opportunities from climate-smart agriculture is through technology neutral clean fuel policy which stands up markets to help offset farmer cost of adoption. For example, in 2020, Argonne National Laboratory indicated no-till, cover crops and nutrient management could be worth $279 per acre if they were allowed to generate credits under California's Low Carbon Fuel Standard (LCFS).16 At that value, farmers would rapidly adopt practices leading to meaningful reductions in the lifecycle carbon emissions of biofuels. [EPA-HQ-OAR-2022-0829-0613, pp. 6-7]

16 https://iopscience.iop.org/article/10.1088/1748-9326/ab794e.

Unfortunately, the California LCFS does not yet allow carbon credits for biofuels produced from climate- smart agriculture, and since EPA's proposal puts all our eggs in one basket, it fails to unlock the significant carbon mitigation potential from agricultural lands and ethanol. [EPA-HQ-OAR-2022-0829-0613, pp. 6-7]

We can and should do better. With this in mind, the result of our RCPP project will be the establishment of a non-proprietary, scientifically verified protocol for biofuel producers and farmers to document the carbon intensity benefits of changes in agricultural practices that are validated with on-farm data at production level scale. [EPA-HQ-OAR-2022-0829-0613, pp. 6-7]

ACE is pleased Congress provided significant resources in the IRA for USDA to build upon the progress we are making to validate the benefits of climate smart practice adoption and view this as an opportunity to scale farmer access to state LCFS markets and federal policies such as the RFS. We have briefed top EPA leadership about this partnership and want to work in collaboration with the Agency on this project to ensure corn ethanol benefits are acknowledged by EPA as part of the climate solution. [EPA-HQ-OAR-2022-0829-0613, pp. 6-7]

In conclusion, EPA should reconsider its proposal, develop a technology-neutral approach to decarbonizing transportation fuel, and engage with ACE as we implement our project to ensure fair and accurate accounting for GHG reductions from climate-smart agriculture and ethanol. [EPA-HQ-OAR-2022-0829-0613, pp. 6-7]

Organization: American Council for an Energy-Efficient Economy (ACEEE)

The U.S. needs the strongest vehicle standards

The United States will need to greatly reduce light-duty vehicle (LDV) greenhouse gas emissions if it is to have any chance of meeting the Biden Administration's economy-wide emissions reduction goal of 50% by 2030 and stave off the worst impacts of climate change. Transportation is now the largest source of greenhouse gas emissions in the United States and the light-duty sector makes up 58% of those emissions.1 Reducing carbon emissions is critical to tackling climate change but increasing LDV efficiency will also have significant benefits to air quality and will reduce driver fueling costs. Vehicles are a significant contributor to local air pollution and the associated health impacts, leading to increased rates of asthma, increased risk of heart attacks, strokes, and lung cancer.2 These impacts are particularly bad in low-income communities and communities of color, which bear a disproportionate air pollution burden.3 Greater efficiency can also provide significant cost savings for drivers when they refuel their vehicles. Low-income households are especially burdened by fueling costs, paying three times more than their higher-income counterparts on gasoline, as a percent of their total income.4 [EPA-HQ-OAR-2022-0829-0642, pp. 1-2]

1 https://www.epa.gov/greenvehicles/fast-facts-transportation-greenhouse-gas-emissions

2 https://www.consumerreports.org/emissions/how-your-car-can-make-the-air-cleaner/

3 https://www.lung.org/clean-air/outdoors/who-is-at-risk/disparities

4 https://www.aceee.org/white-paper/2021/05/understanding-transportation-energy-burdens

The Infrastructure Investment and Jobs Act (IIJA) and the Inflation Reduction Act (IRA) have set aside historic amounts of funding for electric vehicles and will greatly reduce greenhouse gas (GHG) emissions from the transportation sector if that money is invested with climate impacts in mind. EPA's standards must build off of these investments. While we commend EPA for proposing strong standards that help the U.S. achieve President Biden's 2030 goal of 50% zero emission new vehicle sales, these historic investments mean we can go even further.5 Since the IRA was signed into law, $50 billion in investments in EV and battery manufacturing, and supply chain projects have been announced.6 These investments could get the U.S. to over 60% new light-duty EV sales by the early 2030s.7 But more will be needed to adequately address the climate emergency. EPA's MY 2027-2032 standards should fully account for the recent federal activity and build off them to achieve further emissions reductions. [EPA-HQ-OAR-2022-0829-0642, pp. 1-2]

5 https://www.whitehouse.gov/briefing-room/statements-releases/2021/08/05/fact-sheet-president-biden-announces-steps-to-drive-american-leadership-forward-on-clean-cars-and-trucks/

6 https://www.charged-the-book.com/na-ev-supply-chain-map

7 https://theicct.org/wp-content/uploads/2023/01/ira-impact-evs-us-jan23.pdf; https://rmi.org/insight/how-inflation-reduction-act-will-affect-ev-adoption-in-the-united-states/

Continued improvement in internal combustion engine vehicles is needed

Even under Alternative 1, there would still be over 40 million new ICEVs sold over the life of these standards. These vehicles could be on the road for two decades, contributing significantly to local air pollution, climate change, and costing drivers considerably at the pump. It is critical that the new standards continue improvements on ICEV efficiency while also pushing the market to electrify. Our modelling shows that under EPA's achieved emissions rates, ICEV emission rates would needlessly rise and would be as high as MY 2023 levels. Under the proposed standard, ACEEE estimates that average ICEV emissions could increase by up to 2.9% per year, contributing an extra 805 million metric tons of lifetime CO2 compared to a future where ICEV performance flatlines at model year 2026 levels. This is equivalent to an approximately 11% increase in emissions from the projected savings in the rule of 7,300 million metric tons of CO2 (FR 29198, Table 3). [EPA-HQ-OAR-2022-0829-0642, pp. 3-4]

This calculation assumes BEV penetration reaches what EPA projects under its proposal and includes upstream emissions accounting for all vehicles. However, it also factors in the reduction of credits, which limits the increase in ICEV emissions compared to model year 2026 (when there are significantly more credits available). Removing the effects of the proposed off-cycle and A/C credit changes in both model year 2026 and under the proposed standards means that ICEVs emissions reductions backslide even further, reaching almost 5% annually. [EPA-HQ-OAR-2022-0829-0642, pp. 3-4]

Under EPA's proposed standards, rapid electrification can allow automakers to meet their targets even while letting ICEVs worsen, squandering some of the emissions benefit of electrification and missing an important opportunity for further emissions reductions. This is unacceptable given that mature emissions-reducing technologies, such as hybridization, already exist on the market today and often go underutilized by manufacturers. Our modeled findings are consistent with EPA's own analysis, which projects that ICEV emissions rates will increase over the life of the standard. In fact, EPA compliance modeling indicates that manufacturers will go so far as to remove emissions-reducing technologies from many ICEV models, a completely counterproductive behavior.10 On the other hand, if manufacturers do not move backwards on ICEV efficiency, they will be able to meet the standards with fewer BEVs than EPA projects, also an undesirable outcome. In either case, the conclusion is that the standards should be strengthened to incentivize ICEV improvements more strongly. [EPA-HQ-OAR-2022-0829-0642, pp. 3-4]

10 Based on analysis of EPA's OMEGA model outputs, 2023_03_14_22_42_30_central_3alts_20230314_Proposal_vehicles.csv

Just a 3% annual reduction in the average emissions for ICEVs — compared, for example, to the 4.6% per-year reduction called for under the 2012 standards for MY 2017-202511 — could lead to a further reduction of almost 800 million metric tons of CO2 and ICEVs that are about 30% cleaner compared to EPA's proposal. Much of this reduction could come from the continued adoption of hybrid vehicles in the US market. EPA expects little contribution from strong hybrids in meeting the proposed standard even though hybridization is a proven technology with decades of usage, as discussed above. EPA projects that strong hybrids will be completely phased out under the proposed standards by 2032 (FR 29329, Table 83), despite hybrids accounting for a record 10% of new vehicles offerings in model year 2022.12 We should not be moving backwards on ICEV performance and the penetration of proven efficiency technologies like hybridization over the life of these standards. [EPA-HQ-OAR-2022-0829-0642, pp. 3-4]

12 https://www.epa.gov/automotive-trends

EPA should implement upstream accounting to encourage BEV Efficiency

EPA proposes to continue, and make permanent, the treatment of electric vehicles as entirely zero emission vehicles (ZEVs)(FR 29252). While it is true that BEVs generate no emissions at the tailpipe, charging these vehicles does create emissions upstream. The major flaw with ignoring refueling emissions is that EPA loses the opportunity to influence the efficiency of a growing component of the vehicle market. EPA is both empowered and required to regulate the emissions from on-road light duty vehicles. Given that BEVs are expected to reach the majority of new sales within this decade,13 it is imperative we address their emissions. Using the rule to improve BEV efficiency will accomplish this. Upstream accounting in compliance is a simple and effective way to promote efficiency. It recognizes that different BEVs, by virtue of their wide range of efficiencies, are responsible for different levels of emissions from our still fossil fuel-based electricity grid. EPA's GHG standards for LDVs have historically led to innovations in emissions reduction technology and design for ICEVs and the same should be true in an all-electric future. [EPA-HQ-OAR-2022-0829-0642, pp. 4-6]

13 https://www.whitehouse.gov/briefing-room/statements-releases/2021/08/05/fact-sheet-president-biden-announces-steps-to-drive-american-leadership-forward-on-clean-cars-and-trucks/

Our own analysis shows that even among BEVs of the same vehicle type and weight there can be considerable differences in efficiency and, therefore, upstream emissions, as shown in Figure

1.14 Not all BEVs are created equal and there is still plenty of room for innovation and emissions improvements in the BEV market. The fact that BEVs with curb weights of 5,000 pounds can have efficiencies varying from under 2.5 mi/kWh to over 4 mi/kWh demonstrates how important it is that these standards continue their historical role in advancing automotive innovation as we electrify. [EPA-HQ-OAR-2022-0829-0642, pp. 4-6]

14 https://www.aceee.org/blog-post/2023/04/boosting-ev-efficiency-would-cut-emissions-and-reduce-strain-grid

[See original for graph titled "Figure 1. Efficiency versus weight in model year 2023 BEVs"]

By our calculations, if upstream accounting, or another mechanism, led to a 3% annual growth in BEV efficiency over the life of the standards, lifetime emissions from MY 2027- 2032 vehicles would be reduced by over 170 million metric tons under both the proposed standards and Alternative 1. This does not include the benefits from vehicles sold from model year 2033 onwards that would take advantage of advancements in efficiency technologies and designs potentially spurred by this standard. [EPA-HQ-OAR-2022-0829-0642, pp. 4-6]

Greater BEV efficiency has a number of benefits beyond just reducing upstream emissions. Greater BEV efficiency can allow a vehicle to go the same distance with a smaller battery, effectively reducing the use of high-demand minerals and the emissions generated from vehicle production (the calculations discussed above do not account for these emissions reductions impacts from improved BEV efficiency). While BEVs are certainly still better from an emissions perspective than their equivalent ICEV when looking at the entire life-cycle, it is still important to reduce their environmental impact. Mineral supply and battery manufacturing capacity also have the potential to be limiting factors for rapid electrification, so reducing battery needs per vehicle by increasing efficiency can facilitate achievement of the MY 2027-2032 standards. [EPA-HQ-OAR-2022-0829-0642, pp. 4-6]

Greater BEV efficiency also means a smaller impact on our electricity grid and drivers' wallets, as less electricity is needed to drive the same distance.15 If all LDVs on the road were electric and had an average efficiency equivalent to the highest-efficiency vehicle on the market today, we could save enough electricity annually to power 21 million homes. Full on- road fleetwide electrification is not expected for decades so this improvement in BEV efficiency is feasible and could even be surpassed if incentivized by the standards.16 [EPA-HQ-OAR-2022-0829-0642, pp. 4-6]

15 https://www.aceee.org/blog-post/2022/09/evs-surge-utilities-need-transparent-equitable-comprehensive-plans-support-them

16 https://www.aceee.org/blog-post/2023/04/boosting-ev-efficiency-would-cut-emissions-and-reduce-strain-grid

Organization: American Free Enterprise Chamber of Commerce (AmFree) et al.

EPA also unreasonably ignored alternative solutions to the proposed light- and medium-duty emissions standards. Agencies are required, as part of any reasoned decisionmaking process, to consider all "significant and viable and obvious alternatives" to their proposed action. Dist. Hosp. Partners, 786 F.3d at 59 (citation omitted); see Spirit Airlines, Inc. v. DOT, 997 F.3d 1247, 1255 (D.C. Cir. 2021) ("[T]he failure of an agency to consider obvious alternatives has led uniformly to reversal.” (quoting Yakima Valley Cablevision, Inc. v. FCC, 794 F.2d 737, 746 n.36 (D.C. Cir. 1986))). [EPA-HQ-OAR-2022-0829-0683, p. 65]

Here, EPA failed to consider any alternatives that did not fall within the narrow category of tailpipe-emissions standards. The agency instead considered only whether emissions standards of varying level of stringency or with differing phase-in periods may be appropriate alternatives. See 88 Fed. Reg. at 29,201. But tailpipe-emissions standards are not the only means available to achieve EPA’s stated goal of “reduc[ing] . . . criteria pollutants and GHG emissions from the transportation sector.” Id. at 29,186. [EPA-HQ-OAR-2022-0829-0683, p. 65]

For instance, as EPA acknowledges in the proposed rule, the agency has authority to impose fuel controls, one possible alternative to emissions standards. 88 Fed. Reg. at 29,397–98. But EPA requested comment only on whether fuel controls should be used in the future as a “complement” to emissions standards, rather than as an alternative to them. Id. That omission violates the requirement of reasoned decisionmaking.10 Cf. Am. Radio Relay League, Inc. v. FCC, 524 F.3d 227, 242 (D.C. Cir. 2008) (remanding where agency did not “consider responsible alternatives to its chosen policy and . . . give a reasoned explanation for its rejection of such alternatives” (citation omitted)). EPA’s failure to consider any non-emissions-standard-based alternatives to the proposed rule renders the proposed rule arbitrary and capricious. [EPA-HQ-OAR-2022-0829-0683, p. 66]

10 We do not at this time express any view on any particular fuel-control measure, and any regulation incorporating such measures would first have to be proposed for public comment. See 42 U.S.C. § 7607(d). We simply note the proposed rule’s failure to address fuel controls as an alternative.

Organization: American Fuel & Petrochemical Manufacturers

We are also troubled by EPA’s failure to evaluate the lifecycle emissions of various powertrains and the national security implications of the proposal. Focusing exclusively on “tailpipe” emissions paints a distorted picture and perpetuates the false notion that electric vehicles are “zero emitters.” EPA must present the public with a complete picture, one that shows how the various powertrains stack up against each other cradle-to-grave and the major carbon reductions that vehicle manufacturers and fuel producers have made over the last few decades and continue to make. EPA’s failure to do so would render any final rule arbitrary and capricious. [EPA-HQ-OAR-2022-0829-0733, pp. 1-2]

EPA offers no support for its conclusion that there will be substantial consumer adoption of ZEVs to achieve the increases projected by the Proposed Rule. To the contrary, recent polling shows that most Americans continue to say that they are unlikely, or will categorically refuse, to buy an EV. As just one example, a Gallup poll conducted in April revealed that only 4 percent of adults owned an EV and just 12 percent are seriously considering buying one. However, 41 percent of adults said they would never buy an EV, raising fundamental questions about how EPA can predict that ZEV sales will reach 67 percent in 2032.136 [EPA-HQ-OAR-2022-0829-0733, p. 31]

136 Megan Brenan, Gallup, Most Americans Are Not Completely Sold on Electric Vehicles (April 12, 2023). Retrieved a https://news.gallup.com/poll/474095/americans-not-completely-sold-electric-vehicles.aspxt .

According to Wards Intelligence, through May 2023, Americans purchased 5.9 million ICEVs, representing 93 percent of all LDVs sold during the first five months.137 At this pace, more than 14 million new ICEVs will be purchased during 2023.138 With the continued sales of ICEVs, this Rule's effort to limit the ability to purchase ICEVs, and more than 50 percent of ICEVs remaining in service, it is mindboggling, as discussed in Section IV.6 below, that EPA never considered the alternative scenarios using vehicle technologies and lower carbon fuels. [EPA-HQ-OAR-2022-0829-0733, p. 31]

138 Id.

6. EPA failed to consider, let alone evaluate, alternative emissions reductions strategies

Despite all the well-known constraints with mandating electrification of the transportation sector and building the necessary nationwide infrastructure, EPA never considered, let alone evaluated, emissions reductions from modifications to ICEVs' emissions control systems, bio and renewable fuels, alternative fuels (e.g., hydrogen), and use of carbon capture and sequestration. To reduce carbon emissions and ensure energy security and independence, Congress created the RFS, which requires increasing volumes of renewable fuel to be blended into transportation fuel. The four categories of renewable fuel must emit anywhere from 20 percent to 80 percent fewer GHGs relative to the fossil fuel it replaces. In response to this mandate, U.S. refineries dramatically increased renewable fuel production and invested billions of dollars to expand U.S. production of liquid renewable fuels, which can now achieve 79 to 86 percent GHG emissions reductions as compared to petroleum fuels.188 [EPA-HQ-OAR-2022-0829-0733, pp. 40-41]

188 Hui Xu, Longwen Ou, Yuan Li, Troy R. Hawkins, and Michael Wang, Environmental Science & Technology 2022, 56 (12), 7512-7521. DOI: 10.1021/acs.est.2c00289

According to the Energy Information Agency's June 2023 Short-Term Energy Outlook (STEO), [EPA-HQ-OAR-2022-0829-0733, pp. 40-41]

- Biomass diesel (which includes biodiesel and renewable diesel) production averaged 3.1 billion gallons in 2022. EIA expects production to average 4.0 billion gallons in 2023 and 4.8 billion gallons in 2024.

- Ethanol and renewable oxygenate production is expected to increase from 18.4 billion gallons in 2022 to 19.2 billion gallons in 2023, and to 20.4 billion gallons in 2024.

- Biodiesel production averaged 1.6 billion gallons in 2022. Production is expected to decline to 1.5 billion gallons in 2023, and to 1.4 billion gallons in 2024.

- Renewable diesel production averaged 1.5 billion gallons in 2022. Production is projected to increase to 2.4 billion gallons in 2023, and to 3.4 billion gallons in 2024. [EPA-HQ-OAR-2022-0829-0733, pp. 40-41]

In response to the RFS and other government programs encouraging the production of lower carbon renewable liquid fuels, U.S. refiners are undertaking significant capital expenditures to reduce GHG emissions such as: [EPA-HQ-OAR-2022-0829-0733, pp. 40-41]

- Taking advantage of Congress' 45Q tax credit for CCS, ethanol producers are looking to used carbon capture and sequestration to reduce GHG emissions from the 15 billion gallons of ethanol blended into our nation's gasoline.189 [EPA-HQ-OAR-2022-0829-0733, pp. 40-41]

189 Erin Voegele, Carbon America to develop CCS project at Nebraska ethanol plant, Ethanol Producer Magazine, October 4, 2022 (Carbon America announced its third CCS project at a U.S. ethanol plant). Retrieved at https://ethanolproducer.com/articles/19655/carbon-america-to-develop-ccs-project-at-nebraska-ethanol-plant.

- Renewable diesel and sustainable aviation fuel production capacity will total 5.1 billion gallons per year if all announced expansion projects, which represent $10.8 billion in investments, are completed.190 [EPA-HQ-OAR-2022-0829-0733, pp. 40-41]

190 EIA,U.S. renewable diesel capacity could increase due to announced and developing projects, Today in Energy, July 29, 2021. Retrieved at https://www.eia.gov/todayinenergy/detail.php?id=48916

Although the RFS, an EPA program, has achieved significant emissions reductions for more than a decade, there is no mention in the Proposal or the DRIA of alternative emissions standards that could be achieved through the use of additional changes to emissions control equipment, alternative fuels, or bio and renewable fuels. Lifecycle assessments (LCAs) of GHG emissions from ICEVs reveal that 73 percent of lifecycle GHG emissions come from fuel combustion.191 By comparison, lifecycle emissions from ZEVs occur not from fuel combustion from the vehicle, but from fuel use and various energy and material inputs upstream from the vehicle. Therefore, EPA's failure to consider standards that reduce the carbon intensity of liquid fuels used in ICEVs and ignoring the carbon intensity of EVs is arbitrary and capricious. It results in a highly flawed assessment of emissions from new motor vehicles which "cause, or contribute to, air pollution" as envisioned in CAA section 202(a) and demonstrates its unvarnished bias in favor of EVs. The Agency's refusal to evaluate biofuels illustrates EPA's tunnel vision that proposes a single panacea for a highly complex problem in a rapidly changing world [EPA-HQ-OAR-2022-0829-0733, pp. 40-41]

191 Decarbonizing Combustion Vehicles – A Critical Part in Reducing Transportation Emissions - Transportation Energy Institute.

As discussed above, because EPA may only prescribe standards applicable to vehicles that "cause or contribute" to air pollution, its standards cannot account for ZEVs with no tailpipe emissions. However, if EPA is authorized to promulgate such standards, those standards must account for any upstream emissions from upstream electric generating units, the mining of battery materials, and the production of the vehicle.197 Without consideration of upstream and full life- cycle impacts (e.g., frequent battery replacements), EPA has failed to inform the public of the comparative costs of emission reductions, whether from ZEVs, ICEVs, energy efficiency, or other sectors. EPA's continued failure to address this "major aspect of the problem" is another example of EPA moving toward its predetermined outcome—the forced electrification of U.S. transportation.198 AFPM has continually put EPA on notice of the need to include a LCA to avoid an arbitrary comparison—the agency continues to ignore this issue of central relevance to EPA's benefit analysis. [EPA-HQ-OAR-2022-0829-0733, pp. 42-44]

197 Proposed Rule at 29,353–55.

198 See, e.g., Comments of the American Fuel & Petrochemical Manufacturers on EPA's Reconsideration of a Previous Withdrawal of a Waiver of Preemption 10 (July 6, 2021), https://www.regulations.gov/comment/EPA-HQ-OAR-2021-0257-0139, Comments of the American Fuel

& Petrochemical Manufacturers on EPA's/NHTSA's Proposed The Safe Affordable Fuel-Efficient Vehicles Rule for Model Years 2021-2026 Passenger Cars and Light Trucks 68-73 (Aug. 24, 2018), https://www.regulations.gov/comment/EPA-HQ-OAR-2018-0283-5698; Comments of the American Fuel & Petrochemical Manufacturers on EPA's California State Motor Vehicle Pollution Control Standards; Advanced Clean Trucks; Zero Emission Airport Shuttle; Zero Emission Power Train Certification; Request for Waiver of Preemption 7-12 (Aug. 2, 2022), https://www.regulations.gov/comment/EPA-HQ-OAR-2022- 0331-0088.

For instance, the fuel source of a PEV, like a ZEV—a battery composed of carbon intensive minerals and the electricity generated to power the battery—produces emissions. The fact that emissions occur 100 percent upstream of the vehicle's operation and therefore fall outside of the tailpipe emissions calculation does not make these emissions any less significant. There is no logical basis for this omission because, as EPA is aware, concerns about GHG emissions relate to their longer-term global concentrations. Consequently, air pollutant emissions are an important consideration regardless of where such emissions occur. Without comparing lifecycle ZEV emissions to lifecycle emissions from ICEVs, EPA cannot know if or how much its standards are decreasing total emissions. Thus, while EPA is not required to solve all emissions problems in one rulemaking, EPA cannot claim to be solving part of the problem here without addressing upstream and downstream emissions. EPA's approach of mandating ZEVs cannot possibly be reasonable if it is merely shifting emissions from one source to another at the cost of hundreds of billions of dollars—trillions when costs to upgrade EV infrastructure are factored in— or could do so more cost-effectively by choosing a different approach.199 [EPA-HQ-OAR-2022-0829-0733, pp. 42-44]

199 5 U.S.C. § 706(2)(A); cf. Antonin Scalia, "Regulatory Review and Management," Regulation Magazine 19 (Jan./Feb. 1982) ("Is it conceivable that a rule would not be arbitrary or capricious if it concluded with a statement to the effect that 'we are taking the foregoing action despite the fact that it probably does more harm than good, and even though there are other less onerous means of achieving precisely the same desirable results'?").

The flaw in EPA's approach is illustrated by the fact that emissions standards easily become meaningless by changing the engine's location. The proposed rule would treat a ZEV charged by a diesel-powered generator as if it had zero tailpipe emissions, notwithstanding the fact that it remains "powered" by a diesel engine located outside the vehicle. A LDV directly powered by a diesel engine inside the vehicle, however, is credited with the emissions produced by that engine. EPA's inconsistent approach begs the question of how nascent technologies such as a vehicle propelled by compressed air would be evaluated. Thus, the energy source of the "fuel" matters and EPA arbitrarily ignores lifecycle emissions from ZEVs and also proposes to remove requirements for upstream emissions calculations.200 EPA admits "the program has now been in place for a decade, since MY 2012, with no upstream accounting and has functioned as intended, encouraging the continued development and introduction of electric vehicle technology."201 EPA's mandate is to establish feasible standards rooted in the statute, not to ignore real-world emissions to "encourage" the development of its favored technology. EPA requested comment on whether it should account for upstream emissions for all fuel and vehicles. If technologies are being treated equally, as they must, the answer is an unequivocal yes. [EPA-HQ-OAR-2022-0829-0733, pp. 42-44]

Organization: American Highway Users Alliance

In addition, EPA seems to have given little or no consideration to incentives for lower emission liquid fuels as part of the solution to reducing lifecycle emissions from these vehicles. Such fuels are already in the marketplace; increasing their use would appear to be achievable. Policy approaches to help encourage the production of lower emission liquid fuels could offer near-term emissions reductions from existing vehicles, potentially at a lower cost to society. Yet, EPA's proposal in this docket (as well as in the heavy-duty vehicle docket) focuses on electrification as the sole means of reducing emissions from vehicles, even though in 2022 EVs constituted less than 7 percent new light duty vehicle sales. [EPA-HQ-OAR-2022-0829-0696, p. 4]

Greater use of lower-emission liquid fuels should be part of the overall approach to reducing emissions from vehicles

Further, and as noted earlier, the discussion in the NPRM and in the heavy-duty vehicle Phase 3 NPRM seem to have given little or no consideration to the potential gains in emissions reductions that could be achieved through greater use of lower emission fuels. Fuels produced with lower emission renewable feedstocks and traditional fuels produced with lower carbon intensities, such as in association with carbon capture and sequestration, exist today and are scalable with the right policy support. Greater use of these fuels could help reduce emissions from the hundreds of millions of vehicles already on the road while EV charging infrastructure, fueling infrastructure for other alternate fuels, and critical mineral supply chains develop and don't otherwise create additional energy security or geo-political risks. [EPA-HQ-OAR-2022-0829-0696, p. 5]

Even with the accelerated fleet turnover the EPA's proposed standards seek, hundreds of millions of vehicles with internal combustion engines will remain on the roads in the coming decades. Instead of pursuing policies that focus on a sole technology pathway for achieving transportation-related emissions reductions, EPA should allow for multiple technology pathways – including pathways that recognize how to improve the overall lifecycle carbon intensity for existing vehicles and fuels. This might include linked carbon-intensity based vehicle and fuel standards that enable consumers to retain the preference for engine type or powertrain, while still participating in societal aims to achieve emissions reductions. [EPA-HQ-OAR-2022-0829-0696, p. 5]

Organization: American Petroleum Institute (API)

a. API Supports Emission Reductions in the Transportation Sector.

API appreciates EPA's efforts to address transportation sector emissions. As detailed in the API Climate Action Framework1, we support technology-neutral policies at the federal level that drive GHG emissions reductions in the transportation sector and our members have committed to delivering solutions that reduce the risks of climate change while meeting society's growing energy needs. API members work to advance the development, transmission, and use of lower carbon intensity and lower criteria pollutant fuels and technologies to provide choices for consumers. Specifically, API members have made, and continue to make, significant investments in new technologies that reduce emissions in transportation, including: [EPA-HQ-OAR-2022-0829-0641, p. 4]

1 https://www.api.org/climate.

GHG Emission Reduction [EPA-HQ-OAR-2022-0829-0641, p. 4]

- Stand-alone production and coprocessing of bio-feedstocks to make renewable fuels.
- Manufacturing of low-carbon ethanol.
- Manufacturing of renewable natural gas from wastewater, landfill gas, and biodigesters at farms as fuel for compressed natural gas (CNG) vehicles.
- Production of blue and green hydrogen for transportation and stationary applications including building infrastructure.
- Direct air carbon capture.
- Carbon capture and sequestration of CO2.
- Development of advanced plastics to meet auto industry standards and consumer expectations while mitigating environmental impact through emissions reduction and improved vehicle efficiency by light-weighting.
- Installation of electric vehicle charging stations.
- Installation of hydrogen fueling stations. [EPA-HQ-OAR-2022-0829-0641, p. 4]

Criteria Pollutant Reduction [EPA-HQ-OAR-2022-0829-0641, p. 4]

- Tier 3 gasoline sulfur standards
- MSAT II gasoline benzene standards
- Lower vapor pressure reformulated gasoline [EPA-HQ-OAR-2022-0829-0641, p. 4]

API shares the goal of reduced emissions across the broader economy and, specifically, those from energy production, transportation and use by society. To achieve meaningful emissions reductions that meet the climate challenge, it will take a combination of policies, innovation, industry initiatives and a partnership of government and economic sectors. The objective is large enough that no single approach can achieve it. [EPA-HQ-OAR-2022-0829-0641, p. 4]

ii. EPA failed to address emission reductions in the existing LMDV fleet to help achieve near-term emission reductions.

Fuel- and vehicle-based GHG emissions reduction solutions are currently available in the marketplace and could achieve nearer-term emission reductions from the existing light- and medium-duty vehicle fleet. A singular focus on future ZEV technologies does not seem to meet the stated goals of the proposed program. The proposal would require a significant ramp-up of electric vehicle production in relation to the scale of the current market, would depend on infrastructure that may not be readily available at the scale needed to meet the proposal’s requirements, and would be on an extremely challenging (at best) timeline. Meaningful emission reductions are achievable sooner, and potentially at lower cost, via the use of proven and available technology. For example, the U.S. Department of Energy (DOE) Co-Optimization of Fuels & Engines (Co-Optima) initiative examined fuels and engine/vehicle technologies simultaneously.18 The combination of sustainable fuels uncovered by the Co-Optima research can reduce the emissions of vehicles now, while enabling a faster transition to net-zero-carbon emissions for on-road transportation in the future. The lifecycle GHG emissions of these studied fuels were found to be reduced by more than 60%.19 Such an approach could be utilized by EPA to better achieve the stated goals of the agency. EPA must address this factor. [EPA-HQ-OAR-2022-0829-0641, pp. 8-9]

18 U.S. Department of Energy Offce of Energy Effciency & Renewable Energy, "The Road Ahead Toward a Net-Zero- Carbon Transportation Future Findings and Impact, FY15–FY21." https://www.energy.gov/sites/default/files/2022- 06/beto-co-optima-fy15-fy21-impact.pdf

19 Gaspar, Daniel J., West, Brian H., Ruddy, Danial, Wilke, Trenton J., Polikarpov, Evgueni, Alleman, Teresa L., George, Anthe, Monroe, Eric, Davis, Ryan W., Vardon, Derek, Suton, Andrew D., Moore, Cameron M., Benavides, Pahola T., Dunn, Jennifer, Biddy, Mary J., Jones, Susanne B., Kass, Michael D., Pihl, Josh A., Pihl, Josh A., Debusk, Melanie M., Sjoberg, Magnus, Szybist, Jim, Sluder, C S., Fioroni, Gina, and Pitz, William J. 2019. "Top Ten Blendstocks Derived From Biomass For Turbocharged Spark Ignition Engines: Bio-blendstocks With Potential for Highest Engine Efficiency". United States. https://doi.org/10.2172/1567705.

2. Current and future solutions – lower carbon fuels, hydrogen, ICE-based solutions.

As previously noted in our comments, lower-carbon options currently exist and could be used for near-term reductions. Lower carbon fuels are available in the market now, and research and development to bring costs down and improve operability is ongoing. [EPA-HQ-OAR-2022-0829-0641, pp. 10-11]

Bio and renewable fuels can and should be considered as part of an "all-of-the-above" approach to decarbonization of the transportation sector, including biocircularity. As previously noted, API members are currently investing heavily in renewable fuel production – continued investment and development will increase the available volumes of such fuels in the marketplace and allow them to serve both as a viable lower carbon solutions leading up to the start of the EPA proposed rule, throughout implementation, and beyond. [EPA-HQ-OAR-2022-0829-0641, pp. 10-11]

Further, EPA's LCA modeling for the proposal is based on biocircularity with atmospheric CO2 consumed by biomass, resulting in zero tailpipe carbon emissions if the combusted biofuels were made from renewable biomass. The agency is thus not taking the source of carbon into account and is classifying all carbon tailpipe emissions as the same related to their atmospheric GHG impact. [EPA-HQ-OAR-2022-0829-0641, pp. 10-11]

Organization: Andrea Strzelec

[*From Hearing Testimony, May 11, 2023*] Let me start by acknowledging that I absolutely support the goal of this proposal and believe that we need to work to further reduce pollutant and GHG emissions however I emphatically do not support the specifics of this proposed rule. I believe that both the EPA and the passionate speakers from the past couple of days are very well intentioned but you are also likely familiar with the quote that the road to Hell is paved with them, because intentions can have unintended consequences. We cannot make such gravely important decisions based on intentioned or impassioned pleas. The stakes are much too high. It is imperative that we make decisions based on science, in this case, it means including lifecycle analysis in policy development because dirty is in the details. My strong concern with the proposed rule is the unintended consequences that we risk because of the outdated methodology that has been used to develop it. The EPA claims that the proposed rule is technology neutral but functionally it is not as it only considers tailpipe emissions. Because mobile and stationary source emissions are not coupled in the regulatory sense though of course they are in reality, it means if we only consider tailpipe emissions for this rule, electric vehicles are then considered to be zero-emissions. Let me be clear this is a policy based definition and is not factually true. Zero emissions is a physical impossibility, you can blame thermodynamics. EVs simply move the mobile source emissions that would have come out of the tailpipe to the stationary power generating source. In the United States that means a vast majority of EVs are actually being powered by coal or fossil fuels. The hardware is not the problem. Neither the engine nor the electric drive motor are bad. In fact they both suffer from the same fundamental problem in terms of emissions, the energy source that allows them to deliver power. In addition only considering the tailpipe emissions does not consider the emissions from manufacturing and I'll note that battery materials and manufacturing issues have been described by previous speakers. The only way to truly understand the impact of any standard technology or rule is by looking at the entire picture by doing accurate lifecycle analysis that considers all the inputs and outputs, not just the convenient ones. Therefore I urge the EPA to reconsider the rule using lifecycle analysis. [From Hearing Testimony, EPA-HQ-OAR-2022-0829-5115, Day 3]

Organization: Anonymous

There should be provisions in the rule for the handling of biofuels and/or synthetic fuels ("efuels") in GHG emission calculations. Phasing out fossil fuels for ICEVs while phasing in renewable fuels/efuels could be just as effective in achieving climate goals as a shift to so-called "zero-emission" vehicles (most likely BEVs), possibly even more so. In fact, even if 100% of new vehicle sales are BEV by 2035, or any other date for that matter, it could potentially be counterproductive from an environmental perspective. ICEVs will be on the road for decades even if new ICEVs are effectively banned by regulation, and those vehicles would be contributing to significantly reduced GHG emissions with bio/efuels, while still in use. The European Union just adopted a provision to allow new ICEVs to be sold after 2035 if efuels are used exclusively to fuel the vehicles, in spite of efforts to "ban" ICEVs after 2035 [EPA-HQ-OAR-2022-0829-0490, p. 1]

According to Argonne National Laboratory (ANL), efuels produced by the Fischer- Tropsch (FT) process can actually be carbon NEGATIVE from a well-to-wheels perspective if the system is properly configured (https://pubs.acs.org/doi/10.1021/acs.est.0c05893). Some FT biofuels can also be carbon negative with CCS (e.g., https://velocys.com/2019/10/10/negative-emission-fuel-agreement/), or by sequestering carbon produced as a byproduct from the process (https://www.greencarcongress.com/2023/04/20230415-terrastar.html). There are no pathways in ANL's GREET model for BEVs to be carbon negative, or even carbon neutral, not even with 100% renewable electricity. If GHG emission reduction is really the goal, these fuels should be given top priority from a regulatory perspective. It should also be pointed out that FT ediesel fuel has very low upstream (well-to-tank) criteria pollutant air emissions according to ANL's GREET model. The Renewable Fuel Standard (RFS) could be used as a mechanism for phasing out fossil-based fuels in favor of biofuels/efuels. Alternatively, the U.S. could follow the European model and allow only ICEVs that use efuels/biofuels exclusively to be produced post 2035. Some consideration of biofuels/efuels should be adopted. [EPA-HQ-OAR-2022-0829-0490, p. 1]

Organization: Billy Brooks

[*From Hearing Testimony, May 10, 2023*] I agree with the need to reduce emissions however I believe the proposed ruling is shortsighted and needs to focus on the lifecycle emission of light and medium-duty vehicles from the production of the component in vehicle to the useful life of the vehicle instead of focusing solely on the tailpipe emissions. This ruling is pushing for the extinction of internal combustion engines while small businesses have shown the success in the reduction of tailpipe emissions with alternative fuel technology. COBB Tuning is one of many in the aftermarket auto sector that has shown fuel technologies specifically flex fuel and ethanol blends. New engines and transmission calibrations, emission control equipment, hybrid and other technologies, a reduction of tailpipe emissions while ultimately leading to improved lifecycle emissions. These areas of innovation still has potential to be realized and continue feasibility demonstrated. We know technological breakthroughs usually don't come as quickly as most would like but innovation does pay off. We just need to give it time. We need to approach the goals outlined in the EPA ruling with an all of the above approach with diverse fuel technology not just electric. Without focusing on lifecycle emissions, we may be reducing tailpipe emissions but continuing to pollute our world with no real way to recycle the batteries from the EVs. Here in Texas as in many parts of the country, the infrastructure can't handle the current electrical grid requirements for the amount of EVs that would be proposed. Roughly two years ago the majority of Texas was without power during the freeze. There needs to be more R&D before making EVs the only option. In the meantime, bring other technologies to light, give the innovators of this country a level playing field. I am confident we can reach our desired environmental goals by clearing the way of technology to provide us with the answers. [From Hearing Testimony, EPA-HQ-OAR-2022-0829-5115, Day 2]

Organization: Brian Kalina

[*From Hearing Testimony, May 11, 2023*] I am aligned with the EPA's end goals and because of this alignment I do encourage EPA to not discount renewable fuel and combustion engine technology as an important neighbor of the greenhouse portion of these goals. In my own personal and professional studies over the last 15 years, I continue to come across evidence that pursuing a mix of clean solutions and not just battery electric will lead to greatest environmental economic and geo political sustainability. I am concerned by not considering battery electric vehicle upstream emissions, emissions which are typically greater than that of internal combustion engine vehicles, the proposal as it presently stands would treat battery electric as a less greenhouse gas intensive technology than it really is. In effect the proposal in its current stance would force a greater fraction of battery electric vehicle sales than I do believe is optimal for a minimized greenhouse gas emissions and moreover is optimal for a country's economic and geo political interests. There are four issues associated with increased battery electric vehicle production and use that I would like to highlight. Number one, increase in adverse environmental impact associated with battery raw material extraction, battery manufacturing and electricity generation for battery charging. Number two, political conflict which may arise from over reliance on battery raw materials which often times must be sourced from certain regions of the world. Number three and this hits close to home, permanent reduction in auto industry job counts seeing how battery electric does not use as many parts as an internal combustion engine. These parts frankly power thousands of good paying jobs. And number four, the decimation of U.S. biofuels industry, an industry that would otherwise be poised to greatly assist in bringing to fruition EPA's greenhouse gas emissions goals. To help protect against the issues, I strongly encourage EPA to adopt greenhouse gas quantification methods which are guided by lifecycle assess. To only focus on tailpipe emissions is to discount very important big picture factors. If we are to achieve balance which is essential for long term sustainability, I sincerely believe that renewable fuel, internal combustion engine must play a similarly important role as battery electric as we make transportation clean and sustainable. [From Hearing Testimony, EPA-HQ-OAR-2022-0829-5115, Day 3]

Organization: Charles Forsberg

There are lower cost options to reduce greenhouse gas emissions built upon American strengths and thus can be implemented much less time. The U.S. globally leads in five areas: finance, software (but the Chinese are closing in fast), weapons, agriculture and oil/gas. The U.S. is far behind in mining and manufacturing. Betting on weak industries with near total dependence on foreign suppliers for non-earth-abundant materials is a good way to assure failure. Furthermore, it will not take long for the supplier nations to get together and further increase prices. Because the U.S. is unwilling to expand its mining industry by orders of magnitude, it can't win this game. [EPA-HQ-OAR-2022-0829-0738, pp. 3-4]

We use liquid hydrocarbons (gasoline, diesel and jet fuel) because of their remarkable chemical properties including high energy density, low storage costs and low cost to transport long distances from producer to consumer. If crude oil had never existed, we would have invented gasoline, diesel and jet fuel. These liquid fuels can be made from many feed stocks. They are currently made from crude oil, coal, natural gas and biomass. [EPA-HQ-OAR-2022-0829-0738, pp. 3-4]

We assessed the demand for liquid hydrocarbons-gasoline, diesel, jet fuel and chemical feed stocks. The U.S. currently consumes 18 million barrels per day. That demand could go as low as 10 million barrels per day before the costs of replacing liquid hydrocarbons with other technologies dramatically increases with serious reductions in the U.S. standard of living. We include the adoption of hybrid and plug-in hybrid electric vehicles in estimates of future liquid hydrocarbon fuel demand but no significant number of battery electric vehicles. The demand could be as high as 20 million barrels per day if liquid fuels have to replace any significant fraction of the current energy storage functions of natural gas and coal. All electric vehicles are not included in the analysis of the need for gasoline, diesel and jet fuel because (1) they are unaffordable for the majority of Americans and (2) their large-scale use significantly increases electricity prices. [EPA-HQ-OAR-2022-0829-0738, pp. 3-4]

We developed a pathway to replace all crude oil with cellulosic hydrocarbon drop-in fuels that (1) could produce 25 million barrels of hydrocarbon liquids per day without significant impacts on food and fiber prices and (2) simultaneous sequestration of atmospheric carbon dioxide. Cellulosic biomass include materials such as com stover, trees and kelp. It does not include sugars, vegetables oils or carbohydrates-that are currently used for most biofuels production. These feed stocks are insufficient to replace crude oil and compete with human food demand. [EPA-HQ-OAR-2022-0829-0738, pp. 3-4]

The major difference between this biofuels strategy and the traditional biofuels strategy is the abandonment of the 100,000 year old campfire model of biomass that should be left to the Boy

Scouts. Gasoline, diesel and jet fuel are made of carbon and hydrogen. Most current biofuels strategies use biomass as (1) a carbon source to produce the hydrocarbon product and (2) an energy and chemical source for the conversion process. The traditional conversion of biomass into gasoline, diesel and jet fuel involves using some of the biomass carbon for (1) removal of 40% by weight of the oxygen in biomass as carbon dioxide, (2) the production of hydrogen and (3) the energy to operate the process. Only a fraction of the biomass carbon ends up in the final product. Our cellulosic biofuels strategy uses external heat and hydrogen for converting cellulosic biomass into hydrocarbon liquids. With the conventional strategy, U.S. biofuels production is limited to something like 6 million barrels per day versus 25 million barrels per day with external heat and hydrogen inputs. The use of external heat and hydrogen inputs have two effects: (1) doubles hydrocarbon liquid fuels produced per ton of biomass and (2) makes hydrogen (not biomass) the primary cost of liquid fuels. If biomass feedstock is not the primary cost component of biofuels, one can pay more for cellulosic biomass without large impacts on final liquid fuel costs. [EPA-HQ-OAR-2022-0829-0738, pp. 3-4]

In the near term, the low cost hydrogen source is conversion of natural gas to hydrogen with underground sequestration of the byproduct carbon dioxide. For 10 million barrels per day of liquid hydrocarbons, this input will require a quarter to a third or more of U.S. natural gas production capability. There are internal tradeoffs between hydrogen, quantities of biomass and biomass characteristics. Hydrogen would be shipped via pipeline to the bio-refineries. The main conversion processes would be done at large bio-refineries with capacities of 250,000 barrels per day-mostly existing refineries with front-end modifications. The gigawatts of heat required per refinery would ultimately be provided by nuclear reactors co-located with refineries. Heat can only be shipped short distances. Nuclear energy is the only credible low-carbon energy source today for gigawatts of 24/7 heat that is required by integrated refineries. [EPA-HQ-OAR-2022-0829-0738, pp. 4-5]

This strategy requires major changes in agriculture and modifications of the big refineries but not changing the entire U.S. economy-enabling a fast transition off fossil crude oil with large scale sequestration of atmospheric carbon dioxide and massive economic benefits to rural America. The natural gas industry becomes the hydrogen supply industry where the primary market is perhaps a100 integrated bio-refineries. American agriculture provides most of the biomass with systems that recycle nutrients and carbon char to the soils for long-term agricultural and forest sustainability. Example feed stocks include com stover (the part of the com plant you do not eat) and double cropping. Double cropping was done in the Midwest in the early 1900s to grow forage crops for horses-plant in the fall and harvest in the spring. When tractors arrived, the horses disappeared and the land was left bare in winter-accelerating soil erosion. The right strategy will not impact food or fiber prices while increasing the sustainability of American soils. [EPA-HQ-OAR-2022-0829-0738, pp. 4-5]

This approach is built upon American strengths in agriculture and the oil/gas industry-thus the fast track option. It provides an evolutionary pathway for the oil/gas industry to become a negative carbon emitter. Industry is slowly heading toward this solution. Our recent analysis (below) indicates there is the possibility of replacing all crude oil within 20 years. [EPA-HQ-OAR-2022-0829-0738, pp. 4-5]

C. Forsberg and B. Dale, "Can We Replace All Crude Oil Within 20 Years with Cellulosic Liquid Hydrocarbons?", The Biofuels Digest, May 29,

2023. https://www.biofuelsdigest.com/bdigest/2023/05/29/can-we-replace-all-crude-oil-within-20- years-with-cellulosic-liquid-hydrocarbons/

Recommended EPA action. Develop a technologically-neutral strategy for decarbonization. The record on predictions of future technologies is one of failure. U.S. emissions per unit of GDP are substantially lower than other countries because of the development of natural gas fracking that is rapidly pushing coal out of the market-a technology that nobody in government predicted. Having the EPA chose future technologies for a low-carbon economy will delay decarbonization by decades with massive negative impacts on American standards of living. There are many technology neutral regulatory options-including clean fuel standards adopted by California, Oregon, Washington and British Columbia or carbon taxes. Carbon dioxide coming out of the tail pipe may or may have a greenhouse impact depending upon whether it is fossil carbon (net addition of carbon to atmosphere) or bio-carbon (net negative carbon emission for many production options). [EPA-HQ-OAR-2022-0829-0738, pp. 4-5]

Organization: Chevron

3. The role of biofuels.

The light and medium duty proposal does not address the potential for biofuel use to create energy security benefits. EPA should consider options to reduce the nation's dependence on a single transportation energy resource infrastructure while it supports a reliable and affordable decarbonization plan for transportation. EPA should support the use of diversified fuels in the nation's transportation fleet to meet nationwide GHG reduction goals. [EPA-HQ-OAR-2022-0829-0553, pp. 5-6]

Chevron is investing in capabilities to increase the supply of biofuels. In 2022, Chevron acquired Renewable Energy Group, a leading biodiesel and renewable diesel fuel producer. Chevron announced a collaboration with Corteva to introduce winter canola that will produce lower carbon intensity feedstocks. Chevron has invested in CoverCress to develop and introduce small winter oilseeds that will also produce lower carbon intensity feedstocks. A Chevron joint venture with Bunge, a leading oilseed processor, will expand crush capacity to yield greater access to lower carbon intensity feedstocks. The biomass-based diesel fuels resulting from these technology and commercial initiatives are well-suited to reduce emissions from the medium duty vehicles that are powered by diesel engines. [EPA-HQ-OAR-2022-0829-0553, pp. 5-6]

We believe there is also potential for increased use of lower CI ethanol and other renewable fuels to produce renewable gasoline blends for the light and medium-duty fleet. With more than 265 million gasoline-powered vehicles on the road today in the United States, renewable gasoline blends could empower virtually all drivers to contribute to a lower carbon transportation future. Recently, we partnered with Toyota to demonstrate lower carbon technologies are compatible with internal combustion engines by demonstrating the use of fuel with more than 40% lower carbon intensity than traditional gasoline on a life cycle basis. [EPA-HQ-OAR-2022-0829-0553, pp. 5-6]

Looking into our transportation future, Chevron is developing, producing, and testing blends of lower carbon intensity renewable gasoline. These blends can be manufactured using today's facilities and used in almost any gasoline-powered vehicle, delivering an immediate GHG reduction compared to traditional gasoline. Renewable gasoline blends use a variety of feedstocks and technologies to achieve carbon intensity reductions. Along with innovation from engine manufacturers and public policies supporting lower carbon intensity fuels, renewable gasoline blends are intended to reduce the carbon intensity of light and medium duty vehicles already on the road. [EPA-HQ-OAR-2022-0829-0553, pp. 5-6]

Organization: Clean Fuels Alliance America

The biodiesel and renewable diesel industry is on a path to sustainably double the market to 6 billion gallons annually by 2030, eliminating at least 35 million metric tons of CO2 equivalent greenhouse gas emissions annually with our members leading the U.S. companies investing in new biodiesel, renewable diesel and SAF capacity. These fuels are among the cleanest and lowest-carbon fuels available today to help reduce greenhouse gas (GHG) emissions now and are available to meet President Biden's near- and long-term climate goals.2 To date, the utilization of low carbon liquid fuels like biodiesel and renewable diesel reduces greenhouse gas emissions by more than 70% on average, directly and immediately reducing GHG emissions from the vehicles that use our fuels. [EPA-HQ-OAR-2022-0829-0626, pp. 1-2]

2 Executive Office of the President. Executive Order 14008: Tackling the Climate Crisis at Home and Abroad, 86 FR 7619 (February 1, 2021), available at https://www.federalregister.gov/d/2021-02177

Our fuels reduce more than just greenhouse gas emissions. Biodiesel and renewable diesel also reduce criteria pollutants from existing diesel engines, reducing health and environmental impacts in major trucking corridors, warehouse distribution centers and other diesel hot spots close to major population sectors. This means that using these fuels today will also lower health care impacts and costs for all populations living in and near these areas including minority, low-income, and indigenous populations. [EPA-HQ-OAR-2022-0829-0626, pp. 1-2]

Low-carbon liquid fuels are the lowest cost option for decarbonization and can be used in every diesel- fueled application or engine technology today. Our fuels are being used in fleets utilizing medium-duty vehicles around the country and provide reliable transportation for those with unknown schedules and unplanned routes, including emergency vehicles, tow trucks, and snowplows. It cannot be overlooked that the medium-duty sector will continue to rely on the internal combustion engines when you consider the decades it will take to pursue across the board electrification and other decarbonization strategies. As a result, EPA cannot discount the immediate benefits biodiesel and renewable diesel have and will continue to bring as we decarbonize the medium-duty sector. [EPA-HQ-OAR-2022-0829-0626, pp. 1-2]

While the proposed rule outlines fuel neutral standards, in order to meet the across-fleet average of a 44% GHG reduction by 2032, EPA is in fact forcing the adoption of zero-emission vehicles. The proposed rule ignores the potential to achieve similar emissions reduction goals by simply increasing the use of biodiesel and renewable diesel in existing and future engines. These emission reductions benefits are already being seen by fleets that have chosen to lower their GHG emissions through the adoption of biodiesel. [EPA-HQ-OAR-2022-0829-0626, pp. 1-2]

Climate and Air Quality Urgency

Clean Fuels clearly understands the urgency we face in terms of addressing climate and air quality. When looking at greenhouse gas (GHG) reductions today, biodiesel is a solution that reduces carbon dioxide now. Specifically, when compared to electric vehicles (EVs), utilizing biomass-based diesel now will allow the United States to meet our carbon reduction goals earlier than if we were to rely on EVs alone. The benefits of using and increasing the use of biomass-based diesel now will not only provide immediate greenhouse gas reductions, but also will have a positive impact on health in disadvantaged communities. [EPA-HQ-OAR-2022-0829-0626, p. 2]

When considering options to help reduce greenhouse gas emissions from vehicles and equipment, there are two essential elements to consider: the amount of the reduction and when it happens. This is because carbon emissions are persistent and accumulate. The resulting increased levels of GHGs in the atmosphere contribute to global warming now and for decades to come. A reduction in GHG emissions now can avoid decades of associated heating, thus having significantly more value than carbon reductions made in the future. The time value of carbon is key, and the next decade is critical.3 The importance of reducing carbon today cannot be understated as the Intergovernmental Panel on Climate Change (IPCC) clearly reaffirmed in their Sixth Assessment Report: Carbon reductions today are more important than carbon reductions in the future.4 [EPA-HQ-OAR-2022-0829-0626, p. 2]

3 National Biodiesel Board. Biodiesel.org. (2021). Cutting Carbon: Comparing Biomass-Based Diesel & Electrification for Commercial Fleet Use.

4 Intergovernmental Panel on Climate Change. (2021). Climate Change 2021: The Physical Science Basis. Contribution of Working Group I to the Sixth Assessment Report of the Intergovernmental Panel on Climate Change.

Greenhouse Gas Emissions Standards

Per Argonne National Labs GREET model, biodiesel and renewable diesel reduce greenhouse gas emissions by more than 70% on average compared to petroleum, directly and immediately reducing GHG emissions from the vehicles that use our fuels. [EPA-HQ-OAR-2022-0829-0626, p. 3]

The immediate reductions achieved by biodiesel and renewable diesel are crucial to reach our near- and long-term carbon reduction goals. Importantly, biofuels are already reducing GHG emissions. The biodiesel and renewable diesel industry is on a path to sustainably double the market size to 6 billion gallons annually by 2030 if not earlier and eliminating over 35 million metric tons of CO2 equivalent greenhouse gas emissions annually. Removing this important mechanism will be detrimental to meeting our nation's clear air and energy goals. [EPA-HQ-OAR-2022-0829-0626, p. 3]

Criteria Pollutant Emissions and Environmental Justice

In addition to reducing greenhouse gas emissions, biodiesel also reduces particulate matter emissions. This benefits all populations including minority, low-income, and indigenous populations. Clean Fuels Alliance America, through our continued partnership with Trinity Consultants, quantified the health benefits and corresponding economic savings from converting petroleum-based diesel to 100% biodiesel at 23 sites across the country. 5 [EPA-HQ-OAR-2022-0829-0626, p. 3]

5 Trinity Consultants, Assessment of Health Benefits from Using Biodiesel as a Transportation Fuel and Residential Heating Oil, (April 2022). https://cleanfuels.org/resources/health-benefits-study

The Trinity Report assesses the health benefits of substituting biomass-based diesel in transportation- related sources currently fueled by conventional ultra-low sulfur diesel (ULSD or diesel fuel) at 14 locations and as a replacement for home heating oil in one location throughout the United States. This study expands upon the Assessment of Health Benefits from Using Biodiesel as a Transportation Fuel and Residential Heating Oil completed by Trinity Consultants in 2021. This study uses a "bottom-up" approach, focusing on specific population groups such as those living in crowded urban housing complexes and portside communities. Even greater total benefits can be seen when considering comparable communities outside of these specific markets and locations. [EPA-HQ-OAR-2022-0829-0626, p. 3]

The research finds that switching to 100% biodiesel can provide immediate community health improvements including more than 436,000 fewer/reduced asthma cases per year; more than 137,000 fewer sick days per year; nearly 9,400 less cancer cases; the prevention of more than 885 premature deaths per year; over $7.4 billion in avoided health costs annually; and a 45% reduction in cancer risk when legacy heavy-duty trucks such as older semis use B100.6 [EPA-HQ-OAR-2022-0829-0626, p. 3]

6 id.

The immediacy of these potential health benefits, especially for disadvantaged communities, is even more critical when one considers the years, possibly decades, it will take for states to pursue deep electrification and other decarbonization strategies. [EPA-HQ-OAR-2022-0829-0626, p. 3]

Costs and Consumer Savings

While the stated purpose of the proposed rule is to significantly reduce greenhouse gas emissions, hydrocarbons, nitrogen oxides, and particulate matter to result in widespread reductions in air pollution, EPA has discounted the known benefits of biodiesel and renewable diesel. Meeting clean air demands does not require switching to a zero-emissions vehicle. Biodiesel and renewable diesel are drop-in alternatives, achieving valuable carbon reductions today at a relatively low cost.7 Fleets utilizing biodiesel today view it as an opportunity to maximize their emissions reductions while minimizing any effect on their operations. [EPA-HQ-OAR-2022-0829-0626, pp. 3-4]

7 Source: Frank, J. et al. Quantifying and comparing the cumulative greenhouse gas emissions and financial viability of heavy-duty transportation pathways for the Northeastern, United States. Fuel, 323, 124243, Sep. 2022. https://doi.org/10.1016/j.fuel.2022.124243. See Table 4.

These fuels offer owners, users, and fleet operators affordable, low-carbon solutions to immediately improve the sustainability of their operations. These fuels are available now and can be used in every diesel fueled application and every engine technology. Nearly all medium-duty original equipment manufacturers (OEMs) support using biodiesel blends of 20% or more in the vehicles they produce, and the vast majority of OEMs support the use of biodiesel blends up to 20%. For those that do not, warranties cannot be voided or impacted in any way using biodiesel, due to existing federal law.8 [EPA-HQ-OAR-2022-0829-0626, pp. 3-4]

8 Magnuson-Moss Warrant Act, P.L. 93-637

When compared to other decarbonization strategies such as zero emissions and specifically electrification approaches, which require both new vehicles and infrastructure to realize the benefits, biodiesel and renewable diesel remain the lowest cost option. According to a report by Diesel Technology Forum, prospective fleets contemplating EVs immediately face 3.8 times higher upfront cost to their diesel counterparts.9 While new technology diesel vehicles fueled with biodiesel and renewable diesel have three times lower cost.10 [EPA-HQ-OAR-2022-0829-0626, pp. 3-4]

9 Environmental Benefits of Medium- and Heavy Duty Zero Emission Vehicles Compared with Clean Bio- & Renewable-Fueled Vehicles 2022-2032, Prepared for Diesel Technology Forum By Stillwater Associates LLC, Irvine, California, USA, July 19, 2022, available at https://dieselforum.egnyte.com/dl/MWHPcRW4e6

10 id.

Infrastructure

As EPA looks to the Inflation Reduction Act (IRA) as a policy to support charging infrastructure in conjunction with the proposed rule, it is important for EPA to consider the timeframe of such investments along with the timeframe of growing and transitioning an existing fleet. Congress demonstrated when passing IRA, the need to continue to support biofuels infrastructure growth to supply low carbon biofuels remains a priority. The U.S. Department of Agriculture's Higher Blends Infrastructure Incentive program (HBIIP) increases the sales and use of higher blends of biodiesel by expanding the infrastructure for renewable fuels derived from U.S. agricultural products. The program by design encourages a more comprehensive approach to market higher blends by sharing the costs related to building out biofuel-related infrastructure. The expansion of biofuel infrastructure, as facilitated by HBIIP, broadens the availability of renewable fuels like B20 and higher blends while reducing carbon emissions and harmful tailpipe pollution today. Under HBIIP, the grants support fueling stations, convenience stores, hypermarket fueling stations, and fleet and fuel distribution facilities, including terminal operations and home heating oil distribution centers throughout the country. Federal matching grants have helped and continue to help the industry build or retrofit terminals, storage, and rail capacity to enable broader consumer access to these clean fuels and in turn clean air. This infrastructure complements existing fueling infrastructure throughout the country and does not require investment in new vehicles and a full infrastructure overhaul to realize GHG benefits. [EPA-HQ-OAR-2022-0829-0626, p. 4]

Conclusion

The immediate and compounding benefits that biodiesel and renewable diesel provide cannot be underscored enough. We ask that EPA adjust the fuel neutral standards to reflect a more appropriate and feasible mix of technologies available in the time frame proposed to meet the future standards as we work together to decarbonize the transportation sector today and, in the years to come. Clean Fuels looks forward to working with EPA to ensure the optimization of the immediate benefits of biodiesel and renewable diesel as you address multi-pollutant emissions from medium duty vehicles. [EPA-HQ-OAR-2022-0829-0626, p. 5]

Organization: Clean Fuels Development Coalition (CDFC)

B. Higher ethanol blends lower carbon intensity.

The proposal projects that millions of liquid fueled vehicles will continue to be sold throughout the compliance period and that millions more will remain on the road in the decades to come. There are two ways to reduce the greenhouse gas emissions from this fleet: improve the fuel efficiency of the vehicles or reduce the carbon intensity of the fuel. While vehicles running on these fuels would emit approximately the same amount of CO2 from their tailpipes, the net CO2 emitted would be substantially reduced. This is because these fuels make use of carbon that was recently sequestered by plants, and thus removed from the atmosphere in the same quantity that it will reenter it. Converting plants to biofuels does not result in any net increase in carbon emissions within this natural cycle. [EPA-HQ-OAR-2022-0829-0712, p. 40]

When ethanol is blended into gasoline, the carbon intensity of the fuel decreases from average life cycle number of 95.3 gCO2e/MJ down toa 90.2 gCO2e/MJ for E15 and 79.8 gCO2e/MJ for E30, after adjusting for the lower energy density of ethanol. See Steffen Mueller, High Octane Low Carbon Fuels: The Bridge to Improve Both Gasoline and Electric Vehicles, The University of Illinois at Chicago (Mar. 22, 2021), https://erc.uic.edu/wp-content/uploads/sites/633/2021/03/UIC-Marginal-EV-HOF- Analysis-DRAFT-3_22_2021_UPDATE.pdf. If liquid fuel consumption stays constant at approximately 135 billion gallons per year, adopting nationwide E15 would reduce carbon emissions between 2027 and 2032 by 384 million tons, 1.65 times more than the proposal's estimate 232 million tons over the same time frame. Adopting nationwide E30 could reduce emissions by 1,167 million tons, five times the savings of EPA's proposed rule. Id. Other studies have confirmed this result, suggesting that the adoption of even mid-level ethanol blends would reduce pollution emissions at least as much as EPA's electrification approach, and at far less cost. See Brian West, Higher Ethanol Blends Support the Transition to a Low-Carbon Future, SAE Int'l Update (Feb. 2023), https://www.nxtbook.com/smg/sae/23UPD02/index.php#/p/2. [EPA-HQ-OAR-2022-0829-0712, p. 40]

But 2012, EPA declined to extend these FFV incentives. 77 Fed. Reg. 62,624. After EPA's discontinuation. FFV production dropped from 20% of all 2014 light-duty vehicles to only 8% of 2016 vehicles. See The 2020 EPA Automotive Trends Report, EPA-420-R-21-002, Environmental Protection Agency (Jan. 2021), https://ne-pis.epa.gov/Exe/ZyPDF.cgi?Dockey=P1010U68.pdf. FFV production has dropped even further since 2016 due to EPA's failure to recognize the real-world lifecycle benefits of bioethanol used in FFVs. [EPA-HQ-OAR-2022-0829-0712, pp. 43-44]

EPA removed these incentives because it believed that greenhouse gas emissions compliance must be based on "demonstrated GHG emissions performance." 77 Fed. Reg. 62,823. Commentors agree. Because of their "demonstrated GHG emissions performance," EPA should reintroduce crediting for vehicles that can utilize higher blends of renewable fuels and should expand the program to include technologies other than just FFVs. [EPA-HQ-OAR-2022-0829-0712, pp. 43-44]

F. EPA should account for the benefits of fuel improvements by accounting for lifecycle emissions and allowing for new higher ethanol certification fuels.

There are two ways EPA can account for the benefits of renewable fuels to reduce greenhouse-gas emissions and improve the feasibility of its standards. First, should use lifecycle emissions to account for the net emissions reductions that come from renewable fuels in the fleet. EPA has detailed knowledge of the exact volumes and benefits of these fuels because it administers the Renewable Fuel Standard and has significant data about the volumes of these fuels that are already used by the fleet.24 Accounting for the current emissions savings of renewable fuels sets the stage for fuel improvements that dramatically reduce lifecycle emissions. [EPA-HQ-OAR-2022-0829-0712, p. 44]

V. The Proposed Rule Fails to Adequately Consider Fuels Related Alternatives.

Beneath the complexity of its reverse-engineered system, the proposal's plan for reducing greenhouse gas emissions is remarkably straightforward: electrify the light-duty fleet as fast as—or perhaps even faster—than possible. But this narrow vision of pursuing a singular regulatory White Whale entirely neglects other more feasible technological solutions auto manufacturers could adopt to meet the standards if they were properly credited for them: namely, the manufacture of vehicles that run on low-carbon, renewable fuels. [EPA-HQ-OAR-2022-0829-0712, pp. 36-37]

There are 281 million internal combustion engine vehicles on the road today and 100 million more will be built in the next two decades. All of these vehicles could be improved—and for far less than what EPA's proposal would cost—with an improvement in fuel quality and the blending of renewable fuels. Gasoline blended with renewable ethanol up to 10 percent by volume, E10, already reduces greenhouse gas emissions from the light-duty fleet by tens of millions of tons a year. And we could do better. EPA has determined that E15 is suitable for use in all model year 2001 and later vehicles. See e.g., Regulation History of the E15 Partial Waivers Under the Clean Air Act, EPA-420-F-15-044, Environmental Protection Agency (Sep. 2015), https://www.epa.gov/sites/default/files/2015-09/documents/420f15044.pdf. [EPA-HQ-OAR-2022-0829-0712, pp. 36-37]

Many newer vehicles on the road could run on mid-level blends like E25. See e.g., Amber Rucker, EPA Approves The Use Of E30 In Nebraska Fleet Demonstration Poised To Reduce Costs, Pollution, State of Nebraska (Oct. 21, 2022), https://etha- nol.nebraska.gov/epa-approves-the-use-of-e30-in-nebraska-fleet-demonstration- poised-to-reduce-costs-pollution/. Every automaker could readily make vehicles designed to run on mid-level blends with only minimal design changes. And over 27 million flex-fuel vehicles ("FFVs") are capable of running on approximately 85% ethanol are already on the road. See Growth Energy, Flex Fuel Database, https://growthenergy.org/choice-at-the-pump/flex-fuel-database/ (last accessed July 5, 2023). [EPA-HQ-OAR-2022-0829-0712, pp. 36-37]

Increased ethanol blends have a myriad of benefits: they reduce the carbon intensity of liquid fuels, they enable higher compression rations and thus more fuel- efficient engines, and they reduce the aromatics and particulate matter that come out of the tailpipe. The auto industry,20 the petroleum industry,21 and the renewable fuels industry22 are all on the record calling for EPA to use its power to improve fuel quality by increasing the minimum octane number. And there are many direct fuel-related ways EPA might act to incentivize better fuel quality and the adoption of higher-level blends: through increased volumes of low-carbon renewable fuels under the Renewable Fuel Standard, through alternative, low-carbon certification fuels, and through Section 211(c) rulemaking—as the proposal itself suggests. [EPA-HQ-OAR-2022-0829-0712, pp. 37-38]

20 See, e.g., Letter from Mitch Bainwol, President and CEO, Alliance of Automobile Manufacturers, to Lisa Jackson, Administrator, EPA (Oct. 6, 2011), available at https://legacy-assets.ee-news.net/openfiles/assets/2011/10/31/document_pm_04.pdf ("recommend[ed] increasing the mini- mum gasoline octane rating, commensurate with increased use of ethanol" to "help achieve future requirements for the reduction of greenhouse gas emissions."); Julian Soell & R. Thomas Brunner, Mercedes-Benz,

Comments on Proposed Tier 3 Rule, EPA-HQ-OAR-2011-0135-4676 (June 28, 2013), at 3–4 ; Robert Babik, General Motors LLC, Comments on Proposed Tier 3 Rule, EPA-HQ-OAR-2011- 0135-4288 (June 28, 2013), at 14 (“support[ing] the future of higher octane and higher ethanol content in order to provide a pathway to improved vehicle efficiency and lower GHG emissions”); Cynthia Williams, Ford Motor Company, Comments on Proposed Tier 3 Rule, EPA-HQ-OAR-2011-0135-4349 (July 1, 2013), at 16 (“Ford supports the development and introduction of an intermediate level blend fuel (E16-E50), with a minimum octane rating of 91 anti-knock index (AKI) that increases proportionally as ethanol is splash-blended on top of the base Tier 3 gasoline emission test fuel. The development of such a fuel would enable the first steps to the development of a new generation of highly efficient internal combustion engine vehicles. We look forward to future collaboration with the EPA on this item.”); id. at 3 (commending the idea of “maximiz[ing] vehicle efficiency in tandem with use of renew- able fuels”).

21 See, e.g., Testimony of Chet Thompson, President and CEO, American Fuel & Petrochemical Manufacturers before U.S. House Energy and Commerce Subcommittee on the Environment (Apr. 13, 2018), https://www.afpm.org/sites/default/files/issue_resources/20180411-AFPM-Written-Testi- mony.pdf (“a 95-RON used in optimized high-compression engines would provide more than a three percent efficiency gain.”) 95 RON Octane Standard: A Smarter Way to Cut Carbon from Vehicles, American Fuel & Petrochemical Manufacturers (May 27, 2021), https://www.afpm.org/news- room/blog/95-ron-octane-standard-smarter-way-cut-carbon-vehicles (a nationwide 95 RON octane standard “can deliver major carbon reductions in the nation’s light-duty vehicle fleet faster and at a lower cost than any other proposal being considered by policymakers at the national level right now.”).

22 See, e.g., RFA Welcomes Inclusion of High Octane Fuels in 2021-2026 CAFE/GHG Proposal, Renewable Fuels Association (Aug. 2, 2018), https://ethanolrfa.org/media-and-news/category/news-re-leases/article/2018/08/rfa-welcomes-inclusion-of-high-octane-fuels-in-2021-2026-cafe-ghg-proposal (“high octane fuels can help enable more efficient engines and reduce GHG emissions, and we believe the Agency should use its authority to include high octane low carbon fuels as an option available to automakers for meeting more stringent fuel economy and emissions standards in the future.”); Kevin Heavican, Corn Growers Back Higher Ethanol Blends, Brownfield Ag News (Mar. 11, 2021), https://brownfieldagnews.com/news/corn-growers-back-higher-ethanol-blends/ (“Nebraska Corn introduced a resolution at the recent Corn Congress calling for 95 RON E15, a 15-percent blend of ethanol to raise octane to help auto makers create cleaner engines.”).

But EPA also has the authority to consider the impact of these fuels in its consideration of life-cycle emissions under the agency’s Section 202 powers. The agency has done so in the past, and acknowledging these benefits again would incentivize the use of more renewable fuels, and allow automakers to achieve greater emissions reductions, in a shorter time frame, and at a net savings to consumers. Agencies are required, as part of any reasoned decision making process, to consider all “‘significant and viable and obvious alternatives’” to their proposed action. Dist. Hosp. Partners, L.P. v. Burwell, 786 F.3d 46, 59 (D.C. Cir. 2015); see Spirit Airlines, Inc. v. DOT, 997 F.3d 1247, 1255 (D.C. Cir. 2021) (“‘[T]he failure of an agency to consider obvious alternatives has led uniformly to reversal.”’). Ignoring the benefits of renewable fuels— and of ethanol in particular—violates EPA’s duty to give “appropriate consideration to the cost of compliance” with the proposed regulations, 42 U.S.C. § 7521(a)(2), and would render the rule arbitrary and capricious. [EPA-HQ-OAR-2022-0829-0712, pp. 38-39]

C. Higher ethanol blends raise octane number, improving engine efficiency.

In addition to reducing carbon-intensity, higher ethanol blends of gasoline benefit from higher octane numbers. After reducing carbon intensity, improving engine efficiency is the only way to reduce greenhouse gas emissions from internal combustion engine vehicles. Engine efficiency has improved dramatically over the last fifty years, through a blend of technologies that are now widely used in all new vehicles. But future improvements to vehicle technology to further reduce CO_2—as EPA is well aware—will come at steep and increasing marginal cost. Internal combustion engines operate together with their fuel as a system and engine efficiency is now limited by the fuel that is available. Specifically, low-octane gasoline, standard in the U.S. market, limits the ability of automobile manufactures to produce high compression, and thus high efficiency, engines. Without higher octane gasoline, the cost of higher efficiency vehicles will rise, slowing their adoption and raising the overall CO2 emissions of the American fleet. [EPA-HQ-OAR-2022-0829-0712, pp. 40-41]

Raising the minimum Research Octane Number (RON) of gasoline to 95, would have immediate impact. Existing vehicles would, overnight, become more fuel efficient. Thomas G. Leone, et al., The Effect of Compression Ratio, Fuel Octane Rating, and Ethanol Content on Spark-Ignition Engine Efficiency, 49 Environmental Science & Technology 10778, 10781 (2015), https://pubs.acs.org/doi/abs/10.1021/acs.est.5b01420?src=recsys. With calibration, the entire existing U.S. fleet would gain up to 4.4% in engine efficiency and see larger reductions in CO2. Id. Future vehicles, equipped with high compression engines, would achieve even higher efficiencies. Emissions savings from these high-octane vehicles would rapidly outstrip those of electric vehicles and cumulatively save nearly 700 million tons of CO2 by 2035. And these benefits would come at only marginal increases in fuel costs – likely less than $0.03 per gallon. David S. Hirshfeld, et al., Refining Economics of U.S. Gasoline: Octane Ratings and Ethanol Content, 48 Environmental Science & Technology 11064, 11067 (2014), https://pubs.acs.org/doi/10.1021/es5021668. [EPA-HQ-OAR-2022-0829-0712, pp. 40-41]

These benefits are why individual auto manufacturers, industry groups, and groups across the liquid fuels space have all called for a high-octane fuel standard. Testimony of Chet Thompson, President and CEO, American Fuel & Petrochemical Manufacturers before U.S. House Energy and Commerce Subcommittee on the Environment (Apr. 13, 2018), https://www.afpm.org/sites/default/files/issue_re sources/20180411-AFPM-Written-Testimony.pdf ("a 95-RON used in optimized high- compression engines would provide more than a three percent efficiency gain."). As American Fuel & Petrochemical Manufacturers has explained, a nationwide 95 RON octane standard "can deliver major carbon reductions in the nation's light-duty vehicle fleet faster and at a lower cost than any other proposal being considered by policy makers at the national level right now." 95 RON Octane Standard: A Smarter Way to Cut Carbon from Vehicles, American Fuel & Petrochemical Manufacturers (May 27, 2021)," https://www.afpm.org/newsroom/blog/95-ron-octane-standard-smarter- way-cut-carbon-vehicles. [EPA-HQ-OAR-2022-0829-0712, pp. 41-42]

E. Flex-fuel vehicles are at least as effective as electric vehicles at reducing greenhouse gas emissions.

EPA's proposal also neglects the potential benefits of FFVs. Over 27 million FFVs capable of running on approximately E85 ethanol are already on the road. See Growth Energy, Flex Fuel Database, https://growthenergy.org/choice-at-the- pump/flex-fuel-database/ (last accessed July 5, 2023). Because of the lower carbon intensity of ethanol, FFVs produce far less greenhouse gas emissions than conventional gasoline vehicles. An FFV running E85 made from corn starch ethanol and natural gasoline reduces greenhouse gas emissions as compared to a conventional liquid fueled vehicle by 46 percent. EPA's Proposed Tailpipe Standards Overlook Ethanol's Low-Carbon, Efficiency Benefits, Renewable Fuels Association (Apr. 12, 2023), https://ethanolrfa.org/media-and-news/category/news-releases/article/2023/04/epa-s- proposed-tailpipe-standards-overlook-ethanol-s-low-carbon-efficiency-benefits. Using corn kernel fiber ethanol and renewable naptha reduces emissions as compared to a conventional liquid fueled vehicle by 77 percent. Id. This is more than the net emissions reductions realized by electric vehicles. Id. [EPA-HQ-OAR-2022-0829-0712, p. 43]

Recognizing these benefits, in EPA rules through model year 2015, and in the existing NHTSA fuel economy standards, FFVs received compliance benefits. See EPA regulations at 40 CFR 600.510-12(j)(2)(iv)(B) (providing FFV crediting through Model Year 2015); see also 49 CFR 536.10 (indicating that dual-fuel vehicles can earn credits under the standards); 77 Fed. Reg. 62,624, 62,829–30 (Oct. 15, 2012) (providing that FFVs could generate credits under the standards). These standards incentivized FFVs by accounting for E85's real-world greenhouse gas reductions, and not merely tailpipe emissions. [EPA-HQ-OAR-2022-0829-0712, p. 43]

Second, EPA must update its certification pathways to allow vehicles to certify on dedicated alternative fuels, like the various, widely available high ethanol blends. As detailed in the next section, there are several problems with the way EPA handles its Tier 3 certification fuel that penalizes renewable fuels. EPA should fix these problems and establish new pathways for higher ethanol blends—like EPA is proposing to do with hydrogen—to open new routes by which auto manufacturers can seek to reduce the emissions from their vehicles. [EPA-HQ-OAR-2022-0829-0712, pp. 44-45]

By failing to consider the benefits of renewable fuels, EPA precludes the most effective way for automakers to reduce emissions and meet EPA's standards. This would violate EPA's statutory duties under Section 202 and would, at the very least, make the proposed rule arbitrary and capricious. [EPA-HQ-OAR-2022-0829-0712, pp. 44-45]

Organization: Countymark

The Environmental Protection Agency (EPA) should consider an alternative approach and propose a multipollutant fuel rule. The proposed rule should include requirements to improve fuel quality by establishing a higher federal octane standard and allowing higher ethanol blends. It should also incentivize the reduction of carbon and aromatic compounds through reformulation or increased ethanol blending. [EPA-HQ-OAR-2022-0829-0665, p. 3]

Additionally, the rule should incentivize automakers to produce more efficient vehicles by creating alternative certification pathways for higher ethanol blends and addressing issues with R Value, CO2 penalty, and the Volumetric Conversion Factor in fuel economy calculations. Adopting a life-cycle analysis approach to compare emissions from different technologies would yield many benefits. For instance, embracing and enabling a pathway to improve fuel quality would lead to increased and accelerated emission reductions, improved public health, environmental justice goals, greater versatility, and improved reliability, all at a lower cost. The Clean Air Act authorizes the consideration of this pathway by the EPA. Even mid-level ethanol blends would reduce pollution emissions at least as effectively as the EPA's electrification approach and at a significantly lower cost. Incorporating a fuel improvement strategy would double the EPA's projected emissions reduction. However, the current rule disregards this option, leaving pollutants in the air and leaving the EPA with less than optimal outcomes. [EPA-HQ-OAR-2022-0829-0665, p. 3]

Organization: Darius

While the goal of this proposal is to reduce the U.S. automotive fleet's carbon footprint, it simply shifts how emissions are produced. The EPA is ignoring the value of technologies produced by American workers, manufacturers, and farmers that are critical to our transportation future. Specialty automotive aftermarket businesses are leading the way through alternative fuel innovations from replacing older engine technologies with newer, cleaner versions to converting older ICE vehicles to new electric, hydrogen, and other alternative fuels. Sadly, the EPA's plans to reduce greenhouse gases and criteria pollutants do not factor this in. [EPA-HQ-OAR-2022-0829-0519, p. 1]

Organization: Departments of Transportation of Idaho, Montana, North Dakota, South Dakota and Wyoming

Before closing we note that there are many other concerns with this proposal that may well be developed by others commenting to this docket. For example, we are struck by the singular focus in the NPRM on tailpipe emissions reduction that virtually compel a transition to EVs and inadequate attention to low carbon liquid fuels and biofuels as additional means of addressing emissions concerns that would not be dependent on an adequate electric vehicle charging network, something that certainly is not available at this time, particularly in rural areas. [EPA-HQ-OAR-2022-0829-0525, p. 2]

Questions could be raised regarding: life-cycle rather than tailpipe emissions; and the ability of the electric grid, even with costly additions and connections to charging stations, to support all the EVs. [EPA-HQ-OAR-2022-0829-0525, p. 2]

Organization: East Kansas Agri-Energy (EKAE)

As a member of the EPA Farm Ranch and Rural Communities Committee I am looking to help our rural communities prosper and operating ethanol plants do just that. EVs are not practical for everyday use here in rural America so let's make regulations that benefit the whole country. Ethanol is a clean low carbon fuel that's environmentally friendly and overlooked in most every conversation on lowering carbon emissions. [EPA-HQ-OAR-2022-0829-0734, p. 1]

Thank you for the opportunity to comment on this important issue. As a member of the Renewable Fuels Association, we also wish to endorse and support their written comments, as submitted. EPA-HQ-OAR-2022-0829-0734, p. 1]

Organization: Energy Marketers of America (EMA)

EMA member companies provide a growing portfolio of affordable, efficient, and greener liquid fuels and alternative energy sources. These liquid fuels have played a critical role in lowering emissions over the past half century. Through innovation and technological advancements, liquid fuels will continue to reduce emissions further and be a crucial driver of economic growth in this country in the coming decades. Therefore, EMA fully supports and endorses the comments submitted by the American Fuel & Petrochemical Manufactures (AFPM) regarding EPA’s GHG standards for light-duty and medium-duty vehicles for model years 2027 and later. [EPA-HQ-OAR-2022-0829-0616, p. 1]

EMA urges the EPA to consider lifecycle emissions and a technology neutral approach when considering emission reductions. The proposed rule should consider the lifecycle emissions associated with EV production, usage, and end-of-life disposal including emissions from raw material mining and refining, battery manufacturing, and electricity generation for EV charging. Further EPA needs to consider the logistics, investment, and timing associated with EV and battery production, electric generation and transmission, and EV charging to support a substantial increase in EV production. Achieving a significant ramp up of domestic supply of raw materials for batteries, mineral refining, and battery and vehicle manufacturing as well as upgrades to the electricity generation and transmission will be complex and take time. [EPA-HQ-OAR-2022-0829-0616, pp. 1-2]

Again, EMA urges the EPA to consider lifecycle emissions and a technology neutral approach when it comes to promoting policies to reduce emissions. The most cost-effective and timely way to reduce emissions from transportation is to support multiple technologies that do so for both new vehicles and vehicles currently on the road. [EPA-HQ-OAR-2022-0829-0616, pp. 1-2]

Organization: Exxon Mobil Corporation

EPA's Proposal establishes standards for emissions reductions that can be achieved only through a rapid transformation of the transportation sector and through limited technology pathways. Specifically, the proposed standards could require as many as two-thirds of all new light-duty vehicle purchases to be battery electric vehicles (BEVs) by 2032. ExxonMobil believes BEVs will play an important role in reducing transportation sector emissions. Indeed, we produce plastics that can help reduce vehicle weight and increase fuel efficiency, butyl rubber that improves air retention in tires and can improve BEV range by up to 7 percent,6 and our Mobil EV™ suite of electric vehicle fluids and products help enable further, longer, and safer performance for electric cars, vans, and trucks.7 We believe, however, that EPA should encourage a diversity of technology pathways that allow for consumers to choose between vehicle types. Standards that encourage a combination of BEVs, plug-in hybrids, full hybrids, and efficient internal combustion engine vehicles, that could operate with bio and renewable fuels, are a better way to reduce GHG emissions and manage dependence on foreign critical minerals. Such a technology-neutral policy approach would foster innovation and competition across all technologies and could ultimately help encourage more effective and lower cost solutions for consumers and businesses. [EPA-HQ-OAR-2022-0829-0632, p. 2]

6 ExxonMobil Advancing Climate Solutions 2023 Progress Report (2023), page 20.

7 www.mobil.com/en-us/commercial-vehicle-lube/pds/na-xx-mobil-ev-drive-201-

EPA's Proposal further relies exclusively on vehicle fleet turnovers to accomplish emissions reductions and thus misses the opportunity to reduce emission from vehicles already in use and that will continue to be in use for decades. About 12 million new vehicles are sold in the U.S. each year8 while there are about 280 million cars, S.U.V.s, vans, and pickup trucks on America's roads today.9 Even after the proposed standards are fully implemented for MY 2032 vehicles, the majority of vehicles on the road in 2035 are still expected to be powered using conventional fuels such as gasoline.10 [EPA-HQ-OAR-2022-0829-0632, pp. 2-3]

ExxonMobil believes that existing transportation sector-based federal policies could be improved to achieve meaningful GHG emissions reductions through complementary fuel and vehicles standards. Specifically, we encourage EPA to consider how it may assist with the development and implementation of a federal low carbon fuel standard that would encourage investment in lowering the carbon intensity of fuels (liquid, compressed/liquefied gas, electricity, hydrogen) and vehicle standards that account for lifecycle GHG emissions, including emissions upstream of a vehicle's tailpipe. [EPA-HQ-OAR-2022-0829-0632, p. 3]

To encourage investment in technologies to reduce GHG emissions from existing fuels, ExxonMobil is encouraging U.S. policymakers to consider the development of a federal lifecycle and carbon-intensity based fuel standard measured in gCO2e per Mega Joule (MJ) of fuel energy (gCO2e/MJ) that would provide a long-term market signal for the production and use of lower carbon fuels. Such a standard, which could be increased in stringency over time, would establish a market for credit trading that would offer compliance flexibility and would underpin investments in technologies to reduce carbon emissions from gasoline and diesel used for existing vehicles. Examples of lower carbon-intensity fuels that might generate credits under such a standard would include ethanol, biodiesel, renewable diesel, renewable natural gas, hydrogen, electricity produced for EVs, and traditional fuels produced with lower emission technology such as carbon capture and sequestration. Moreover, the standard could be expanded beyond road transportation to the marine and aviation sectors in the future. [EPA-HQ-OAR-2022-0829-0632, p. 3]

Organization: Fuel Freedom Foundation

The central role of liquid fuels in transportation

Due to the diverse and all-American energy sources used for power generation, electric vehicles are structurally decoupled from the fluctuations of petroleum market. However, there is significant uncertainty surrounding the market's ability to transition to electrification as quickly as anticipated by EPA's proposal, which exceeds the goal previously established and reiterated by the Biden Administration.1,2,3 Further, even if the ambition in the proposed rule is fully realized and two-thirds of vehicle sales are electric vehicles by 2032, about 75% of the vehicles on the road will still use liquid fuels. A more holistic approach is warranted to avoid ceding the light- duty liquid fuel market to petroleum dominance—and the attendant upstream GHG emissions— for the period covering this rulemaking as well as many years beyond. [EPA-HQ-OAR-2022-0829-0711, pp. 1-2]

1 Energy Policy Research Foundation "EV Electricity Requirements and EPA's Challenging Rules", Chart 26 at https://eprinc.org/chart-of-the-week/

2 Alliance for Automotive Innovators comment to docket of this Proposed Rule "Auto Innovators does not believe [GHG and criteria pollutant standards] can be met without substantially increasing the cost of vehicles, reducing consumer choice, and disadvantaging major portions of the United States population and territory. EPA's proposed rules effectively assume that everything will go perfectly in the transformation to electric vehicles (EVs) between now and 2032."

3 President Biden Executive Order of Aug 5, 2021 "…bolstering our domestic market by setting a goal that 50 percent of all new passenger cars and light trucks sold in 2030 be zero-emission vehicles, including battery electric, plug-in hybrid electric, or fuel cell electric vehicles" accessed at https://www.whitehouse.gov/briefing-room/presidential-actions/2021/08/05/executive- order-on-strengthening-american-leadership-in-clean-cars-and-trucks/ and U.S. National Blueprint for Transportation Decarbonization (2023) "Government, industry, and labor set a target of 50% new light-duty EV sales share by 2030" accessed at https://www.epa.gov/greenvehicles/us-national-blueprint-transportation-decarbonization

More than 280 million ICEs are on the road today, and about 90 million are expected to be sold by the end of the period covered under this rulemaking. In order to provide insurance for maximum success of the GHG Standards, EPA should encourage all viable decarbonization pathways in the light-duty sector. Specifically, the final rule should incorporate provisions to incentivize the production of vehicles that facilitate decarbonization of the liquid fuels that will power light-duty transportation for decades to come. [EPA-HQ-OAR-2022-0829-0711, pp. 1-2]

By not including provisions to incentivize the production of flex-fuel vehicles (FFVs) including plug-in hybrid electric vehicles that can take advantage of the favorable properties of higher ethanol blends including high octane, the EPA risks leaving on the table GHG emissions reductions sooner rather than later. Extrapolating from California's current E85 use in the current onroad FFV fleet to a national level, annual GHG emissions would be reduced 4.27 MMT tons of GHG in 2022 and 74.71 MMT in 2032.4 We strongly encourage EPA to leverage the GHG-reduction potential of FFVs. [EPA-HQ-OAR-2022-0829-0711, p. 2]

4 Pearson Fuels, Comment letter to Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles rulemaking, p. 11

There are multiple public policy rationales for crediting FFVs within the GHG program:

Maximize cost effectiveness of GHG reductions. As GHG reduction targets are strengthened over time to achieve Net Zero carbon emissions in transportation, economic costs will inevitably increase. However, the total economic burden can be lessened, and the social benefits maximized, by keeping the door open to the most cost-effective fuel pathways. Fuel Freedom funded a study by Lifecycle Associates to evaluate possible scenarios for achieving an 80% fuel cycle reduction in light-duty vehicle GHG emissions for the U.S. and for California by 2050.7 The analysis used government estimates8 of fuel carbon intensity, vehicle efficiency improvements, and incremental costs for each fuel-vehicle combination, to develop feasible market penetrations for various pathways, including high-octane fuels with high-compression-ratio ICEs coupled with electrification, biofuels used in ICEs with and without hybridization, hybrid and plug-in hybrid vehicles, fuel cell EVs, and battery electric vehicles, to compare both feasibility and relative cost effectiveness for carbon reductions.9 Long-term results to 2050 show that it is critical to provide market flexibility for both electrification and liquid pathways in the near term to promote long-term feasibility and cost-effectiveness of GHG reductions. Regulations should therefore encourage and/or facilitate all feasible vehicle-fuel pathways that can 1.) immediately reduce carbon intensity in the transportation sector and, 2.) maximize long-term GHG reductions by transitioning to renewable sources, including electricity, hydrogen, and increasingly lower-carbon and advanced biofuels. [EPA-HQ-OAR-2022-0829-0711, pp. 2-3]

7 Life Cycle Associates, "Assessing Greenhouse Gas Emission and Petroleum Reduction Scenarios for the U.S. and California Transportation Sectors Final Report" (March 2019) – Submitted in conjunction with previous comments at Docket EPA–HQ– OAR–2021–0208

8 EIA Annual Energy Outlook 2016; Argonne National Laboratory (ANL), Greenhouse Gasses, Regulated Emissions and Energy Use in Transportation (GREET) Model, VISION2015, and Cradle-to-Grave Lifecycle Analysis of U.S. Light Duty Vehicle Fuel Pathways (2016);); National Academies of Science Transitions report (2013); EPA-NHTSA Draft Technical Assessment Report, EPA Fuel Economy Guide; CARB VISION2.1 and CA-GREET2 models

9 Each pathway centered on a dominant vehicle technology, constrained by practical limitations and the attributes of cars versus trucks or SUVs. Vehicles not suitable for battery electric propulsion were assumed to be ICEs.

Realize GHG reductions sooner rather than later. Given the urgency to forestall the increasing effects of climate change, the EPA should not foreclose pathways that can immediately reduce GHG emissions. With a signal from EPA that FFVs will be recognized for their decarbonization value, higher blends of low-carbon ethanol can be made quickly available in the marketplace to immediately displace higher-carbon gasoline. Today, more than 20 million FFVs are already on the road, compared to 3.8 million plug-in EVs. FFVs are a mature vehicle technology that can quickly be reintegrated into OEM offerings at virtual price parity to existing internal combustion engine (ICE) vehicles. E85 also has widely available distribution and dispensing infrastructure to deliver the fuel to retailers and consumers. Another key finding of the Lifecycle Associates analysis is that policies accelerating a decrease in the carbon intensity of fuels reduce total GHGs sooner. As EPA has noted, “future [GHG] emissions are expected to produce larger incremental damages as physical and economic systems become more stressed in response to greater climatic change.”10 Given the uncertainties in measuring the long-term impacts of GHG emissions,11 and the accumulated impacts of carbon emissions,12 EPA should not discount the benefits of pathways with significant promise to reduce emissions more quickly in the near-term. [EPA-HQ-OAR-2022-0829-0711, p. 3]

Minimize consumer disruption and cost. Since first being introduced more than 15 years ago, FFVs have been manufactured and sold with no consumer disruption. The functioning and fueling are virtually indistinguishable to drivers, and from a policy perspective are only limited in utility by uneven availability of E85. However, the state of California offers an illuminating example of FFVs fueled by a more robust fueling infrastructure. Due to a long-term sustained discount of E85 relative to regular gasoline (87 RON), California drivers have continued to increase use in the state. E85 consumption in California has been increasing by an average of 33% per year—and 40% from 2021 to 2022.14 The usage rate of E85 in FFVs was 16% in 2022 for a total of 103 million gallons.15 A primary driver of increased E85 use has been its sustained discount relative to retail gasoline. E85 has consistently offered a steady pump price discount of ~$1.00/gallon in California. Further, when gasoline prices spiked after Russia’s invasion of Ukraine, FFV drivers in the State were buffered from the impact. Unlike gasoline prices, ethanol prices are not dependent on world oil prices. Consequently, while gasoline prices spiked, E85 prices remained stable, resulting in a discount of up to $2.50/gallon for E85 relative to regular gasoline, and in some cases more. [see Appendix A] [EPA-HQ-OAR-2022-0829-0711, pp. 4-5]

14 California Air Resources Board E85 consumption data

15 California Air Resources Board and Pearson Fuels data

FFVs are already equivalent to existing vehicles in cost, attributes and convenience. Reinvigorating FFV production can leverage the major evolution since the FFV credit was eliminated. The Department of Agriculture, pump manufacturers and fueling stations have dedicated significant investments to increasing distribution infrastructure. Ethanol has become much less carbon intensive and is price advantaged in many areas of the country that sell blends above E10, while FFVs can use any blend up to E85. [EPA-HQ-OAR-2022-0829-0711, p. 5]

Summary

By not incorporating a program incentive for the production of FFVs, the proposed GHG Standards leave on the table the most substantial opportunity to rapidly and cost-effectively reduce GHG emissions in light-duty transportation in the near term. As acknowledged in the U.S. Blueprint "Some biofuels and biofuel blends are drop-in replacements for tradi4onal fossil fuels and offer the most substan4al immediate GHG emissions reduc4ons." Further, foreclosing the best possibility of lowering the carbon intensity of the liquid fuels that will dominate roadways for many years effectively cedes the liquid fuel market to petroleum-based fuels and the attendant climate consequences for the long-term. Even for California, which leads the nation in EV adoption, ICEs are expected to remain in significant numbers after 2035 and beyond and beyond. The Institute for Transportation Studies report "Driving California's Emissions to Zero" concluded that achieving carbon neutrality required a complete transition to bio-based gasoline and equivalents by 2045.16 [EPA-HQ-OAR-2022-0829-0711, pp. 4-5]

16 University of California Institute of Transportation Studies, "Driving California's Transportation Emissions to Zero" (April 2021) accessed at https://escholarship.org/uc/item/3np3p2t0

Because consumer sales determine the vehicles on the road, affordability and convenience are critical to the success of the GHG Standards, and ultimately the transition to a zero-carbon transportation system. Encouraging the purchase and use of lower-carbon technologies and fuels in the vehicles that Americans buy today will set us on a path toward that goal, given that these cars and trucks will be on the road for 15 to 20 years. [EPA-HQ-OAR-2022-0829-0711, pp. 4-5]

Organization: Green Diesel Engineering LLC

There is a consensus that the rising rate of CO2 is leading to global climate change. CO2 does fluctuate naturally on this planet over time, and it can change rapidly when a calamitous natural disaster occurs, such as a large volcanic eruption, or meteor impact that burns a significant portion of the planet. These have happened several times on planet earth. CO2 spikes from a natural disaster are somewhat similar to the CO2 spike we have seen in the last 100 years. With the advent of the industrial revolution, the imprint of human activity contributed significantly to the release of CO2. If this trend continues, subsequent generations will be at risk. [EPA-HQ-OAR-2022-0829-0457, p. 4]

The goal should be carbon neutral, but this will take decades to achieve and new technology required. In the interim, we must limit CO2 generation as best we can. Changing to plant-based fuels offer the largest net decrease in CO2 formation. If all transportation was converted to plant-based fuel, net CO2 would drop 70% on a yearly basis. This approach offers the lowest net carbon in the atmosphere. [EPA-HQ-OAR-2022-0829-0457, p. 4]

The graph above is from a NASA satellite image which highlights the areas with NOx issues. [See original comment for map of nitrogen dioxide levels throughout the Unites States] Since these areas are predominantly urban vicinities or downstream of power plants, it would be more beneficial to focus on localized efforts to reduce NOx. A good 70% of people live in the urban areas and reducing NOx in these inner cities will provide the most focused assistance. Ideally, most city transportation would be electric to eliminate emissions at source. Cities could build large parking lots outside urban areas for combustion vehicles and mass electric transit into city center. Keep in mind, electric vehicles do not reduce emissions, but rather change where those emissions are produced (battery mining / manufacturing / recycling plants) and electric power-distribution facilities. Moving the emissions away from where most people live would be prudent. Electric transportation does not reduce CO2 emissions over the vehicle life cycle due to battery manufacturing, mining, recycling and charging. Electric vehicles will help reduce smog in LA, Denver, etc. where there is poor airflow, however, they will not reduce carbon emissions when battery recycling/lifespan is incorporated in the well to wheels analysis. (https://climate.mit.edu/ask-mit/are-electric-vehicles-definitely-better-climate-gas-powered-cars),(https://www.iea.org/data-and-statistics/charts/comparative-life-cycle-greenhouse-gas-emissions-of-a-mid-size-bev-and-ice-vehicle),(https://www.epa.gov/greenvehicles/comparison-your-car-vs-electric-vehicle), (https://www.sciencedirect.com/science/article/pii/S1361920921000614). [EPA-HQ-OAR-2022-0829-0457, p. 4]

Proposed Emission Standard Guidelines [EPA-HQ-OAR-2022-0829-0457, p. 6]

- Modify the emission standards on gasoline and diesel with the primary emphasis to be on minimizing CO2.

- Increase NOx limit for diesel engines to 3 gram/mile on EPA emission test cycles. This is still cleaner than 1980 standards. With proper engine tuning, the smaller NOx increase allows for a decrease of 100 gram/mile of CO2.

- Maintain the theme of clean diesel and keep particulate filters to prevent PM (particulate matter) emissions. [EPA-HQ-OAR-2022-0829-0457, p. 6]

- Manufacturers could add GPS software to go into low NOx mode when near NOx abatement zones.

- Re-allocate tax incentives for urban residents to purchase BEV (battery electric vehicle)

- Work with states on regional smog issues as these are very limited in geographical area. The top cities are: Los Angeles, Denver, Miami, New York City, Houston, Atlanta, etc. Moving to primarily electric vehicles in dense population zones eliminates point of use emissions.

- Work with bio-fuel producers, farmers, refineries as needed to promote plant- based fuels that do not impact the food system. Hemp would be a good starting point as the entire plant can be utilized. The seed oil produces bio-diesel and the stalk produces ethanol. A robust bio fuel industry could reduce CO2 up to 1000 million metric tons yearly.

- Electric is a good solution for local driving patterns. It is not good for long distance runs or pulling loads and does suffer in range with extreme cold or heat.

- Re-calibrating vehicles in the field for low CO2 will yield the quickest return on investment. [EPA-HQ-OAR-2022-0829-0457, p. 6]

Organization: GROWMARK, Inc.

Our system's approach to fuel and energy business is to provide the fuel and energy sources that our customers want and use. We do not prefer or advocate for one technology over the other, but we feel that the proposed rule will cause a tremendous burden on farmers and rural Americans, where the lack of charging infrastructure will make the conversion to EVs at the rates necessitated by this proposed rule extremely difficult. Furthermore, current EVs lack the capabilities that internal combustion engine (ICE) vehicles currently have, which are vital for farmers as they work to feed our nation and the world. Additionally, we feel that the prioritization this proposed rule places on EVs ignores the tremendous potential of biofuels as a low-carbon fuel source, especially given the current realities of carbon intensity for EVs and biofuels. [EPA-HQ-OAR-2022-0829-0560, p. 1]

Prioritization of EV Technology Over Biofuels

Given the percentage of new vehicle sales that will be required to be EVs in order to comply with these standards, the EPA is picking EV technology over biofuels grown and produced in America, much to the detriment of American farmers and the environmental goals of the EPA. [EPA-HQ-OAR-2022-0829-0560, p. 2]

According to Dr. Steffen Mueller at the University of Illinois Chicago (UIC) Energy Resources Center, a high-octane fuel (HOF) of E30 or higher that utilizes carbon capture and storage (CCS) results in fewer greenhouse gas (GHG) emissions per mile than EVs operated on the Marginal Midwest Grid. E85 with CCS results in fewer GHG emissions per mile than the U.S. Baseload Average Electricity Grid and the California Marginal Electricity Grid.8 [EPA-HQ-OAR-2022-0829-0560, p. 2]

8 Mueller, S. (2021, December). Life Cycle Emissions of Different Vehicle/Fuel Technology Pathways [PowerPoint slides]. Illinois Commerce Commission. https://www.icc.illinois.gov/downloads/public/informal-processes/Doc%203_UIC%20ICC%20EV%20Emissions%20Final_12-15-21.pdf

The EPA's approach with these proposed standards ignores these scientific analyses, and as a result the unnaturally created leap in adoption of EVs will lead to less investment in biofuel advancements. Besides actually creating more GHG emissions, this will cause a major economic burden in rural America as an important market of crops produced by farmers will be diminished at the same time that they are forced to adopt a more expensive, less reliable technology. [EPA-HQ-OAR-2022-0829-0560, pp. 2-3]

Our system thanks you for your consideration of these comments, and we ask that you reconsider this rule that will have such a negative effect on the farmers and customers that we serve across our nation. [EPA-HQ-OAR-2022-0829-0560, pp. 2-3]

Organization: Growth Energy

Yet the Proposed Rule almost entirely ignores the GHG-reduction and other benefits of ethanol and other biofuels. Most significantly, it fails even to consider the upstream carbon sink that results from growing crops used in biofuels while simultaneously dismissing the upstream carbon emissions of building and powering EVs. EPA assesses the emissions lifecycles of two complex vehicle systems—EVs and internal combustion engine ("ICE") vehicles—in a way that heavily puts the thumb on the scale in favor in EVs. First, although both EVs and ICE vehicles generate "upstream" emissions from vehicle and engine production and power generation, EPA dismisses this reality. Second, although ICE vehicles can run on a diverse range of fuels with vastly different GHG emissions profiles, EPA fails to consider this diversity when assessing "downstream" emissions from petroleum-based and biofuels-based vehicle systems. The result is a proposal that inaccurately treats EVs as if they generate zero grams per mile of carbon and just as inaccurately treats emissions from the use of biofuels the same as emissions from combusting petroleum fuels. [EPA-HQ-OAR-2022-0829-0580, p. 3]

EPA's failure to adequately incorporate the benefits of biofuels into its analysis of the comparative GHG emission profiles of EVs and ICE vehicles pervades the Proposed Rule. For example, EPA arbitrarily assumes that biofuels will stay at a constant percentage of the nation's liquid fuel supply, ignores the potential of greater blends of biofuels in its cost and feasibility analyses, and fails to consider the potential for incentivizing greater biofuel use through credits. Of course, as the agency charged with administering the Renewable Fuel Standard, EPA is uniquely positioned to promote biofuels and increase their percentage of the nation's transportation fuel supply, all in accordance with Congress's understanding that renewable fuels must play a central role in reducing the impact of transportation-related GHG emissions. [EPA-HQ-OAR-2022-0829-0580, pp. 3-4]

The Proposed Rule's blind spot for biofuels has major policy consequences. EPA misses an opportunity to further reduce emissions with a biofuel like ethanol that has 46 percent lower GHG emissions on average and is already in use in the vast majority of light-duty vehicles and fuels markets across the country. EVs are undoubtedly an important and growing technology, but not every consumer or business in the country can adopt EVs and not every electricity source in the country will be able to meet more stringent GHG emissions standards in the timeframe established in the proposal. The Proposed Rule thus would perversely incentivize EVs in regions where electricity will continue to be generated from fossil fuels when incentivizing higher biofuel use in those areas instead could achieve greater emissions reductions. [EPA-HQ-OAR-2022-0829-0580, pp. 3-4]

The Proposed Rule is different in kind than EPA's prior tailpipe rules. For one, it makes permanent EPA's disregard of the upstream emissions of EVs, which prior rules promised would be temporary. [EPA-HQ-OAR-2022-0829-0580, p. 4]

There are several steps that EPA can and should take to address those deficiencies, both in the final rule and in other contexts: [EPA-HQ-OAR-2022-0829-0580, p. 4]

- First, EPA should fix its system of scoring the emissions from vehicles, which both undercounts EV emissions and overcounts emissions from biofuels used in ICE vehicles. The most accurate way to do so would be by conducting a complete lifecycle analysis for BEVs—using the Argonne laboratory's GREET model or its equivalent—and compare that to a lifecycle analysis for ICE vehicles using various blends of liquid fuels. Alternatively, if EPA does not use a lifecycle analysis, it should at a minimum assign the portion of fuel used in ICE vehicles attributable to biofuels a value of zero g/mi in recognition of the fact that the carbon emitted from combusting biofuels is biogenic carbon sequestered from the atmosphere by crops. [EPA-HQ-OAR-2022-0829-0580, p. 4]

- Second, EPA should account for the potential of higher blends of biofuels. At a minimum, EPA should use E15 as its test fuel and strongly promote E15 as an in-use fuel, because current ICE technology is capable of using E15. EPA should also adjust its methodology to account for increasing use of mid-level and higher-blend fuels such as E30 and E85. Fuels and vehicles act as a system, so naturally an improvement in fuels will help EPA achieve its emissions goals. [EPA-HQ-OAR-2022-0829-0580, p. 4]

- Third, EPA should use credits to incentivize biofuel use in ICE vehicles. EPA can and should use its Section 202 authority to provide credits to manufacturers who create engines and other technologies that facilitate use of higher blends of ethanol and other biofuels. And, as part of or in addition to that program, EPA should award credits that are tied to actual use of biofuels in ICE vehicles. [EPA-HQ-OAR-2022-0829-0580, p. 4]

- Fourth, EPA should also consider additional actions outside of Section 202 to further incentivize biofuel use. One such action would be to incentivize increased ethanol and other biofuel production through appropriate volumes under the Renewable Fuel Standard (“RFS”) program. Another would be to establish a minimum octane standard and approve a high-octane, low-carbon mid-level ethanol blend, which would lower GHG emissions both by ensuring that ethanol makes up a greater part of the liquid fuel supply and by allowing auto manufacturers to manufacture more efficient engines. [EPA-HQ-OAR-2022-0829-0580, p. 4]

Ethanol also has lower emissions of numerous other pollutants. To begin with, ethanol boosts octane in fuel without the harmful impacts of alternative octane-boosting fuel additives such as methyl tert-butyl ether (MTBE), lead, and aromatics (including benzene, toluene, ethylbenzene, and xylene) or olefins. Indeed, the level of aromatics in fuel decreases by about seven percent for every 10 percent by volume increase in ethanol content.3 Decreasing aromatics in fuel has direct impacts on tailpipe emissions, with higher-ethanol fuels resulting in lower emissions of black carbon (BC), particle number (PN), benzene, toluene, ethylbenzene, m/p- xylene and o-xylene (BTEX), and olefins.4 Using higher blends of ethanol also reduces total hydrocarbon (THC), carbon monoxide (CO), and particulate matter (PM) emissions. For PM emissions in particular, recent studies have demonstrated substantial benefits from higher blends of ethanol in fuel.5 [EPA-HQ-OAR-2022-0829-0580, p. 5]

II. The Benefits of Biofuels

In its extensive proposal and preamble, EPA included next to no analysis of the benefits ethanol and other biofuels. That omission is glaring because of the significant GHG-reductions and other benefits that biofuels offer. [EPA-HQ-OAR-2022-0829-0580, p. 5]

To begin with, the carbon absorbed by agricultural crops when they grow means that the lifecycle emissions of biofuels are significantly lower than petroleum fuels. A recent meta-analysis by Harvard researchers that accounted for all aspects of the lifecycle emissions of corn ethanol concluded that ethanol reduces GHG emissions by 46 percent compared to gasoline.1 Recent developments in the biofuels industry, such as the increasing use of carbon capture and storage and clean power sources at biofuel production facilities, are helping to drive lifecycle emissions from biofuels even lower.2 And innovative "climate smart" agricultural practices continue to increase yields while minimizing inputs and lower the GHG emissions from biofuels feedstock production as well. [EPA-HQ-OAR-2022-0829-0580, p. 5]

1 Scully, et. al., Carbon intensity of corn ethanol in the United States: state of the science 16 Environ. Res. Lett. 043001 (2021).

2 Growth Energy, Putting Carbon to Work: Biorefineries' Critical Contributions to Net-Zero, https://growthenergy.org/wp-content/uploads/2022/06/GROW-22019-Issue-Brief-Carbon-Capture-2022-06-22- R8.pdf.

Biofuels also provide significant flexibility in achieving GHG emissions goals because they can be used in existing ICE vehicles and fueled at existing gas stations. Consumers and operators of fleets around the country have the ability to use more biofuels. To the extent that some upgrades are necessary to facilitate storage and fueling with higher blends, the marginal cost of doing so is minimal. The carbon-reduction benefits of biofuels are therefore achievable in the near-term even without the massive expansion in electricity generation (and low-carbon electricity generation in particular) that will be required to power EVs. [EPA-HQ-OAR-2022-0829-0580, p. 5]

Indeed, a recent National Academy of Sciences ("NAS") assessment explained that an approach like EPA's fails to "fully capture" emissions from "the total light-duty vehicle system."8 NAS noted that one issue of that type of non-system-based analysis is that it would lead to inaccurate comparisons between vehicles using different fuels.9 And NAS further opined that: [EPA-HQ-OAR-2022-0829-0580, pp. 6-7]

8 National Academy of Sciences (NAS), Assessment of Technologies for Improving Light-Duty Vehicle Fuel Economy—2025-2035 at 13-416 (2021).

9 Id.

[I]f deep GHG emissions reduction is a goal, then there will need to be consideration of not only onboard vehicle emissions, but also the emissions from related sectors, like electricity (for vehicle charging), and manufacturing (of vehicles and their materials and components). This motivates the need for life cycle thinking.10 [EPA-HQ-OAR-2022-0829-0580, pp. 6-7]

10 Id.

Moreover, EPA has not acknowledged the inaccuracy of failing to account for the carbon absorbed by biofuel feedstocks when they are grown. Because all of the carbon emitted from a tailpipe is sequestered by crops while they grow, EPA's emissions values assigned to ICE vehicles using biofuels misses dramatically in the other direction. [EPA-HQ-OAR-2022-0829-0580, pp. 7-8]

The fundamental scientific reality that emissions from combusting biofuels is offset by crops' absorption of carbon is reflected in other EPA programs like the Renewable Fuel Standard program. There, emissions from combustion of biofuels in a vehicle are excluded in lifecycle analyses because “[o]ver the full lifecycle of the fuel, the CO2 emitted from biomass-based fuels combustion does not increase atmospheric CO2 concentrations, assuming the biogenic carbon emitted is offset by the uptake of CO2 resulting from the growth of new biomass.” 74 Fed. Reg. 24,904, 25040 (May 26, 2009). Similarly, the IPCC excludes emissions from combustion of fuels from biogenic sources when assessing national or sectoral carbon emissions. See 2006 IPCC Guidelines for National Greenhouse Gas Inventories Vol. 2 at 2.3.3.4. [EPA-HQ-OAR-2022-0829-0580, pp. 7-8]

EPA’s failure to recognize biofuels’ upstream carbon benefits leads to absurd results in the context of the Proposed Rule. For example, a 2019 MIT study found that, when accounting for emissions from all aspects of a vehicle’s manufacturing, fueling, and use, EVs emitted about 200 grams/mile over their lifetimes, compared to about 350 grams per mile for gasoline powered cars, for an emissions reduction of about 43 percent.11 That emissions reduction is very similar to the 46 percent reduction of 100 percent ethanol compared to petroleum.12 Yet, the Proposed Rule would treat an EV as emitting zero GHGs while treating an ICE vehicle running on 100 percent ethanol as having the same lifecycle GHG emissions as petroleum. [EPA-HQ-OAR-2022-0829-0580, pp. 7-8]

11 Massachusetts Institute of Technology, Insights into Future Mobility (2019), available at https://energy.mit.edu/wp-content/uploads/2019/11/Insights-into-Future-Mobility.pdf.

12 Scully, et. al., Carbon intensity of corn ethanol in the United States: state of the science 16 Environ. Res. Lett. 043001 (2021). Regional differences in electricity generation and the fuel efficiency of certain ICE vehicles can make the Proposed Rule’s comparison even more absurd. For example, driving a flex-fuel vehicle that can run on E85 would have significantly lower GHG emissions than using an EV in a state like West Virginia where electricity is generated largely from combustion of coal.13 Indeed, driving a highly fuel-efficient ICE vehicle or non-plug-in-hybrid like a Toyota Prius with higher blends of biofuels would compare favorably in those circumstances.14 Yet, the proposal would still treat EVs as emitting no GHGs and biofuels as achieving no emissions reductions. [EPA-HQ-OAR-2022-0829-0580, pp. 8-10]

IV. EPA Must Consider the Benefits of Biofuels and Higher Biofuel Blends Throughout the Rule.

In addition to treating biofuels unfairly and inaccurately when assessing GHG emissions compared to EVs, EPA systematically ignores the benefits of biofuels throughout the Proposed Rule. In the vast majority of the proposal, EPA assumes a binary choice between petroleum fuels and EVs. And when EPA does include any consideration of ethanol, it fails to explore the potential of higher blends—it assumes that all gasoline contains and will always contain at most E10. [EPA-HQ-OAR-2022-0829-0580, p. 12]

A. Other Pollutants

In discussing the impacts of the rule on emissions of other pollutants, EPA entirely leaves out consideration of biofuels. As discussed above, ethanol has lower emissions of many pollutants than petroleum gasoline. Indeed, recent studies by the University of California Riverside and the University of Illinois at Chicago found that use of more ethanol and ethanol- blended fuel significantly reduces harmful pollutants such as particulate matter (PM), carbon monoxide, and benzene.19 Just as with GHGs, that failure renders EPA's assessment of emissions of other pollutants inaccurate. And just as with GHGs, EPA misses an opportunity to reduce emissions through incentivizing biofuel use. [EPA-HQ-OAR-2022-0829-0580, p. 12]

19 Patrick Roth et al., Investigating the Effect of Varying Ethanol and Aromatic Fuel Blends on Secondary Organic Aerosol (SOA) Forming Potential for a FFV-GDI Vehicle: Comparison of Exhaust Emissions Between E10 CaRFG and Splash Blended E15, University of California Riverside (2018); Steffen Mueller, The Impact of Higher Ethanol Blend Levels on Vehicle Emissions in Five Global Cities, University of Illinois at Chicago Energy Resources Center (November 2018).

That failure is particularly egregious in the context of EPA's efforts reduce aromatics in petroleum fuels that contribute to PM emissions. 88 Fed. Reg. at 29,401. As discussed above, ethanol has an excellent octane rating, and blending it into gasoline in greater quantities can therefore allow reductions in aromatics and associated PM emissions. EPA explicitly sought comment on ways to reduce aromatic content, but it completely ignored that increasing the ethanol content of gasoline is a simple way to do so that has significant benefits. Multiple studies continue to show that increasing ethanol content in gasoline reduces PM emissions.20 Indeed, the benefits of ethanol in reducing PM were recently confirmed in EPA's own work with Environment and Climate Change Canada.21 In that study, fuel with increased ethanol content showed the deepest reduction in PM compared to the baseline fuel with heavy aromatics. Growth Energy therefore urges EPA to explore the widespread use of higher ethanol blends to replace heavy aromatics to significantly reduce PM emissions. [EPA-HQ-OAR-2022-0829-0580, p. 12]

20 Growth Energy has provided such studies in previous submissions to EPA, including our comment in support of EPA's proposal to implement the "Request from States for Removal of Gasoline Volatility Waiver."

21 EPA, Exhaust Emission Impacts of Replacing Heavy Aromatic Hydrocarbons in Gasoline with Alternate Octane Sources (Apr 2023), Dkt ID: EPA–420–R–23–008.

B. Other Considerations

EPA also continues to ignore biofuels in other parts of its proposal and preamble. To give just a few examples, EPA ignores biofuels entirely or fails to examine the impacts of different blends in the following ways [EPA-HQ-OAR-2022-0829-0580, p. 13]:

- EPA considers impacts of the proposed rule on employment in the petroleum industry, but not in the biofuels industry. Id. at 29,393.

- EPA considers the energy security risks of petroleum fuels, but not the energy security benefits of biofuels. Id. at 29,388.

- EPA uses a Tier 3 test fuel that is 10 percent ethanol and makes no effort to quantify how GHG emissions reductions would be altered by different levels of use of E15, E85, or other biofuel blends. Id. at 29,240. [EPA-HQ-OAR-2022-0829-0580, p. 13]

EPA is therefore failing entirely to look at an important consideration in numerous places throughout the proposal. That failure is inexcusable given that E15 use is currently increasing in use around the country, and EPA itself has undertaken to allow for year-round sale of E15. In the final rule, EPA should consider all of the benefits of biofuels—and consider the impacts of incentivizing adoption of higher blends—in each of its analyses of costs, benefits, and impacts. [EPA-HQ-OAR-2022-0829-0580, p. 13]

In particular, EPA should ensure that its test fuel is not limited permanently only to E10. It should instead project increasing biofuel use going forward, and it could potentially test with multiple different blends based on different projected scenarios of biofuel adoption across the country. Doing so will ensure that the test fuel reflects the growing range of options for ethanol use across the country. [EPA-HQ-OAR-2022-0829-0580, p. 13]

B. Options Outside of Section 202

EPA should also consider taking actions outside of Section 202 to further incentivize biofuels. To begin with, EPA should set robust renewable volume obligations under the RFS program for total and advanced biofuels. The RFS is one of America's most successful clean energy policies, and it has abundant potential to further reduce emissions. Yet, just a few weeks ago, EPA set the total and advanced volumes for 2023, 2024, and 2025 significantly below what the industry can achieve, despite Congress's desire that the RFS be a technology-forcing and demand-driving program. EPA must do more to help incentivize production of biofuels through the RFS, which means that it must set volumes going forward that expand market opportunities for higher blends like E15 instead of leaving readily available carbon reductions on the table. [EPA-HQ-OAR-2022-0829-0580, pp. 16-17]

Another such action would be to require a higher octane standard and approve a high- octane, midlevel ethanol blend. Growth Energy has been a leader on the need for higher octane, mid-level ethanol blends, first submitting a proposal for a 100 RON, E30 fuel nearly a decade ago. A higher octane requirement that incentivizes greater use of mid-level ethanol blends would reduce emissions by ensuring that a greater portion of the gasoline supply consists of ethanol. But that is not the only benefit—moving towards using a higher octane, mid-level blend would also enable automakers to optimize engines to improve efficiency by making engines smaller and increasing the use of turbocharging.22 So, a higher octane standard would be a win-win that would reduce emissions of GHGs and other pollutants both by incentivizing more ethanol use and by facilitating more efficient engines. [EPA-HQ-OAR-2022-0829-0580, pp. 16-17]

22 See, e.g., Oak Ridge National Laboratory, Summary of High-Octane, Mid-Level Ethanol Blends Study (July 2016), available at https://info.ornl.gov/sites/publications/Files/Pub61169.pdf.

VI. EPA Should Establish or Expand Credits for Biofuels and Should Consider Other Measures to Encourage Greater Biofuel Use.

A. Credits and Other Measures Under Section 202

Simply addressing EPA's errors regarding the lifecycle emissions of biofuels and EVs will not sufficiently drive biofuel use in a manner consistent with Section 202 and the RFS. EPA should also establish credits that specifically reward auto manufacturers for taking measures to incentivize increased biofuel use. [EPA-HQ-OAR-2022-0829-0580, pp. 15-16]

EPA clearly has authority to issue such credits under Section 202. It has for years issued credits for various measures that reduce emissions that are not reflected in tailpipe emissions, including credits for efficient air conditioning and off-cycle credits. 88 Fed. Reg. at 29,246. [EPA-HQ-OAR-2022-0829-0580, pp. 15-16]

The simplest type of credits to incentivize biofuels are those that allow greater biofuel use in vehicles, such as flex-fuel vehicles (“FFVs”) that can use E85 and higher blends of ethanol. EPA, along with the National Highway Traffic Safety Administration (“NHTSA”), has already established credits both under CAFE and Section 202 that provide an incentive for E85 use. 77 Fed. Reg. at 62,829. Those credits were initially awarded to FFVs regardless of the fuel they actually used, but were later adjusted to account for the amount of fuel actually used. In its 2012 rulemaking for MY 2017 and later years, EPA explained that: [EPA-HQ-OAR-2022-0829-0580, pp. 15-16]

In the final rulemaking for MYs 2012-2016, EPA promulgated regulations for MYs 2012-2015 ethanol FFVs that provide significant GHG emissions incentives equivalent to the long-standing “CAFE credits” for ethanol FFVs under EPCA, since many manufacturers had relied on the availability of these credits in developing their compliance strategies. Beginning in MY 2016, EPA ended the GHG emissions compliance incentives and adopted a methodology based on demonstrated vehicle emissions performance. This methodology established a default value where ethanol FFVs are assumed to be operated 100 percent of the time on gasoline, but allows manufacturers to use a relative E85 and gasoline vehicle emissions performance weighting based either on national average E85 and gasoline sales data, or manufacturer-specific data showing the percentage of miles that are driven on E85 vis-[a]-vis gasoline for that manufacturer's ethanol FFVs. [EPA-HQ-OAR-2022-0829-0580, pp. 15-16]

EPA should, at a minimum, extend and expand upon existing credits for FFVs. Existing credits are limited in several ways—they do not provide an incentive for other technologies that facilitate biofuel use in vehicles, they do not incentivize investments in blending infrastructure or other non-vehicle equipment for biofuel use, and they do not incentivize greater use of biofuels in standard, non-FFV engines. EPA therefore should also develop additional credits that can further reduce GHG emissions by incentivizing greater biofuel use. To begin with, EPA could expand credits to include technologies that facilitate different biofuel blends, like E30, and investments that help facilitate fueling of vehicles with higher blends. [EPA-HQ-OAR-2022-0829-0580, pp. 15-16]

An even better system of credits would be to provide credits based on overall biofuel use in the manufacturer’s fleet, regardless of whether the manufacturer manufactures FFVs or any specific technology. That type of credit would give manufacturers incentives to increase biofuel use in their fleet in any way possible—everything from making more FFVs, to making it easier for non-FFVs to run on higher blends, to facilitating investments in fueling with higher blends. [EPA-HQ-OAR-2022-0829-0580, pp. 15-16]

Given the discussion of various credit programs in the proposal and past FFV incentive programs, EPA can finalize a credit program based on biofuel use in this rule. But to the extent that EPA believes it would require an additional rulemaking proposal, EPA should propose and finalize such an incentive program as quickly as possible—it need not wait until the end of its currently proposed standards to develop an important additional mechanism for reducing greenhouse gas emissions while continuing to maintain options for multiple types of vehicles in our transportation system. [EPA-HQ-OAR-2022-0829-0580, pp. 15-16]

VII. Conclusion

The proposed rule misses a significant opportunity to reduce GHG emissions through biofuels. EPA should adjust its proposal by: (1) accounting for the upstream emissions of EVs and the upstream carbon sinks of biofuels; (2) considering the potential for higher blends of biofuels in EPA's test fuel and throughout the rule; and (3) developing credit programs and other measures that incentivize greater biofuel use. [EPA-HQ-OAR-2022-0829-0580, p. 17]

Organization: HF Sinclair Corporation

EPA's regulations also have a chilling effect on additional investments by companies, such as HF Sinclair, in carbon reducing technologies like carbon capture and sequestration projects, green hydrogen, renewable fuels and other low-carbon liquid fuel technologies that can reduce emissions from ICE vehicles. In addition, HF Sinclair has voluntarily announced a target to reduce its net greenhouse gas emissions intensity by 25% by 2030 compared to a 2020 baseline. [EPA-HQ-OAR-2022-0829-0579, p. 2]

Organization: Illinois Corn Growers Association

A new technology path is need that would, in the best-case scenario, lower greenhouse gas emissions from the transportation sector to a greater extent than the proposed standards and, in the worst-case scenario, make up for any shortfalls if electrification does not go as planned. [EPA-HQ-OAR-2022-0829-0756, p. 1]

A new technological pathway would need to dramatically reduce CO2 emissions, displace fossil fuels and be readily implemented on liquid fueled new vehicle. This would involve changes to vehicle fuels in harmony with changes in vehicle design. [EPA-HQ-OAR-2022-0829-0756, p. 1]

For a decade, the National Laboratories and Department of Transportation have been evaluating fuel blends that would replace a significant amount of fossil fuel with low-carbon renewable fuel and have properties that would allow automakers to produce more efficient internal combustion engines. After evaluating over 400 possible compounds, one compound emerged that is highly effective and had the fewest barriers to implementation: ethanol. [EPA-HQ-OAR-2022-0829-0756, p. 1]

It is imperative that any consideration of potential fuels controls include the implementation of regulations and standards that, within the agency's authority, would help bring about a cleaner, more renewable and less expensive high-octane fuel for use in the advanced, high efficiency internal combustion engines of the future. [EPA-HQ-OAR-2022-0829-0756, p. 1]

Over the last decade, there has been much discussion within the automotive and ethanol industries about a new pathway that automakers could use to lower CO2 tailpipe emissions – High Octane Low Carbon (HOLC) fuel. [EPA-HQ-OAR-2022-0829-0756, pp. 5-6]

A brief summary of key events in the development of HOLC fuels is shown in Table 3.

[See original attachment for figure "Table 3. Development Timeline for High Octane Low Carbon Fuel] [EPA-HQ-OAR-2022-0829-0756, pp. 5-6]

These include: [EPA-HQ-OAR-2022-0829-0756, pp. 5-6]

High octane fuels symposiums. Two Society of Automotive Engineers (SAE) high octane fuels symposiums were held in Washington, DC in February 2013 and January 2014 to discuss the potential of using higher levels of ethanol in gasoline to reduce vehicle emissions. Research from automakers, Oak Ridge National Laboratory and others presented at these symposiums showed that an ethanol-gasoline blend fuel made up of 20% - 30% ethanol would have an octane rating of 95 to 98 Research Octane Number (RON), which is significantly higher than today's 91 RON regular grade fuel. The higher-octane rating in the fuel would allow automakers to design more efficient engines which would minimize or eliminate the mileage penalty associated with ethanol blend fuels. Since the resulting fuel would have less carbon than gasoline alone, vehicles would emit lower CO2 emissions. Also, adding ethanol (a single compound with known properties) to gasoline (a mixture of hundreds of compounds) dilutes the concentration of non-ethanol compounds in the final blend. The impact of HOLC fuels on octane rating and aromatic concentrations is shown in Figure 1. [EPA-HQ-OAR-2022-0829-0756, pp. 5-6]

[See original attachment for "Figure 1. Ethanol Blended with Regular Grade Petroleum Blend Stock"] [EPA-HQ-OAR-2022-0829-0756, pp. 5-6]

A Federal research program called Co- Optima. Begun in 2016, Co-Optima is a U.S. Department of Energy program that coordinates the work of nine national laboratories to evaluate various compounds to determine their suitability as a blending agent with gasoline. The basic goals of creating a new HOLC fuel was expressed in the most recent public report of the Co-Optima program: [EPA-HQ-OAR-2022-0829-0756, pp. 6-7]

"The urgent need to decarbonize our transportation system—switching from petroleum-based fuels to cleaner, more sustainable energy sources—has become ever more apparent. While the nation is moving to rapidly boost production of electric vehicles, the transportation of goods and people will still rely heavily on gasoline and diesel fuel for decades to come. [EPA-HQ-OAR-2022-0829-0756, pp. 6-7]

In just a few short years, breakthroughs from the recently completed U.S. Department of Energy (DOE) Co-Optimization of Fuels & Engines (Co-Optima) initiative could improve cars' fuel economy by 10% for today's turbocharged engines and as much as 14% more for advanced engines using multiple combustion modes, compared to a 2015 baseline. At the same time, new bio-based fuel components could produce at least 60% fewer greenhouse gas (GHG) emissions than those generated by petroleum-based fuels for all on-road vehicles."4 [EPA-HQ-OAR-2022-0829-0756, pp. 6-7]

4 "The Road Ahead Toward a Net-Zero-Carbon Transportation Future, Findings and Impact FY15–FY21," DOE/EE-2539 June, 2022

After evaluating over 400 possible blending options, the program narrowed it down to six compounds that "were determined to have the fewest barriers to adoption and use."5 The evaluation process distilled the results for each of the candidate compounds into a merit function score, which reflected how well the compound: 1) increased the research octane number and octane sensitivity, 2) lowered the heat of vaporization, and 3) could be expected to reduce particulate mater emissions. Of the six compounds out of 400 deemed to have the fewest barriers to implementation, ethanol had the best merit function score. [EPA-HQ-OAR-2022-0829-0756, pp. 6-7]

5 Gaspar, Daniel. 2019. Top Ten Blendstocks For Turbocharged Gasoline Engines: Bioblendstocks With Potential to Deliver the for Highest Engine Efficiency. PNNL-28713, Pacific Northwest National Laboratory.

From the original work done by Oak Ridge National Laboratory as presented at the SAE symposiums to the extensive evaluation done by Co-Optima, the result has been the same: the best way to reduce fossil fuel use and carbon emissions while lowering aromatics and increasing octane in liquid fuels is to increase the amount of ethanol blended into that fuel. [EPA-HQ-OAR-2022-0829-0756, p. 7]

A bipartisan bill in Congress outlining the steps necessary to bring HOLC fuel to the market. Based on the findings presented at SAE and the corroborating work done in Co-Optima, the "Next Generation Fuels Act" has been introduced into the 116th, 117th and 118th Congresses. This bill would require the phase-in of a new fuel with higher octane and lower aromatics and carbon intensity beginning in 2028. Vehicle manufacturers would then need to produce vehicles optimized to run on high octane fuel and warrant these vehicles for higher concentrations of ethanol in the fuel. It also requires new certification test fuels for 95 and 98 RON fuels with higher levels of ethanol. Finally, it removes legal barriers to the introduction of these fuels into the market. [EPA-HQ-OAR-2022-0829-0756, p. 7]

The Greenhouse Gas Benefits of Using HOLC Fuel. What is referred to as "gasoline" is a blend of a fossil fuel (gasoline blend stock) and a renewable fuel (ethanol). Nearly all such blended fuel consists of 90% gasoline blend stock and 10% ethanol known as E10. As shown in Figure 4, the total volume of gasoline blend fuels peaked just prior to the Covid pandemic. [EPA-HQ-OAR-2022-0829-0756, pp. 10-11]

Thus, due to the blending of ethanol into gasoline, the fossil fuel component of liquid fuel peaked in 2006 while total gasoline blend usage peaked in 2018. [EPA-HQ-OAR-2022-0829-0756, pp. 10-11]

The first substantial reduction in the use of fossil fuels in the transportation sector occurred over a relatively short period of time. While the overall use of motor fuel began to stabilize starting in 2005, the replacement of gasoline blend stock by ethanol reduced fossil fuel use enough to turn the trend downward. This was due primarily to the enactment of the Renewable Fuel Standards (RFS) which dictated the annual volume of biofuel that must be blended into gasoline and diesel fuels. [EPA-HQ-OAR-2022-0829-0756, pp. 10-11]

[See original attachment for "Figure 5. Impact of Proposed GHG Emission Reductions on U.S. Fuel Consumption" and "Figure 6. Benefits from a Possible HOLC Fuel"] [EPA-HQ-OAR-2022-0829-0756, pp. 10-11]

Figure 5 illustrates what these trends would look like if the current rulemaking would achieve the results shown in Table 1. Note that while overall liquid fuel use goes down, the amount of ethanol used also declines because the concentration of ethanol in gasoline has remained unchanged at 10%. Thus, the full potential of the proposed shift to electric vehicles is blunted by the decreased use of ethanol. [EPA-HQ-OAR-2022-0829-0756, pp. 10-11]

If, on the other hand. EPA were to adopt changes to the regulations to bring about widespread use of HOLC fuel with triple the ethanol that is in today's fuel, an additional 8% to 16%10 of the fossil fuel portion of the fuel (the gasoline blend stock) would be displaced by 2055. Figure 6 illustrates what the trends would look like if the current rulemaking would achieve the results shown in Table 1. [EPA-HQ-OAR-2022-0829-0756, pp. 10-11]

10 This assumes a 2% reduction in mpg due to ethanol after energy density, heat of vaporization and optimization impacts are considered.

To illustrate the difference, consider that the amount of petroleum used for light and medium duty vehicles in 2055 if the proposed standards are successful would drop to 1962 levels. If, however, HOLC fuel with 20% to 30% ethanol were to replace E10 by 2055, the amount of petroleum used would drop to levels not seen since 1952. [EPA-HQ-OAR-2022-0829-0756, pp. 10-11]

Organization: Illinois Farm Bureau (IFB)

Therefore, in developing the final rule, we urge USEPA to consider an all-of-the-above, technology-neutral approach to GHG reductions, to create opportunities for market-based solutions and innovations without picking "winners and losers." A diversified portfolio of vehicle and fuel technologies that meets the diverse transportation needs of Americans and makes meaningful GHG reductions can be achieved while also allowing new zero-emission vehicle ("ZEV") and battery electric vehicle ("BEV") technologies to advance. In addition, improved crop yield, innovative biofuel and refined product processing, and manufacturing efficiency tied with carbon capture each represent promising advancements for liquid fuels to continue to accelerate emissions reductions. Finally, significant opportunities remain to improve ICEV efficiency by itself and when tied to electrification technology. [EPA-HQ-OAR-2022-0829-0532, pp. 2-3]

Current and more near-term solutions exist for medium and light duty vehicles that are on the road today and will remain in use for decades to come. Accelerating the turnover of existing fleets to advanced diesel technology and using more renewable and alternative fuels will deliver substantially more GHG reductions sooner and at significantly lower cost than the current USEPA proposed rule. These technologies can help to reduce emissions from light and medium duty vehicles while ZEV infrastructure and vehicles envisioned by the proposal are being developed, tested, and eventually deployed. [EPA-HQ-OAR-2022-0829-0532, pp. 2-3]

Organization: KALA Engineering Consultants

Before full comments begin, a personal note

As a personal note, the principal of KALA Consulting wants to let all of EPA administrators, scientists, and engineers know that I am ON YOUR SIDE. I happen to disagree with the approach used in this proposed rulemaking that appears to promote extensive electrification of the US fleet, which I believe to be unsupportable from a GHG reduction standpoint. I believe that you may not have reviewed the National Academy of Sciences 2010 report that shows, when all knowable upstream and downstream GHG emissions are considered, BEV associated GHG emissions are essentially the same as conventional gasoline-fueled vehicles for a projected 2030 time frame. Once Republican law makers and think tank mavens read my section on that study, they may use it to bash this attempted rulemaking the likes of which you may never have experienced. I hate to do this to the EPA because I support most of the emissions reduction efforts you have made up to now and your agency and the national laboratories were so beleaguered and mistreated by the Trump Administration. [EPA-HQ-OAR-2022-0829-0617, p. 2]

However in my best engineering judgement, this rulemaking is misguided. There is a biofuel substitute that could make significant reductions in both criterial pollutants and GHG emissions if it were to be made from cellulosic sources and entrained into the national fuel mix in high percentages. We have done extensive research and engineering adaptation of this biofuel, butanol, that could surprise many of you. We ask your forbearance as we have included a discussion of this advanced biofuel in our comments as an alternative to mass electrification. Therefore, we are extending our hand and our knowledge base to EPA and the Department of Energy to contact us and discuss what we might learn from each other. [EPA-HQ-OAR-2022-0829-0617, p. 2]

No Conflict of Interest Disclaimer Statement: The author(s) of this document, principals, officers, staff and others associated with KALA Consulting hereby declare that none of those persons or the Corporation itself have any potential employment, contracted services, financial, or familial interests or connections of any kind to any interest, corporations or other entities mentioned, referenced, or in any other way could be construed to benefit either financially, public relations or potential contracting of services or equipment sales from any statements or mentions by name or other reference in this document. No one associated with KALA Consulting has ever been employed nor wishes to be employed by any entity mentioned or refenced herein. [EPA-HQ-OAR-2022-0829-0617, p. 2]

Changing fuel composition to lessen both GHG and many emission species

Shortly after incorporating in 2009, KALA looked at what could be done quickly and efficiently to significantly reduce GHG emissions from transportation sources, and soon discovered a new genetic engineering breakthrough made by researchers at UCLA, headed by Dr. James C. Liao, with extended enhancements to candidate fermentation organisms by UC Berkely researchers. The breakthrough was a novel method of engineering the metabolic pathways in certain microbes to produce iso-butanol from the same feedstock materials as ethanol is now made and any sugars obtained from saccharification of cellulosic biomass. [EPA-HQ-OAR-2022-0829-0617, pp. 30-31]

When we looked at the possibilities for GHG reductions by substituting cellulosic feedstocks for grains like corn, we realized that this breakthrough had enormous possibilities for substituting carbon-neutral butanol for fossil petroleum liquid fuels By substituting butanol that is superior in virtually all respects to ethanol and can be blended with gasoline in greater percentages because it has lower oxygen content than ethanol we could make significant GHG reductions. Butanol can also be transported in regular hydrocarbon liquid transport pipelines, where ethanol cannot. [EPA-HQ-OAR-2022-0829-0617, pp. 30-31]

However, the main concern for how to drastically reduce GHG emanating from fossil petroleum use was the short amount of time in which we have to make those changes. The United Nations' Intergovernmental Panel on Climate Change (IPCC) has for a number of years stated that we have limited time left, especially considering the potential for runaway warming from release of methane stored in frozen states in the arctic regions of the planet. https://www.scientistswarning.org/2022/09/01/methane-emergency/ [EPA-HQ-OAR-2022-0829-0617, pp. 30-31]

KALA performed a systems analysis of the pathways to drastically (greater than 80%) reduce GHG emissions from the Transportation Sector. The first system element steps we considered were from what has become the standard answer for many so-called Climate Change experts and that is Electrification of the fleet. This so-called “solution” appears not to take into consideration the amount of time it will take to convert the existing and near-term fleet of vehicles using petroleum derived liquid fuels and change out the existing infrastructure of gasoline distribution and dispensing in favor of electric recharging facilities. [EPA-HQ-OAR-2022-0829-0617, pp. 30-31]

The second systems analysis we looked at was for introducing and eventual full to nearly full displacement of petroleum-based fuels with carbon-neutral cellulosic butanol.

We offer a comparison of the system steps for electrification and then displacement of petroleum fuels with cellulosic butanol or analog hydrocarbon fuels derived from butanol. [EPA-HQ-OAR-2022-0829-0617, pp. 30-31]

System: Electrification Scenario Elements:

Step 1. Initiate a system driver or drivers that requires replacement of liquid fueled vehicles in favor of electrified vehicles (usually BEV technology). The “forcing” (driver) factor that the EPA is attempting to promulgate in the EPA–HQ–OAR– 2022–0829 Docket appears to be how EPA intends to initiate this step. [EPA-HQ-OAR-2022-0829-0617, pp. 30-31]

Step 2. Replace the multi-trillion dollar petroleum fuels (mostly gasoline) distribution and dispensing infrastructure with electric recharging (i.e., electric “fuel” dispensing) infrastructure, in effect discarding the existing liquid fuel infrastructure. [EPA-HQ-OAR-2022-0829-0617, pp. 30-31]

Step 3. Since the United States is not a command economy, attempt to convince vehicle consumers that they should accept electrified vehicles as the new form of personal and work transportation. [EPA-HQ-OAR-2022-0829-0617, pp. 30-31]

Step 4. Fortify the electric grid and encourage Utility Companies to create additional electric generating facilities to handle the increased demand for electricity for recharge and improve electric transmission capabilities to handle increased power demands. [EPA-HQ-OAR-2022-0829-0617, pp. 30-31]

Ostensibly, the ideal additional generating capacity should be from renewable sources, but the choice of how to produce electricity is still left up to private Utility Companies. [EPA-HQ-OAR-2022-0829-0617, pp. 30-31]

Each of these system steps has a time element associated with it. Various estimates for the amount of time it will take for Electrification Step 2 have varied between 25 and 75 years, but those estimates did not take into account the “forcing” factor of an EPA set of regulatory mandates. Even so, EPA admits that the amount of time it will take for the existing fleet will be lengthy with estimates that use the year 2055, 28 years after the first model year, 2027, affected by the EPA–HQ–OAR– 2022–0829 rulemaking occurs. [EPA-HQ-OAR-2022-0829-0617, pp. 30-31]

The next major transportation GHG reduction system analysis target KALA looked at was the breakthrough in genetic engineering that allows fermentation of sugars into the advanced biofuel Butanol. [EPA-HQ-OAR-2022-0829-0617, pp. 34-36]

System: Large-Scale displacement of Fossil liquid Fuels with Butanol:

Step 1. Initiate a system driver or drivers that requires replacement of fossil carbon containing petroleum liquid fuels with the Carbon-Neutral advanced biofuel, cellulosic Butanol. This, at a minimum, would require the Federal Government, probably through the Renewable Fuels Standard (RFS) authority, to declare the government’s intention to move from ethanol as the majority renewable fuel to butanol and its intention to move butanol production to entirely cellulosic by a date certain. This requirement should not become an ”unfunded mandate” and, therefore, should be backed by commitment of Federal funding for existing ethanol producers to replace the fermentation and distillation equipment in their production trains to new equipment that will produce butanol from sugars being supplied by their current methods (usually corn mash). As requirements for cellulosic feedstock sourcing are put in place, additional funding will be required to assist butanol producers to add cellulosic processing equipment. Think of these funds as one-time subsidies as per-gallon subsidies are phased out. [EPA-HQ-OAR-2022-0829-0617, pp. 34-36]

Step 2. Leverage the multi-trillion dollar petroleum fuels (mostly gasoline) distribution and dispensing infrastructure to begin displacing fossil carbon containing fuels with the advanced biofuel, butanol, that at first will be made from the same grains (mostly corn) as ethanol was made from in the same production plants and later moving to cellulosic sources of fermentable sugars that will reduce the GHG impact of burning cellulosic butanol fuels dramatically. [EPA-HQ-OAR-2022-0829-0617, pp. 34-36]

Step 3. Implement a consumer education campaign about the new fuel they are putting in their gas tanks that is more than an oxygenate because it also naturally reduces the tendency of our fuels to jump into the air as volatile organic compounds (VOC) that are one of the ingredients of Ozone formation. An emphasis should be put on the fact that a much larger percentage of the fuel they are using is made right here in America by American workers. [EPA-HQ-OAR-2022-0829-0617, pp. 34-36]

Step 4. Promote moves in Congress to legislate around cellulosic butanol as a major solution to GHG emissions both from our Transportation Sector and the US as a whole. Explain to members of Congress that voting for measures that will promote the production and use of butanol at high blend percentages will bring new good-paying jobs to their districts as butanol production expands all across the country. These changes will require changes to new vehicles that are similar to existing Flex Fueled Vehicles [FFV] but do not need the extra “hardening” of gas tanks, fuel pumps and lines that the high percentage of E85 require – in all, about $20 to $40 worth of changes to allow those new vehicles to operate with up to 85% butanol (Bu85) and 15% gasoline. [EPA-HQ-OAR-2022-0829-0617, pp. 34-36]

When we looked at the comparative system steps between the two alternatives and we learned from the Hidden Costs of Energy report that the upstream GHG emissions attributable to BEVs might well be about the same or, as we have described above and MPTODR considerations, even higher than downstream GHG emissions from gasoline vehicles, it became a slam dunk that cellulosic butanol was the correct solution to current and near-term transportation GHG emissions. The speed at which the US could implement a fuel change over as described in Large-Scale Displacement with Butanol Step 2 above, where the existing refueling infrastructure is leveraged to entrain larger and larger percentages of carbon-neutral butanol into the US fuel mix could be astonishingly fast. As we have discussed, it is likely that Climate Change related calamities may well overwhelm any life-saving results of the new proposed EPA–HQ– OAR–2022–0829 Docket rulemaking. Which in our view, makes drastic GHG reductions from both Electrical Generation and Transportation a priority – a priority which should inform the EPA to make proper and realistic decisions about what solutions should be applied. We believe that Fuel Changeover with cellulosic butanol is the correct solution for drastically reducing Transportation GHG emissions. Let us explain why below. [EPA-HQ-OAR-2022-0829-0617, pp. 34-36]

Introduction to fuel butanol

We are adding an introduction to butanol as a fuel (not an oxygenate even though it serves that purpose as well) to the readers of these comments, because very many of them may not know what butanol is and may have never heard of it. That, by the way, is exactly how the Oil Companies would like to keep it because they know full well that butanol is a serious threat to their continued profits from petroleum sales where ethanol could never be. [EPA-HQ-OAR-2022-0829-0617, pp. 36-44]

Butanol Facts Generated by KALA Consulting, LLC Lakewood, CO [EPA-HQ-OAR-2022-0829-0617, pp. 36-44]

What is Butanol? : Butanol is a 4-carbon “higher” alcohol that can be used as a motor fuel.

What is the difference between ethanol which we use in our gasoline now and butanol?

1. Ethanol is a 2-carbon alcohol made from fermenting starches and sugars with yeasts

2. Butanol has 4 carbons in each molecule and is made from the same material with bacteria

3. Butanol has 26% more energy in a gallon than ethanol, and nearly the same as E10 gasoline (16.4% lower energy content)

4. Unlike ethanol, butanol does not corrode vehicle fuel systems in blends higher than 10%

5. Unlike ethanol, butanol can be moved and stored using our existing petroleum infrastructure [EPA-HQ-OAR-2022-0829-0617, pp. 36-44]

Can Butanol be used as a motor fuel; can it replace gasoline in our existing cars?

1. Butanol is a direct substitute for E-10 gasoline in your existing vehicle up to about 48%

2. Butanol can be expected to yield slightly lower to better gas mileage and safer emissions

3. N-butanol has a Cetane rating of 25 and can be blended up to 30% with diesel fuel

4. Iso-Butanol has an R+M/2 octane rating of 97 and will not lower octane in gasoline blends [EPA-HQ-OAR-2022-0829-0617, pp. 36-44]

Any drawbacks to using Butanol?

Butanol has a higher viscosity than gasoline – about the same as diesel fuel and it will gel at very low temperatures (-25°F). It may need an anti-gelling agent for extremely low temperatures but some gasoline like that in E85 will serve as anti-gel in cold weather. [EPA-HQ-OAR-2022-0829-0617, pp. 36-44]

Why haven't I heard more about butanol as a replacement for gasoline before now?

Butanol has been known as a replacement fuel since World War 2. In fact, British and Japanese fighter planes ran on butanol during that war! If an oil company viewed your knowledge of butanol as a threat to their business and profits, would they try to keep you from hearing about it, having the Federal Government test it or acknowledge it as an alternative fuel? [EPA-HQ-OAR-2022-0829-0617, pp. 36-44]

The Federal Government has known what the problem is with our dependence on oil for some time and a succinct statement of the problem was issued by Oak Ridge National Laboratory in a May 2006 report where authors David Greene and Paul Leiby stated: [EPA-HQ-OAR-2022-0829-0617, pp. 36-44]

Section 4. Oil Security and Energy Technology R&D: The root of the United States' oil security problem is economic and strategic dependence on an energy commodity, (1) whose resources are concentrated in an unstable region, (2) whose supply is vulnerable to disruption by various causes and subject to substantial collusive control by a cartel of oil producing nations, and (3) for which demand and supply are highly inelastic, especially in the short-run. Petroleum is the single largest source of energy for the U.S. economy and its use is highly concentrated in the transportation sector, a sector vital to all economic activity and one that to this day has found no ready substitute for petroleum fuels. The combination of these factors has created a situation in which supply disruptions, whether intentional or unintentional, can produce very large and sudden price increases that do significant damage to the U.S. economy. [EPA-HQ-OAR-2022-0829-0617, pp. 36-44]

This report states that as of 2006: "Petroleum is the largest single source of energy for the U.S… and one that to this day has found no ready substitute…" If the consequences of being strategically dependent on one source of energy, especially for transportation, can result in sharp rises in the price of that commodity which can result in damage to the economy of the United States, why is there "no ready substitute?" If that source of energy is so vitally important to our country and its national security and its availability is questionable and using it results in global climate change, why has the Federal Government not found and promoted introduction of a "ready substitute?" Are there ready substitutes out there waiting to take the place of oil – biofuels perhaps? [EPA-HQ-OAR-2022-0829-0617, pp. 36-44]

With the 2022 Russian invasion of Ukraine, we once again learned the fragility of supply and the enormous economic damage spikes in the price of our fuels can do to the American economy. Just as our economy suffered in 1973 when the OPEC oil cartel embargoed oil imports to the US and once again when crude oil reached an unprecedented high price of $147.50 per barrel in August 2008, our dependency on this atmosphere-damaging commodity has consequences not only to our national security but to our economic security. [EPA-HQ-OAR-2022-0829-0617, pp. 36-44]

Our central question is when are we going to realize there is a “ready substitute,” butanol, already being made for chemical feedstocks and fuel that will stabilize the cost of fuels at a reasonable price and, in so doing, stabilize the American economy? [EPA-HQ-OAR-2022-0829-0617, pp. 36-44]

We Americans may think we are exceptional, but we are not free of the stranglehold our dependence on fossil petroleum has on us. We need to ask how we can eliminate the use of fossil fuels in an environmentally responsible way. How much is it worth to America to prevent the economic chaos brought on by world events and a capricious commodity market over which we have no control. [EPA-HQ-OAR-2022-0829-0617, pp. 36-44]

Could Butanol Actually be a Substitute for Petroleum Fuels

We know how to convert many different types of biomass into different types of fuel and some sources can lead to a variety of end products. Most scientists in the field consider using crop items that could be used as either human or animal food as not the best ultimate feedstock sources for biofuels. [EPA-HQ-OAR-2022-0829-0617, pp. 36-44]

Most biofuels scientists would prefer the use of what are called ligno-cellulosic sources to produce liquid biofuels that are similar to gasoline.

[See original attachment for possible biofuel production pathways] [EPA-HQ-OAR-2022-0829-0617, pp. 36-44]

There are two principal methods for converting ligno-cellulosic materials into liquid biofuels:

1) Fermentation and 2) Pyrolytic Deconstruction

Each of these methods have their advantages and their drawbacks. [EPA-HQ-OAR-2022-0829-0617, pp. 36-44]

The reason these raw materials are called ligno-cellulosic is because most plant body parts are constructed of three major constituents:

1) Cellulose 2) Hemicellulose and 3) Lignin

We will not discuss Pyrolysis here because fermentation with bio-engineered microbes seems to be the best way to arrive at purified butanol.

[See original attachment for the chemical pathway to make Butanol] [EPA-HQ-OAR-2022-0829-0617, pp. 36-44]

Major advances in genetic manipulation of microorganisms commonly used as fermentation agents have been made in the last few years, principally in the private sector as patentable proprietary organisms. Native bacteria or yeasts that might ordinarily make several by-products, only one or two of which could be used as fuels have been genetically transformed by knocking out the undesired production pathways and enhancing or leaving only the pathway for producing the desired fuel metabolic products. Groups like that at UCLA under Dr. James Liao have been using the techniques of "synthetic biology" to add highly productive fuel producing pathways to bacteria, yeasts, and cyano- bacteria. [EPA-HQ-OAR-2022-0829-0617, pp. 36-44]

[See original attachment for composition of typical woody lignocellulosic compared to corn grain and stover] [EPA-HQ-OAR-2022-0829-0617, pp. 36-44]

To use cellulose for fermentation, it must be broken down into the sugars that made up the original polymers. [EPA-HQ-OAR-2022-0829-0617, pp. 36-44]

Were it not for the remarkable advancements in bioengineering and gene manipulation the fermentation organisms that can now use sugars from starches and cellulose processed into fermentable sugars we would not have a way produce a single desirable product, butanol. The companies that are using these bioengineering methods to produce butanol have developed a number of methods to separate butanol from the fermentation broth and remove the last traces of water to produce purified butanol. [EPA-HQ-OAR-2022-0829-0617, pp. 36-44]

The next question for viability as a fuel must answer is, "Can we make enough of it to make a difference? If we are going to make this fuel from cellulosic material, is there enough that we can harvest all over the country? Fortunately, that question has been answered by a study done by the Federal Government. [EPA-HQ-OAR-2022-0829-0617, pp. 36-44]

We know from a study done by the Oak Ridge National laboratory and the US Department of Agriculture that with minor changes in land use, the nation could harvest up to 1.3 billion tons of varieties of biomass. This study published in 2005 is commonly called the "Billion Ton Study (BTS)." [EPA-HQ-OAR-2022-0829-0617, pp. 36-44]

The BTS divided the sources of ligno- cellulosic feedstocks into two broad categories: Agricultural residues and forest- derived woody biomass. The changes in land use that the report assumed to arrive at the maximum figure of 1.3 billion tons per year involved land owners devoting some of their land to the production of dedicated energy crops (EC), growing such plants as switchgrass and fast-growing hybrid poplar trees. Other land use assumptions were that land now used for purposes other than food crop production or that is now considered marginal land would be put into EC production. A 2011 update of the BTS found that the earlier estimate of 1.3 billion dry tons of biomass could actually be 1.6 billion tons with similar land use changes. [EPA-HQ-OAR-2022-0829-0617, pp. 36-44]

The next question to be asked is, if we seem to have enough biomass available, how much butanol can we get from each dry US ton. That does not mean that the cellulosic biomass that would be brought into butanol processing facilities would need to be absolutely dry, but for calculation purposes, normalizing the biomass to complete dryness puts those calculations on an equal footing. [EPA-HQ-OAR-2022-0829-0617, pp. 36-44]

The chart at right shows the theoretical maximum yield of ethanol from common cellulosic biomass types such as corn stover (the residue from the corn plant that does not include the corn kernels) and waste paper. Several strategies can be used to recover carbon that might otherwise be wasted from the fermentation process and the lignin leftovers that still have carbon in them. The theoretical maximum yields shown do not include any conversion of lignins, which up to now have been considered not to be able to be convertible into fuel products. If lignins can be converted, these maximums would be higher. [EPA-HQ-OAR-2022-0829-0617, pp. 36-44]

[See original attachment for chart of the theoretical maximum yield of ethanol from common cellulosic biomass] [EPA-HQ-OAR-2022-0829-0617, pp. 36-44]

KALA has set a goal of 100 gallons per dry ton of cellulosic biomass for the idealized butanol production process we have considered. Even if we are only able to get 90 gallons per dry ton, a total of 90 * 1.6 billion DTons = 144 billion gallons of butanol possible each and every year. If further fuel economy standards were put in place, lowering our national annual gasoline consumption to around 120 billion gallons, we would have an extra 24 billion gallons of butanol to devote to other purposes or to cover volumetric losses from conversion of butanol to analog hydrocarbon fuels that we call “Green” gasoline and “Green” diesel. [EPA-HQ-OAR-2022-0829-0617, pp. 36-44]

Yes butanol with its 4-carbon molecule (iso- butanol shown at right) can be converted into hydrocarbon fuels using well known and understood process technologies from oil refining and post fractional distillation reformation. Iso-butanol is dehydrated to iso- butylene, which is reformed by oligomerization methods into different hydrocarbon fuels, such as Gasoline, Diesel, and Aviation Jet fuel. The type of hydrocarbon is dependent on the oligomerization techniques used. [EPA-HQ-OAR-2022-0829-0617, pp. 36-44]

https://www.globenewswire.com/news-release/2020/08/18/2079991/0/en/Gevo-and-Praj-to-Commercialize- Sustainable-Aviation-Fuel-in-India.html [EPA-HQ-OAR-2022-0829-0617, pp. 36-44]

[See original attachment for hydrocarbons from Cellulose Process Schematic] [EPA-HQ-OAR-2022-0829-0617, pp. 36-44]

So, there is a possibility that current engine control computers could handle higher percentages of neat butanol blended with either petroleum gasoline or gasoline made from butanol. This strange “Green” gasoline has interesting properties because it is made from a pure feedstock instead of being fractionated out of a refining stream that has numerous side chemicals incorporated into what we know as gasoline. Green gasoline made from butanol would have no benzene, toluene, ethylbenzene or xylene as well as a host of other substances such as polycyclic aromatic hydrocarbons (PAH), other aromatics and metals. Many of the air toxics and criteria pollutants are products of combustion of the other organic chemicals in gasoline other than the 4-carbon to 12- carbon hydrocarbon molecules making up the bulk of gasoline. Butanol derived gasoline would have none of those side organics in its makeup. [EPA-HQ-OAR-2022-0829-0617, pp. 36-44]

A 2021 study done by University of Nebraska at Lincoln has done testing on numerous Tier 2 and Tier 3 non-flex fuel vehicles (NFFV) that shows that the engine control computers are able to adapt to the oxygen content of a 30% ethanol, 70% gasoline fuel blend (E30). https://ethanol.nebraska.gov/wp-content/uploads/2021/03/E30-Demonstration-FINAL-1.pdf

If this study holds up and NFFV’s ECUs are capable of adjusting to the oxygen content in a 30% ethanol blend, there is an opportunity to run NFFV vehicles with up to 48% butanol and 52% gasoline blends rather than an E30 ethanol blend. [EPA-HQ-OAR-2022-0829-0617, pp. 36-44]

Note: To obtain the oxygen equivalent percentage content from ethanol percentage to equivalent butanol percentage, divide the ethanol percentage by 0.62. Therefore, an E30 blend would translate to a 48% butanol blend based on oxygen content. [EPA-HQ-OAR-2022-0829-0617, pp. 36-44]

The thought of operating an older or non-FFV vehicle that has not been “hardened” to handle ethanol percentages higher than 10% (E10) is daunting. The reason non-FFV vehicles are not recommended by the manufacturers to use ethanol percentages greater than 10% in fuel is that the vehicle’s gas tank, the fuel pump, metal fuel lines, elastomeric (rubber) fuel lines and injection components have not been adjusted in their composition to handle ethanol blends greater than 10% for any length of time. It seems odd that in the Nebraska research there has not been a tear-down of any of the aforementioned components to check for excessive corrosion or decomposition of the interior of elastomeric hoses that handle fuel. The folks in Nebraska so desperately want to show that more ethanol can be used in ordinary vehicles that they may have missed some important ethanol attack issues. However, the important part of the Nebraska research for the use of high percentages of butanol is the reported tolerance of the engine control computer (ECU) to the oxygen percentage in E30 not causing problems with fuel trim, which opens the door to much larger butanol percentage blends if the EPA and Department of Energy will look at the research closely. [EPA-HQ-OAR-2022-0829-0617, pp. 36-44]

All these suggestions to drastically change fuel blend compositions represent conflicts with the antiquated Fuel Blend Waiver structure incorporated into the Clean Air Act (CAA). Requirements in the CAA for private parties requesting waivers for fuel blends demands those parties perform testing for their particular fuel blend and then present that evidence to the EPA, upon which the EPA would then rule on the request. [EPA-HQ-OAR-2022-0829-0617, pp. 36-44]

However, in the case of the Growth Energy universal waiver request for increases in the ethanol content of gasoline from 10% (E10) to 15% (E15), the EPA and Department of Energy (DOE) insisted that the Federal Government carry out testing of its own rather than asking the private concern who brought the waiver request to conduct further tests. In fact, the principal reasons given by the EPA for delaying a decision on the E15 waiver was to allow more time for the EPA and DOE to conclude their own testing. [EPA-HQ-OAR-2022-0829-0617, pp. 36-44]

In our view, this process destroyed any pretense that a private party could mount a research effort and present evidence that would make a fundamental change in the US gasoline supply without the Federal Government conducting its own battery of tests and research in the matter. In essence, Growth Energy was forced to waste its own private resources in generating test results when it became apparent that the Federal Government was determined to conduct its own duplicative research and testing. In our opinion, the Federal Government should drop that pretense and not force private parties to go to the horrendous expense of conducting private testing only to have their testing duplicated and, perhaps, expanded upon by Federal agencies or laboratories. If the E15 waiver experience is any indication of what the Federal Government intends to do in response to future similar waiver requests made under provisions of the CAA, both EPA and DOE should simply require a well-reasoned request for a waiver and conduct the testing themselves as they did for the E15 waiver. [EPA-HQ-OAR-2022-0829-0617, pp. 36-44]

In this context, we ask that the EPA and DOE conduct testing for several blend ratios of iso-butanol blended with ordinary gasoline and with gasoline converted from butanol, if available, to determine engine performance and emission results in real-world conditions. What in the world are the National Laboratories for if they cannot be tasked with a simple task such as this. Several national laboratories have already done research on butanol blends, so any additional testing would be adding to that body of research. The potential for drastic GHG reductions by substituting fossil petroleum- based fuels for both butanol and gasoline made from butanol are stunning to say the least. Therefore, it is in the national interest to proceed with butanol blend testing forthwith. [EPA-HQ-OAR-2022-0829-0617, pp. 36-44]

Organization: Kentucky Office of the Attorney General et al.

The Proposed Rule also runs contrary to Congress's intent by frustrating the purpose of the Renewable Fuel Standards program. See Brief of Amici Curiae State of West Virginia and 5 Other States, Texas v. EPA, No. 22-1031 (D.C. Cir. Nov. 15, 2022), ECF 1973638, at 24-27 ("WV Amicus Brief"). Through that program, Congress intended the renewable fuel standards program to act as "market forcing policy," increasing utilization of renewable fuels. Growth Energy v. EPA, 5 F.4th 1, 33 (D.C. Cir. 2021). The program has led to a reduction in air pollution and oil imports, and the creation of American jobs. See Renewable Fuel Standard, Renewable Fuels Ass'n, https://bit.ly/3TWyRxa. But pushing EVs as aggressively as the Proposed Rule does is directly at odds with the promoted utilization of renewable fuels. "It is well established that when two regulatory systems are applicable to a certain subject matter, they are to be reconciled and, to the extent possible, both given effect." Pennsylvania v. ICC, 561 F.2d 278, 292 (D.C. Cir. 1977). The Proposed Rule does nothing to "give effect" to the statutory authority Congress provides to the Department of Transportation and for the Renewable Fuel Standards Program. Indeed, the Proposed Rule does not even mention the Program at all. [EPA-HQ-OAR-2022-0829-0649, p. 5]

Organization: Kia Corporation

Kia Supports Fuel Standard Improvements

Kia urges EPA to take further action to improve fuel standards that will help lower vehicle fuel consumption and emitted GHG and non-GHG emissions from legacy and new ICE vehicles. As Kia is significantly increasing resources for developing and transitioning to electrified powertrains, Kia will have fewer resources available to improve ICE. Kia urges EPA to adopt cost effective solutions to lower emissions from ICE vehicles such as stringent fuel standards. [EPA-HQ-OAR-2022-0829-0555, p. 16]

Kia offers the following on gasoline fuel property standards:

- Kia recommends EPA increase the minimum research octane number (RON) in market gasoline to 95-98. This increase in RON could improve efficiency by 3-5 percent. An increase in RON could be achieved in multiple ways, through increasing the ethanol content of market gasoline or altering the composition of hydrocarbons during the reforming process to higher octane molecules. For a small segment of legacy vehicles, this increase could improve their efficiency simply with the fuel change. [EPA-HQ-OAR-2022-0829-0555, p. 16]

- The EPA must mandate that all market fuels meet or exceed the octane of Tier 3 certification fuel. Sub 87 Anti-Knox Index (AKI) fuel is still sold despite no longer needing to do so. Mandating market fuels meet this standard could decrease fuel consumption, lower the likelihood that enrichment will be needed, and lower GHG, CO and HC emissions. [EPA-HQ-OAR-2022-0829-0555, p. 16]

- The EPA should leverage a new national Clean Fuel Standard similar to California's Low Carbon Fuel Standard. A national Clean Fuel Standard requiring lower or net-zero emission liquid fuels would improve emissions in new and legacy ICE vehicles. [EPA-HQ-OAR-2022-0829-0555, p. 16]

- EPA's Tier 3 rules lowered the gasoline maximum average sulfur level from 30 parts per million (ppm) to 10 ppm stating that "any amount of gasoline sulfur will deteriorate catalyst efficiency."29 Yet refiners are still allowed 80 ppm with a 95 ppm downstream cap. Kia urges EPA to require a gasoline retail cap – not average – of 10 ppm. This standard is more aligned with global standards and aligns with the EPA proposed lower NMOG + NOx standard. [EPA-HQ-OAR-2022-0829-0555, p. 16]

29 Control of Air Pollution from Motor Vehicles: Tier 3 Motor Vehicle Emission and Fuel Standards, Proposed Rule, 78 Fed. Reg. 29816, 29,821 (May 21, 2013).

Organization: Letter Campaign, Ethanol Producers

EPA's own research has shown that high-octane, low-carbon renewable fuels like ethanol, when paired with appropriate engine technologies, deliver immediate improvements in fuel efficiency and carbon performance. Flex fuel vehicles (FFVs) using E85 and other ethanol flex fuels offer significant emission reduction opportunities. High-compression-ratio engines running on higher-octane fuels provide substantial fuel efficiency gains and emissions reductions without relying on foreign mineral imports or causing unintended environmental and economic consequences. Unfortunately, EPA's proposal does nothing to recognize or encourage growth in the use of low-carbon liquid fuels in advanced internal combustion engines. [EPA-HQ-OAR-2022-0829-0739, p. 2]

We urge EPA to reconsider its proposal and adopt a technology-neutral approach that treats all low-carbon transportation options fairly and equally. We ask that EPA use this rulemaking to establish a full lifecycle approach for assessing carbon emissions from all fuel and vehicle options. We also request that EPA use this regulatory opportunity to increase the required minimum octane rating of our nation's light-duty vehicle fuel, as well as encouraging increased production of FFVs. [EPA-HQ-OAR-2022-0829-0739, p. 2]

Thank you for the opportunity to comment on this important issue. As a member of the Renewable Fuels Association, we also wish to endorse and support their written comments, as submitted. [EPA-HQ-OAR-2022-0829-0739, p. 2]

Organization: Marathon Petroleum Corporation (MPC)

EPA should consider changes to how it treats CO_2 emissions from renewable liquid fuel combustion in vehicles to be consistent across programs it oversees. EPA mandates the blending and use of renewable liquid fuels in vehicles in its Renewable Fuel Standard while simultaneously ignoring the positive impacts of this use in the vehicle emissions standards. Consistency across programs would eliminate disparate treatment and reduce regulatory ambiguity. [EPA-HQ-OAR-2022-0829-0593, p. 2]

MPC supports the comments that have been entered into the docket by American Fuel & Petrochemical Manufacturers and American Petroleum Institute. [EPA-HQ-OAR-2022-0829-0593, p. 1]

Organization: Mass Comment Campaign sponsored by Missouri Corn Growers Association (MCGA). (web) (168 signatures)

As a corn grower or allied industry member of the Missouri Corn Growers Association (MCGA), I write to share my comments on EPA's proposed Multi-Pollutant Emissions Standards for model year 2027 and later vehicles. As producers of feedstocks for low-emission biofuels, farmers across the country share EPA's emission reduction goals. However, this proposal limits fuel and energy options unnecessarily and fails to take greater advantage of clean, low-carbon ethanol to contribute to greater emission reductions that consumers can more readily afford. There is no one-size-fits-all solution to lowering vehicle emissions. Through this rule, EPA has an opportunity to level the playing field for all low-carbon fuels and technologies and use ethanol's proven potential to support sustainability in the transportation sector. [EPA-HQ-OAR-2022-0829-0718]

Today's ethanol cuts greenhouse gas emissions in half compared to gasoline and has pathways to achieve net zero emissions. Clean, high-octane fuel from mid-level ethanol blends, used as a system with advanced engines, offers an essential pathway for achieving significant greenhouse gas and complementary criteria emission reductions from model year 2027 and later vehicles. It also offers substantial public health benefits by reducing particulate matter emissions from gasoline, all while reducing costs for consumers. In addition to focusing on outcomes and enabling a wider range of vehicle and fuel choices, I ask EPA to set a clean, high-octane fuel standard that takes advantage of higher ethanol blends to enable automakers to deploy advanced engine technologies. [EPA-HQ-OAR-2022-0829-0718]

I strongly urge EPA not to focus on one single solution but to consider all options that advance transportation toward our shared goal of reducing emissions. [EPA-HQ-OAR-2022-0829-0718]

Respectfully submitted by the following list of 168 Missouri corn farmers and allied industry members who stand in support of MCGA opposing this proposed rule. [EPA-HQ-OAR-2022-0829-0718]

Organization: Mass Comment Campaign sponsored by Missouri Corn Growers Association (MCGA). (web) (168 signatures)

Organization: Mass Comment Campaign sponsored by Michigan Corn Growers Association (MCGA). (email) (30 signatures)

I am submitting comments today to express my concern over the EPA's proposed Multi-Pollutant Emissions Standards for model year 2027 and later vehicles. This proposed rule is irresponsible and foolish. Instead of working to achieve an environmental goal, the EPA is effectively mandating the use of electric vehicles, which will have significant impacts on my farm. [EPA-HQ-OAR-2022-0829-0757]

Primarily, I am concerned with an estimated 1 billion bushels in lost corn demand from 2022-2032 due to USEPA regulations dictating electric vehicles as the only option. This rule could decimate corn prices. This rule will hurt family farms all over the country, including my own. [EPA-HQ-OAR-2022-0829-0757]

Secondarily, I understand that the rule will force 67 percent of light duty vehicle sales and nearly 50 percent of trucks sold to be battery electric vehicles (BEVs) by 2032. The infrastructure does not yet exist in rural America for my family to efficiently utilize a BEV, nor am I convinced that a BEV will do the work that I need it to do on my family farm. As a result, when I purchase an internal combustion engine vehicle for my family, I know I will pay more, impacting the economic health of our family farm. This is yet another unfair burden for rural America. [EPA-HQ-OAR-2022-0829-0757]

Finally, the impact of this forced reliance on BEVs will compromise our national security. This will incentivize batteries and minerals produced and mined in countries hostile to the U.S. that have questionable labor standards. Knowing that a disproportionate amount of those that enlist in the U.S. military come from rural areas of our country, I'm very concerned about rulemaking that would potentially send more rural family members to new wars over batteries. [EPA-HQ-OAR-2022-0829-0757]

Should the U.S. EPA honestly wish to tackle carbon emissions, they should not dictate how regulated parties must achieve the lowered emissions and they should not dictate the use of a specific fuel or vehicle. Rather, the EPA should set a standard for emissions that opens the marketplace to a broad array of technologies, removes its arcane regulatory barriers, and lets the market work its magic. [EPA-HQ-OAR-2022-0829-0757]

Organization: Mass Comment Campaign sponsoring organization unknown (76 signatures)

I am a small business energy marketer who provides a growing portfolio of affordable, efficient, and greener liquid fuels and alternative energy sources. These liquid fuels have played a critical role in lowering emissions over the past half century. Through innovation and technological advancements, they will continue to reduce emissions further and be a crucial driver of economic growth in this country in the coming decades. [EPA-HQ-OAR-2022-0829-1709]

I'm also a member of the Energy Marketers of America (EMA) which is a federation of 48 state and regional trade associations representing family-owned and operated small business energy marketers throughout the United States. [EPA-HQ-OAR-2022-0829-1709]

As a small business owner, I am concerned that EPA's tailpipe emission standards for light and medium duty vehicles for model year 2027 and beyond will effectively discourage investment in lower carbon liquid fuels and more efficient internal combustion engines. This focus on EV production will essentially eliminate an opportunity to provide liquid fuels that immediately lower emissions not only for new vehicles, but for the vehicles currently on the road. In addition, the rule will limit consumer choice on cleaner internal combustion engines and threaten the viability and jobs of small business energy marketers around the country. [EPA-HQ-OAR-2022-0829-1709]

I urge the EPA to consider the lifecycle emissions associated with EV production, usage, and end-of-life disposal including emissions from raw material mining and refining, battery manufacturing, and electricity generation for EV charging. An assumption of zero emissions from EVs fails to consider the significant emissions associated with a transition to EV. For instance, a Hummer EV, with its near-3,000-pound battery weighing more than a full Hyundai Elantra, would count as having ZERO emissions and less impact on the environment than a Prius. [EPA-HQ-OAR-2022-0829-1709]

Further, the EPA needs to consider the logistics, investment, and timing associated with EV and battery production, electric generation and transmission, and EV charging to support a substantial increase in EV production. Achieving a significant ramp up of domestic supply of raw materials for batteries, mineral refining, and battery and vehicle manufacturing as well as upgrades to the electricity generation and transmission will be complex and take time. [EPA-HQ-OAR-2022-0829-1709]

Again, I urge the EPA to consider lifecycle emissions and a technology neutral approach when it comes to promoting policies to reduce emissions. The most cost-effective and timely way to reduce emissions from transportation is to support multiple technologies that do so for both new vehicles and vehicles currently on the road. [EPA-HQ-OAR-2022-0829-1709]

Thank you for the opportunity to submit comments on this important rulemaking that affects small business energy marketers nationwide.

Organization: Mass Comment Campaign sponsoring organization unknown (1,851 signatures)

I am submitting comments today to express my concern over the EPAs proposed Multi-Pollutant Emissions Standards for model year 2027 and later vehicles. Instead of working to achieve an environmental goal, the EPA is effectively mandating the use of electric vehicles, which will have significant impacts on rural America. This rule could severely diminish corn and soybean prices and put rural Americans whose economies rely on agriculture at a disadvantage. This rule will hurt family farms all over the country. [EPA-HQ-OAR-2022-0829-1710]

I understand that the rule will force 67 percent of light duty vehicle sales and nearly 50 percent of trucks sold to be battery electric vehicles (BEVs). By mandating electric vehicles, EPAs proposal inhibits the marketplace from identifying the most efficient, lowest cost opportunities to reduce GHG emissions from vehicles and greatly restricts consumer choice. I am concerned that such a prescriptive policy is not in the best interest of the consumer or the U.S. economy. Vehicle technologies have made great strides in emission reductions from common pollutants. By dictating electric vehicles as the only option, on-going investments in vehicle improvement will be severely hampered. The proposal will also tie the hands of American automakers flexibility to develop and implement innovative strategies for decarbonizing vehicles. [EPA-HQ-OAR-2022-0829-1710]

Of additional concern is the infrastructure for electric vehicles does not yet exist in rural America. This is further discrimination against rural communities, family farms and agribusiness as they do not have the ability to efficiently utilize BEVs. [EPA-HQ-OAR-2022-0829-1710]

I am also concerned with the shift from supporting Illinois produced fuels - corn-based ethanol and soy-based biodiesel to supporting batteries produced overseas (i.e. Australia, Chile and China). I am not in favor of a move that will incentivize batteries and minerals produced and mined in countries that are hostile to the U.S. over renewable liquid fuels grown in the Midwest. [EPA-HQ-OAR-2022-0829-1710]

In closing, the EPA should not bet the farm on a defacto electric vehicle mandate with many deficiencies including removing incentives for innovation, not appropriately analyzed costs, nor an effective implementation plan. Please think of the renewable supply of corn and soybeans grown on my farm and farms across Illinois and the Midwest. As a life long dairy farmer who uses renewable resources your approach using a limited supply material is just not well researched or sustainable. Please use the renewable approach. [EPA-HQ-OAR-2022-0829-1710]

As a corn grower in Sd, I write to share my comments on EPAs proposed Multi-Pollutant Emissions Standards for model year 2027 and later vehicles. As producers of feedstocks for low-emission biofuels, farmers across the country share EPAs emission reduction goals. However, this proposal limits fuel and energy options unnecessarily and fails to take greater advantage of clean, low-carbon ethanol to contribute to greater emission reductions that consumers can more readily afford. There is no one-size-fits-all solution to lowering vehicle emissions. Through this rule, EPA has an opportunity to level the playing field for all low-carbon fuels and technologies and use ethanols proven potential to support sustainability in the transportation sector. [EPA-HQ-OAR-2022-0829-1716]

Todays ethanol cuts greenhouse gas emissions in half compared to gasoline and has pathways to achieve net zero emissions. Clean, high-octane fuel from mid-level ethanol blends, used as a system with advanced engines, offers an essential pathway for achieving significant greenhouse gas and complementary criteria emission reductions from model year 2027 and later vehicles. It also offers substantial public health benefits by reducing particulate matter emissions from gasoline, all while reducing costs for consumers. In addition to focusing on outcomes and enabling a wider range of vehicle and fuel choices, I ask EPA to set a clean, high-octane fuel standard that takes advantage of higher ethanol blends to enable automakers to deploy advanced engine technologies. [EPA-HQ-OAR-2022-0829-1716]

I strongly urge EPA not to focus on one single solution but to consider all options that advance transportation toward our shared goal of reducing emissions. [EPA-HQ-OAR-2022-0829-1716]

Organization: Matthew DiPaulo

While the goal of this proposal is to reduce the U.S. automotive fleet's carbon footprint, it simply shifts how emissions are produced. The EPA is ignoring the value of technologies produced by American workers, manufacturers, and farmers that are critical to our transportation future. Specialty automotive aftermarket businesses are leading the way through alternative fuel innovations from replacing older engine technologies with newer, cleaner versions to converting older ICE vehicles to new electric, hydrogen, and other alternative fuels. Sadly, the EPA's plans to reduce greenhouse gases and criteria pollutants do not factor this in. [EPA-HQ-OAR-2022-0829-1514, p. 1]

Organization: Mazda North American Operations

In March 2019, the Company assessed the life cycle CO2 emissions from internal combustion engine vehicles and electric vehicles (EVs) in five regions of the world. The results revealed that the significance of CO2 emissions from internal combustion engine vehicles and EVs during their life cycles depends on the electric power supply status, fuel/electrical power cost, total mileage, and other factors in each region. Conclusion being EVs do not necessarily have the advantage when it comes to life cycle of CO2 emissions in certain markets globally. For this reason, as well as others, Mazda has adopted the Building-Block concept to steadily realize its goal of reducing CO2 emissions and raising the average fuel economy of Mazda vehicles. The Building Block Concept calls for the commercial introduction of electric, plug-in and other electrified vehicles (EVs) with the combination of optimal control technology and efficient electrification technologies in consideration of each country or region's energy resources, regulations, power generation methods, infrastructure, and so on. [EPA-HQ-OAR-2022-0829-0595, p. 1]

Organization: MEMA, The Vehicle Suppliers Associated

The success of our industry is interwoven with the success of this proposal and the ability of the government to work with industry and other stakeholders to meet significant challenges. Therefore, the rule must address: [EPA-HQ-OAR-2022-0829-0644, pp. 2-3]

- The need for regulatory certainty. The final rule must contain an effective mix of feasible, demonstrated technology along with emerging technology, leaving options to improve emissions reductions in today's advanced propulsion designs. This will foster innovation in a coordinated direction, aligned with U.S. policy, but not mandate application of a narrowly defined technology path to make a positive impact on the country's urgent environmental goals. [EPA-HQ-OAR-2022-0829-0644, pp. 2-3]

- The influence of other technologies - including internal combustion engines fueled by hydrogen and other renewable carbon-neutral fuels - which can impact measurable environmental improvements at scale technologies can provide immediate improvement to the environment. This is important not only for environmental improvements but for environmental justice in providing cleaner consumer vehicles immediately to communities living and working close to busy streets, highways, and other transportation networks. Inclusion of all technologies that can decarbonize the transportation sector will foster the necessary growth in manufacturing capacity, vocational performance, infrastructure improvements, and consumer acceptance. [EPA-HQ-OAR-2022-0829-0644, pp. 2-3]

- Technology Neutrality and BEV Emissions. EPA should ensure that battery electric vehicles (BEV) are included in metrics for vehicle-to-vehicle comparison by assigning a metric that captures the pollutant emissions related to BEV operation, aligned with national electricity generation figures. [EPA-HQ-OAR-2022-0829-0644, pp. 2-3]

- Challenges in our nation's infrastructure and power grid. MEMA appreciates the significant public investments being made to support clean transportation infrastructure. As these new investments in highways and main corridors are deployed, federal and state incentives are needed to further expand the EV charging and refueling infrastructure in areas that connect these major thoroughfares. Urban industrial centers will need focused buildout while rural areas will need thoughtful rollouts to achieve an effective EV charging infrastructure. These buildouts must include Direct Current Fast Charge (DCFC) and vehicle-to-grid (V2G) bidirectional charging. [EPA-HQ-OAR-2022-0829-0644, pp. 2-3]

- Supply chain challenges. The proposed rule assumes that all materials advanced vehicles, which are not available today in the quantities needed to support the massive growth in vehicle construction, will become available within sufficient time. This places a significant and unnecessary risk on manufacturers and suppliers. Furthermore, once a company has converted production to new technology lines, that company cannot easily pivot its facilities and workforce back to the previous technology if EPA projections are not realized by the mid-to-late-2020s. [EPA-HQ-OAR-2022-0829-0644, pp. 2-3]

- Workforce challenges. A significant increase in skilled workers will be needed to support the implementation of this rule and long-term success thereof [EPA-HQ-OAR-2022-0829-0644, pp. 2-3]

- Extended warranty. The necessity to clearly define the applicability of the extended warranty and the need to provide repair access to service these new vehicles. [EPA-HQ-OAR-2022-0829-0644, pp. 2-3]

MEMA members are working to accelerate the performance and availability of clean-operating vehicle technologies and are directly contributing to their realization. Besides battery electric options, effective low- and zero-carbon technologies for future and current in-use vehicles also exist and can readily be put to use to reduce nationwide emissions and help EPA meet its climate goals. The success of this rule depends on greater inclusion of all available emissions reduction technologies, significant investment in infrastructure, careful understanding and investment in the domestic and global supply chain and ensured repair access to serve the improved and enhanced domestic vehicle fleet. [EPA-HQ-OAR-2022-0829-0644, pp. 2-3]

It is imperative that EPA aligns with the Joint Office of Energy and Transportation through the implementation period of this rule to identify shared concerns and solutions for the many moving parts of the rule. Failure in one key sector, lithium sourcing as one example, could result in significant cost or schedule impacts, stunting availability or adoption of these new vehicles. Positive regulatory certainty bolsters consumer confidence in new technologies and decreases the use of gasoline- and diesel-fueled vehicles. EPA should adopt an "all hands on deck" approach with regards to emissions-lowering technologies and encourage greater acceptance of and investment in renewable fuels, which can positively impact the net emissions of the entire U.S. internal combustion engine (ICE) vehicle fleet. [EPA-HQ-OAR-2022-0829-0644, p. 4]

Technology Neutrality Pairs with Regulatory Certainty

The proposed rule disproportionally favors battery electric propulsion, which in turn discourages any further advancements for internal combustion technology, including carbon-neutral renewable fuels. Emerging innovations and recent technologies offer significant reduction in emissions from ICE vehicles, in both future and current fleets. [EPA-HQ-OAR-2022-0829-0644, pp. 5-6]

Technology-forcing regulations that foster innovation aligned with policy, rather than regulations that mandate a narrowly defined technology path, will lead to a more positive national outcome. [EPA-HQ-OAR-2022-0829-0644, pp. 5-6]

MEMA recognizes that the proposal attempts a performance-based standard, and the agency makes forecasts that estimate a variety of technology combinations in future fleets. By accepting the potential for technologies other than battery electric and hydrogen fuel cell, EPA can make a more immediate, widespread, positive impact on nationwide emissions reductions. Therefore, EPA must incent the development and deployment of advanced technology options to include advanced internal combustion (ICE) technologies, renewable fuels, and post-combustion CO2 capture (known as mobile carbon capture). These incentives will assist in accelerating the necessary infrastructure improvements needed to support advanced technology vehicles. [EPA-HQ-OAR-2022-0829-0644, pp. 5-6]

One of the pathways which deserves to be highlighted is the Hydrogen Internal Combustion Engine (H2ICE). This technology is a promising pathway which for certain applications is preferable to other alternate advanced technologies in the proposed rule. For example, a vehicle towing a trailer requires sustained torque output to tow a heavy load. H2ICE would offer the best solution for this vehicle to achieve the emission targets while fulfilling the customer needs for range and load. BEVs and fuel cell electric vehicles (FCEV) have weight and load limitations that might not allow this vehicle to meet its operational requirements. Indeed, the agency has recognized the benefit of H2ICE in the separate rulemaking for "Greenhouse Gas Emissions Standards for Heavy-Duty Vehicles - Phase 3 [1]. We refer to section II. Proposed CO2 Emission Standards, D. Vehicle Technologies, 1. Technologies to Reduce GHG Emissions from

HD Vehicles with ICES, paragraph 5 [2] which states: [EPA-HQ-OAR-2022-0829-0644, pp. 5-6]

1 https://www.regulations.gov/document/EPA-HQ-OAR-2022-0985-1423121

2 11. Proposed CO? Emission Standards, D. Vehicle Technologies, 1. Technologies to Reduce GHG Emissions from HD Vehicles with ICES, paragraph 5

Manufacturers may develop new ICE vehicle technologies through the MY 2032 timeframe. An example of a new technology under development that would reduce GHG emissions from HD vehicles with ICES is hydrogen-fueled internal combustion engines (H2ICE). These engines are currently in the prototype stage of innovation for HD vehicles but have also been demonstrated as technically feasible in the past in the LD fleet. H2ICE is a technology that produces zero hydrocarbon (HC), carbon monoxide (CO), and CO2 engine-out emissions. [EPA-HQ-OAR-2022-0829-0644, pp. 5-6]

Furthermore, a large portion of manufacturing technology and workforce skills needed to manufacture H2ICE equipment may be adapted from currently available gasoline or diesel manufacturing footprints. H2ICE also builds hydrogen demand, which is a nascent market in the U.S. Building that market will help supply the needs of hydrogen fuel cell electric vehicles in due course. The two are complementary to each other's growth and commercialization. MEMA therefore strongly suggests that EPA adopt a consistent pathway for H2ICE for light-duty and medium-duty vehicles just as proposed for heavy-duty vehicles. [EPA-HQ-OAR-2022-0829-0644, pp. 5-6]

Renewable fuels, such as hydrogen, ethanol, renewable natural gas (RNG) and carbon-neutral renewable diesel are viable, proven pathways to lower emissions in the transportation sector almost immediately. The EPA has dismissed alternate fuel options, and as a result is missing opportunities for greater emissions reductions. We refer the EPA to the U.S. DOE alternate fuels data center for detailed examples of how alternate fuels can reduce vehicle emissions.1 Several studies and programs run by Argonne National Laboratory also point to reduced emissions through alternate fuels.2 EPA should include more analysis of these alternatives and do more to encourage investment and deployment of these technologies. We note CARB recognizes one renewable fuel3 and allows it to be used for compliance with certain regulations. EPA should consider similar provisions. [EPA-HQ-OAR-2022-0829-0644, p. 6]

1 https://afdc.energy.gov/fuels/

2 https://www.anl.gov/taps/fuels

3 See § 2449.1(f) of the CARB In-Use Off-Road Diesel-Fueled Fleets Regulation https://ww2.arb.ca.gov/sites/default/files/barcu/regact/2022/off-roaddiesel/ord15dayatta-1.pdf

MEMA urges: [EPA-HQ-OAR-2022-0829-0644, p. 7]

- EPA to move beyond tailpipe emissions and include emissions from electricity generation in BEV calculations.

- EPA to act decisively to further encourage and incentivize the development and deployment of advanced clean ICE technologies, including renewable fuels, and mobile carbon capture.

- EPA to develop an efficiency metric to comparatively analyze ZEV energy needs and if not incorporated into this rule - report that metric to the public as an initial step. [EPA-HQ-OAR-2022-0829-0644, p. 7]

Organization: Minnesota Biofuels Association

While we appreciate EPA's focus on strengthening tailpipe emissions standards for light-duty and medium-duty vehicles to reduce harmful air pollutants like carbon monoxide, benzene, and other particulates from the transportation sector, we are concerned that the proposed rule undervalues and overlooks the contributions that American-made biofuels can make in achieving enhanced vehicle efficiency and emissions reductions. [EPA-HQ-OAR-2022-0829-0672, pp. 1-2]

Rather than giving automakers the flexibility to pursue innovative strategies for reducing emissions from the current and future light- and medium-duty fleets through environmentally friendly, lower cost options like E15 and E85, the proposal tips the scale toward a single technology – electric vehicles. [EPA-HQ-OAR-2022-0829-0672, pp. 1-2]

A level playing field for all technologies and fuels is the key to reaching net-zero greenhouse gas emissions by mid-century. In its overview of the proposed standards1 EPA notes a "…shift away from a focus on internal-combustion engines (ICE) technologies and toward zero-emission technologies, including electrification." We disagree with the assertion that electrification is the only zero-emission technology available and that ICE technologies cannot play a meaningful role in the decarbonization of the U.S. transportation sector. [EPA-HQ-OAR-2022-0829-0672, pp. 1-2]

1 https://www.epa.gov/system/files/documents/2023-04/420f23009.pdf

First, Minnesota-made biofuel is a readily available renewable energy solution that has a proven track record of reducing carbon emissions. The Department of Energy's Argonne National Laboratory has shown that today's low-carbon corn ethanol reduces greenhouse gas emissions by nearly 50 percent compared to gasoline. According to recent estimates and projections, internal combustion engine vehicles will still occupy more than half the light-duty vehicle marketplace by 2040. Incentivizing the use of higher blends of ethanol like E15 and E85 can immediately reduce carbon emissions from those vehicles. [EPA-HQ-OAR-2022-0829-0672, pp. 1-2]

Moving forward, technology investments will ensure that ethanol reduces greenhouse gas emissions by 70 percent on average by 2030 and 100 percent by 2050. Many production facilities are already utilizing or plan in the next three to five years to adopt a combination of technologies and practices that lower the carbon intensity of the ethanol produced. These include production plant upgrades (combined heat and power, fermentation efficiencies, renewable electricity integration, heat/exhaust recovery), carbon capture, sequestration, and utilization (CCUS), and carbon-efficient farming practices. [EPA-HQ-OAR-2022-0829-0672, pp. 1-2]

Organization: Minnesota Corn Growers Association (MCGA)

In addition to improving this proposal to enable more solutions than only electric vehicles, we urge EPA to advance a much-needed rulemaking addressing fuel quality to cut emissions from the millions of liquid fuel vehicles on the road now and the new vehicles that will be sold through the compliance period. Greater lifecycle emission reductions are available from sustainable, affordable low-carbon ethanol through a clean, high-octane standard, by removing barriers to higher ethanol blends and by equitably incenting all alternative fuels and vehicles. [EPA-HQ-OAR-2022-0829-0612, pp. 1-2]

There are many obstacles to this shift including geopolitics, long lead times, capital investments, and consumer acceptance. In order to achieve emission reduction goals in the most robust, rapid, and affordable way, EPA must instead encourage multiple additional solutions such as hybrid electric vehicles (including plug-in hybrids), reinstating meaningful flex-fuel vehicle credits, and the introduction of credits that encourage the utilization of internal combustion engines (ICE) designed to utilize higher blends of biofuels (such as ethanol) by recognizing the combined carbon and multi-pollutant emission reduction benefits of the engine technology and fuel. [EPA-HQ-OAR-2022-0829-0612, p. 3]

Low-carbon liquid fuels have a unique and important role to play, immediately and in the long term. Fuels such as E15 (15% ethanol) are approved for and available for use in the millions of vehicles already on the road today, and thus offer immediate emissions benefits on a much larger scale than changes to only new vehicles. In the longer term, low-carbon or zero-carbon liquid fuels offer emissions solutions for market segments and customers that may not be well served by battery electric vehicles. [EPA-HQ-OAR-2022-0829-0612, p. 3]

To foster a vibrant and competitive landscape of multiple solutions, it is critical for EPA to set performance-based and technology-neutral emissions standards. Unfortunately, the proposed standard falls short of this ideal. It is essential to look beyond the tailpipe and use life cycle analysis for fair comparisons and a “level playing field”. [EPA-HQ-OAR-2022-0829-0612, p. 3]

Under the Clean Air Act, EPA has an obligation to protect the health and welfare of Americans. While EPA projects the proposed standards will result in 7.3 billion cumulative tons of avoided GHG emissions through 2055, EPA leaves significant GHG emission reductions on the table if the agency fails to take steps in this proposal, or in a parallel action, to also improve liquid fuels along with vehicles. EPA must include complementary fuel improvements that would enable greater total GHG reductions, greater fuel efficiency and substantially greater air quality improvements than the current proposal offers. [EPA-HQ-OAR-2022-0829-0612, p. 3]

Low-carbon liquid fuels can achieve GHG reductions faster than new vehicles can displace the existing fleet. A relatively simple change such as replacing E10 (10% ethanol) with E15 (15% ethanol) can offer greater GHG reductions3 than the phase-in of battery electric vehicles, because it can immediately affect a huge fleet of vehicles that are already in use. [EPA-HQ-OAR-2022-0829-0612, p. 4]

3 Fuels Institute report “Decarbonizing Combustion Vehicles: A Portfolio Approach to GHG Reductions”, June 2023.

But E15 is not the only way to achieve large emissions benefits with ethanol. To enable further displacement of petroleum by ethanol, many stakeholders have agreed to support E25 (25% ethanol) capability in all vehicles by 2028, and E30 by 2033, as specified in the Next Generation Fuels Act. However, EPA currently has authority to support the production of new vehicles with E25/E30 capability through new fuel standards, as well as incentivize flex-fuel vehicles (FFVs) with E85 capability. Getting these vehicles on the road quickly will build the foundation for future increases in cleaner liquid fuels, resulting in GHG and multi-pollutant emissions reductions. [EPA-HQ-OAR-2022-0829-0612, p. 4]

Recognizing vehicles and fuels as a complete system, increasing the octane rating of the nation's fuel supply through a clean, high-octane standard would deliver greater GHG emission reductions from the approximate 281 million internal combustion engine (ICE) vehicles on the road today and the 100 million projected to be added by MY 2032, and during the 15 to 20 years those vehicles remain on the road after introduction. [EPA-HQ-OAR-2022-0829-0612, p. 4]

In summary, EPA should pursue stringent new fuel standards – not only for reduced particulate emissions but also for dramatically lower GHG emissions. Fuel standards can achieve benefits much more quickly than standards which only impact new vehicles. [EPA-HQ-OAR-2022-0829-0612, pp. 10-11]

EPA's STATUTORY AUTHORITY and ACTIONS NEEDED

NCGA believes EPA should take the following actions to improve the proposal and through rulemaking on fuel property standards: [EPA-HQ-OAR-2022-0829-0612, p. 11]

Set a minimum fuel octane level of 98 RON, phasing out lower octane fuels as new optimized vehicles enter the market.

NCGA believes EPA has ample authority to regulate fuel octane because of the impact higher fuel octane would have on reducing GHG and criteria emissions from the vehicle fleet. EPA has previously acknowledged the agency has authority to regulate fuel octane under Section 211(c). [EPA-HQ-OAR-2022-0829-0612, p. 11]

Approve a high-octane, midlevel ethanol blend vehicle certification fuel (98-100 RON, E25-E30).

EPA's timely approval of a high-octane, midlevel ethanol blend vehicle certification fuel would enable automakers to expedite design and testing of optimized vehicles for use with this new low carbon fuel. [EPA-HQ-OAR-2022-0829-0612, pp. 11-12]

Lower summer vapor pressure to 9 psi or less for all fuel or provide parity in Reid Vapor Pressure (RVP) treatment for all ethanol blends with E10.
Higher ethanol blends such as E15 offer an immediate decarbonization opportunity and support a transition to low carbon, high octane fuel. However, outdated RVP rules and the oil industry's refusal to produce lower volatility blend stock prevents E15 – which is lower in evaporative, tailpipe and GHG emissions – from reaching the market on the same terms as standard E10 fuel. [EPA-HQ-OAR-2022-0829-0612, p. 12]

By using existing authority in the Clean Air Act to require lower volatility conventional gasoline blend stock during the summer months to reduce emissions of volatile organic compounds and decrease the potential for ozone formation, EPA would simultaneously open the market to E15 year-round. NCGA urges EPA to take this action to improve air quality while simultaneously eliminating outdated barriers to cleaner, low carbon higher ethanol blends like E15 and future high-octane fuel. [EPA-HQ-OAR-2022-0829-0612, p. 12]

Reinstate the 0.15 volumetric conversion factor for FFVs. [EPA-HQ-OAR-2022-0829-0612, p. 13]

Organization: Missouri Corn Growers Association (MCGA)

Immediate progress toward decarbonizing the light duty fleet will help meet the Administration's goal of cutting emissions by 2030 and reaching net zero emissions by 2050. Achieving those decarbonization goals in transportation will require a mix of solutions. As recent analysis from the Rhodium Group concludes, a "portfolio of strategies is the lowest cost and most likely to succeed," including low carbon liquid fuels such as biofuels.1 However, the singular focus of the currently proposed multi-pollutant emission standards for model year (MY) 2027 through 2032 light and medium duty vehicles on battery electric vehicles (BEVs), ignores the immediate and long-term benefits of leveraging a portfolio of various transportation technologies and the emission reductions they can achieve. [EPA-HQ-OAR-2022-0829-0612, p. 3]

1 Rhodium Group, "Closing the Transportation Emissions Gap with Clean Fuels," January 15, 2021. https://rhg.com/research/closing-the- transportation-emissions-gap-with-clean-fuels/

The proposed rule and EPA's larger policy vision around vehicles ignore the broad and diverse range of powertrain and liquid fuel options that could be more widely deployed to reduce emissions. This includes the use of domestically produced biofuels, like high-octane, low-carbon ethanol blends used in conjunction with advanced high-technology engines and flex-fuel hybrid vehicles. This path would leverage existing fueling infrastructure and avoid the vast number of implementation challenges if this rule is adopted. [EPA-HQ-OAR-2022-0829-0578, p. 3]

That's why MCGA, state and national corn partners, as well as a growing list of businesses, support the Next Generation Fuels Act (NGFA). NGFA, introduced in both the U.S. Senate and House of Representatives, can bridge this divide. NGFA would update U.S. gasoline fuel standards to more efficient, high-octane, low-carbon fuels beginning in 2028. It does not dictate how regulated entities must achieve the higher octane and lower carbon requirements, nor does it require the use of a specific fuel or vehicle. Instead, it sets the criteria for a new high-octane fuel standard optimized for tomorrow's high-tech, low-emission engines. This opens the marketplace to a broad array of high-octane, low-carbon fuel sources, providing consumers and businesses with various choices and options to meet their transportation needs. [EPA-HQ-OAR-2022-0829-0578, p. 3]

Organization: Missouri Farm Bureau (MOFB)

EPA's proposed rule gives no consideration or opportunity for other liquid fuel technologies to meet emissions goals, and effectively bans gasoline- and diesel-powered vehicles by mandating that auto manufacturers build EVs. Again, MOFB urges EPA to thoroughly consider an all-of- the-above approach, and not overlook the important role that biofuels such as ethanol and biodiesel, produced in Missouri and throughout the heartland of America, can and should play in this policy discussion. [EPA-HQ-OAR-2022-0829-0590, p. 2]

According to a 2021 study conducted by the U.S. Department of Energy and published by Argonne National Laboratory, ethanol has 52 percent less greenhouse gas (GHG) emissions than gasoline.5 In addition, biodiesel and renewable diesel reduce GHG emissions 50-80 percent when compared to petroleum diesel, depending on the feedstock used.6 Meanwhile, EPA's proposed rule, which appears to be an attempt to completely electrify the light-duty vehicle market, projects to achieve a mere 26 percent decrease in cumulative GHG emissions through

2055.7 EPA must look to biofuels as a key part of the solution, instead of the approach taken by its proposed rule, which will surely prop up the economies of foreign countries – namely China's instead of our own. EPA should acknowledge that higher utilization of biofuels and subsequent greenhouse gas reductions can occur today with the majority of vehicles on our nation's roadways, rather than attempting to replace all of the internal combustion engines being driven by Americans on a daily basis. [EPA-HQ-OAR-2022-0829-0590, p. 2]

Organization: National Association of Convenience Stores (NACS) et al.

Renewable fuels such as ethanol materially lower gasoline's carbon footprint. If properly incentivized, these technologies' capability to reduce emissions can continue to grow alongside other decarbonization technologies such as clean electricity. Pursuing one solution does not require abandoning others. [EPA-HQ-OAR-2022-0829-0628, pp. 1-2]

As articulated in this letter, and in our associations' respective comments in response to the Proposal, we are concerned that EPA is pursuing a single technology as the solution to decarbonize light-duty transportation. The speed at which the Agency appears to anticipate the market and consumers will transition to electric vehicles is divorced from our members' assessment of reality. The Proposed Rule does not appreciate the market obstacles associated with such a massive transition in consumer behavior. It also abandons proven decarbonization technologies, such as higher-octane liquid fuels, that can deliver material emissions reductions using existing infrastructure, existing vehicles, and working with consumers' existing behavior. [EPA-HQ-OAR-2022-0829-0628, pp. 1-2]

Our associations support the Agency's stated goal of improving the emissions consequences of over-the-road transportation. The Proposed Rule's approach toward realizing that objective, however, is flawed. A technology-neutral approach to transportation decarbonization will help to mitigate costs, promote innovation, and address the practical challenges associated with electrification. All fuels and technologies should be treated equally within the context of emissions standards. The Proposal does not do this, but instead artificially tilts the scale towards electric vehicles ("EVs") by only accounting for emissions from one segment of the value chain: vehicle tailpipes. [EPA-HQ-OAR-2022-0829-0628, pp. 1-2]

I. Renewable Liquid Fuels Meaningfully Reduce Emissions.

During the past few decades, there has been extraordinary growth in the consumption of biofuels such as ethanol and biodiesel, as well as other low-carbon fuels such as renewable natural gas, compressed natural gas, and renewable diesel. These liquid fuels are all mostly compatible with existing infrastructure that was originally developed for hydrocarbons and is already ubiquitous throughout the country. [EPA-HQ-OAR-2022-0829-0628, pp. 2-3]

Biofuels and other renewable fuels work to build and maintain a competitive marketplace, maximize the climate benefits of liquid fuels, minimize fuel supply disruptions, and impose meaningful downward pressure on fuel prices. Existing alternative fuel incentives, including the Renewable Fuel Standard ("RFS") and biofuel blending and alternative fuel infrastructure tax credits, have successfully enabled our collective membership to build a robust renewable fuel value chain in the United States. The incentives Congress established over the past few decades have caused the displacement of significant volumes of petroleum-based fuel with renewable fuels. [EPA-HQ-OAR-2022-0829-0628, pp. 2-3]

Congress, in designing programs such as the RFS, recognized that the most effective way to get American motorists to purchase lower-carbon alternatives is to make renewable fuel blends less expensive than the petroleum-based fuels they are designed to displace. Over the past few years, the economic opportunities associated with selling higher biofuel blends have grown. As petroleum prices rise and refined product supplies tighten, blending incentives tend to increase as retailers gravitate toward lower-priced, lower-carbon alternatives such as ethanol and other renewable fuels. [EPA-HQ-OAR-2022-0829-0628, pp. 2-3]

It is also important to recognize the role renewable liquid fuels play in harnessing existing infrastructure to maximize diverse investments and achieve emissions reduction goals. Importantly, renewable fuels do not require new vehicle purchases and lead to significant emissions reductions by improving the emissions profile of vehicles already on the road. It is exponentially less expensive to leverage existing infrastructure than to create entirely new supply chains and infrastructure. To the extent environmental objectives can be achieved by utilizing the infrastructure already in place, consumers will more seamlessly gravitate to new types of fuels and vehicles. [EPA-HQ-OAR-2022-0829-0628, pp. 2-3]

If the final rule better leverages the existing low-carbon fuel value chain and retailers' understanding of consumer behavior, vehicle manufacturers will be able to lower emissions in new vehicles (including EVs) while also reducing emissions in the current fleet. Given the uncertainty surrounding the Agency's overly optimistic timelines, this represents a commonsense approach to reducing both tailpipe emissions and lifecycle emissions in the most timely, cost-effective, and efficient way possible. [EPA-HQ-OAR-2022-0829-0628, pp. 2-3]

IV. The Proposed Rule Blunts Innovation and Competition.

Climate research has consistently emphasized the importance of near-term emissions reductions relative to future reductions.41 More efficient vehicle engines coupled with low-carbon, renewable liquid fuels can reduce emissions immediately. [EPA-HQ-OAR-2022-0829-0648, pp. 12-13]

41 See G. Cornelis van Kooten, Patrick Withey, and Craig M.T. Johnston, BIOMASS AND BIOENERGY 151 "Climate Urgency and the Timing of Carbon Fluxes," (Aug. 2021) available at https://doi.org/10.1016/j.biombioe.2021.106162. ("The current climate emergency dictates that immediate action is required to mitigate climate change, which implies that carbon fluxes occurring 20 or more years from now are too late to have any mitigative effect.")

EPA's effort to mandate a shift to EV technologies directly disincentivizes investment in new technologies that have the potential to deliver tangible emissions savings in both the near and long term. Indeed, EPA's proposal risks zeroing out new innovations in the ICE vehicles that most consumers are still expected to drive for decades to come. There is no way for manufacturers to comply with the Proposal by producing ICE vehicles alone. This means their only choice will be to divert investments away from ICE fuel economy improvements. [EPA-HQ-OAR-2022-0829-0648, pp. 12-13]

An analysis conducted by McKinsey & Company estimates that if, in 2030, 50 percent of new vehicle sales are EVs, given the rate of turnover of the fleet, the number of used vehicle sales, and other factors, EVs will constitute just 17 percent of the vehicles in operation around the country. Importantly, this analysis also projected the impact of partial electrification on gasoline demand. Based on those figures, and the fact that many of the ICE vehicles on the road at that time will be less efficient than the vehicles that the new EVs replaced, McKinsey concludes that the reduction in gasoline demand based on the increased number of EVs on the road will be only four percent. This further underscores the importance of adopting a technology-neutral approach to decarbonization. A laser-focus on electrification means that we will not have maximized the decarbonization potential of 83 percent of vehicles (ICE engines) that will be on the road in 2030. [EPA-HQ-OAR-2022-0829-0648, pp. 12-13]

There are many decarbonization technologies beyond even improved fuel economy that EPA leaves on the table. Higher octane gasoline blended with higher concentrations of biofuels can allow ICE vehicles to be far more efficient in terms of emissions and fuel economy. There have also been increasingly innovative technologies surrounding expanded natural gas vehicle ("NGV") production in recent years. But the Proposed Rule fails to provide the automotive sector with any meaningful incentive to continue developing such technology or similar vehicles that can effectively rely on renewable natural gas ("RNG"). The latest data available from the California Low Carbon Fuel Standard Program indicates that the average carbon intensity of bio-CNG (compressed natural gas) sold in 2020 was -5.85gC)2e/MJ.42 In the coming years, the carbon intensity of RNG is expected to be even lower as greater amounts of low-carbon dairy gas is produced and used in NGVs. This is especially important in light of market considerations. [EPA-HQ-OAR-2022-0829-0648, pp. 12-13]

42 CALIFORNIA AIR RESOURCES BOARD, "LCFS Pathway Certified Carbon Intensities" (2023) available at https://ww2.arb.ca.gov/resources/documents/lcfs-pathway-certified-carbon-intensities.

Further, existing alternative fuel incentives—such as the Renewable Fuel Standard ("RFS") and biofuel blending and alternative fuel infrastructure tax credits—have allowed fuel retailers to offer less expensive, lower carbon fuels to our customers, while also supporting investments in renewable fuel production. The incentives Congress established over the past few decades have caused the displacement of significant volumes of petroleum-based fuel with renewable fuels. [EPA-HQ-OAR-2022-0829-0648, pp. 12-13]

Increased utilization of renewable fuels could lead to significant emissions reductions by improving the emissions profiles not only of new vehicles but existing vehicles as well.43 The Proposed Rule surrenders the market's ability to deliver near-term emissions savings by imposing a top-down, hurried transition to one technology. It will ensure that any technological breakthroughs with respect to any of these or other liquid fuels and ICE engines in the future simply will not happen because there will be no economic incentive to pursue those advances. [EPA-HQ-OAR-2022-0829-0648, pp. 12-13]

43 The automotive industry has demonstrated consistent reductions in emissions and gains in efficiency through focus on the ICE. The Department of Energy's Office of Energy Efficiency and Renewable Energy has estimated that over the past 30 years, advances in internal combustion engines have reduced emissions of criteria pollutants by more than 99%. See DEP'T. OF ENERGY, "Internal Combustion Engine Basics" (Nov. 22, 2013), available at https://www.energy.gov/eere/vehicles/articles/internal-combustion-engine-basics. Since MY2004, carbon dioxide emissions have fallen 25% and improved in fourteen of seventeen years while fuel efficiency has increased by 32%. EPA, "Highlights of the Automotive Trends Report" (Dec. 12, 2022), available at https://www.epa.gov/automotive- trends/highlights-automotive-trends-report#Highlight1. Similarly, data from the Bureau of Transportation Statistics from 2011 to 2018 shows that engine efficiency has reduced light duty fuel consumption. BUREAU OF TRANSP'N STATISTICS, "Vehicle Miles Traveled by Highway Category and Vehicle Type" (Dec. 2022), available at https://www.bts.gov/browse-statistical-products-and-data/freight-facts-and-figures/vehicle-miles-traveled-highway.

Organization: National Corn Growers Association (NCGA)

As the producers of the low carbon feedstock for low carbon ethanol, corn farmers are part of the solution to cut transportation emissions. We urge EPA to focus less on one solution, electric vehicles, and instead focus on outcomes and opening pathways for all low carbon fuels and technologies that enable more stringent vehicle emission standards, taking advantage of not only the low carbon benefits of higher ethanol blends, but also the cuts in toxic emissions, greater fuel efficiency and consumer cost savings that come with more renewables. For automakers to use new technologies and enhanced engines to meet stringent standards, they need updated fuel that enables new vehicles and fuels to work as a system to enhance greenhouse gas (GHG) and other tailpipe emissions reductions. Higher ethanol blends used with advanced engines optimized for higher octane would provide a much-needed pathway for low carbon, low-emission fuels. [EPA-HQ-OAR-2022-0829-0643, p. 1]

Higher octane fuel is an essential tool for automakers to meet revised standards, but higher octane must also be clean octane to meet emission reduction goals. Clean octane from today's ethanol is 50 percent lower in GHG emissions than gasoline and replaces the most harmful hydrocarbon aromatics to improve air quality and prevent adverse health impacts. EPA failed to use the proposal to broaden the solutions that reduce transportation emissions by beginning a transition to low carbon, high-octane fuels to advance climate, air quality and environmental justice goals with these and future standards. Furthermore, alternative fuel vehicles such as flex-fuel vehicles, which have the potential to reach zero emissions, should be equitably incentivized through these vehicle standards. [EPA-HQ-OAR-2022-0829-0643, p. 1]

Low-carbon liquid fuels have a unique and important role to play, immediately and in the long term. Fuels such as E15 (15% ethanol) are approved for and available for use in the millions of vehicles already on the road today, and thus offer immediate emissions benefits on a much larger scale than changes to only new vehicles. In the longer term, low-carbon or zero-carbon liquid fuels offer emissions solutions for market segments and customers that may not be well served by battery electric vehicles. [EPA-HQ-OAR-2022-0829-0643, p. 2]

To foster a vibrant and competitive landscape of multiple solutions, it is critical for EPA to set performance-based and technology-neutral emissions standards. Unfortunately, the proposed standard falls short of this ideal. It is essential to look beyond the tailpipe and use life cycle analysis for fair comparisons and a "level playing field". [EPA-HQ-OAR-2022-0829-0643, p. 2]

Under the Clean Air Act, EPA has an obligation to protect the health and welfare of Americans. While EPA projects the proposed standards will result in 7.3 billion cumulative tons of avoided GHG emissions through 2055, EPA leaves significant GHG emission reductions on the table if the agency fails to take steps in this proposal, or in a parallel action, to also improve liquid fuels along with vehicles. EPA must include complementary fuel improvements that would enable greater total GHG reductions, greater fuel efficiency and substantially greater air quality improvements than the current proposal offers. [EPA-HQ-OAR-2022-0829-0643, p. 2]

Each year, sales of new vehicles displace a small fraction of the existing vehicle fleet. EPA estimates that 67% of new vehicles sales will be battery electric in 2032. The projections for battery electric vehicle adoption are based on very few—and very small—real-world data points. See generally 88 Fed. Reg. 29,187–90. Battery electric vehicles made up 5.8 percent of the new light-duty passenger vehicle market in 2022. Id. at 21,190. EPA needs these sales to increase by a factor of ten over the next 8 years. [EPA-HQ-OAR-2022-0829-0643, pp. 2-3]

Clearly, a large number of new vehicles that burn liquid fuels will continue to be produced for many years, and those vehicles will remain on the road for many additional years. According to data from the Department of Energy's Oak Ridge National Lab, 2 16% of passenger cars and 32% of light-duty trucks remain on the road for more than 20 years. If new electric vehicles are more expensive or less attractive to consumers, older liquid-fueled vehicles will remain on the road even longer. [EPA-HQ-OAR-2022-0829-0643, pp. 2-3]

2 Davis and Boundy, "Transportation Energy Data Book: Edition 40", Oak Ridge National Laboratory report ORNL/TM-2022/2376, February 2022; https://tedb.ornl.gov/wp-content/uploads/2022/03/TEDB_Ed_40.pdf

Low-carbon liquid fuels can achieve GHG reductions faster than new vehicles can displace the existing fleet. A relatively simple change such as replacing E10 (10% ethanol) with E15 (15% ethanol) can offer greater GHG reductions 3 than the phase-in of battery electric vehicles, because it can immediately affect a huge fleet of vehicles that are already in use. [EPA-HQ-OAR-2022-0829-0643, pp. 2-3]

3 Fuels Institute report "Decarbonizing Combustion Vehicles: A Portfolio Approach to GHG Reductions", June 2023

But E15 is not the only way to achieve large emissions benefits with ethanol. To enable further displacement of petroleum by ethanol, many stakeholders have agreed to support E25 (25% ethanol) capability in all vehicles by 2028, and E30 by 2033, as specified in the Next Generation Fuels Act. However, EPA currently has authority to support the production of new vehicles with E25/E30 capability through new fuel standards, as well as incentivize flex-fuel vehicles (FFVs) with E85 capability. Getting these vehicles on the road quickly will build the foundation for future increases in cleaner liquid fuels, resulting in GHG and multi-pollutant emissions reductions. [EPA-HQ-OAR-2022-0829-0643, p. 3]

Recognizing vehicles and fuels as a complete system, increasing the octane rating of the nation's fuel supply through a clean, high-octane standard would deliver greater GHG emission reductions from the approximate 281 million internal combustion engine (ICE) vehicles on the road today and the 100 million projected to be added by MY 2032, and during the 15 to 20 years those vehicles remain on the road after introduction. [EPA-HQ-OAR-2022-0829-0643, p. 3]

The Renewable Fuel Standard (RFS) has already resulted in more 1 billion metric tons of cumulative GHG savings from 2008-2021, exceeding original projections largely due to the reduced carbon intensity of corn ethanol, highlighting the importance of using biofuels like ethanol to enhance the GHG emissions reductions from transportation with the right policies. 18 [EPA-HQ-OAR-2022-0829-0643, p. 6]

18 Unnasch, S. & Parida, D., Healy, B. “GHG Emissions Reductions due to the RFS2: A 2022 Update,” February 2023; chrome-extension://efaidnbmnnnibpcajpcglclefindmkaj/https://d35t1syewk4d42.cloudfront.net/file/2424/GHG%20Emissions%20Reductions%20due%20to%20the%20RFS2%20-%20Feb%202023.pdf

The most recent assessment from the Department of Energy’s Argonne National Laboratory concludes corn ethanol’s carbon intensity decreased 23 percent from 2005 to 2019 due to increased corn yield, reduced fertilizer intensity and improved ethanol production efficiency, with corn ethanol now between 44 and 52 percent lower in carbon intensity (CI) than the gasoline it replaces. 19 Argonne’s conclusions are similar to analysis from Environmental Health and Engineering finding ethanol now results in 46 percent fewer GHG emissions compared to gasoline, due to improved corn production, ethanol production efficiencies and land productivity. 20 [EPA-HQ-OAR-2022-0829-0643, p. 6]

19 Lee, Uisung & et al. ANL, “Retrospective Analysis of the U.S. Corn Ethanol Industry for 2005–2019: Implications for Greenhouse Gas Emission Reductions,” (2021). https://onlinelibrary.wiley.com/doi/10.1002/bbb.2225

20 Scully, Melissa J., et al, “Carbon intensity of corn ethanol in the United States: state of the science,” (2021) Environmental Research Letters 16 043001. https://iopscience.iop.org/article/10.1088/1748-9326/abde08

Bringing high octane fuel to market in the form of midlevel ethanol blends will be significantly less capital-intensive than attempting to increase blend stock octane with hydrocarbon components at refineries. It will also be incredibly cleaner. The avoided production cost and offset emissions lower end-costs to consumers, reducing both economic costs and social costs related to health and environment, key considerations in advancing environmental justice and avoiding adverse impacts from oil refineries on communities that have historically borne them. [EPA-HQ-OAR-2022-0829-0643, p. 7]

Increased volumes of ethanol in fuel displace the most harmful compounds from gasoline. 25 These aromatic hydrocarbon additives (i.e. benzene, toluene, ethylbenzene, xylene – or BTEX) have high cancer-causing potential. Increasing the ethanol volume in fuel to a midlevel blend has a positive impact on tailpipe emissions of toxins, including significant reductions in particulates and carbon monoxide. These same aromatic hydrocarbons are also precursors to the formation of secondary organic aerosols (SOA), which in turn are a major contributor to particulate matter emissions (PM 2.5). [EPA-HQ-OAR-2022-0829-0643, pp. 7-8]

25 Environmental and Energy Study Institute. Ethanol and Air Quality – Separating Fact from Fiction. October 12, 2018. https://www.eesi.org/articles/view/ethanol-and-air-quality-separating-fact-from-fiction

According to EPA’s review for the 2020 Anti-backsliding Study, ethanol does not form SOA directly or affect SOA formation. However, as EPA states, toluene is a large contributor to SOA. Ethanol’s high-octane value “greatly reduces the need for other high-octane components including aromatics such as toluene.” 26 [EPA-HQ-OAR-2022-0829-0643, pp. 7-8]

26 U.S. Environmental Protection Agency, Clean Air Act Section 211 (v)(1) Anti-backsliding Study, (2020) Appendix A, Page 61.

Perhaps the most credible and comprehensive study on the effects of ethanol on particulate emissions topic was published by the University of California Center for Environmental Research and Technology. 30 The study showed statistically significant improvements in particulate emissions for E15 compared to E10. [EPA-HQ-OAR-2022-0829-0643, p. 8]

30 Tang et al., "Expanding the ethanol blend wall in California: Emissions comparison between E10 and E15", Fuel, June 2023; https://doi.org/10.1016/j.fuel.2023.128836

EPA should adopt rules to limit PMI of both finished fuels and the hydrocarbon blend stocks used for E10, E15, and E85. Limiting PMI of hydrocarbon blend stocks will ensure that the particulate emissions benefits of ethanol are not offset by negative changes at refineries. [EPA-HQ-OAR-2022-0829-0643, p. 8]

Improved fuel property standards should be a high priority because they can achieve significantly lower particulate emissions and dramatically lower GHG emissions. California's Low Carbon Fuel Standard already recognizes the importance of fuel standards, and it has led to dramatic increases in sales of E85 and other low-carbon biofuels. High-octane low-carbon fuels are a key enabler for continued GHG emissions improvements in the millions of liquid-fueled vehicles which will be produced over the next 10+ years, as documented by the U.S. Department of Energy Co-Optimization of Fuels & Engines initiative and in numerous other studies, such as those by MIT and by automakers. A detailed proposed blueprint for future high-octane low-carbon fuels exists in the Next Generation Fuels Act, and EPA has the statutory authority to make these changes without waiting for Congress to act. [EPA-HQ-OAR-2022-0829-0643, pp. 8-9]

In summary, EPA should pursue stringent new fuel standards – not only for reduced particulate emissions but also for dramatically lower GHG emissions. Fuel standards can achieve benefits much more quickly than standards which only impact new vehicles. [EPA-HQ-OAR-2022-0829-0643, pp. 8-9]

Beyond ethanol's utility in all gasoline engines to reduce GHG emissions, other alternative vehicle technologies can also harness the GHG reductions and air quality benefits of ethanol, such as Flex Fuel Vehicles (FFVs). FFVs utilizing higher blends of low carbon ethanol, such as E85, can provide immediate emissions reductions without tangibly altering the price of the vehicle and reducing fuel costs. In fact, E85 is typically sold at a substantially lower price than gasoline, translating to monetary savings in addition to the significant air pollution savings. [EPA-HQ-OAR-2022-0829-0643, p. 9]

Compared to gasoline, E85 leads to significant reductions in NOx and GHG emissions. E85 avoids use of toxic hydrocarbon aromatics in gasoline that are precursors to secondary organic aerosols that result in harmful fine particulate matter emissions that cause serious respiratory, cardiovascular, and other health harm, including premature death, according to the American Lung Association. [EPA-HQ-OAR-2022-0829-0643, p. 9]

Incentivized to reduce emissions through the state's Low Carbon Fuel Standard (LCFS), in California some FFVs are even powered by a blend of 15 percent renewable naphtha with 85 percent ethanol. These vehicles use zero fossil fuels, have improved air emissions profiles, and have an extremely low carbon intensity. [EPA-HQ-OAR-2022-0829-0643, p. 9]

NCGA believes EPA should take the following actions to improve the proposal and through rulemaking on fuel property standards:

Set a minimum fuel octane level of 98 RON, phasing out lower octane fuels as new optimized vehicles enter the market. NCGA believes EPA has ample authority to regulate fuel octane because of the impact higher fuel octane would have on reducing GHG and criteria emissions from the vehicle fleet. EPA has previously acknowledged the agency has authority to regulate fuel octane under Section 211(c). [EPA-HQ-OAR-2022-0829-0643, pp. 9-10]

Approve a high-octane, midlevel ethanol blend vehicle certification fuel (98-100 RON, E25-E30).

EPA's timely approval of a high-octane, midlevel ethanol blend vehicle certification fuel would enable automakers to expedite design and testing of optimized vehicles for use with this new low carbon fuel. [EPA-HQ-OAR-2022-0829-0643, pp. 9-10]

Correct the fuel economy formula by updating the R-Factor to 1.0 to reflect documented operation of modern engine technology.

Correcting the R-Factor in the fuel economy formula would support automakers developing high efficiency engines that require higher octane ratings and a higher ethanol content. EPA has acknowledged that the current EPA-mandated R-Factor of 0.6, originally established in the 1980s, is outdated and fails to achieve the statutory purpose of making fuel economy testing on today's fuel equivalent to fuel economy testing in 1975. An update to 1 from 0.6 would reflect results of analysis by the Department of Energy and EPA using modern engines and fulfill previous observations and commitments from EPA to address this issue. Published studies have shown that R for modern vehicles should be around 0.93 to 0.96. 31[EPA-HQ-OAR-2022-0829-0643, pp. 9-10]

31 Sluder, C., West, B., Butler, A., Mitcham, A. et al. 2014. Determination of the R Factor for Fuel Economy Calculations Using Ethanol-Blended Fuels over Two Test Cycles. SAE Int. J. Fuels Lubr. 7(2):2014, doi:10.4271/2014-01-1572.

Setting the R-factor to 1.0 sets fuel economy results on an energy basis. In application, the R factor equation is a "fuel response factor," adjusting for more than just energy density. An R of 1.0 essentially converts fuel economy to mile per gallon gasoline equivalent (MPGge), which is how other alternative fuels such as propane, natural gas, and electricity have been compared to their gasoline counterparts for decades. Setting R to 1.0 provides equitable treatment to renewable ethanol that other alternative fuels already receive. This change could help speed the transition to certification with Tier 3 fuel as well as encourage vehicle manufacturers to seek certification for even higher ethanol blends, such as E15 or the high octane E30 EPA suggested in its Tier 3 proposal several years ago. Manufacturers are not incentivized to build dedicated high-octane vehicles that reduce GHG emissions when those low carbon benefits are penalized by a low R factor. [EPA-HQ-OAR-2022-0829-0643, pp. 9-10]

Lower summer vapor pressure to 9 psi or less for all fuel or provide parity in Reid Vapor Pressure (RVP) treatment for all ethanol blends with E10.

Higher ethanol blends such as E15 offer an immediate decarbonization opportunity and support a transition to low carbon, high octane fuel. However, outdated RVP rules and the oil industry's refusal to produce lower volatility blend stock prevents E15 – which is lower in evaporative, tailpipe and GHG emissions – from reaching the market on the same terms as standard E10 fuel. [EPA-HQ-OAR-2022-0829-0643, pp. 9-10]

By using existing authority in the Clean Air Act to require lower volatility conventional gasoline blend stock during the summer months to reduce emissions of volatile organic compounds and decrease the potential for ozone formation, EPA would simultaneously open the market to E15 year-round. NCGA urges EPA to take this action to improve air quality while simultaneously eliminating outdated barriers to cleaner, low carbon higher ethanol blends like E15 and future high-octane fuel. [EPA-HQ-OAR-2022-0829-0643, p. 10]

Organization: National Farmers Union (NFU)

National Farmers Union (NFU) appreciates the opportunity to comment on the proposed Multi- Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles ("Proposed Rule"), published at 88 Fed. Reg. 29,184. NFU has long supported biofuels and has urged the U.S. Environmental Protection Agency (EPA) to facilitate the use of mid-level ethanol blends (e.g., E20-E40), which are the most economical high-octane fuels available today. Despite EPA's limited actions to date in this regard, there remains widespread agreement regarding the need to move this country toward high octane fuels to take advantage of improved engine technologies for internal combustion engine (ICE) vehicles that are likely to continue to be a significant portion of the transportation sector for years to come. Although EPA is well aware of the benefits of high octane fuels, NFU is disappointed that EPA has yet again largely ignored and failed to capitalize on the benefits of biofuels, particularly mid-level ethanol blends, in establishing its vehicle emissions rules. These are technologies available today and can achieve significant reductions in greenhouse gas (GHG) and criteria pollutant air emissions and help this country reach its climate change goals. [EPA-HQ-OAR-2022-0829-0581, p. 1]

NFU submits these comments to urge EPA to take a more balanced, technology neutral approach to emissions standards that better reflects the benefits of biofuels and achieves much needed emissions reductions sooner rather than later. We further, again, urge EPA to take necessary administrative actions to support the use of mid-level ethanol blends that provide a significant cost-effective means of reducing GHG and other air pollutant emissions. [EPA-HQ-OAR-2022-0829-0581, p. 1]

I. Executive Summary

The proposed EPA standards for 2027 and later set very aggressive goals for reducing GHG and criteria emissions. Achieving these goals will require dramatic changes not only in vehicle design, but in the entire automotive supply chain. Battery electric vehicles will play a large role in achieving the goals, but this will require huge investments and rapid growth in many industries including the mining and processing of key minerals, the generation and distribution of electricity, and the recharging of electric vehicles. [EPA-HQ-OAR-2022-0829-0581, p. 2]

It would be naive to believe that these dramatic changes will be achieved smoothly and quickly. There are many obstacles including geopolitics, long lead times, capital investments, and consumer acceptance. In order to achieve emissions goals in the most robust, rapid, and affordable way, EPA should encourage multiple additional solutions such as hybrid electric vehicles (including plug-in hybrids), biofuels, and E-Fuels. [EPA-HQ-OAR-2022-0829-0581, p. 2]

Low-carbon liquid fuels have a unique and important role to play, immediately and in the long term. Biofuels, including mid-level ethanol blends, are compatible with a large number of vehicles on the road today, and thus offer immediate emissions benefits on a much larger scale than changes to only new vehicles. Moreover, recent reports show that Americans are holding on to their vehicles longer than in prior years.1 In the longer term, low-carbon or zero-carbon liquid fuels offer emissions solutions for market segments and customers that may not be well served by battery electric vehicles. [EPA-HQ-OAR-2022-0829-0581, pp. 2-3]

1 Tom Krisher, Repelled by high car prices, Americans are holding on to their vehicles longer than ever, Associated Press, May. 15, 2023, https://apnews.com/article/cars-older-record-age-prices-shortages-supply-6e3273208399803a402e707e1393475c ("The average age of a passenger vehicle on the road hit a record 12.5 years this year, according to data gathered by S&P Global Mobility. Sedans … are even older, on average — 13.6 years.").

In order to foster a vibrant and competitive landscape of multiple solutions, it is critical for EPA to set performance-based and technology-neutral emissions standards. Unfortunately, the proposed standard falls short of this ideal. It is essential to look beyond the tailpipe and use lifecycle analysis for fair comparisons and a "level playing field". [EPA-HQ-OAR-2022-0829-0581, pp. 2-3]

II. Ethanol Can Provide Cost-Effective Emissions Reductions Today

NFU continues to believe that high octane fuels "are the cheapest CO2 reduction."2 Improved engines and high octane fuels, specifically mid-level ethanol blends, are technologically feasible and economically reasonable means to achieve reduced GHG emissions, as well as reduced emissions of criteria pollutants and air toxics that have significant adverse health impacts. [EPA-HQ-OAR-2022-0829-0581, p. 3]

2 Eric Brandt, 100-Octane, Super Premium Fuel is Coming to a Pump Near You, The Drive, May 1, 2017, http://www.thedrive.com/news/9836/100-octane-super-premium-fuel-is-coming-to-a-pump-near-you.

Increased volume of ethanol increases the octane level of gasoline across grades. In addition to its higher octane level, ethanol also features high sensitivity and high heat of vaporization, which increase engine efficiency.3 In short, ethanol offers engine knock resistance at a lower cost than any other octane booster in gasoline. Higher ethanol blends can increase fuel octane without expensive refinery upgrades. [EPA-HQ-OAR-2022-0829-0581, p. 3]

3 Ricardo, Inc., The Draft Technical Assessment Report: Implications for High Octane, Mid-Level Ethanol Blends, Final Report, at 24 (2016), available at https://ethanolrfa.org/library/reports-studies-and-white-papers/mid-level- blends-octane-and-fuel-properties.

Ethanol is also substantially cleaner than petroleum-based octane additives. It reduces emissions of particulate matter and air toxics such as benzene, toluene, and xylene. Ethanol further provides GHG emissions reductions, which is increasingly important as the carbon intensity of gasoline is increasing with greater use of unconventional fossil fuels. "Emissions from fossil fuel combustion comprise the vast majority of energy-related emissions," with an increase in emissions from the transportation sector largely attributed to increased vehicle miles travelled and motor gasoline consumption by light-duty vehicles.4 At the same time, energy use in ethanol production and lifecycle GHG emissions have decreased with changes in farming practices and increased intensification (e.g., higher yields). As EPA has found, the land use, land-use change, and forestry sector resulted in a net increase in carbon stocks (i.e., net CO2 removals).5 This has occurred despite the loss of cropland and the struggle to retain existing agricultural lands against the ongoing pressures from urban and industrial expansion. [EPA-HQ-OAR-2022-0829-0581, p. 3]

4 EPA, Inventory of U.S. Greenhouse Gas Emissions and Sinks: 1990–2021, at 3-1, 3-23-3-24 (2023), available at https://www.epa.gov/system/files/documents/2023-04/US-GHG-Inventory-2023-Main-Text.pdf.

5 Id. at 6-2. Low-carbon liquid fuels can achieve GHG reductions faster than new vehicles can displace the existing fleet. As illustrated in Figure 21 below,8 a relatively simple change such as replacing E10 (10% ethanol) with E15 (15% ethanol) can offer greater GHG reductions than the phase-in of battery electric vehicles, because it can immediately affect a huge fleet of vehicles that are already in use. [EPA-HQ-OAR-2022-0829-0581, pp. 5-6]

8 John Eichberger, Decarbonizing Combustion Vehicles, June 2023, https://www.transportationenergy.org/resources/blog-post/decarbonizing-combustion-vehicles-a-critical-part-in- reducing-transportation-emissions/.

[See original comment for Figure 21, Light and Medium Duty Vehicle Annual GHG Emissions Reduction Scenario (2022-2023)] [EPA-HQ-OAR-2022-0829-0581, pp. 5-6]

Ethanol can continue to significantly contribute to reductions in GHG emissions from the transportation sector. Argonne National Laboratory published a study finding that the carbon intensity of corn-based ethanol improved 23% from 2005 to 2019 and that “displacement of gasoline by corn ethanol on an energy equivalent basis from 2005 to 2019 has resulted in a cumulative GHG emissions reduction of 544 MMT CO2e.”9 To enable further displacement of gasoline by ethanol, many stakeholders have agreed to support E25 (25% ethanol) capability in all vehicles by 2028, and E30 by 2033, as specified in the Next Generation Fuels Act.10 EPA need not wait for legislation, however. It can use existing authority to mandate or encourage the production of new vehicles with E25/E30 capability, as well as flex-fuel vehicles with E85 capability. Getting these vehicles on the road quickly will build the foundation for future increases in ethanol usage, and consequent dramatic GHG emissions reductions. [EPA-HQ-OAR-2022-0829-0581, pp. 5-6]

9 Uisung Lee, et al., Retrospective analysis of the U.S. corn ethanol industry for 2005-2019: implications for greenhouse gas emission reductions, Biofuels, Bioproducts and Biorefining, May 2021, available at https://doi.org/10.1002/bbb.2225.

10 The Next Generation Fuels Act was reintroduced by a bipartisan group of Senators in March of 2023. See Sen. Grassley Mar. 22, 2023 Press Release, Grassley Introduces Bipartisan Bill to Improve Vehicle Efficiency and Lower Fuel Costs, https://www.grassley.senate.gov/news/news-releases/grassley-introduces-bipartisan-bill-to-improve- vehicle-efficiency-and-lower-fuel-costs.

While not the only available biofuel to support GHG emissions reductions in the transportation fuel sector, ethanol is well-developed and cost-effective. Moreover, gasoline vehicles continue to dominate and likely will continue to make up a significant portion of the light-duty and medium-duty vehicle market. Further, ethanol is compatible with efforts toward renewable gasoline.11 [EPA-HQ-OAR-2022-0829-0581, p. 6]

11 See, e.g., https://www.chevron.com/-/media/chevron/newsroom/2023/Q2/renewable-gasoline-blend-factsheet-may-2023.pdf; https://pressroom.toyota.com/exxonmobil-and-toyota-team-up-to-test-fuels-with-a- lower-carbon-footprint/; Uisung Lee, et al., Carbon Intensities of Refining Products in Petroleum Refineries with Co- processed Biofeedstocks, Argonne National Laboratory, ANL/ESD-21/20, at 19 (2022), available at https://greet.es.anl.gov/files/refinery_co_processing_ci (discussing lifecycle emissions reductions for various feedstocks for co-processed fuels).

Organization: Natural Gas Vehicles for America

EPA must act now to adopt regulations that reward, credit, or account for the emission reductions provided by biofuels. Without this requested action, eventually there could be no new natural gas vehicles or other biofuel vehicles, and consequently no use of biofuels in transportation unless they are used to produce electricity for electric vehicles. To continue to certify and sell new natural gas vehicles, the current and proposed approach means that natural gas vehicle manufacturers will eventually be forced to subsidize electric vehicle truck sales to offset their tailpipe greenhouse gas emissions. This factor combined with regulations adopted by California and approved by EPA that mandate the sale of zero- tailpipe vehicles eventually will force manufacturers to stop offering natural gas trucks despite delivering substantial criteria pollutant and greenhouse gas emission reductions, and supplying a significant portion of the on- and off-road vehicles that will not be able to be electrified. This will have a negative impact on emission reductions and will be extremely financially detrimental to businesses that have invested in and employ workers in supporting the use of natural gas in transportation. [EPA-HQ-OAR-2022-0829-0597, pp. 4-5]

The pressure on natural gas vehicle manufacturers is not limited to the U.S. Similar regulatory proposals in Europe could have the same effect of marginalizing or limiting the future role of biofuel powered vehicles. NGVA Europe recently wrote that: It is necessary to break silos when designing fuel and mobility policies. Vehicle manufacturers must be encouraged to invest in solutions that can immediately reduce CO2 emissions, including vehicles with Internal Combustion Engines (ICE) that can run on fuels with lower GHG footprints, such as fuels from renewable sources.2 We wholeheartedly agree with that sentiment and admittedly lean heavily on our European trade association partners in our comments. [EPA-HQ-OAR-2022-0829-0597, pp. 4-5]

2 CO2-HDV Position-paper-Eurogas-NGVAv2.pdf

Emission Benefits of Natural Gas Vehicles

Numerous studies and analyses support the conclusion that there are significant environmental benefits associated with powering natural gas vehicles with RNG to displace petroleum motor fuels. Many of these studies support the conclusion that RNG fueled vehicles offer superior benefits to electric vehicles. To be fair, that should not be a requirement for equitable treatment. It should not be the job of RNG advocates to prove that RNG is superior to electricity or hydrogen, or that it is more cost-effective, or more readily deployable, or doesn’t rely on rare earth minerals, etc. [EPA-HQ-OAR-2022-0829-0597, p. 5]

EPA must stop favoring one technology over others by relying on outdated methods of certifying vehicles and engines. There is not a single environmental journal that would publish a paper or study that evaluates greenhouse gas emissions by only looking at tailpipe emissions or tank to wheel emissions. They would not do it because it is not defensible and would be an absurd comparison. The same is true for retaining greenhouse gas vehicle regulations that only look at tailpipe emissions. It is no longer rational, defensible, or equitable. [EPA-HQ-OAR-2022-0829-0597, p. 5]

As noted in the introduction, data from California's Low Carbon Fuel Standard (LCFS) program demonstrates how clean and low carbon these RNG fueled heavy-duty vehicles truly are. The most recent data confirms that the average carbon intensity (CI) value of California's bio-CNG is negative 99 gCO2e/MJ and has been negative for three consecutive years. In California, 97 percent of the natural gas consumed or credited to on-road transportation fuel in 2022 was renewable natural gas. Nationally the percentage was 69 percent in 2022 including fuel used in California. California continues to be a critical market for natural gas vehicles, but it is noteworthy that nearly 50 percent of the RNG reported in 2022 was for use in areas outside of California. [EPA-HQ-OAR-2022-0829-0597, p. 5]

RNG Supply Can Support Additional NGV Uptake Here and Abroad

The International Energy Agency's (IEA) World Energy Outlook 2022 projects that, under its different scenarios to 2050, renewable biogases (hydrogen and others) reach more than 400 billion cubic meters (bcm) by 2050; around 65 percent of that (260 bcm) is biomethane.5 The World Biogas Association's far more aggressive outlook estimates that biomethane could substitute 993 to 1380 bcm of natural gas, equivalent to 26-37 percent of the current natural gas consumed globally.6 European authorities recently set a target of achieving 35 bcm of biomethane by 2030.7 That target is roughly the energy equivalent of 8.9 billion diesel gallons. The European target is notable in that if achieved it would represent a ten-fold increase in production levels in less than ten years.8 [EPA-HQ-OAR-2022-0829-0597, pp. 7-9]

5 International Energy Agency, World Energy Outlook, Chapter 8, Outlook for Gaseous Fuels pp. 370, 377, and 380.

7 European Parliament supports 35 bcm biomethane target in EU Gas Package (gasworld.com)

8 EBA: 30% increase in European biomethane plants since 2021 | Bioenergy Insight Magazine (bioenergy-news.com)

Part of the reason NGV advocates are confident there are ample supplies is that the RNG industry and technology associated with it is very mature and existing domestic resources have not been fully exploited. Another reason is that NGVs are expected to make up a portion of the on-road market but not totally displace all gasoline or diesel vehicles. For example, NGVAmerica projects that successful future commercialization of NGVs in the heavy-duty market segment, specifically Class 8 trucks, in the U.S. could begin to displace between 10 – 15 percent of annual sales in the next several years. [EPA-HQ-OAR-2022-0829-0597, pp. 7-9]

If NGVs sales attain and maintain a level of 10 – 15 percent of new Class 8 sales, over the next decade that could result in several hundred thousand Class 8 NGV trucks consuming the equivalent of roughly 3 – 3.5 billion diesel gallon equivalents of fuel. Based on projections developed by the America Gas Foundation and other organizations, this level of fuel consumption -- even if the vehicles were operated 100 percent on biomethane -- would represent only a small portion of the available RNG supplies projected to be available in the U.S. As noted above, natural gas vehicles operating on blends considerably less than 100 percent still offer significant greenhouse gas benefits. [EPA-HQ-OAR-2022-0829-0597, pp. 7-9]

Various reports include projections of U.S. renewable natural gas supply. The most recent is a 2019 report prepared by ICF for the American Gas Foundation.9 Based on the projections in that report and shown below, there is more than sufficient potential supply of RNG to meet the demand posed by on-road NGVs. NGVs today consume approximately 75 trillion Btu per year (tBtu/y) and based on NGVAmerica's projections could grow to about 485 tBtu/y by 2035. This amount is far below what the AGF report projects is possible in the future. [EPA-HQ-OAR-2022-0829-0597, pp. 7-9]

[See original comment for Figure 2: Estimated Annual RNG Production, High Resource Potential Scenario, tBty/u] [EPA-HQ-OAR-2022-0829-0597, pp. 7-9]

The graphic below shows how the AGF figures compare with other less recent reports.

[See original comment for RNG Supply Forecasts (Billion DGE Year)] [EPA-HQ-OAR-2022-0829-0597, pp. 7-9]

EPA Must Amend its Proposal to Account for Benefits of Biofuels

NGVAmerica is not alone in making the case that EPA must amend its proposal. Other organizations including the refinery industry, independent fuel retailers, and the ethanol industry have argued that EPA must make a course correction and following through on its prior commitment to do so. [EPA-HQ-OAR-2022-0829-0597, pp. 9-10]

In 2012, EPA10 committed to sunset the use of the 0 g/mi allowance for electric vehicles as explained below:

10 2012-21972.pdf (govinfo.gov)

EPA is finalizing the full net upstream GHG emissions approach for the compliance treatment for EV/PHEV/ FCVs beyond the per-company vehicle production threshold caps in MYs 2022–2025. EPA is not adopting any type of ‘‘phase-in’’, i.e., the compliance value will change from 0 g/mi to the full net upstream GHG emissions value once a manufacturer exceeds the cap. EPA believes that the levels of the per company vehicle production caps in MYs 2017–2025 are high enough to provide a sufficient incentive such that any production beyond those caps should use the full net upstream GHG emissions accounting. [EPA-HQ-OAR-2022-0829-0597, pp. 9-10]

The preamble to that rule included the following discussion aptly summarizing the opposition to the use of the 0 g/mi standard. [EPA-HQ-OAR-2022-0829-0597, pp. 9-10]

(1) EPA should amend its greenhouse gas regulations for all types of vehicles including light-, medium-, and heavy-duty motor vehicles and incorporate the well-to-wheel benefits of natural gas and renewable natural gas as part of the engine and vehicle certification regulations; [EPA-HQ-OAR-2022-0829-0597, pp. 14-15]

(2) EPA to the extent it incorporates other technology advancement credits in its vehicle regulations should extend these incentives to natural gas and natural gas hybrid- electric vehicles

based on the demonstrated benefits of these vehicles and the need to accelerate the introduction of a diverse mix of cleaner vehicle technologies; [EPA-HQ-OAR-2022-0829-0597, pp. 14-15]

(3) EPA should provide enhanced SmartWay designations for trucks powered by low-NOx engines and fueled by carbon-neutral or even carbon-negative renewable natural gas; [EPA-HQ-OAR-2022-0829-0597, pp. 14-15]

(4) Federal agencies should fund pilot programs and infrastructure development that demonstrate the ways in which natural gas can be used to fuel a variety of different transportation sectors by supporting the purchase of vehicles and equipment at multimodal facilities such as ports and rail facilities; [EPA-HQ-OAR-2022-0829-0597, pp. 14-15]

(5) Federal agencies should ensure that federal funding provided under the CMAQ Program and the DERA Program and other programs enacted as part of the Bipartisan Infrastructure Law and Inflation Reduction Act are competitively awarded for projects that provide the most cost-effective emission reductions and offer increased funding levels for engines and vehicles that are certified to more demanding standards in advance of EPA's adoption of such standards; [EPA-HQ-OAR-2022-0829-0597, pp. 14-15]

(6) Federal agencies should work with state authorities to ensure that transportation policies include performance metrics and consider a variety of different technologies as opposed to only promoting specific technologies regardless of their cost; [EPA-HQ-OAR-2022-0829-0597, pp. 14-15]

(7) The Administration should work with Congress to amend the federal excise tax on new trucks to reduce the impediment to fleets and businesses purchasing cleaner new trucks by either eliminating the tax altogether since it discourages new purchases or amend the tax so that it does not penalize more costly, lower polluting technologies (i.e., eliminate the excise tax on the incremental cost). [EPA-HQ-OAR-2022-0829-0597, pp. 14-15]

Organization: Nebraska Corn Board (NCB) and Nebraska Corn Growers Association

On behalf of the nearly 2,500 Nebraska Corn Growers Association (NeCGA) dues paying members and the over 21,000 corn farmers in Nebraska who contribute to the state's corn checkoff program through the Nebraska Corn Board (NCB), we appreciate the opportunity to comment on the Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles. [EPA-HQ-OAR-2022-0829-0583, p. 1]

Nebraska corn farmers and ethanol producers have worked diligently in reducing greenhouse gas emissions while supplying the fuels industry with a low carbon, high octane alternative. However, the EPA seemingly overlooks the contribution that biofuels, such as ethanol, can provide to reducing carbon emissions through tailpipes and internal combustion engines. [EPA-HQ-OAR-2022-0829-0583, p. 1]

This proposal gives EVs an unfair advantage when the EPA upstream emissions. [EPA-HQ-OAR-2022-0829-0583, p. 1]

As most Americans will continue driving their current vehicle, it is crucial to ensure they have access to an affordable and environmentally friendly product such as gasoline with 15% ethanol, known as E15. This is a fuel that is acceptable for vehicles 2001 and newer which are 97% of the vehicles on the road. If made available to every consumer in the country, this would reduce carbon emissions by 280 million tons in the next decade. We ask the EPA to consider the University of California, Riverside's study on the Comparison of Exhaust Emissions between E10 and splash blended E15 as it demonstrates the opportunity that E15 has at reducing emissions. This study states around 54% reduction in carbon emissions compared to E10. We strongly believe in the role biofuels have as a critical step in reducing carbon emissions and being a cost-effective fuel for consumers. [EPA-HQ-OAR-2022-0829-0583, p. 2]

Organization: Nebraska Farm Bureau Federation (NEFB)

Rather than selecting winners and losers, EPA should pursue an "all-of-the-above", technology-neutral approach and ensure a place for both electric and liquid fuel, including biofuel, powered vehicles. A continued diversified fuel portfolio can meet meaningful green-house gas emission reductions and also acknowledges our nation's continued need for biofuels and other liquid fuel products. [EPA-HQ-OAR-2022-0829-0660, p. 1]

Farm and ranch families want clean air just as much as the rest of the nation. At the same time, we'd also urge your Administration reconsider these proposals from EPA to better allow for emissions reductions from a myriad of vehicle and fuels technologies while at the same time meeting Americans' transportation needs. [EPA-HQ-OAR-2022-0829-0660, p. 1]

Organization: North Dakota Farmers Union (NDFU)

NDFU urges the Environmental Protection Agency (EPA) to take a more balanced, technology neutral approach that better reflects the benefits of biofuels to emissions reductions efforts. [EPA-HQ-OAR-2022-0829-0586, pp. 1-2]

Background

NDFU is a strong supporter of renewable fuels, which provide high octane fuels with lower greenhouse gas (GHG) emissions. Renewable fuels also provide a critical market for farmers' crops and create well-paying jobs in our rural communities. However, barriers to the growth in renewable fuels markets remain. We continue to urge EPA to support the use of mid-level ethanol blends that provide a significant cost-effective means of reducing GHG and other air pollutant emissions. Unfortunately, the proposed rule ignores those benefits. [EPA-HQ-OAR-2022-0829-0586, pp. 1-2]

The proposed standards for 2027 and later set very aggressive goals for reducing GHG and criteria emissions. Achieving these goals will require dramatic changes not only in vehicle design, but in the entire automotive supply chain. To achieve these goals with a heavy reliance on battery electric vehicles (BEVs) will require huge investments and rapid growth in many industries including the mining and processing of key minerals, the generation and distribution of electricity, and the recharging of electric vehicles. [EPA-HQ-OAR-2022-0829-0586, pp. 1-2]

We are concerned that a swift and dramatic shift to BEVs will be difficult to achieve. The obstacles include geopolitics, long lead times, significant capital investments, and lagging consumer acceptance. In a state like North Dakota where drivers face cold weather and long driving distances, it is difficult to imagine a large portion of the population using BEVs in four years. [EPA-HQ-OAR-2022-0829-0586, pp. 1-2]

On the other hand, renewable fuels are already compatible with many vehicles on the road today and can offer immediate emissions benefits on a larger scale than relying solely on new vehicles to achieve EPA's targets. Recent reports show that Americans are keeping their vehicles longer than in prior years.1 In the long-term, promoting multiple solutions, including renewable fuels offers solutions for customers who may not be well served by BEVs. [EPA-HQ-OAR-2022-0829-0586, pp. 1-2]

1 Krisher, T. (2023, May 15). Repelled by high car prices, Americans are holding on to their vehicles longer than ever. Associated Press. Retrieved from https://apnews.com/article/cars-older-record-age-prices-shortages- supply-6e3273208399803a402e707e1393475c.

In order to foster a vibrant and competitive landscape where multiple solutions co-exist, EPA should set performance-based and technology-neutral emissions standards. Unfortunately, the proposed standard falls short of this ideal. We urge EPA to look beyond tailpipe emissions and use life cycle analysis for fair comparisons and a "level playing field." [EPA-HQ-OAR-2022-0829-0586, pp. 1-2]

Benefits of Renewable Fuels

NDFU continues to believe that high octanes fuels are the cheapest method for reducing GHG emissions. Improved engines and high octane fuels, specifically mid-level ethanol blends, are technologically feasible and economically reasonable means to achieve reduced GHG emissions. Increased ethanol volume increases the octane level of gasoline across grades. In addition to its higher octane level, ethanol also boosts engine efficiency.2 Higher ethanol blends can increase fuel octane without expensive refinery upgrades. [EPA-HQ-OAR-2022-0829-0586, p. 2]

2 Ricardo, Inc. (2016, September 20). The draft technical assessment report: Implications for high octane, mid- level ethanol blends, Final report. Prepared for Renewable Fuels Association. Retrieved from https://d35t1syewk4d42.cloudfront.net/file/1607/ATTACHMENT-A_Ricardo-TAR-Report-for-RFA_2016_09-20.pdf.

Ethanol is substantially cleaner than petroleum-based octane additives. It reduces emissions of particulate matter and air toxics, such as benzene, toluene, and xylene. Ethanol further provides GHG emissions reductions, which is increasingly important as the carbon intensity of gasoline is increasing with greater use of unconventional fossil fuels. "Emissions from fossil fuel combustion comprise the vast majority of energy-related emissions," with an increase in emissions from the transportation sector largely attributed to increased vehicle miles travelled and motor gasoline consumption by light-duty vehicles.3 At the same time, energy use in ethanol production and lifecycle GHG emissions have decreased with changes in farming practices and higher yields. As EPA has found, the land use, lang-use change, and forestry sector generated a net increase in carbon stocks.4 [EPA-HQ-OAR-2022-0829-0586, p. 2]

3 Environmental Protection Agency (2023). Inventory of U.S. greenhouse gas emissions and sinks: 1990-2021. U.S. Environmental Protection Agency, EPA 430-R-23-002. https://www.epa.gov/system/files/documents/2023-04/US-GHG-Inventory-2023-Main-Text.pdf.

4 Id. Low-carbon liquid fuels can achieve GHG reductions faster than new vehicles can displace the existing fleet. As illustrated below [See original comment for Figure 21. Light and Medium Duty Vehicle Annual GHG Emissions Reduction Scenario (2022-2023)], a relatively simple change such as replacing E10 (10% ethanol) with E15 (15% ethanol) can offer greater

GHG reductions than the phase-in of BEVs,7 because it can immediately affect a huge fleet of vehicles that are already in use. [EPA-HQ-OAR-2022-0829-0586, pp. 4-5]

7 Eichbethanolerger, J. (2023, June). Decarbonizing combustion vehicles – A critical part in reducing transportation emissions. Transportation Energy Institute. Retrieved from https://www.transportationenergy.org/resources/blog-post/decarbonizing-combustion-vehicles-a-critical-part-in-reducing-transportation-emissions/.

Ethanol can continue to significantly contribute to reductions in GHG emissions from the transportation sector. Argonne National Laboratory published a study finding that the carbon intensity of corn-based ethanol improved 23% from 2005 to 2019 and that "displacement of gasoline by corn ethanol on an energy equivalent basis from 2005 to 2019 has resulted in a cumulative GHG emissions reduction of 544 MMT CO2e."8 To enable further displacement of gasoline by ethanol, many stakeholders have agreed to support E25 capability in all vehicles by 2028, and E30 by 2033, as specified in the Next Generation Fuels Act.9 EPA need not wait for legislation, however. It can use existing authority to mandate or encourage the production of new vehicles with E25/E30 capability, as well as flex-fuel vehicles with E85 capability. Getting these vehicles on the road quickly will build the foundation for future increases in ethanol usage and dramatic GHG emissions reductions. [EPA-HQ-OAR-2022-0829-0586, pp. 4-5]

8 Lee, U., Kwon, H., Wu, M., and Wang, M. (2021, May 4). Retrospective analysis of the U.S. corn ethanol industry for 2005-2019: implications for greenhouse gas emissions reductions. Biofuels, Bioproducts and Biorefining. Retrieved from https://onlinelibrary.wiley.com/doi/10.1002/bbb.2225.

9 Grassley, C. (2023, March 22). Grassley introduces bipartisan bill to improve vehicle efficiency and lower fuel costs. [Press Release]. Retrieved from https://www.grassley.senate.gov/news/news-releases/grassley- introduces-bipartisan-bill-to-improve-vehicle-efficiency-and-lower-fuel-costs.

Unfortunately, the significant GHG benefits of ethanol and other low-carbon fuels are not accounted for in the proposed rulemaking. EPA should use life cycle analysis to properly account for and incentivize their use. [EPA-HQ-OAR-2022-0829-0586, pp. 4-5]

Biofuels have an important role to play in supporting family farms and rural communities. Renewable fuels can also significantly contribute to EPA's emissions reduction goals. However, we are concerned that EPA's proposal is biased in favor of BEVs and against renewable fuels. [EPA-HQ-OAR-2022-0829-0586, p. 6]

We also urge EPA to take appropriate regulatory actions to promote higher blends of ethanol and support any legislative changes necessary to overcome limits to EPA's authority. These actions include ensuring that vehicles can use mid-level ethanol blend and revising the certification fuel as needed to do so. We believe this would also provide reduced emissions for particulate matter and air toxics, providing a truly multi-pollutant emissions reduction solutions. [EPA-HQ-OAR-2022-0829-0586, p. 7]

Organization: Novozymes North America

Novozymes' Innovative Technologies Result in Lower Biofuel Lifecycle Emissions

Novozymes' enzymatic catalyst solutions, also known as biocatalysts, make the production of biofuels more efficient and environmentally friendly. Enzymes increase yield, reduce waste, reduce raw material input, and produce higher energy savings. Enzymes enable biofuel producers to convert corn kernel, corn stover, wheat straw, wood chips, sawdust, waste, and sugarcane bagasse into fuel, while collectively increasing yield and energy efficiency throughout the sector. Our enzymes help biofuel producers get more energy out of every harvest. These technologies have already helped the U.S. replace about 10% of liquid fuels with renewable alternatives. [EPA-HQ-OAR-2022-0829-0650, pp. 2-3]

Fiberex is a platform designed by Novozymes to utilize waste cellulosic material found in agricultural products. These cellulase enzymes can convert the cellulosic fiber found in, for example, corn kernel fiber, into high-value, low-CI products including cellulosic ethanol and increases corn oil yield that may be utilized as a raw material for renewable diesel production. This process is critical in maximizing fermentation efficiency and generating the low carbon products the markets (and consumers) are demanding. This technology has been instrumental in generating the roughly 120 million gallons of cellulosic ethanol that is currently being shipped to California every year. With a CI score 70 percent lower than gasoline, this cellulosic ethanol made from the corn kernel is helping to lower carbon emissions, drive sustainability in our transportation sector and create economic impacts from coast to coast. It is vital that, moving forward, this cellulosic technology can be applied not only to the production of low carbon ethanol, but increasingly to low carbon biochemicals as well as Sustainable Aviation Fuel (SAF). This includes supporting large-scale production of critical enzymes and yeast used in fiber conversion as well as ensuring that modeling (i.e. Argonne GREET) accurately accounts for the benefits being seen via this advanced technology. [EPA-HQ-OAR-2022-0829-0650, pp. 2-3]

Novozymes Innova yeast products deliver unparalleled robustness, help increase ethanol yield, and reduce fermentation time and operational costs. Novozymes launched its first yeast product in North America in 2018, and it has now launched 11 yeast products across the globe. Novozymes’ yeast allows producers to consistently reduce corn and chemical inputs and power through the most challenging conditions. Most of Novozymes’ yeast products express enzymes required to hydrolyze starch to produce glucose. Delivering enzymes via yeast decreases exogenous enzyme requirements resulting in a more sustainable, and lower CI fermentation process. Novozymes also developed the Cellerity® yeast platform for second generation biomass refineries. Cellerity enables increased ethanol yield and improved xylose conversion and inhibitor tolerance. [EPA-HQ-OAR-2022-0829-0650, pp. 2-3]

Above the inherent efficiencies and savings achievable with Novozymes’ enzymes alone, the company’s yeast technologies provide additional benefits. Many of our yeasts express critical enzymes needed for the lowest emissions biofuel production, in addition to converting available sugars to ethanol. These enzymes reduce the need for exogenous enzyme addition, further enabling overall lower CI values for today’s biofuels. [EPA-HQ-OAR-2022-0829-0650, pp. 2-3]

EPA Should Issue a Final Rule That is Technology Neutral and Promotes All Available Lower Emissions Transportation Fuels

Whether intended or not, the practical effect of the proposed rule in its current form would be to pick winners and losers and would fail to help encourage and facilitate the continued growth, production and use of vehicles that run on all lower emissions transportation fuels, including low CI biofuels. This effect would make it harder for the United States to attain its necessarily ambitious goal to achieve net zero emissions by 2050. This conclusion is especially true considering that many in the auto and other industries have predicted as overly ambitious and impractical the myriad policy goals to phase out the sale and production of light and medium duty vehicles with internal combustion engines by 2030 to 2040. [EPA-HQ-OAR-2022-0829-0650, pp. 2-3]

Although, through this proposal, EPA appears to be essentially directing the auto industry to sell approximately 67 percent of new cars and trucks as EVs by 2032, there are real questions whether that many consumers will want to buy them and whether the necessary infrastructure and grid enhancements to handle that many EVs on the road will be available by that time. Meantime, the federal government has formulated laws and policies to encourage the increased investment in and production and use of the cleanest biofuels that have been and continue to be responsible for massive emissions reductions in the transportation fuel sector over the last two decades. These policies and laws, including the federal Renewable Fuel Standard (RFS), have worked together to encourage these outcomes and the ongoing innovation within the biofuels industry that has and continues to improve the carbon and other GHG emissions reduction capabilities of the biofuels used in transportation fuel. [EPA-HQ-OAR-2022-0829-0650, pp. 2-3]

We respectfully urge the EPA to revise the proposed rule, so that when it is issued in its final form, the regulation will not only help facilitate the wider production, sale and use of EVs, but will simultaneously recognize and build on the enormous emissions reduction success and potential of biofuels. Both of these outcomes will be needed to meet the transportation fuel need in this country at least over the next two decades. Moreover, they will be necessary for this country to achieve net zero emissions by 2050, especially given the realities of legacy ICE vehicles expected to be on the road at least through the 2040s. Put another way, to achieve this country's collective net zero by 2050 emissions reduction goals, U.S. policies and laws will need to recognize and encourage every potential source of clean energy. Biofuels must continue to be on top of this list for the foreseeable future, and the final rule must reflect this fact so as to avoid inadvertently leaving behind millions of tons of avoided emissions reductions, or discouraging the continued investment, innovation and use of low carbon and other GHG emissions fuels in this country. [EPA-HQ-OAR-2022-0829-0650, pp. 2-3]

Organization: Oryxe International Inc.

1. EPA Should Affirm Vehicle Manufacturers Can Use Low Emission Fuel Additives to Achieve Compliance under the Proposed Rule

In the Proposed Rule, EPA states that it "anticipates that a compliant fleet under the proposed standards would include a diverse range of technologies, including higher penetrations of advanced gasoline technologies ..." Oryxe strongly agrees with this and urges EPA to include low emission fuel additives in the list of technology examples. Moreover, Oryxe urges EPA to ensure that any final rule recognizes the ability of vehicle manufacturers to use fuel additives to comply with the carbon dioxide and criteria pollutant standards. Internal combustion engine ("ICE") vehicles are and will continue to be a major part of the domestic fleet for many years to come. EPA's rule should explicitly acknowledge that the fuel placed into ICE vehicle engines will have a significant impact on carbon dioxide and criteria pollutant emissions, as well as on fuel economy. By EPA's own estimation, "tens of millions of gasoline-powered sources will remain in use well into the 2030s." 88 Fed. Reg. 29397. Notably, the Proposed Rule already recognizes the emission reduction benefits associated with using ethanol as a gasoline additive. As stated in the preamble, using gasoline containing 10 percent ethanol results in approximately 1.5 percent lower carbon dioxide emissions than using pure gasoline. Starting in Model Year

2027, the Proposed Rule would require manufactures of light-duty gasoline powered vehicles to demonstrate compliance using gasoline containing 10% ethanol, referred to as Tier 3 fuel. 88 Fed. Reg. 29240-41. Given that EPA understands and accepts the use of fuel additives to reduce emissions, it makes sense for EPA to ensure that any final rule explicitly provide that manufacturers are permitted to use fuel additives to comply with the emission standards. [EPA-HQ-OAR-2022-0829-0752, p. 2]

Oryxe's experience clearly demonstrates that fuel additives such as BetterFill provide an immediate opportunity to achieve significant cost-effective carbon dioxide and criteria pollutant emissions reductions that should be maximized. Such emission reductions will play an important role while the electric utility generation sector transitions to less emitting technologies and as the infrastructure for electrified vehicles develops. [EPA-HQ-OAR-2022-0829-0752, p. 2]

Oryxe's fuel additive technology significantly reduces emissions of carbon dioxide, nitrogen oxides, and particulate matter from gasoline, diesel, and biodiesel. For example, Oryxe has reduced more than 70 million metric tons of carbon dioxide equivalent over the past five (5) years in the United States alone and has recently proven to reduce 4.2 grams of carbon dioxide equivalent per megajoule of energy (gCO2e/MJ) in gasoline and 2.15 gCO2e/MJ in diesel fuel. It is important to note that the reductions associated with the use of fuel additives are immediate and low-cost, without the need for long and costly capital expenditure investments. Treating all diesel and gasoline consumed in the United States would prevent more than 30 billion tons of carbon dioxide from entering the atmosphere each year. It would also result in a reduction of annual emissions of nitrogen oxides and particulate matter by up to eight (8) and 30 percent respectively. Additional benefits would result from treating biodiesel with Oryxe's fuel additive technology. [EPA-HQ-OAR-2022-0829-0752, pp. 2-3]

A final rule that recognizes the ability of vehicle manufacturers to use low emission fuel additives for ICE vehicles to comply with the emissions standards is necessary and appropriate to achieving meaningful reductions, as well as within the scope of the rule. Oryxe understands that in promulgating past emissions standards for vehicles, EPA dismissed comments urging it to set a minimum octane fuel standard as a means of achieving the proposed emission standards as non-germane. 2 Oryxe's comments on the Proposed Rule differ from those comments and should not be dismissed. Here, Oryxe is not seeking a change, for example, to the octane levels; rather, Oryxe is asking EPA to give credit to fuel additives towards meeting the carbon dioxide and criteria pollutant emission standards. Such explicit acknowledgement is germane to this rulemaking, which requires the fuel efficiency gains and emissions reductions to achieve compliance standards without mandating a specific technology. [EPA-HQ-OAR-2022-0829-0752, pp. 2-3]

2 See, e.g., EPA, Revised 2023 and Later Model Year Light-Duty Vehicle Greenhouse Gas Emission Standards: Response to Comments, EPA-420-R-21-027 (Dec. 2021).

As noted above, the preamble to the Proposed Rule maintains that "EPA anticipates that a compliant fleet under the proposed standards would include a diverse range of technologies, including higher penetrations of advanced gasoline technologies as well as zero-emission vehicles. It is therefore important to consider the environmental and other implications of the ICE portion of the fleet." 88 Fed. Reg. 29187. Oryxe agrees that vehicle manufacturers will rely on a diverse portfolio of technologies to achieve the emissions standard. For this reason, Oryxe respectfully requests that EPA ensure any final rule clearly provides that vehicle manufactures may use low emission fuel additives to comply with the carbon dioxide and criteria pollutant standards. [EPA-HQ-OAR-2022-0829-0752, p. 4]

Organization: Our Children's Trust (OCT)

Specifically, there is a clear consensus that decarbonizing transportation requires a rapid shift away from fossil fuel vehicles toward Zero Emissions Vehicles ("ZEVs"), including battery-electric vehicles ("BEVs"), plug-in hybrid vehicles running primarily on electricity ("PHEVs"), and hydrogen fuel cell electric vehicles ("FCEVs"). [EPA-HQ-OAR-2022-0829-0542, p. 1]

1 Transitioning from conventional internal combustion engine vehicles to electric vehicles is believed to be one of the most promising pathways for decreasing greenhouse gas ("GHG") emissions from the road transportation sectors and thus should be pursued aggressively.2 While improving fuel efficiency can help to reduce emissions in the short-term, it cannot achieve the emissions reductions needed to achieve the Administration's net zero emissions target, it contributes to ongoing dangerous levels of GHG emissions, and experts have concluded that the continued use of fossil fuel vehicles is considered "a technological dead end."3 [EPA-HQ-OAR-2022-0829-0542, p. 1]

Organization: Pearson Fuels

On behalf of Pearson Fuels, thank you for the opportunity to submit comments on the Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles (the "Proposed Standards"). These comments are focused on the light-duty greenhouse gas emissions standards (the "GHG Standards"). As the leading supplier of E85 fuel in California, Pearson Fuels' primary interests in this proceeding are to ensure that: 1) the tremendous policy value of flex fuel vehicles (FFVs) that utilize E85 fuel is recognized as an important GHG mitigation strategy, and 2) this policy value is reflected programmatically by EPA re-integrating a commensurate level of FFV crediting into the EPA's GHG Standards. Through precisely calibrated FFV crediting, EPA will revitalize FFV manufacturing by some automakers and facilitate the development of hybrid FFVs like the Toyota Hybrid Flex Corolla that is being pioneered by Toyota of Brazil.1 This revitalization will not impede EPA's aggressive goal of rapid light-duty electrification but will diversify EPA's portfolio of decarbonization strategies for internal combustion engines thereby catalyzing more rapid and comprehensive decarbonization of the light-duty sector. [EPA-HQ-OAR-2022-0829-0577, pp. 1-2]

1 See ET Auto, "Toyota launches pilot project on flex-fuel strong hybrid EVs in India," at https://auto.economictimes.indiatimes.com/news/toyota-launches-pilot-project-on-flexi-fuel-strong-hybrid-electric- vehicles-ffv-shev-in-india-signs-mou-with-iisc-bengaluru/94786626, and Nikkei Asia, "Toyota to invest $334m to make compact biofuel hybrids in Brazil, Carmaker seeks to provide consumers with cheaper, eco-friendly vehicles," at https://asia.nikkei.com/Business/Automobiles/Toyota-to-invest-334m-to-make-compact-biofuel-hybrids-in-Brazil.

FFVs are a proven, robust, cost-saving and energy security enhancing GHG reduction tool that the U.S. Environmental Protection Agency ("EPA") integrated into the 2012-2016 light-duty GHG standards in a manner that aligned with the methodology of the Corporate Average Fuel Economy ("CAFE") program and facilitated extensive FFV manufacturing. Beginning in 2016, EPA eliminated its use of the 0.15 multiplier in the EPA's GHG Standards which triggered the rapid decline of FFV manufacturing. EPA explained its elimination of the multiplier based on the distinct goals of the CAFE program wherein the use of E85 achieves an 85% reduction in petroleum use thereby justifying the multiplier as compared to the EPA's GHG program which is focused on GHG reduction with no comparable justification for a multiplier.2 [EPA-HQ-OAR-2022-0829-0577, pp. 1-2]

2 77 FR 62816.

If the U.S. as a nation leveraged E85 as California does now, the benefit would be an estimated MMT tons of GHG reduction and petroleum displacement annually in 2022 and 74.71 MMT in 2032.5 We appreciate the opportunity to present these comments to this critical rulemaking and are hopeful that EPA will reassess and leverage the GHG-reduction potential of FFVs. [EPA-HQ-OAR-2022-0829-0577, p. 3]

5 See p. 10-12 of this Comment for the data and analysis underlying these figures.

EPA went on to assert in the Final Rule that despite the very substantial reduction of GHG emissions incentives that would result from the elimination of the 0.15 multiplier in 2016, automakers would continue to manufacture FFVs: [EPA-HQ-OAR-2022-0829-0577, pp. 4-5]

"There are approximately 10 million ethanol FFVs on the road in the U.S. today (far more than any other incentivized technology), and automakers produced approximately 2 million ethanol FFVs in MY 2011 alone. Although the great majority of ethanol FFVs currently use gasoline, EPA believes that automakers will continue to produce ethanol FFVs, as more consumers begin to fuel their ethanol FFVs with E85 fuel. Given the long history of federal incentives for ethanol FFVs, and the fact that ethanol FFVs can achieve small GHG emissions credits after the GHG emissions incentives expire, the Agency believes that there is no need to provide additional incentives for ethanol FFVs in this rulemaking, beyond those already provided."9 [EPA-HQ-OAR-2022-0829-0577, pp. 4-5]

9 77 FR 62823-4.

In making this assertion, EPA failed to recognize that distinct and tailored program structures and incentives are necessary to incentivize GHG-reducing technologies and fuels from different market participants. The 0.15 multiplier was highly effective in motivating automakers to manufacture FFVs. By contrast, the small GHG emissions credits based solely on tailpipe GHG emissions proved to be insufficient to motivate automakers to manufacture FFVs. This deficient GHG program incentive was not overcome by the existence of incentives for ethanol production that exist in RFS2. The credits in the RFS2 program are known as Renewable Identification Numbers (RINs), and are generated by fuel producers of ethanol and other qualifying RFS2 fuels. However, there is no opportunity for automakers to benefit from RINs generated for ethanol production, so the RFS2 program does not influence their manufacturing behavior. [EPA-HQ-OAR-2022-0829-0577, pp. 4-5]

In order to effectively achieve GHG reductions, it is necessary to develop and maintain programs that both put the right vehicles on the road (in this case, FFVs) as well as programs that put the right fuels in fueling stations (in this case, E85). The rapid expansion of the U.S. FFV fleet preceded both the existence of a robust E85 station network and widespread customer recognition of the benefits of ethanol, as well as consumer awareness of FFV capabilities. As a result, the 2012-2015 FFV fleet initially utilized relatively small quantities of E85. In sharp contrast today in California, the drivers of that same fleet (that remains on the road today) are using the Pearson Fuel application on their smart phones to access a burgeoning E85 station network and check local station prices. Upon identifying a cost savings opportunity, the customer is motivated to drive to a targeted E85 station to save money and fill up with an American-grown, low-carbon, octane-boosting fuel. [EPA-HQ-OAR-2022-0829-0577, p. 5]

This GHG Standards rulemaking provides EPA with the unique opportunity to leverage a GHG reducing tool that is already proven in the marketplace and is complementary rather than competitive with EPA's core decarbonization strategy of light-duty electrification. [EPA-HQ-OAR-2022-0829-0577, p. 5]

Restoring more harmonized FFV crediting between the CAFE and GHG programs would benefit automakers, consumers, and marketers by affording all a choice in the market and by establishing a diversified technology portfolio approach to decarbonization. FFVs deliver a wide array of real-world benefits when fueled with E85 or other gasoline-ethanol blends, including improved U.S. energy security, support for the U.S. farm economy, as well as significant reductions in GHG emissions. FFV consumers can respond to fuel market signals by utilizing high blend E85 ethanol when the fuel is at the greatest discount to petroleum and conventional gasoline when ethanol prices are relatively high as compared to gasoline (which has rarely been the case in the past five years). [EPA-HQ-OAR-2022-0829-0577, p. 6]

These are all vital flexibilities to a successful evolution of the vehicle market and to achieving the goals of the GHG rulemaking – increased efficiency, improved energy security, reduced costs to consumers, and reduced GHG emissions from the transportation sector. [EPA-HQ-OAR-2022-0829-0577, p. 6]

c. The use of sustainable biofuels is internationally recognized as a vitally important GHG reduction strategy.

The Intergovernmental Panel on Climate Change (IPCC) recently released a critical GHG report entitled, "Climate Change 2022, Mitigation of Climate Change, Summary for Policymakers."11 [EPA-HQ-OAR-2022-0829-0577, p. 7]

11 IPCC, 2022: Summary for Policymakers, https://www.ipcc.ch/report/ar6/wg3/downloads/report/IPCC_AR6_WGIII_SummaryForPolicymakers.pdf.

The report reached the following findings pertaining to biofuels:

- C.8 (…) Sustainable biofuels can offer additional mitigation benefits in land-based transport in the short and medium term (medium confidence). Sustainable biofuels, low- emissions hydrogen, and derivatives (including synthetic fuels) can support mitigation of CO2 emissions from shipping, aviation, and heavy-duty land transport but require production process improvements and cost reductions (medium confidence). (…) [EPA-HQ-OAR-2022-0829-0577, p. 7]

- C.8.3 (…) Sourced sustainably and with low-GHG emissions feedstocks, bio-based fuels, blended or unblended with fossil fuels, can provide mitigation benefits, particularly in the short and medium term (medium confidence). (…)12 [EPA-HQ-OAR-2022-0829-0577, p. 7]

12 Id. at p. 32.

d. California has recognized the value of biofuels as a vitally important GHG reduction strategy; has leveraged its existing FFV fleet to reduce GHGs in the light-duty sector; and has determined that deploying low carbon liquid fuels in all remaining internal combustion engines is essential to achieve carbon neutrality. [EPA-HQ-OAR-2022-0829-0577, pp. 7-8]

The State of California has taken a leadership role in climate policy dating back to 2006, and has developed a network of policies and strategies to enable decarbonization. Consistent with this, Governor Jerry Brown signed Executive Order No. B-55-18 in 2018. The Executive Order established a new statewide goal to achieve carbon neutrality as soon as possible, and no later than 2045, and to achieve and maintain net negative emissions thereafter. Further to that goal, the California Legislature approved the Budget Act of 2019 (AB 74) that funded two studies, administered by the California Environmental Protection Agency, to: 1) identify strategies to reduce emissions from transportation energy use, and 2) identify strategies to manage the decline in fossil fuel production and associated emissions in parallel with reductions in demand. The study to reduce emissions from transportation use was conducted by the University of California Institute of Transportation Studies ("ITS") at four campuses, UC Davis, UC Berkeley, UC Irvine, and UCLA. [EPA-HQ-OAR-2022-0829-0577, pp. 7-8]

The resulting ITS report is entitled, "Driving California's Transportation Emissions to Zero."13 While California leads the nation in electrifying transportation, the report recognized the reality that a significant number of internal combustion engines will remain on the road beyond 2035. As a result, the Driving California's Transportation Emissions to Zero report concluded that to achieve carbon neutrality it was necessary for California to make a complete transition by 2045 from petroleum-based gasoline to bio-based gasoline including ethanol blends as is illustrated in the following graph. The only existing vehicles that can utilize E85, the only type of bio-based gasoline that has been commercialized, are FFVs. GHG-reducing innovations in fuels as well as vehicles are necessary to meet President Biden's climate goals and should be supported by the EPA's GHG Standards. [EPA-HQ-OAR-2022-0829-0577, pp. 7-8]

13 Institute of Transportation Studies, "Driving California's Transportation Emissions to Zero," (April 2021), available at https://escholarship.org/uc/item/3np3p2t0.

SEE ORIGINAL COMMENT FOR BAR GRAPH of Fuel Consumption 2010-2045 [EPA-HQ-OAR-2022-0829-0577, pp. 7-8]

e. California marketers have identified and promoted E85 as a consumer- friendly fuel; built out a massive E85 station network including in disadvantaged communities; and leveraged California's existing FFV fleet to reduce petroleum dependence and GHG emissions. [EPA-HQ-OAR-2022-0829-0577, pp. 8-9]

As previously noted, Pearson Fuels is the largest distributor of E85 in California and supplies more than 315 retail E85 stations under long-term contracts. Pearson Fuels continues to open 3-4 new E85 stations per month. These stations are spread throughout the state with a high concentration in disadvantaged communities where the fuel savings from E85 are most valuable to low and moderate-income consumers. The following map was developed based on the Pearson Fuels network of stations in Los Angeles overlayed on the California Legislature's SB 535 "Disadvantaged Communities Map" that highlights CalEPA designated communities in red, as further discussed in the attached Exhibit 2. [EPA-HQ-OAR-2022-0829-0577, pp. 8-9]

SEE ORIGINAL COMMENT FOR MAP of LA area [EPA-HQ-OAR-2022-0829-0577, pp. 8-9]

During 2022, Pearson Fuels' station network delivered E85 at massive discounts to conventional gasoline, even after adjusting for fuel mileage per gallon, with price discounts ranging from $1.00-$2.20 on an average monthly basis as compared with same station gasoline prices.14 [EPA-HQ-OAR-2022-0829-0577, pp. 9-10]

14 Pricing graph based on Pearson Fuels' internal price tracking of all grades of unleaded gasoline vs. E85, supporting information available upon request.

SEE ORIGINAL COMMENT FOR Progression Line Graph of Cost of Pearson Fuels E85 vs California Gasoline January- December. [EPA-HQ-OAR-2022-0829-0577, pp. 9-10]

In the aftermath of the Russian invasion of the Ukraine and the resulting price spike in world and U.S. national crude oil prices, E85 offered a refreshingly cost-effective and non-petroleum dependent fuel alternative to FFV drivers- but only to FFV drivers. The price discount spurred a remarkable year-on-year E85 demand growth rate of over 65% in California. Through its E85 program found at Title 13, California Code of Regulations, section §2292.4, CARB tracks every gallon of E85 sold in the state. The following table and chart reflect the dramatic growth in E85 that California has achieved.15 [EPA-HQ-OAR-2022-0829-0577, pp. 9-10]

15 See California Air Resources Board, "Alternative Fuels: E85 Ethanol," website page at https://ww2.arb.ca.gov/our-work/programs/alternative-fuels/alternative-fuels-e85-ethanol, "Annual E85 Volumes based on Reported Test Program Exemption Data," at https://ww2.arb.ca.gov/our-work/programs/alternative- fuels/alternative-fuels-e85-ethanol See also Exhibit 4 attached.

SEE ORIGINAL COMMENT FOR BAR GRAPH of Annual E85 Volumes (Million Gallons) for 2006-2022 [EPA-HQ-OAR-2022-0829-0577, pp. 9-10]

SEE ORIGINAL COMMENT FOR TABLE of Total Volume (gal) for 2006-2022 [EPA-HQ-OAR-2022-0829-0577, pp. 9-10]

Given that the size of the California E85 market in 2022 was 103 million gallons and using Pearson Fuels' corn starch ethanol/renewable naphtha as the reference fuel, California FFVs using E85 displaced the use of approximately 80 million gallons of petroleum gasoline in 2022.20 According to EPA's Green Vehicle Guide, a typical light-duty vehicle emits 8.9 kg CO2/gallon.21 Using this figure, the light-duty vehicle use of 80 million gallons of gasoline will result in 712,000 MT of GHG emissions. The use of the Pearson Fuels' E85 renewable naphtha blend across all of California's demand would provide a 60% GHG reduction, or a 427,000 MT annual reduction in GHG emissions. [EPA-HQ-OAR-2022-0829-0577, pp. 11-12]

20 See U.S. Department of Energy, "Is E85 Fuel Right for You?," referencing a 15-27% mileage penalty due to the lesser energy density of ethanol, at https://www.energy.gov/energysaver/articles/e85-fuel-right-you.

21 U.S. Environmental Protection Agency, "Tailpipe Greenhouse Gas Emissions from a Typical Passenger Vehicle," at https://www.epa.gov/greenvehicles/tailpipe-greenhouse-gas-emissions-typical-passenger-vehicle.

According to the U.S. Energy Information Administration ("EIA"), California accounts for one- tenth of U.S. motor gasoline consumption.22 Thus if California's utilization of E85 in FFVs as a GHG reduction strategy were replicated nation-wide, the U.S. would reap the benefit of 4.27

MMT of GHG reduction per year solely from E85 usage in FFVs. Based on California's 10-year, year-on-year growth rate of 33%, this would reach 17.82 MMT based on 432 MG of E85 in 2027, and 74.71 MMT based on 1.8 BG of E85 in 2032. However, given the sharp decline in FFV manufacturing, this rate of expansion could only be sustained with the re-introduction of additional FFV models by the automakers. [EPA-HQ-OAR-2022-0829-0577, pp. 11-12]

22 U.S. Energy Information Administration, "California State Energy Profile," at https://www.eia.gov/state/print.php?sid=CA.

SEE ORIGINAL COMMENT FOR TABLE Year/Gallons of E85/%Growth 23/ MMT GHG [EPA-HQ-OAR-2022-0829-0577, p. 12]

The above chart is based on the assumption of a continuation of linear growth based on the 10- year average annual growth rate. [EPA-HQ-OAR-2022-0829-0577, pp. 11-12]

23 Chart forecast for future years utilizes Annual Average Growth Rate (AAGR) based on past 10 years of California's E85 market growth as reported by California Air Resources Board 2012-2022. 66% growth rate for 2022 based on actual reported growth rate.

ICF completed an analysis of the growth of E85 in the California marketplace and forecasted a similar growth rate for 2023-2027 (the "ICF E85 Report). However, ICF capped market growth based on a maximum anticipated average usage rate of E85 per FFV of 50%, and also projected a decline in registered FFVs beginning in 2025 because of fleet turnover and the rapid decline in FFV manufacturing. The ICF report, "Forecasting E85 Consumption in California" provides the background and details of the ICF E85 forecast and is attached as Exhibit 3. [EPA-HQ-OAR-2022-0829-0577, p. 12]

The ICF E85 Report also analyzed the current usage rate of E85 in FFVs in California for 2022, and determined this rate to be 0.16. As previously noted, the usage rate of E85 is known as the F Factor that is utilized in determining crediting for FFV manufacturing for the CAFE and GHG programs. Based on California Energy Commission data pertaining to the number of registered FFVs in California and the rapid growth in demand for E85, the ICF Report E85 forecasts the F Factor for California FFVs to grow from 0.16 to 0.50 over the next five years. [EPA-HQ-OAR-2022-0829-0577, p. 12]

Table 2 of the Proposed Rule is entitled the "Projected GHG Emission Impacts in 2055 From The Proposed Rule, Light-Duty and Medium-Duty." For CO2 emissions, the Table contains a projected reduction of 440 MMT in 2055. Thus, even the 2022 national opportunity of GHG reductions from FFVs of 4.27 MMT represents nearly 1% of EPA's total targeted reductions for 2055. Coupled with the California E85 growth rate of 33%, the leveraging of the E85/FFV opportunity through 2032 could contribute to 17% annual GHG reduction opportunity in the internal combustion engine sector of the market. From a policy design perspective, FFV crediting in the GHG program represents low-hanging fruit that EPA should harvest in this rulemaking. [EPA-HQ-OAR-2022-0829-0577, pp. 12-13]

However, as illustrated by the ICF report, in order to realize these potential GHG reduction gains from E85 usage nation-wide, EPA must make a course correction in the light-duty GHG Standards to reinstate a reasonable level of crediting for FFV manufacturing. Without this adjustment, the automakers will continue to manufacture light-duty vehicles that can only be operated on fossil-based gasoline and the nation's FFV fleet will continue to decline. [EPA-HQ-OAR-2022-0829-0577, pp. 12-13]

g. The use of E85 as a decarbonization strategy is a uniquely cost-efficient GHG strategy that reduces petroleum dependence and enhances energy security

As has been discussed, it is now clear that Californians are embracing E85 fuel with the second largest gasoline market in the country showing 66% year-on-year growth in E85 sales from 2021 to 2022. CARB has confirmed the rigor of its oversight program and the rate of E85 growth in a letter to Pearson Fuels that is attached as Exhibit 4 to this comment.24 The sustained growth in demand for E85 from FFVs in California is remarkable, surging from less than 6.5 MGY in 2006 to over 103 MGY in 2022. [EPA-HQ-OAR-2022-0829-0577, p. 13]

24 Letter from Alexander "Lex" Mitchell, Manager, Emerging Technologies Section, California Air Resources Board regarding E85 use, to Graham Noyes, Noyes Law Corporation. This CARB letter is attached as an exhibit to the comment of Pearson Fuels to this proceeding.

The primary reason E85 use is on the rise in California is a typical and crucial driver in the fuel market, price. At the retail level, California FFV owners can fill up on E85 and routinely save 10 percent or more compared to conventional unleaded on a price per mile basis. It is due to these favorable economics that FFV stations are flourishing in disadvantaged communities where spiking gasoline prices are most damaging to consumer budgets. FFV owners previously unable to fuel with E85 because of limited availability are just now being exposed to a robust network of E85 stations offering steep price discounts to gasoline, and providing a cleaner fuel that simultaneously boosts octane, the farm economy, and U.S. energy security. E85's rapidly growing market appeal is not limited to California and is part of a broader U.S. market transition toward higher ethanol blends. This rapid growth in E85 demand is occurring at the same time that diminished FFV crediting under the GHG program has undercut the incentive for automakers to manufacture FFVs. This deployment of FFVs utilizing E85 by U.S. consumers to save money and reduce GHG emissions would be greatly enhanced to the extent EPA establishes an appropriate GHG emissions factor for FFVs. [EPA-HQ-OAR-2022-0829-0577, p. 13]

DOE's analysis of corn ethanol provides an appropriate reference for determining the appropriate multiplier for the use of E85 in FFVs. The midpoint of the range is 48%, and the annualized rate of CI reduction is approximately 1.5% for the period 2005-2019. Applying a steady rate of carbon intensity reduction between 2019 and 2027 provides a forecasted carbon intensity reduction of 12%. This would establish a carbon intensity reduction rate vs. gasoline of 48% (2019) + 12% (8 years of 1.5%/year) = 60% for 2027-2032. This carbon intensity reduction rate is conservative as it is based solely on corn starch ethanol, which is the predominant feedstock for the production of U.S. ethanol but is also the highest carbon intensity ethanol that is supplied in significant quantities. It is forecast that there will be a substantial expansion of new carbon intensity reduction technologies including carbon capture and sequestration, and climate smart agriculture that will significantly lower the CI of corn starch ethanol over the next decade.26 It is also anticipated that there will be a substantial expansion of ethanol produced from lower carbon intensity feedstocks as has occurred in the California marketplace.27 [EPA-HQ-OAR-2022-0829-0577, p. 14]

26 See Reuters, "Ethanol could get boost from carbon capture credits in Biden climate law, at https://www.reuters.com/markets/commodities/ethanol-could-get-boost-carbon-capture-credits-biden-climate-law- 2022-08-18/ and Investigate Midwest, "As U.S. pushes 'climate-smart' agriculture, hopes and fears collide," at https://investigatemidwest.org/2023/03/30/as-us-pushes-climate-smart-agriculture-hopes-and-fears-collide/.

27 U.S. Department of Agriculture, “The California Low Carbon Fuel Standard: Incentivizing Greenhouse Gas Mitigation in the Ethanol Industry,” (November 2020), at https://www.usda.gov/sites/default/files/documents/CA- LCFS-Incentivizing-Ethanol-Industry-GHG-Mitigation.pdf.

i. EPA established a new methodology for calculating FFV crediting for MY 2016 and later in its joint rule with NHTSA for MY 2012-2016.

In the joint NHTSA Final Rule for MY 2012-2016 (“Joint 2012 Final Rule”), EPA established first the approach for FFV crediting for 2012-2016:

(1) The assumption that the vehicle is operated 50% of the time on the conventional fuel and 50% of the time on the alternative fuel, (2) that 1 gallon of alternative fuel is treated as 0.15 gallon of fuel, essentially increasing the fuel economy of a vehicle on alternative fuel by a factor of 6.67, and (3) a ‘‘cap’’ provision that limits the maximum fuel economy increase that can be applied to a manufacturer’s overall CAFE compliance value for all CAFE compliance categories (i.e., domestic passenger cars, import passenger cars, and light trucks) to 1.2 mpg through 2014 and 1.0 mpg in 2015.28 [EPA-HQ-OAR-2022-0829-0577, pp. 14-15]

28 75 FR 25432.

The Joint 2012 Final Rule also established the methodology for FFV crediting for MY 2016 and subsequent years as being distinct from the 2012-2016 methodology as follows:

Starting with model year 2016, as proposed, EPA will no longer allow manufacturers to base FFV emissions on the use of the 0.15 factor credit described above, and on the use of an assumed 50% usage of alternative fuel. Instead, EPA believes the appropriate approach is to ensure that FFV emissions are based on demonstrated emissions performance.29 [EPA-HQ-OAR-2022-0829-0577, pp. 14-15]

29 Id. at 25433.

EPA provided the following example calculation:

For example, for a flexible-fuel vehicle that emitted 300 g/mi CO_2 operating on E85 ten percent of the time and 350 g/mi CO_2 operating on gasoline ninety percent of the time, the CO_2 emissions for the vehicles to be used in the manufacturer’s fleet average would be calculated as follows:

CO_2 = (300 x 0.10) + (350 x 0.90) = 345 g/mi30

[EPA-HQ-OAR-2022-0829-0577, pp. 15-16]

30 Id. at 25434.

Regarding the method of apportionment between E85 usage and gasoline usage, EPA stated:

One option EPA is finalizing is establishing a rebuttable presumption using a national average approach based on national E85 fuel use. (…) EPA plans to make this assigned fuel usage factor available through guidance prior to the start of MY 2016 and adjust it annually as necessary. EPA believes this is a reasonable way to apportion E85 use across the fleet.31 [EPA-HQ-OAR-2022-0829-0577, pp. 15-16]

31 Id.

In subsequent rulemakings, this usage factor has come to be known as the F Factor.32

32 See U.S. EPA, Technical Memorandum Describing Potential Methods for Determining the Weighting Factor (F- Factor) for Testing E85 Flexible Fuel Vehicles (FFV) Light-duty Vehicles, (August 18, 2020), at https://www.epa.gov/sites/default/files/2020-08/documents/f-factor-technical-memo-fy20-determination-2020-08- 18.pdf.

Thus EPA's methodology for determining GHG crediting for FFVs beginning MY 2016 may be summarized as represented by the following equation:

CO2 = (E85 Tailpipe GHG Emissions x F Factor) + [Gasoline Tailpipe GHG Emissions x (1-F Factor)] [EPA-HQ-OAR-2022-0829-0577, pp. 15-16]

Organization: Plains All American Pipeline, L.P.

By 2032—less than 10 years from now—the EPA's Proposal would require nearly 70% of light-duty cars and trucks sold in the U.S. to be electric or "zero tailpipe emission." We have a number of concerns with this approach, a few include: [EPA-HQ-OAR-2022-0829-0713, pp. 1-2]

- By focusing on tailpipe emissions alone, most internal combustion engine vehicles that run on gasoline, diesel and biofuels would be unable to meet the standards set forth in the Proposal. This overlooks critical efforts of the energy and automotive industries to pursue continued innovation and optimization of fuel/vehicle systems to improve efficiency and reduce emissions.1 [EPA-HQ-OAR-2022-0829-0713, pp. 1-2]

- Effectively outlawing most liquid fuel-powered vehicles would undercut U.S. energy security,2 harm our domestic energy industry and leave the U.S. more dependent on foreign-controlled supply chains.3 [EPA-HQ-OAR-2022-0829-0713, pp. 1-2]

- Transferring a significant amount of energy demand to electricity will strain already challenged electrical generation and transmission infrastructure. Without substantial additional investment and significant streamlining of electric transmission permitting, it's unclear whether the electrical grid could support charging new EVs at the level necessary to support the proposed emissions reductions.4 [EPA-HQ-OAR-2022-0829-0713, pp. 1-2]

- Traditional energy sources are essential for ensuring effective evolution of the energy landscape-including the manufacture and growth of renewable energy sources and EVs. However, the Proposal would reduce energy investments and increase costs to consumers for all forms of energy. Furthermore, this policy risks the continued viability of critical domestic energy manufacturing infrastructure, which, if idled, would be very challenging to restore. [EPA-HQ-OAR-2022-0829-0713, pp. 1-2]

- Eliminating most new gasoline and diesel vehicles from the market limits consumer choice. Significantly fewer new affordable vehicles are available for sale today5 than a few years ago. Used cars are also increasing in price6 as some automakers warn that they will be forced to cut back on supplying popular gasoline models because of government regulations restricting sales of traditional vehicles.7 [EPA-HQ-OAR-2022-0829-0713, pp. 1-2]

Organization: POET, LLC

Bioethanol, by contrast, already constitutes a significant share of LDV fuel and can rapidly scale up to significantly reduce GHG emissions from those vehicles. But the Proposed Rule ignores bioethanol. This is a potentially fatal flaw. Bioethanol and other biofuel-derived fuels account for a significant proportion—approximately 10 percent—of current LDV fuel nationwide.5 Over 27 million flex-fuel vehicles capable of running on approximately 85% bioethanol (and 100% renewable energy) are on the road today.6 And, given the many advances in technologies and methods for producing bioethanol discussed above, bioethanol could achieve net-zero emissions before the electric grid is completely decarbonized. [EPA-HQ-OAR-2022-0829-0609, p. 5]

5 See e.g., EIA, More ethanol was blended into U.S. gasoline last summer than ever before (Dec. 1, 2022), available at https://www.eia.gov/todayinenergy/detail.php?id=54839#

6 See Growth Energy, Flex Fuel Database, available at https://growthenergy.org/choice-at-the-pump/flex-fuel- database/ (which notes that over 27 million FFVs are on the road).

If EPA adds incentives for the real-world GHG benefits of renewable liquid fuels, EPA's rule would build on historical carbon-reducing policies and help ensure the success of its light- duty GHG emission reduction program. EPA's vehicle GHG program would not be, as the West Virginia Court put it, an impermissible "transformative expansion of" the agency's "regulatory authority."10 Instead, if EPA revises its proposed approach so as to credit bioethanol's real-world GHG emission reductions, EPA would have more well-considered, legally durable, flexible, cost-effective, and successful regulations to reduce GHG emissions. [EPA-HQ-OAR-2022-0829-0609, p. 6]

10 West Virginia, 142 S. Ct. at 2595.

2. Renewable fuels are a proven technology in a growing industry.

Renewable fuels are proven technology with a well-developed industry that continues to grow. This is due in part to existing federal and state incentive programs for fuels production, including the RFS, California's LCFS, and Oregon's Clean Fuel Standard. EPA can rely on the existing biofuel incentive programs in the same way it relies on the BIL and IRA—which also promote biofuel production—when assessing technology pathways in the Proposed Rule. The existing programs have given EPA years of real-world evidence showing how renewable fuels have succeeded in reducing and replacing fossil transportation fuels at scale. [EPA-HQ-OAR-2022-0829-0609, p. 9]

Beyond innovation in liquid renewable fuels themselves, automakers can readily produce a variety of vehicles capable of running on ethanol blends. Gasoline containing 10% ethanol is the most prevalent gasoline nationwide.19 EPA has determined that E15 can be used as a drop-in fuel for all model year 2001 and later vehicles.20 Many modern vehicles may be able to use E25 as a drop-in fuel, and automakers can readily make vehicles capable of using such "mid-level ethanol blends" ("MLEBs").21 Over 27 million flex-fuel vehicles ("FFVs") capable of running on approximately 85% bioethanol (and 100% renewable energy) are also already on the road.22 Ignoring the significant, real-world emissions reductions from MLEBs and FFVs would run counter to the very purpose of utilizing § 202 to reduce GHG emissions. Instead of encouraging these incredibly promising GHG reduction technologies, the EPA approach would move towards eliminating them from the marketplace by treating MLEB-compatible and FFV vehicles the same as engines that run on only traditional fossil fuel. [EPA-HQ-OAR-2022-0829-0609, p. 9]

19 The Proposed Rule appropriately produces a test fuel that "more closely represents the typical market fuel available to consumers in that it contains 10 percent ethanol." 88 Fed. Reg. at 29,240. See also, EIA, More ethanol was blended into U.S. gasoline last summer than ever before, supra note 5, noting a nationwide average blend rate of 10.5%.

20 See e.g., https://www.epa.gov/sites/default/files/2015-09/documents/420f15044.pdf.

21 See e.g., State of Nebraska, EPA Approves The Use Of E30 In Nebraska Fleet Demonstration Poised To Reduce Costs, Pollution, available at https://ethanol.nebraska.gov/epa-approves-the-use-of-e30-in-nebraska-fleet- demonstration-poised-to-reduce-costs-pollution/.

22 See Growth Energy, Flex Fuel Database, which notes that over 27 million FFVs are on the road, available at https://growthenergy.org/choice-at-the-pump/flex-fuel-database/.

3. Renewable fuels crediting would give vehicle manufacturers more options to comply and make for a more durable emissions reduction program.

Adding a renewable fuel crediting mechanism would make it more feasible for automakers to meet EPA's stringent standards. Renewable fuels would further diversify the pathways for manufacturers to comply with the proposed standards. This would be especially important in places, particularly rural areas with lower population densities, where BEV infrastructure will be difficult to develop at scale and may not be cost-effective. Renewable fuels would serve as a viable alternative to attain significant light-duty vehicle emissions reductions. [EPA-HQ-OAR-2022-0829-0609, p. 10]

EPA and the National Highway Traffic Safety Administration ("NHTSA") have experience with exactly this type of bioethanol crediting that POET proposes. In prior iterations of EPA's § 202 standard through model year 2015, and in the existing NHTSA fuel economy standards, FFVs receive compliance benefits because they can run on alternative fuels such as E85.23 This ability to utilize lower GHG fuels is adjusted by an "F Factor" that represents how much renewable fuel is used in the real world.24 EPA should re-introduce crediting for vehicles that can utilize higher blends of renewable fuels, and should expand the program to include technologies other than just FFVs. [EPA-HQ-OAR-2022-0829-0609, p. 10]

23 See EPA regulations at 40 CFR 600.510-12(j)(2)(iv)(B) providing FFV crediting through Model Year 2015. Regarding currently applicable NHTSA regulations at 49 CFR 523.2 (definition of dual-fuel vehicle includes flexible fuel vehicles); 49 CFR 536.10 (indicating that dual-fuel vehicles can earn credits under the standards); 2017 and Later Model Year Light-Duty Vehicle Greenhouse Gas Emissions and Corporate

Average Fuel Economy Standards, 77 Fed. Reg. 62624, 62829-30 (Oct. 15, 2012) (providing that FFVs could generate credits under the standards). See the discussion in section III.d below for additional details.

24 40 CFR 600.510-12(k).

Crediting vehicle engines that run on biofuels would also create a more durable program. Enabling a broader suite of emissions reduction technologies would avoid supply chain and other problems that threaten to undermine the Proposed Rule as currently structured.25 EPA should take a broader, more diversified approach to guard against other unforeseen events that may affect the flow of critical materials in the international economy that are needed to produce BEVs at the scale EPA is envisioning. [EPA-HQ-OAR-2022-0829-0609, pp. 10-11]

25 See below discussion in Section IV of these comments regarding the supply chain and infrastructure challenges facing EVs.

Incentivizing a broader set of technologies may also protect the rule from being withdrawn by future administrations. Biofuels enjoy broad bipartisan support, as evidenced by the recent debt ceiling negotiations between members of Congress.26 Both Republicans and Democrats in the House of Representatives successfully pressed for the removal of provisions in an early version of the debt ceiling bill that would have cut support for biofuels, and Congress remained steadfast in including important biofuels incentives that should not be undermined by the Proposed Rule.27 A rule that moves the needle too far toward a single technology risks political pushback if that technology loses public support or faces widespread technical challenges. [EPA-HQ-OAR-2022-0829-0609, pp. 10-11]

26 K. Brugger, Clean Energy, Ethanol Concerns Dog Debt Ceiling Bill, E&E Daily (Apr. 25, 2023), https://subscriber.politicopro.com/article/eenews/2023/04/25/clean-energy-ethanol-concerns-dog-debt-ceiling- bill-00093594; J. Dillon et al., GOP Scrambles to Address Energy Concerns with Debt Bill, E&E Daily (Apr. 26, 2023), https://www.eenews.net/articles/gop-scrambles-to-address-energy-concerns-with-debt-bill/.

27 Id.

Finally, affordable ethanol blends may be particularly attractive to diverse, lower and middle income populations and in the parts of the country that are centers of biofuel production. EPA's Proposed Rule should cater to diverse communities with unique needs, including those people who may not be able to afford EVs in the near future.28 Historically, vehicles that can utilize higher ethanol blends have been popular with these communities. While California has dominated EV registrations with approximately 39% of all EV registrations nationwide (followed by Florida at approximately 6% of all EV registrations nationwide), the registrations of FFVs still vastly exceed EV registrations in every state in the country.29 [EPA-HQ-OAR-2022-0829-0609, pp. 10-11]

28 See e.g., CalMatters, Who buys electric cars in California — and who doesn't? (Apr. 12, 2023), available at https://calmatters.org/environment/2023/03/california-electric-cars-demographics/ (finding "Communities with high concentrations of electric cars are affluent, college-educated and at least 75% white and Asian" while "electric cars are almost nonexistent in Black, Latino, low-income and rural communities").

29 See DOE, Vehicle Registration Counts by State, available at https://afdc.energy.gov/vehicle-registration.

C. Ethanol Provides a Key Solution to Statutory Goals that Underpin the Proposed Rule and EPA's Stated Purpose for Undertaking the Rulemaking.

EPA justifies the Proposed Rule based on (i) GHG emission reduction benefits, (ii) manufacturer cost and consumer cost, (iii) energy security, and (iv) "criteria" and toxic air pollutant reductions.41 The Proposed Rule also considers environmental justice impacts.42 The Proposed Rule inadequately addresses each of these key factors because EPA fails to consider the benefits of ethanol for each. [EPA-HQ-OAR-2022-0829-0609, pp. 13-14]

41 See e.g., 88 Fed. Reg. at 29347.

42 Regarding EPA's environmental justice analysis, see e.g., Section VIII.I of the Proposed Rule, 88 Fed. Reg. at 29393-97.

VI. EPA Must Not Inhibit the Use of Bioethanol Through Inappropriate "Adjustment Factors" Including an Erroneous R Factor and Improper CO2 Adjustment Factor.

Regarding EPA's choice of a test fuel, POET agrees with EPA that rather than using Indolene "Tier 3 test fuel more closely represents the typical market fuel available to consumers in that it contains 10 percent ethanol."127 EPA proposes to apply certain test formula "corrections" for CAFE calculations from a May 13, 2020 proposed rule,128 including an "R-factor" regarding fuel energy content. EPA must not inhibit the use of bioethanol through inappropriate "adjustment factors," including an erroneous R-factor. [EPA-HQ-OAR-2022-0829-0609, p. 28]

127 88 Fed. Reg. at 29240.

128 Air Plan Approval; Wisconsin; Redesignation of the Shoreline Sheboygan, WI Area to Attainment of the 2008 Ozone Standards, 85 Fed. Reg. at 28564 (May 13, 2020).

EPA requested comment on several potential alternatives to maintain octane levels, including increasing alkylation operations, increasing isomerization production, or increasing reliance on ethanol blending.145 But increased alkylation and/or isomerization are not workable solutions. Refiners already produce alkylate and isomerized natural gas liquids at near capacity, so additional infrastructure would be required to meaningfully increase production.146 And it is unlikely that refiners will make any significant investments into alkylation/isomerization infrastructure, as the gasoline market is facing long-term decline as alternative fuel vehicles become more popular.147 [EPA-HQ-OAR-2022-0829-0609, pp. 31-32]

145 88 Fed. Reg. at 29401-02.

146 Attachment 3 at 2-3, 9.

147 Id. at 9.

POET strongly supports EPA's third proposed alternative: increasing ethanol blending, specifically bioethanol. Increasing bioethanol blending is feasible. The bioethanol industry continues to grow significantly, and trends indicate that this growth will continue. Unlike the infrastructure that supports alkylation and isomerization capacity, bioethanol production infrastructure continues to expand, providing sufficient capacity for a possible increased reliance on bioethanol to lower vehicle PM emissions. Bioethanol is also cost-effective. Edgeworth Economics assessed economic data provided by POET to compare the costs of using gasoline additives other than ethanol and determined that those alternatives would cost between $0.10 to $0.24 cents more per gallon based on prices from January 2021 through January 2022.148 Adding alkylate, for instance, costs $0.19 more per gallon than ethanol.149 [EPA-HQ-OAR-2022-0829-0609, pp. 31-32]

148 EPA Docket No. EPA-HQ-OAR-2021-0427, comment submitted by POET LLC at 22.

149 Id.

As we have discussed above, bioethanol has a significantly lower PMI value than heavy aromatics. Bioethanol also contributes significantly to octane in gasoline. Increasing ethanol blending from E10 to E15 would more than make up for the octane loss related to reducing heavy aromatics in gasoline.150 Using bioethanol blending as a replacement would significantly reduce the PMI beyond the reductions that would be realized simply by imposing the potential PM emissions standards.151 [EPA-HQ-OAR-2022-0829-0609, pp. 31-32]

150 Attachment 3 at 10.

151 Id. at 10, 12-18.

3. U.S. EPA has failed to incorporate provisions into the Proposed Rule that recognize the ability of ethanol and other renewable biofuels to create reductions in GHG emissions from new light- and medium-duty vehicles. [EPA-HQ-OAR-2022-0829-0609, p. 53]

U.S. EPA's analysis of BEV cost and BEV penetration has other issues as well. Of these, U.S. EPA's failure to perform a comparative lifetime analysis of BEVs and conventional vehicles is particularly significant. As noted in Chapter 4 of the DRIA, the U.S. EPA analysis considers costs for only the first eight years of vehicle operation. In addition, as noted in Chapter 4.2.2, U.S. EPA intentionally ignores differences in insurance and depreciation costs claiming that they are equivalent even though some sources suggest that insurance costs are higher2 and resale values are lower3 for BEVs. U.S. EPA does not even consider the costs associated with battery replacement outside of warranty later in the life of a BEV or the fact that the overall lifetime of BEVs may be shorter than that of a conventional vehicle which would also impact a cost comparison based on vehicle lifetime that would negatively affect BEVs. U.S. EPA should account for these factors in its analysis of BEV penetration and at a minimum perform sensitivity analyses to determine how they could affect demand for BEVs and automakers ability to comply with the Proposed Rule. [EPA-HQ-OAR-2022-0829-0609, p. 59]

Organization: Porsche Cars North America (PCNA)

Porsche recognizes that a portion of our customers may continue to seek out the qualities of advanced combustion vehicles and is working both internally and with external partners to find opportunities for these vehicles to contribute to decarbonization goals. Porsche believes that a limited suite of advanced combustion vehicles, powered by highly innovative, near carbon-neutral fuels can coexist alongside electrification and positively contribute to environmental and energy goals. Near carbon-neutral fuels derived from renewable electricity, water, and non-fossil carbon dioxide, commonly referred to as "eFuels", can enable advanced combustion and hybrid technologies to operate in near-zero manner. Porsche refers to this emerging strategy as our double-e strategy: electromobility and eFuels. [EPA-HQ-OAR-2022-0829-0637, p. 4]

Porsche is working together with external partners who have successfully launched an eFuel pilot project and are now developing strategies to bring these fuels to global markets at scale. eFuels can be processed along with additives to meet market gasoline standards and offer a drop-in solution that requires no unique fueling infrastructure or vehicle modifications. Because eFuel will meet market fuel standards, the near carbon-neutral benefits can be applicable to new vehicles and many of the existing, on-road legacy combustion cars. [EPA-HQ-OAR-2022-0829-0637, p. 4]

Porsche recognizes that within the context of this specific proposal, EPA has not sought comment on how to include the benefits of innovative, near carbon-neutral liquid fuels within the structure of the light-duty greenhouse gas program for 2027 through 2032. Porsche recognizes that innovations like eFuels are still an emerging development and may take time to reach market scale. Porsche looks to future opportunities with EPA and other policy stakeholders to explore how these fuels in a limited number of vehicles, with potentially near carbon-neutral properties, could work within the range of Federal and State regulations. Porsche recognizes that these strategies may extend into future updates to EPA's GHG regulation as well as for other Federal and State regulations. Nevertheless, Porsche very much appreciates the foresight of governments who may consider an inclusive regulatory framework. [EPA-HQ-OAR-2022-0829-0637, p. 4]

Organization: Reginald Modlin and B. Reid Detchon

As discussed below, and then presented in carefully annotated detail, we believe EPA missed an opportunity to consider the benefits of high-octane, low-carbon fuels to contribute to the objectives of the Proposed Rule. Such fuels could deliver average annualized benefits comparable to that claimed for the Proposed Rule and could achieve them sooner. As you prepare the Final Rule, we urge you to consider that potential and to seek input from stakeholders beyond the walls of EPA as to how an improved fuel can be adopted by the market. This consideration should be seen as a companion to the electrification of the transportation sector by application of feasible, available, and affordable technological solutions to climate and health challenges. [EPA-HQ-OAR-2022-0829-0570, p. 1]

The urgent need for action on the growing global danger of climate change could not be clearer. In response, the world is moving toward a goal of zero net carbon emissions by mid-century. The most important near-term steps on that journey will be to decarbonize the global electricity supply and to shift the transportation sector from fossil fuels to electricity. In the U.S., a rapid transition to electric vehicles should be the object of financial and regulatory incentives by all levels of government. [EPA-HQ-OAR-2022-0829-0570, p. 4]

However, the average car on the road today is over 12 years old, with 25% of cars being over 16 years old. Even if the nation moves to end the sale of cars with internal combustion engines by 2035, replacing the existing fleet of 250 million passenger vehicles will take at least until mid-century. During that transition, increasing the use of biofuels, such as ethanol with a lower carbon footprint than gasoline, would unlock direct and indirect benefits for the climate and for the health of Americans: [EPA-HQ-OAR-2022-0829-0570, p. 4]

-Greenhouse gas emissions from cars and light trucks could be reduced by more than 12% (roughly 123 million metric tons annually) principally by enabling vehicles to operate more efficiently (a greater reduction than would be achieved by EPA's proposed new vehicle standards!). [EPA-HQ-OAR-2022-0829-0570, p. 4]

- Coupled with incentives for carbon capture in agriculture, it could shift tens of millions of acres of farmland now under conventional cultivation to low-impact sustainable practices, delivering further carbon benefits and reducing fertilizer runoff into our waterways. [EPA-HQ-OAR-2022-0829-0570, p. 4]

By providing the octane needed for more efficient engines, increased ethanol content in gasoline would also enable a 40% reduction in the use of aromatic hydrocarbons in the fuel. Aromatics are petrochemicals produced in the oil refining process and used to increase gasoline octane. They comprise roughly 20% of all the gasoline sold in the US. Emissions from these toxic chemicals today pose a significant public health risk. Ethanol offers a cleaner source of octane. [EPA-HQ-OAR-2022-0829-0570, p. 4]

The Clean Air Act Amendments of 1990 required control of toxic emissions from motor vehicles. EPA responded in 2001 with standards based on the technologies and understanding of health effects at that time. However, time and science have moved on. Vehicle engine technologies have advanced, the composition of gasoline has changed, and the public health effects of aromatics have become better understood: Carburetors and port fuel injection have largely been replaced by gasoline direct injection (GDI) technology. More than half of the vehicles entering the market use this technology to enhance fuel economy performance. Unfortunately, GDI technology greatly increases emissions of ultrafine particles when using today's gasoline. [EPA-HQ-OAR-2022-0829-0570, p. 5]

It doesn't have to be this way. Technologies and products have come together to define a new solution for what the Clean Air Act requires: "the greatest degree of emission reduction achievable through the application of technology which will be available." Along with a rapid transition to electric vehicles, a complementary program should include adoption of higher ethanol blends, which have been shown by U.S. National Laboratories to enable higher fuel economy and vehicle performance. Such blends would enable a 40% reduction in the use of toxic aromatics in gasoline. An important recent study, co-authored by the Nobel Prize winner Mario Molina, concluded that reducing the smallest (ultrafine) particles "without simultaneously limiting organics from automobile emissions is ineffective and can even exacerbate this problem." [EPA-HQ-OAR-2022-0829-0570, p. 5]

Today, the nation's gasoline fuel pool includes 10% ethanol (E10). Concerns about ethanol consuming food supplies to make transportation fuel, a feared lack of corn and ethanol production capability, and a claimed inability to distribute ethanol to customers have all been considered and assessed as low to no risk in contemporary studies. Gradual uptake of higher-level ethanol blends could be supplied without any expansion of U.S. cropland and offered to consumers at less cost than today's gasoline with lower carbon and toxic emissions. Test programs in the rural Midwest have shown that today's vehicles operate well on higher levels of ethanol blended with conventional gasoline. Automakers have affirmed that such benefits would be realized by both new and existing internal combustion engines and therefore should be encouraged as additional solutions as soon as possible. Consumer demand, supported by automaker recommendations for new cars, would steadily increase the market share of mid-level blends over time. [EPA-HQ-OAR-2022-0829-0570, pp. 5-6]

The pathway to that outcome is straightforward: [EPA-HQ-OAR-2022-0829-0570, pp. 5-6]

- EPA (and similarly the California Air Resources Board) should specify an improved, higher octane gasoline and identify mid-level ethanol blends as the fuel of choice for new vehicles.

- EPA and CARB should cap the permissible level of aromatics allowed in improved gasoline.

- Automakers should optimize new-car design for higher ethanol blends, seek approval for a related certification fuel, and urge its use as a preferred fuel.

g. Groundbreaking research at Pacific Northwest National Laboratory (PNNL) has led to new understanding of the process by which PAHs persist and are transported long distances. It was shown that the most carcinogenic PAH, benzo[a]pyrene (BaP) – often used as a marker for PAH content generally – is efficiently bound to and transported with atmospheric particles: [EPA-HQ-OAR-2022-0829-0570, pp. 20-21]

i. In the laboratory, particle-bound BaP degrades in a few hours, but field observations indicate it persists much longer in the atmosphere and is transported far from its sources – increasing its global lung cancer risk as much as fourfold. BaP from East Asia, for example, has been shown to travel thousands of miles over the Pacific Ocean, reaching the west coast of the United States. [EPA-HQ-OAR-2022-0829-0570, pp. 20-21]

ii. When SOA particles are formed in the presence of gas-phase PAHs, their formation and properties are significantly different from SOA particles formed without PAHs: They exhibit slower evaporation kinetics and have higher fractions of non-volatile components and higher viscosities, assuring their longer atmospheric lifetimes. This increased viscosity and decreased volatility act as a shield that protects PAHs from chemical degradation and evaporation, allowing for their long-range transport. [EPA-HQ-OAR-2022-0829-0570, pp. 20-21]

100 Zelenyuk et al., op. cit., supra note 6.

h. Based on numerous experimental studies, PAHs are also widely accepted to be precursors for soot, or black carbon – a major contributor to climate change. Products of toluene combustion (one of the BTEX aromatics) are known precursors of PAHs that are involved in soot formation. [EPA-HQ-OAR-2022-0829-0570, pp. 20-21]

III. Cleaner burning substitutes are readily available and affordable and should be phased in as quickly as practicable.

1. Ethanol and vehicle performance

a. Like aromatics, alcohols such as ethanol have a much higher octane rating than base refinery gasoline. Increasing ethanol levels raises the octane rating of finished gasoline. In effect, aromatics and ethanol compete for the octane enhancement market. [EPA-HQ-OAR-2022-0829-0570, pp. 30-31]

b. Higher octane enables greater engine efficiency and improved vehicle performance through higher compression ratios and/or more aggressive turbocharging and downsizing – also facilitated by ethanol’s cylinder “charge cooling” effect due to its high heat of vaporization. Raising the engine’s compression ratio from 10:1 to 12:1 could increase vehicle efficiency by 5-7%. [EPA-HQ-OAR-2022-0829-0570, pp. 30-31]

i. The addition of ethanol also hinders the formation of soot precursors, including PAHs, in turn reducing PM emissions. [EPA-HQ-OAR-2022-0829-0570, p. 32]

166 Raza et al., op. cit., supra note 25: p. 15.

ii. Ethanol does not contribute to SOA or PAH formation. [EPA-HQ-OAR-2022-0829-0570, p. 32]

167 U.S. Environmental Protection Agency, "Renewable Fuel Standard Program (RFS2) Regulatory Impact Analysis" (2010): p. 579: https://nepis.epa.gov/Exe/ZyPDF.cgi/P1006DXP.PDF?Dockey=P1006DXP.PDF (accessed Feb. 24, 2021).

d. A 2012 study by Ford engineers examined the influence of ethanol on PM emissions from vehicles with GDI engines. It found a very strong reduction in particle emissions by mid-level ethanol blends above E20. In other words, there was a modest benefit from lower-level blends and a dramatic improvement from mid-level blends: "When the ethanol content increases to >######30%, there is a statistically significant 30%-45% reduction in PM mass and number emissions. [EPA-HQ-OAR-2022-0829-0570, pp. 32-33]

168 M. Matti Maricq et al., "The Impact of Ethanol Fuel Blends on PM Emissions from a Light-Duty GDI Vehicle," Aerosol Science and Technology (2012): 46(5), pp. 576-83: https://www.tandfonline.com/doi/pdf/10.1080/02786826.2011.648780# (accessed June 11, 2021).

- Note: Automakers could quickly adapt to higher-level blends and meet consumer preference for increased engine power and efficiency with a cleaner, often cheaper fuel. In a recent letter, the Alliance for Automotive Innovation, a group of automakers that produce nearly 99% of the new light-duty vehicles sold in the U.S., said: [EPA-HQ-OAR-2022-0829-0570, pp. 32-33]

169 Julia M. Rege, Alliance for Automotive Innovation, letter to Senator Tom Daschle, Chairman, High-Octane Low-Carbon Alliance, June 11, 2021.

[A]s automakers invest significantly in the transition to expanded vehicle electrification, the auto industry is also continuing to invest in vehicle improvements that increase fuel economy and reduce greenhouse gases in internal combustion engine vehicles. Many of the technologies being used to make these improvements can be enhanced or complemented with the use of high octane, low carbon liquid fuels. These fuels would simultaneously support vehicle performance, including fuel economy, and further reduce greenhouse gas emissions during vehicle use. Such benefits would be realized by new and existing internal combustion engines and therefore should be encouraged as additional solutions as soon as possible to maximize environmental benefits across the fleet. Given the timespan over which combustion technology will continue to be sought by new car shoppers, and the timespan that those vehicles will remain in the field, low carbon liquid fuels are an increasingly important technology pathway to help achieve carbon reductions while the electric vehicle market continues to grow. (emphasis added) [EPA-HQ-OAR-2022-0829-0570, pp. 32-33]

e. Ethanol has a long history as a transportation fuel. Henry Ford built his very first car to run on what he called farm alcohol. In 1921 Thomas Midgley, the same engineer who later developed tetraethyl lead for a General Motors subsidiary, drove to a meeting of the Society of Automotive Engineers using a gasoline blend with 30% ethanol. The benefits, he said, included "clean burning and freedom from any carbon deposit … [and] tremendously high compression under which alcohol will operate without knocking. … Because of the possible high compression, the available horsepower is much greater with alcohol than with gasoline." [EPA-HQ-OAR-2022-0829-0570, pp. 32-33]

f. The proven technology used by today's ethanol industry enables rapid scale-up. The industry tripled its production capacity in just four years – from 4.4 billion gallons a year in 2005 to 14.5 billion in 2009. U.S. ethanol production capacity today is 17.4 billion gallons. [EPA-HQ-OAR-2022-0829-0570, pp. 32-33]

172 Renewable Fuels Association, "Essential Energy" (2021): p. 3: https://ethanolrfa.org/wp-content/uploads/2021/02/2021-Pocket-Guide.pdf (accessed Feb. 24, 2021).

i. The transportation fuel infrastructure has also adapted to the increased use of ethanol in cars and light trucks. As 10% ethanol blends became the market's dominant fuel, refiners reduced their use of aromatics and lowered the octane content of their blendstocks. [EPA-HQ-OAR-2022-0829-0570, pp. 33-34]

173 U.S. Environmental Protection Agency, "Modifications to Fuel Regulations To Provide Flexibility for E15," Federal Register (2019): 84(111): p. 26986: https://www.govinfo.gov/content/pkg/FR-2019-06-10/pdf/2019-11653.pdf (accessed Feb. 24, 2021)

174 U.S. EPA, "Fuel Trends Report," op. cit., supra note 14.

ii. New gas pumps are now certified for mid-level ethanol blends.

175 "UL Announces Midlevel Certification for Ethanol Fuel Dispensers," CSP (2009): https://www.cspdailynews.com/fuels/ul-announces-midlevel-certification-ethanol-fuel-dispensers (accessed Feb. 24, 2021).

iii. U.S. ethanol production in recent years has averaged more than 1 million barrels per day. Increasing that level to support an E30 market would displace more oil than the Biden administration's proposed Corporate Average Fuel Economy Standards would save – bringing an oil security premium valued at more than $1 billion per year. [EPA-HQ-OAR-2022-0829-0570, pp. 33-34]

176 U.S. Energy Information Administration, "U.S. fuel ethanol production capacity increased by 3% in 2019," Today in Energy, Sept. 29, 2020: https://www.eia.gov/todayinenergy/detail.php?id=45316 (accessed Aug. 18, 2021); National Highway Traffic Safety Administration, U.S. Department of Transportation, "Corporate Average Fuel Economy Standards for Model Years 2024-2026 Passenger Cars and Light Trucks," proposed rule (Aug. 5, 2021): https://www.nhtsa.gov/sites/nhtsa.gov/files/2021-08/CAFE-NHTSA-2127-AM34-Preamble-Complete-web-tag.pdf (accessed Aug. 18, 2021).

177 U.S. EPA, "Revised 2023 and Later Model Year Light-Duty Vehicle Greenhouse Gas Emissions Standards," op. cit., supra note 128: Table 49, p. 43792.

i. Real-world experience indicates that higher-level blends such as E30 are, like E15, also harmless to existing vehicles. In Watertown, SD, dynamometer testing and on-road driving experience showed that conventional vehicles using E30 benefit from greater horsepower and torque, providing better vehicle performance, drivability, and increased power. They also experience no loss in fuel economy (despite ethanol's lower energy content) due to engine sensors that can recognize the higher octane and adjust spark ignition timing for greater efficiency. [EPA-HQ-OAR-2022-0829-0570, pp. 34-35]

179 Brad Brunner and Andy Wicks, "Fuel Economy and Power Generation of 30% Ethanol (E30) Splash Blended Fuel in Fuel injected Non-FFV Gasoline Engines," Glacier Lakes Energy white paper (2017), gle-e30-challenge-white-paper-1-19-17final.pdf: link at item #12: https://www.forestriverforums.com/forums/f12/towing-with-e30-or-e85-190278.html (accessed Feb. 24, 2021).

1. The State of Nebraska recently conducted similar tests with 50 conventional vehicles and found that "overall performance and adaptability are not compromised by consumption of E30." [EPA-HQ-OAR-2022-0829-0570, pp. 34-35]

180 Adil Alsiyabi et al., "Investigating the effect of E30 fuel on long term vehicle performance, adaptability and economic feasibility," Fuel (2021): 306(121629): https://www.sciencedirect.com/science/article/pii/S0016236121015106 (accessed Aug. 18, 2021).

h. Brazil has been the largest laboratory in the world for ethanol as an automotive fuel, dating back to the launch of the National Alcohol Program in 1975. Ethanol has made up at least 20% of the standard gasoline blend in Brazil almost continuously since 1984. Currently the standard national blend is set at 27%, and one third of the fleet is capable of operating on ethanol alone. [EPA-HQ-OAR-2022-0829-0570, pp. 34-35]

2. Ethanol and climate change

a. A 2017 assessment by the consulting firm ICF concluded that life-cycle greenhouse gas (GHG) emissions associated with producing corn-based ethanol in the United States, using today’s practices in a typical natural gas-powered refinery, are almost 43% lower than those of gasoline on an energy-equivalent basis. [EPA-HQ-OAR-2022-0829-0570, pp. 35-37]

186 M. Flugge et al., “A Life-Cycle Analysis of the Greenhouse Gas Emissions from Corn-Based Ethanol,” Report prepared by ICF for the U.S. Department of Agriculture (2017): p. 166: https://digitalcommons.unl.edu/cgi/viewcontent.cgi?article=2623&context=usdaarsfacpub (accessed Feb. 24, 2021). Similarly: J. Rosenfeld et al. (2018), p. 99: https://www.usda.gov/sites/default/files/documents/LCA_of_Corn_Ethanol_2018_Report.pdf (accessed Feb. 24, 2021).

187 Jan Lewandrowski et al., “The greenhouse gas benefits of corn ethanol – assessing recent evidence,” Biofuels (2018): 11(3): pp. 361-75: https://www.tandfonline.com/doi/full/10.1080/17597269.2018.1546488 (accessed Feb. 24, 2021).

i. This estimate is consistent with more than 15 years of life-cycle analysis at Argonne National Laboratory, recently reaffirmed in a retrospective analysis. It is also more than twice as large as the 21% reduction predicted by EPA in its 2010 life-cycle analysis for ethanol produced by an average natural gas-fired plant in 2022. [EPA-HQ-OAR-2022-0829-0570, pp. 35-37]

188 Argonne National Laboratory, “More about GREET” (The greenhouse gases, regulated emissions, and energy use in transportation (GREET) model), online fact sheet: https://greet.es.anl.gov/homepage2 (accessed Feb. 24, 2021).

190 U.S. EPA, “RFS2 Regulatory Impact Analysis,” op. cit., supra note 167: pp. 468-70.

1. Argonne senior scientist Michael Wang estimates that corn ethanol has resulted in a total GHG reduction in the U.S. of more than 500 million metric tons between 2005 and 2019. [EPA-HQ-OAR-2022-0829-0570, pp. 35-37]

191 Kathryn Jandeska, Argonne National Laboratory, “Corn ethanol reduces carbon footprint, greenhouse gases,” Science X, May 24, 2021: https://phys.org/news/2021-05-corn-ethanol-carbon-footprint-greenhouse.html (accessed Aug. 18, 2021).

ii. A recent “state-of-the-science review” by the consulting firm Environmental Health & Engineering yielded a “central best estimate of carbon intensity for corn ethanol” that was 46% lower than for gasoline. [EPA-HQ-OAR-2022-0829-0570, pp. 35-37]

192 Melissa J. Scully et al., “Carbon intensity of corn ethanol in the United States: state of the science,” Environmental Research Letters (2021): https://iopscience.iop.org/article/10.1088/1748-9326/abde08 (accessed Feb. 24, 2021).

iii. In contrast, for electric and plug-in hybrid vehicles EPA used “tailpipe-only values to determine vehicle GHG emissions, without accounting for upstream emissions” in its proposed rule setting new GHG standards for 2023 and later model years. [EPA-HQ-OAR-2022-0829-0570, pp. 35-37]

193 U.S. EPA, “Revised 2023 and Later Model Year Light-Duty Vehicle Greenhouse Gas Emissions Standards,” op. cit., supra note 128: p. 43746.

1. As EPA notes on its web site, the power used to charge electric vehicles may create carbon pollution, and EPA and DOE’s “Beyond Tailpipe Emissions Calculator” is offered to “help you estimate the greenhouse gas emissions associated with charging and driving an EV or a plug-in hybrid electric vehicle.” [EPA-HQ-OAR-2022-0829-0570, pp. 35-37]

194 U.S. Environmental Protection Agency, “Electric Vehicle Myths” in “Green Vehicle Guide,” online fact sheet: https://www.epa.gov/greenvehicles/electric-vehicle-myths (accessed Aug. 18, 2021).

iv. Another way to assess the value of ethanol is to calculate its net gain in energy content. On that point, a recent USDA report concluded that a corn ethanol plant using conventional fossil fuel power and electricity “produces slightly more than twice the energy in the form of ethanol delivered to customers than it uses for corn, processing, and transportation.” [EPA-HQ-OAR-2022-0829-0570, pp. 35-37]

195 Paul W. Gallagher et al., “2015 Energy Balance for the Corn-Ethanol Industry” (2016), report for U.S. Department of Agriculture, Office of the Chief Economist, Office of Energy Policy and New Uses: p. 18: https://www.usda.gov/sites/default/files/documents/2015EnergyBalanceCornEthanol.pdf (accessed Feb. 24, 2021).

v. California’s Low Carbon Fuel Standard (LCFS) has demonstrated the impact of market-based price incentives for environmental performance. To gain credits under the LCFS, ethanol refineries have steadily reduced their carbon scores through increased production efficiencies, most notably by shifting from coal to natural gas as a process fuel. [EPA-HQ-OAR-2022-0829-0570, pp. 37-38]

1. For the purpose of credits under the LCFS, corn ethanol on average is currently rated as 30% better than its gasoline blendstock. [EPA-HQ-OAR-2022-0829-0570, pp. 37-38]

196 California Air Resources Board, “Low Carbon Fuel Standard – Life Cycle Analysis,” online fact sheet: pp. 16-18: https://ww2.arb.ca.gov/sites/default/files/2020-06/basics-notes_1.pdf (accessed Feb. 24, 2021).

2. LCFS credits have led to an annual average gain in E85 sales of nearly 39% over the last 10 years. [EPA-HQ-OAR-2022-0829-0570, pp. 37-38]

197 California Air Resources Board, "Alternative Fuels: Annual E85 Volumes," online chart (2020): https://ww2.arb.ca.gov/resources/documents/alternative-fuels-annual-e85-volumes (accessed Feb. 24, 2021).

3. Providing credit for soil carbon sequestration under the LCFS would incentivize farmers to employ improved conservation practices. Such practices would reduce ethanol's carbon footprint further – to as much as 70% lower than gasoline, the ICF report found. [EPA-HQ-OAR-2022-0829-0570, pp. 37-38]

198 Flugge et al., op. cit., supra note 186: p. 166. Also Rosenfeld et al., p. 99.

4. In 2020 the House Select Committee on the Climate Crisis recommended that Congress develop a national LCFS reflecting "the best-available science about the carbon intensity of fuel production, farming practices, land use changes, and crop productivity." Such a standard, the report said, should reward producers that use "climate-smart practices that reduce carbon emissions, store soil carbon, and reduce nitrous oxide emissions." [EPA-HQ-OAR-2022-0829-0570, pp. 37-38]

199 U.S. Select Committee on the Climate Crisis, Majority Staff Report: "Solving the Climate Crisis: The Congressional Action Plan for a Clean Energy Economy and a Healthy, Resilient, and Just America" (2020): pp. 101-02: https://climatecrisis.house.gov/sites/climatecrisis.house.gov/files/Climate%20Crisis%20Action%20Plan.pdf (accessed Feb. 24, 2021).

vi. The carbon dioxide produced by the ethanol process is extremely pure – making it easier to capture and reuse than CO2 from a power plant. Ethanol giant Archer Daniels Midland is capturing CO2 from its processing facility in Decatur, IL, and storing it permanently underground – another step that could lower ethanol's carbon footprint. However, this process was made possible by a $141 million federal grant and is not yet justified economically. [EPA-HQ-OAR-2022-0829-0570, pp. 37-38]

200 Archer Daniels Midland Company news release, "ADM Begins Operations for Second Carbon Capture and Storage Project" (2017): https://www.adm.com/news/news-releases/adm-begins-operations-for-second-carbon-capture-and-storage-project-1 (accessed Feb. 24, 2021).

201 U.S. Department of Energy, Office of Fossil Energy, "DOE Announces Major Milestone Reached for Illinois Industrial CCS Project" (2017), news release: https://www.energy.gov/fe/articles/doe-announces-major-milestone-reached-illinois-industrial-ccs-project (accessed Feb. 24, 2021).

1. A recently announced project will capture CO2 from several biorefineries in the Midwest for geologic storage of up to 10 million tons annually in underground saline aquifers in North Dakota. [EPA-HQ-OAR-2022-0829-0570, pp. 38-39]

202 Erin Voegele, "Large-scale CCS project will sequester CO2 from ethanol plants," Ethanol Producer Magazine (2021): http://www.ethanolproducer.com/articles/18001/large-scale-ccs-project-will-sequester-co2-from-ethanol-plants (accessed Feb. 24, 2021).

2. Recently scientists at Argonne National Laboratory reported discovery of a new electrocatalyst that converts CO2 and water into ethanol with very high energy efficiency, high selectivity, and low cost. If proven at scale, this could enable the production of ethanol from CO2 emitted by industrial processes of all kinds. [EPA-HQ-OAR-2022-0829-0570, pp. 38-39]

203 Argonne National Laboratory, "New Electrocatalyst Turns Carbon Dioxide Into Liquid Fuel," SciTechDaily (2020): https://scitechdaily.com/new-electrocatalyst-turns-carbon-dioxide-into-liquid-fuel/ (accessed Feb. 24, 2021).

b. U.S. consumption of gasoline adds roughly 1 billion metric tons of the most significant greenhouse gas, carbon dioxide (CO_2), to the atmosphere per year. [EPA-HQ-OAR-2022-0829-0570, pp. 38-39]

204 U.S. Energy Information Administration, "Monthly Energy Review" May 2020, Table 11.5, Carbon Dioxide Emissions From Energy Consumption: Transportation Sector: https://www.eia.gov/totalenergy/data/monthly/pdf/sec11_8.pdf (accessed Feb. 24, 2021).

i. Based on current consumption rates of gasoline, increasing vehicle fuel economy by 7% with the higher octane of an E30 blend would reduce annual U.S. emissions by 70 million metric tons per year. [EPA-HQ-OAR-2022-0829-0570, pp. 38-39]

205 CO_2 emissions from U.S. light-duty vehicles in 2018 totaled 1050 million metric tons (MMT). A 7% reduction would be 70 MMT per year. U.S. Environmental Protection Agency, "Fast Facts: U.S. Transportation Sector Greenhouse Gas Emissions, 1990-2018," online fact sheet: https://nepis.epa.gov/Exe/ZyPDF.cgi?Dockey=P100ZK4P.pdf (accessed Feb. 24, 2021).

ii. Reducing the share of aromatics in gasoline by 40% – with E30 fuel that is 40% less emitting – would reduce U.S. emissions by another 32 million metric tons per year. [EPA-HQ-OAR-2022-0829-0570, pp. 38-39]

206 Aromatics comprise 20% of U.S. gasoline consumption by light-duty vehicles [U.S. EPA, "Fuel Trends Report," op. cit., supra note 14], producing 200 MMT of CO_2 annually. Replacing 40% of the aromatics, or 80 MMT, with fuel that produces 40% less CO_2 per gallon would reduce total U.S. CO_2 emissions by 32 MMT per year.

iii. GHG emissions from oil refineries would also fall, due to reduced demand for their most intensively refined products. Oil refiners could produce blendstocks for E30 gasoline at a modest additional cost of 1-2 cents per gallon. Reduced refinery throughput and intensity would reduce refinery CO_2 emissions and crude oil consumption. [EPA-HQ-OAR-2022-0829-0570, pp. 38-39]

207 Hirshfeld et al., op. cit., supra note 154: p. 11070.]

1. One assessment found that refinery GHG emissions would decline by 12% to 27% for various E30 cases, due to both lower crude oil throughput and differences in the severity of refining operations. Since the refinery sector emits 180 million metric tons per year, that would mean a further reduction in U.S. GHG emissions of at least 21 million metric tons per year. [EPA-HQ-OAR-2022-0829-0570, pp. 39-40]

208 Vincent Kwasniewski et al., "Petroleum refinery greenhouse gas emission variations related to higher ethanol blends at different gasoline octane rating and pool volume levels," Biofuels, Bioproducts & Biorefining (2016): (10)1: pp. 36-46: https://onlinelibrary.wiley.com/doi/full/10.1002/bbb.1612 (accessed Feb. 24, 2021).

209 U.S. Environmental Protection Agency, "GHGRP Refineries" in "Greenhouse Gas Reporting Program," online fact sheet: https://www.epa.gov/ghgreporting/ghgrp-refineries (accessed Feb. 24, 2021).

iv. Thus, the total reduction in U.S. GHG emissions from adoption of E30 blends – combining fuel economy gains, the replacement of aromatics with a lower-carbon substitute, and the change in refinery operations – would total 123 million metric tons per year. That would be a cut of more than 12% in emissions from light-duty vehicles, which comprise 58% of the emissions from the transportation sector (the source of more GHG emissions than any other sector). It would also exceed the GHG reductions from EPA's strengthened emissions standards for new cars, which reach only 117 million tons in 2050. [EPA-HQ-OAR-2022-0829-0570, pp. 39-40]

210 U.S. EPA, "Revised 2023 and Later Model Year Light-Duty Vehicle Greenhouse Gas Emissions Standards," op. cit., supra note 128: p. 43779.

211 Ibid., Table 43, p. 43778.

1. Valuing the social cost of those avoided emissions at $25 per ton would imply a benefit of more than $3 billion per year. Using the "interim" rate of $51 per ton put forward by the Biden administration in 2021, the benefits would come to more than $6 billion per year. At the rate of $76 per ton used in the administration's proposed Corporate Average Fuel Economy Standards, the benefits exceed $9 billion per year. [EPA-HQ-OAR-2022-0829-0570, pp. 39-40]

212 Interagency Working Group on Social Cost of Greenhouse Gases, United States Government, "Technical Support Document: Social Cost of Carbon, Methane, and Nitrous Oxide Interim Estimates under Executive Order 13990" (2021): Figure ES-1: Frequency Distribution of SC-CO2 Estimates for 2020, p. 5: https://www.whitehouse.gov/wp-content/uploads/2021/02/TechnicalSupportDocument_SocialCostofCarbonMethaneNitrousOxide.pdf (accessed Mar. 1, 2021)

213 National Highway Traffic Safety Administration, op. cit., supra note 176.

v. An aggressive program to increase adoption of electric vehicles is urgently needed to phase out fossil fuels altogether, but even optimistic forecasts recognize that it will take a long time to turn over the U.S. fleet of 250 million light-duty vehicles. (The average age of such vehicles in operation in the U.S. has risen to 12.1 years this year.) Internal combustion engines will still be used in hundreds of millions of vehicles between now and 2050. [EPA-HQ-OAR-2022-0829-0570, p. 40]

214 See, for example, U.S. DRIVE, "Summary Report on EVs at Scale and the U.S. Electric Power System" (2019): U.S. EV Market Penetration Scenarios: pp. 1-2: https://www.energy.gov/sites/prod/files/2019/12/f69/GITT%20ISATT%20EVs%20at%20Scale%20Grid%20Summary%20Report%20FINAL%20Nov2019.pdf (accessed Feb. 24, 2021).

215 IHS Markit, "Average age of cars and light trucks in the US rises to 12.1 years, accelerated by COVID-19," press release, June 14, 2021: https://news.ihsmarkit.com/prviewer/release_only/id/4759502/ (accessed June 21, 2021).

1. California is in the vanguard of the transition to electric vehicles in the U.S., with a newly announced goal of limiting new-car sales in 2035 to zero-emission vehicles. But under the state's LCFS program to date (since 2011), ethanol has reduced GHG emissions nearly three times more than electricity. As more electric vehicles enter the market, that ratio is dropping sharply, but even for the last 12 months reported (through December 2020), ethanol reduced GHG emissions by one third more than electricity – despite being limited almost entirely to E10 blends. [EPA-HQ-OAR-2022-0829-0570, pp. 40-42]

216 Governor of California, Executive Order N-79-20 (2020): https://www.gov.ca.gov/wp-content/uploads/2020/09/9.23.20-EO-N-79-20-text.pdf (accessed Feb. 24, 2021).

217 California Air Resources Board, "2020 LCFS Reporting Tool (LRT) Quarterly Data Summary: Report No. 4" (2021):

https://ww2.arb.ca.gov/sites/default/files/classic//fuels/lcfs/dashboard/quarterlysummary/20210430_q4datasummary.pdf (accessed June 21, 2021).

3. The use of corn for ethanol

a. Almost any plant-based material can made into ethanol. All plants contain sugars, and those sugars can be fermented to make ethanol. Plant material also can be converted to ethanol using heat and chemicals. [EPA-HQ-OAR-2022-0829-0570, pp. 40-42]

b. Today, nearly all ethanol produced in the world is derived from starch- and sugar-based feedstocks. Corn serves as the feedstock for most U.S. ethanol production. Its C4 carbon fixation process (also found in sugarcane) is uncommon among plants and unusually efficient – producing four-carbon compounds instead of the usual three. [EPA-HQ-OAR-2022-0829-0570, pp. 40-42]

218 U.S. Department of Energy, Alternative Fuels Data Center, “Ethanol Feedstocks,” online fact sheet: https://afdc.energy.gov/fuels/ethanol_feedstocks.html (accessed Feb. 24, 2021).

219 Realizing Increased Photosynthetic Efficiency (RIPE), “The difference between C3 and C4 plants,” online fact sheet (2020): https://ripe.illinois.edu/blog/difference-between-c3-and-c4-plants (accessed Feb. 24, 2021).

i. Only about 3% of flowering plant species use the C4 pathway, but this relative handful accounts for 23% of all terrestrial carbon fixation. [EPA-HQ-OAR-2022-0829-0570, pp. 40-42]

220 Elizabeth A. Kellogg, “C4 Photosynthesis,” Current Biology (2013): 23(14): p. R594: https://www.cell.com/current-biology/fulltext/S0960-9822(13)00507-1 (accessed Feb. 24, 2021).

c. Cellulose (plant fiber) also offers several advantages as a biofuel feedstock: It is abundant and can be derived from either agricultural waste or non-food crops such as switchgrass and miscanthus. However, it is challenging to access the sugars in these feedstocks for conversion, and cellulosic ethanol remains more expensive than corn ethanol, which traded for $1.60 a gallon or less for most of the last five years – albeit with a recent spike in 2021. That is roughly half the cost of cellulosic ethanol, which is burdened by the high capital costs of pioneer facilities. [EPA-HQ-OAR-2022-0829-0570, pp. 40-42]

d. The effect of increased corn production to meet ethanol demand has been a subject of long-standing contention in U.S. agricultural and environmental policy. [EPA-HQ-OAR-2022-0829-0570, pp. 40-42]

i. The amount of land planted in corn rose from 60 million acres in 1983 to roughly 90 million since 2010, much of that due to expanding ethanol production, which now accounts for nearly 40% of total corn use. Yet that represents a shift in cropland more than an increase: The overall amount of U.S. cropland in production has changed little over the last 30 years, varying between 300 and 330 million acres+. [EPA-HQ-OAR-2022-0829-0570, pp. 40-42]

224 U.S. Department of Agriculture, Economic Research Service, “Feedgrains Sector at a Glance,” online fact sheet: https://www.ers.usda.gov/topics/crops/corn-and-other-feedgrains/feedgrains-sector-at-a-glance/ (accessed Feb. 24, 2021).

225 U.S. Department of Agriculture, National Agricultural Statistics Service, “2012 Census of Agriculture Highlights: Farms and Farmland” (2014): ACH12-13: https://www.nass.usda.gov/Publications/Highlights/2014/Highlights_Farms_and_Farmland.pdf (accessed Feb. 24, 2021).

226 U.S. Department of Agriculture, National Agricultural Statistics Service, “Crop Production Historical Track Records” (2020): Principal Crops Area Planted and Harvested – United States: 1983-2019: https://downloads.usda.library.cornell.edu/usda-esmis/files/c534fn92g/r781x160h/8w32rq739/croptr20.pdf (accessed Feb. 24, 2021).

ii. Corn yields have increased at a remarkably steady rate of about 1.9 bushels per acre per year since the mid-1950s – quadrupling in that time from 40 to 170 bushels per acre. Between 2002 and 2017 U.S. agriculture gained about 669 million metric tons of corn due to yield improvement. That is equivalent to about 71 billion gallons of ethanol (45% of the ethanol produced during that period) plus 223 million metric tons of byproducts for animal feed. [EPA-HQ-OAR-2022-0829-0570, pp. 40-42]

227 R.L. Nielsen, Purdue University, “Historical Corn Grain Yields in the U.S.” (2020): https://www.agry.purdue.edu/ext/corn/news/timeless/YieldTrends.html (accessed Feb. 24, 2021).

iii. Modern farming uses low-impact, “precision” techniques that require less land, less energy and fewer chemicals for every bushel produced. Since 1980, irrigation water use per bushel has fallen by 46%, energy use by 41%, and greenhouse-gas emissions by 31%. [EPA-HQ-OAR-2022-0829-0570, pp. 42-43]

229 Robert Paarlberg, “The Environmental Upside of Modern Farming,” The Wall Street Journal (2021): https://www.wsj.com/articles/the-environmental-upside-of-modern-farming-11612534962 (accessed Feb. 24, 2021), citing: Field to Market: The Alliance for Sustainable Agriculture, “Environmental and Socioeconomic Indicators for Measuring Outcomes of On Farm Agricultural Production in the United States” (Third Edition) (2016): https://fieldtomarket.org/national-indicators-report-2016/ (accessed Feb. 24, 2021).

iv. With increased acreage and yields meeting the demand for ethanol, the price of corn (apart from a sudden spike in the first half of 2021) traded in a narrow range for the past six years, about half its peak in 2012 and lower than the average inflation-adjusted price from 1981 to the present. [EPA-HQ-OAR-2022-0829-0570, pp. 42-43]

v. Concerns about the impact of ethanol production on food prices have largely abated over that time. A study of eight Asian economies found that 64% of the variance in food prices during the 2000-2016 time period was explained by oil price movement, and only 2% by biofuel prices. [EPA-HQ-OAR-2022-0829-0570, pp. 42-43]

233 Farhad Taghizadeh-Hesary et al., “Energy and Food Security: Linkages through Price Volatility,” Energy Policy (2019): 128: pp. 796-806: https://www.sciencedirect.com/science/article/pii/S0301421518308486 (accessed Apr. 27, 2021).

vi. Controversial claims about large negative “indirect land use” effects of increased corn production have not been borne out by data, as shown in a recent review of the research. Life-cycle analyses by ICF and Argonne both reflect modest assessments of indirect land use effects. EPA and California regulators include land-use factors in their evaluations of ethanol’s GHG emissions, and California’s figure, for example, is only 19% of the very high estimate that kicked off the debate. Argonne’s recent retrospective analysis found that the initial estimate was at least five times overstated – indeed, by Argonne’s estimate, nearly 15 times. [EPA-HQ-OAR-2022-0829-0570, pp. 42-43]

I-25: https://ww2.arb.ca.gov/sites/default/files/classic//fuels/lcfs/iluc_assessment/iluc_analysis.pdf (accessed Feb. 24, 2021) vs. the estimate of 104 gCO2/MJ in Timothy Searchinger et al., “Use of U.S. Croplands for Biofuels Increases Greenhouse Gases Through Emissions from Land-Use Change,” Science (2008), Table 1: 319(5867), pp. 1238-40: https://www.researchgate.net/publication/326450544_Use_of_US_Croplands_for_Biofuels_Increases_Greenhouse_Gases_Through_Emissions_from_Land-Use_Change (accessed Feb. 24, 2021).

239 Lee et al., op. cit., supra note 189, Figure 5.

vii. The Energy Information Administration projects that demand for gasoline will decline from 137.5 billion gallons per year in 2021 to 127 billion gallons in 2050, due to increased vehicle efficiency and greater use of electric vehicles. Fueling the 2050 fleet with higher-level blends such as E30 thus would require little more than a doubling of today’s ethanol capacity. Demand will fall further if electric vehicles are adopted more rapidly than currently envisioned. [EPA-HQ-OAR-2022-0829-0570, pp. 42-43]

240 U.S. Energy Information Administration, “Annual Energy Outlook 2021,” Table 11. Petroleum and Other Liquids Supply and Disposition (Reference case): https://www.eia.gov/outlooks/aeo/data/browser/#/?id=11-AEO2021®ion=0-0&cases=ref2021&start=2019&end=2050&f=A&linechart=ref2021-d113020a.3-11-AEO2021&chartindexed=0&sourcekey=0 (accessed Feb. 24, 2021).

Note: The recurrent affliction of American farmers is overproduction and low prices. Increased demand for ethanol in higher-level blends could be met within today's cropland footprint, absorbing that overproduction and helping to restore farm income. A more robust future market for ethanol would also attract additional investment to the production of next-generation biofuels from cellulosic feedstocks – investment that has been lacking in the face of a saturated market for E10. [EPA-HQ-OAR-2022-0829-0570, pp. 43-45]

e. Environmental concerns about the effects of increased agricultural production on water quality (due to nitrogen fertilizer runoff) can be addressed directly with incentives (e.g., from a low-carbon fuel standard) for improved conservation practices that would increase the amount of carbon sequestered in the soil. [EPA-HQ-OAR-2022-0829-0570, pp. 43-45]

i. Corn may be a particular beneficiary of carbon sequestration incentives, according to studies that looked at carbon stored below the 30-centimeter depth usually measured (12 inches). A long-term study by USDA in eastern Nebraska found that corn grown with best management practices had average annual increases in soil organic carbon of one ton per acre, more than half of it below the 30 cm depth. [EPA-HQ-OAR-2022-0829-0570, pp. 43-45]

241 Ronald F. Follett et al., "Soil Carbon Sequestration by Switchgrass and No-Till Maize Grown for Bioenergy," BioEnergy Research (2012): 5: pp. 866-75: https://www.researchgate.net/publication/256147354_Soil_Carbon_Sequestration_by_Switchgrass_and_No-Till_Maize_Grown_for_Bioenergy (accessed Feb. 24, 2021).

- Note: A combination of best practices – the use of renewable natural gas in processing and carbon-sequestering techniques on the farm – would bring corn ethanol's carbon footprint almost to zero, and carbon capture and storage after processing would make it a carbon-negative fuel. [EPA-HQ-OAR-2022-0829-0570, pp. 43-45]

4. EPA regulation of ethanol blends

a. The Clean Air Act prohibits fuel manufacturers from introducing into commerce, or increasing the concentration of, new fuels and fuel additives unless they are "substantially similar" to fuels or fuel additives used in the certification of motor vehicles. [EPA-HQ-OAR-2022-0829-0570, pp. 43-45]

242 42 U.S. Code, sec.?7545, "Regulation of fuels", subsection (f), "New fuels and fuel additives": https://www.law.cornell.edu/uscode/text/42/7545 (accessed Feb. 24, 2021).

i. Since EPA now uses ethanol (in E10) as its certification fuel for new vehicles, increasing the concentration of ethanol in gasoline is not prohibited. [EPA-HQ-OAR-2022-0829-0570, pp. 43-45]

b. The law separately limits Reid vapor pressure (RVP) – a measure of the fuel's propensity to give off evaporative emissions – for fuel blends containing gasoline and 10% ethanol (E10). EPA granted RVP waivers in 2010 and 2011 to enable the use of E15 in late-model vehicles – those produced from model year 2001 on. [EPA-HQ-OAR-2022-0829-0570, pp. 43-45]

243 Ibid., subsection (h)(4), "Ethanol waiver."

c. In 2019 EPA issued an interpretive rulemaking defining gasoline blended with up to 15% ethanol as "substantially similar" to the E10 fuel it has used since 2014 to certify all new motor vehicles. Referring to the RVP limit, EPA said, “We are interpreting this language as establishing a lower limit, or floor, on the minimum ethanol content … rather than an upper limit on the ethanol content.” However, a federal appeals court struck down that action in 2021. [EPA-HQ-OAR-2022-0829-0570, pp. 43-45]

244 U.S. EPA, “Modifications to Fuel Regulations To Provide Flexibility for E15,” op. cit., supra note 173: pp. 26980-27025.

245 Ibid., p. 26992.

246 American Fuel & Petrochemical Manufacturer v. Environmental Protection Agency, Opinion 19-1124, U.S. Court of Appeals for the D.C. Circuit, July 2, 2021: https://www.cadc.uscourts.gov/internet/opinions.nsf/D33AF132E64A3D1E85258706005062EC/$file/19-1124-1904888.pdf (accessed July 7, 2021).

i. EPA said in its rulemaking, “We are confident that relative evaporative emissions effects for E15 would largely be similar or slightly less than those for E10.” Since the RVP of ethanol blends reaches its maximum level at E10 and then declines as more ethanol is added, this conclusion would be equally true of higher-level blends. In fact, the RVP of E30 is similar to that of E0. [EPA-HQ-OAR-2022-0829-0570, pp. 43-45]

247 U.S. EPA, “Modifications to Fuel Regulations To Provide Flexibility for E15,” op. cit., supra note 173: p. 26993.

248 Wei-Dong Hsieh et al., “Engine performance and pollutant emission of an SI engine using ethanol–gasoline blended fuel,” Atmospheric Environment (2002): 36(3), p. 403: https://www.sciencedirect.com/science/article/abs/pii/S1352231001005088 (accessed Feb. 24, 2021).

249 V.F. Andersen et al., “Vapor Pressures of Alcohol−Gasoline Blends,” Energy Fuels (2010): 24(6): pp. 3647-54, Table S-2: https://pubs.acs.org/doi/full/10.1021/ef100254w (accessed June 11, 2021).

250 C. Hammel-Smith et al., “Issues Associated with the Use of Higher Ethanol Blends (E17-E24)” (2002), Technical Report, National Renewable Energy Laboratory: NREL/TP-510-32206, Table 3-1, p. 13: http://www.nmma.org/lib/docs/nmma/gr/environmental/32206.pdf (accessed July 6, 2021).

- Note: EPA could either certify E30 fuel based on an application from an automaker or simply define E30 as “substantially similar” to E10. The benefits derived from adding ethanol to gasoline – in terms of reduced emissions and improved performance that offsets the lower energy content of ethanol – appear to be optimized around the 30% blend level – as Thomas Midgley found a century ago. [EPA-HQ-OAR-2022-0829-0570, pp. 43-45]

d. Citing the need for “the development of infrastructure and promotion of fuels, including biofuels, which will enable the development and widespread deployment of advanced technologies,” in May 2010 President Obama issued an Executive Memorandum requesting that EPA “review for adequacy the current non-greenhouse gas emissions regulations for new motor vehicles, new motor vehicle engines, and motor vehicle fuels, including tailpipe emissions standards for nitrogen oxides and air toxics, and sulfur standards for gasoline.” Yet no action addressing fuels or mobile source air toxics resulted. [EPA-HQ-OAR-2022-0829-0570, p. 45]

251 The White House, “Presidential Memorandum Regarding Fuel Efficiency Standards” (2010): https://obamawhitehouse.archives.gov/the-press-office/presidential-memorandum-regarding-fuel-efficiency-standards (accessed July 7, 2021).

e. Regarding other air pollutants, a 2008 study by the National Renewable Energy Laboratory found that increasing ethanol content (to E20) reduced hydrocarbon emissions while increasing emissions of ethanol and aldehydes. Vehicles that used a power enrichment strategy called long-term fuel trim (LTFT) to adjust the engine's air-fuel ratio showed no statistically significant fuel effect on emissions, including NOx. [EPA-HQ-OAR-2022-0829-0570, p. 45]

252 Keith Knoll et al., "Effects of Mid-Level Ethanol Blends on Conventional Vehicle Emissions," NREL/CP-540-46570 (2009): 2009-01-2723: pp. 1-16: https://www.nrel.gov/docs/fy10osti/46570.pdf (accessed Feb. 24, 2021).

V. Summary and recommendations

The use of aromatics in gasoline is an unnecessary cause of toxic air pollution that harms and shortens lives – as a major contributor to fine particle emissions, especially dangerous PAHs and secondary organic aerosol. These emissions are a menace to the health and cognitive development of millions of children who live in high-traffic areas. EPA has yet to fulfill its statutory obligation to produce the greatest degree of emission reduction achievable in the hazardous air pollutants from motor vehicles and motor vehicle fuels. The risk to public health has been increased by the shift to new automotive direct-injection engine technology. [EPA-HQ-OAR-2022-0829-0570, pp. 47-49]

Pollution causes many threats to public health, not all of which can be cost-effectively regulated, but it is hard to imagine one that could be solved more easily or at less cost than this one. Reducing the use of aromatics requires only a minor regulatory adjustment and would deliver important benefits for both public health and the environment. Reconsideration of national fuel economy standards provides an opportunity for EPA to: [EPA-HQ-OAR-2022-0829-0570, pp. 47-49]

257 42 U.S. Code, sec.?7521, op. cit., supra note 125.

- -Immediately permit the sale and use of higher-level ethanol blends.

- Encourage their adoption as a standard fuel for vehicles sold in model year 2025 and beyond.

- Reduce the cap on aromatic co ions [EPA-HQ-OAR-2022-0829-0570, pp. 47-49]

The use of aromatics in gasoline is an unnecessary cause of toxic air pollution that harms and shortens lives – as a major contributor to fine particle emissions, especially dangerous PAHs and secondary organic aerosol. These emissions are a menace to the health and cognitive development of millions of children who live in high-traffic areas. EPA has yet to fulfill its statutory obligation to produce the greatest degree of emission reduction achievable in the hazardous air pollutants from motor vehicles and motor vehicle fuels. The risk to public health has been increased by the shift to new automotive direct-injection engine technology. [EPA-HQ-OAR-2022-0829-0570, pp. 47-49]

Pollution causes many threats to public health, not all of which can be cost-effectively regulated, but it is hard to imagine one that could be solved more easily or at less cost than this one. Reducing the use of aromatics requires only a minor regulatory adjustment and would deliver important benefits for both public health and the environment. Reconsideration of national fuel economy standards provides an opportunity for EPA to: [EPA-HQ-OAR-2022-0829-0570, pp. 47-49]

257 42 U.S. Code, sec.?7521, op. cit., supra note 125.

- -Immediately permit the sale and use of higher-level ethanol blends.

- Encourage their adoption as a standard fuel for vehicles sold in model year 2025 and beyond.

- Reduce the cap on aromatic content in gasoline by half – to no more than 12.5% in reformulated gasoline, much as it imposed a cap on benzene in 2007. [EPA-HQ-OAR-2022-0829-0570, pp. 47-49]

258 U.S. EPA, “Control of Hazardous Air Pollutants From Mobile Sources” (2007), op. cit., supra note 131: p. 8477-79.

The California Air Resources Board should do likewise, and its Low Carbon Fuel Standard should become a model for federal legislation, replacing the Renewable Fuel Standard at the national level. Concurrently, automakers should be encouraged to optimize their vehicle designs to take best advantage of ethanol’s beneficial attributes. [EPA-HQ-OAR-2022-0829-0570, pp. 47-49]

We are on the cusp of a rapid global shift to electric vehicles as a necessary and urgent response to climate change, but internal combustion engines will remain a substantial part of the light-duty fleet until mid-century. As a transition strategy for the next 30 years, reducing aromatics through the increased use of ethanol would have significant near-term climate benefits for the transportation sector. The public health benefits – especially to newborn children – demand this change and could be replicated at greater scale, to even greater effect, worldwide. [EPA-HQ-OAR-2022-0829-0570, pp. 47-49]

High-priority opportunities for immediate action

The Clean Air Act prohibits fuel manufacturers from introducing into commerce, or increasing the concentration of, new fuels and fuel additives unless they are “substantially similar” to fuels or fuel additives used in the certification of motor vehicles. Since EPA now uses E10 as its certification fuel for new vehicles, increasing the concentration of ethanol in gasoline to E30 would be permissible. [EPA-HQ-OAR-2022-0829-0570, pp. 47-49]

- EPA should define gasoline blended with 30% ethanol as “substantially similar” to E10. The benefits derived from adding ethanol to gasoline – in terms of reduced emissions and improved performance that offsets the lower energy content of ethanol – appear to be optimized around the 30% blend level. [EPA-HQ-OAR-2022-0829-0570, pp. 47-49]

- Concurrently, upon an automaker’s request for approval of an E30 certification fuel, EPA should move quickly to grant it. This would, among other things, resolve any remaining uncertainties about the effect of higher levels of ethanol on pollutants such as nitrogen oxides and aldehydes, which can be managed by appropriate engine settings and emissions technology. Approval would be a green light to automakers to optimize their new vehicles for higher-octane fuel –enabling them to improve vehicle efficiency and performance. [EPA-HQ-OAR-2022-0829-0570, pp. 47-49]

Near-term regulatory opportunities

- EPA should incorporate the use of higher-octane fuels as an available control strategy for reducing greenhouse gas emissions and increasing fuel economy standards. It should set a minimum octane standard for gasoline used in light-duty vehicles, and that standard should ensure the use of biofuels, not aromatics, to increase octane – either by setting the standard high enough to preclude the use of aromatics only, or by capping the permissible level of aromatics in fuel (at 12.5%, half the current limit for reformulated gasoline), or both. [EPA-HQ-OAR-2022-0829-0570, pp. 47-49]

- EPA and NHTSA should review and revise available incentives for alternative fuels to support the use of biofuels. In particular, the agencies should discard their outdated analysis of ethanol's life-cycle greenhouse gas footprint and conform it to the most recent assessments from USDA and Argonne National Laboratory. [EPA-HQ-OAR-2022-0829-0570, pp. 47-49]

- EPA should revise its MOVES model, which estimates emissions for mobile sources at the national, county, and project level for criteria air pollutants, greenhouse gases, and air toxics. A 2014 update based on erroneous modeling assumptions has caused the model to predict incorrectly elevated emissions factors for ethanol blends. [EPA-HQ-OAR-2022-0829-0570, pp. 47-49]

- More generally, EPA should undertake a thorough revision of its air quality models, which fail to account for secondary organic aerosol – a major contributor to deadly fine particle pollution – and should rely more heavily on atmospheric measurement of pollution levels instead of model predictions. [EPA-HQ-OAR-2022-0829-0570, pp. 47-49]

Longer-term legislative opportunities

The Renewable Fuel Standard has served its purpose but is not well adapted to the urgent need to reduce greenhouse gas emissions. California's Low Carbon Fuel Standard (LCFS) has demonstrated the value, impact, and effectiveness of market-based price incentives for performance and should be adopted by Congress as a substitute for the RFS. [EPA-HQ-OAR-2022-0829-0570, pp. 47-49]

- Congress should develop a national LCFS reflecting "the best-available science about the carbon intensity of fuel production, farming practices, land use changes, and crop productivity." Such a standard should reward producers that use "climate-smart practices that reduce carbon emissions, store soil carbon, and reduce nitrous oxide emissions." In particular, credit for soil carbon sequestration under a national LCFS would incentivize farmers to employ improved conservation practices that would minimize the environmental impacts of corn production. [EPA-HQ-OAR-2022-0829-0570, pp. 47-49]

- Congress should provide incentives to retail gasoline outlets to encourage them to update their refueling infrastructure, including UL-certified pumps and waterproof underground tanks. [EPA-HQ-OAR-2022-0829-0570, pp. 47-49]

Organization: Renewable Fuels Association (RFA)

To achieve the Agency's ambitious emissions reduction goals in the most robust, rapid, and affordable way, EPA should use this rulemaking to encourage multiple additional solutions that can decarbonize light- and medium duty transportation. EPA must also recognize that vehicles and fuels operate as integrated systems. Focusing only on emissions from the vehicle—while ignoring emissions related to the extraction and production of the fuel used to power the vehicle—will almost certainly result in falling far short of the administration's overall climate goals. [EPA-HQ-OAR-2022-0829-0602, pp. 3-4]

Low-carbon liquid fuels like ethanol have a unique and vital role to play in the administration's efforts to combat climate change and reduce overall emissions from the transportation sector—both immediately and in the long term. Fuels such as E15 (15% ethanol) are compatible with nearly all vehicles on the road today, and thus offer immediate emissions benefits on a much larger scale than changes to only new vehicles. In addition, E85 (51-83% ethanol) used in flexible fuel vehicles (FFVs) can substantially reduce GHG emissions from the light-duty vehicle sector. More than 25 million FFVs are already on the road today and FFV production can be ramped up quickly by automakers at no additional cost to the consumer. In the longer term, low-carbon or zero-carbon liquid fuels used in FFVs or plug-in hybrid electric FFVs can offer emissions solutions for market segments and customers that may not be well served by battery electric vehicles (BEVs). [EPA-HQ-OAR-2022-0829-0602, pp. 3-4]

To foster a vibrant and competitive landscape of multiple low-carbon solutions, it is critical for EPA to set performance-based and technology-neutral emissions standards. Unfortunately, the proposed rule falls short of this ideal by focusing narrowly on one technology and only one segment of the GHG emissions lifecycle (i.e., tailpipe emissions). It is essential that EPA look beyond tailpipe emissions; the Agency should use a full lifecycle3 analysis to fairly and accurately compare the climate impacts of all current and future transportation options. [EPA-HQ-OAR-2022-0829-0602, pp. 3-4]

3 Throughout these comments, the terms "full lifecycle analysis" refer to a complete "well-to-wheel" analysis as defined by Argonne National Laboratory.

V. The Proposed Rule Ignores the GHG Reduction Benefits of Ethanol and Other Renewable Liquid Fuels

Renewable fuels like ethanol offer an effective and immediate solution for decarbonizing liquid fuels and ICE vehicles across all segments of the transportation sector. Ethanol has a vital role to play in reducing GHG emissions from the transportation sector, but EPA's proposed emissions standards regrettably fail to provide any mechanisms for capturing these benefits or encouraging greater production and sale of vehicles that can operate on higher levels of low-carbon liquid fuel. [EPA-HQ-OAR-2022-0829-0602, pp. 9-11]

Today's corn starch ethanol already reduces GHG emissions by roughly half, on average, compared to gasoline. According to the Department of Energy's Argonne National Laboratory, typical corn ethanol provides a 44% GHG savings compared to gasoline, even when unverifiable emissions from direct and indirect changes in land cover/land use are included.18 When corn ethanol is compared directly to gasoline (i.e., no indirect emissions included for either fuel), Argonne National Laboratory finds that corn ethanol reduces GHG emissions by 52%, on average, versus gasoline. Similarly, researchers affiliated with Harvard University, MIT, and Tufts University concluded that today's corn ethanol offers an average GHG reduction of 46% versus gasoline, including land use change emissions.19 [EPA-HQ-OAR-2022-0829-0602, pp. 9-11]

18 Lee, U., Kwon, H., Wu, M. and Wang, M. (2021), Retrospective analysis of the U.S. corn ethanol industry for 2005– 2019: implications for greenhouse gas emission reductions. Biofuels, Bioprod. Bioref., 15: 1318- 1331. https://doi.org/10.1002/bbb.2225.

In addition, the California Air Resources Board (CARB) has conducted extensive lifecycle analysis and certified that ethanol produced from the cellulosic biomass found in corn generally reduces GHG emissions by 70-80% compared to gasoline; more than 140 million gallons of ethanol from corn-based cellulosic biomass were used in California in 2021, reducing GHG emissions by nearly 800,000 MT CO2e.20 Overall, CARB found that from 2011 to 2021, the use of ethanol from all feedstocks cut GHG emissions from the California transportation sector by 31 million MT CO2e, more than any other fuel used to meet the state's Low Carbon Fuel Standard (LCFS) requirements.21 All liquid biofuels—including ethanol, renewable diesel, and biodiesel—accounted for 74% of the carbon reductions delivered under the LCFS from 2011 through 2021.22 Similarly, ethanol has generated 45% of the carbon reductions achieved under Oregon's Clean Fuel Program (CFP) since its inception 2016.23 When combined with biodiesel and renewable diesel, liquid biofuels have accounted for 87% of total GHG reductions under the Oregon CFP.24[EPA-HQ-OAR-2022-0829-0602, pp. 9-11]

With the rapid emergence of new technologies and more efficient practices, even greater GHG reductions are coming to the corn ethanol sector. In fact, analysis by the U.S. Department of Agriculture found that some biorefineries are likely already producing corn starch ethanol that offers a 70% GHG reduction versus gasoline.25 Indeed, the U.S. ethanol industry is well on its way to producing corn ethanol that is fully carbon neutral. With the adoption of CCUS, biogas and renewable electricity substitution, and climate- smart farming practices, corn ethanol is expected to achieve net zero emissions, on average, by 2050 or sooner. [EPA-HQ-OAR-2022-0829-0602, pp. 9-11]

25 Jan Lewandrowski, Jeffrey Rosenfeld, Diana Pape, Tommy Hendrickson, Kirsten Jaglo & Katrin Moffroid (2020). "The greenhouse gas benefits of corn ethanol – assessing recent evidence," Biofuels, 11:3, 361-375, DOI: 10.1080/17597269.2018.1546488 https://www.tandfonline.com/doi/full/10.1080/17597269.2018.1546488.

A landmark 2022 study examined numerous technology pathways for corn ethanol producers to achieve net zero emissions, concluding that "…ethanol producers can achieve extremely low corn ethanol emissions and fill a critical need in tomorrow's zero- carbon economy."26 The study found that the corn ethanol industry is likely to meet its goals of producing net-zero ethanol, on average, well before 2050. In fact, RFA's member companies are so confident about the promise of carbon neutral ethanol that they adopted a resolution in 2021 to achieve a net-zero carbon footprint, on average, for ethanol by 2050 or sooner. This pledge was memorialized in a letter to President Biden in July 2021. [EPA-HQ-OAR-2022-0829-0602, pp. 9-11]

26 Emery, Isaac. Informed Sustainability Consulting (2022). “Pathways to Net-Zero Ethanol: Scenarios for Ethanol Producers to Achieve Carbon Neutrality by 2050.” Prepared for the Renewable Fuels Association. https://d35t1syewk4d42.cloudfront.net/file/2146/Pathways%20to%20Net%20Zero%20Ethanol%20Feb%202022.pdf.

It is important to note that the expansion of low-carbon ethanol production in the United States has not resulted in cropland expansion or conversion of native lands (e.g., forest or grassland) to agriculture. As part of the Renewable Fuel Standard (RFS) program, EPA conducts an annual analysis of U.S. agricultural land area to ensure that the RFS has not caused cropland to expand beyond 2007 levels. Each year, EPA’s analysis continues to show that the amount of land engaged in agricultural production is well below the level in 2007 when the RFS was extended and expanded by Congress. Over the last 10 years, the U.S. agricultural land area has averaged 380 million acres, which is 22 million acres less than the agricultural land area in 2007, according to EPA. [EPA-HQ-OAR-2022-0829-0602, pp. 9-11]

In addition to its environmental benefits, ethanol also makes a vital contribution to our nation’s economy. The 199 ethanol biorefineries across the country serve as crucial drivers of employment and income in the communities in which they operate. Even as Russia’s invasion of Ukraine caused a global energy crisis in 2022, and even as abnormally high inflation rates impacted the U.S. economy, the production of 15.4 billion gallons of ethanol directly employed nearly 79,000 American workers in the manufacturing and agriculture sectors. In addition, the ethanol industry supported 343,000 indirect and induced jobs across all sectors of the economy. Meanwhile, the industry generated $35 billion in household income and contributed $57 billion to the national Gross Domestic Product (GDP) in 2022.27 These significant employment impacts and economic contributions should be taken into consideration by EPA as it examines potential future energy and climate regulatory actions that may impact the biofuels sector. [EPA-HQ-OAR-2022-0829-0602, pp. 9-11]

Organization: South Dakota Department of Agriculture and Natural Resources (DANR)

Biofuels

The proposed emissions standards and the effort to use regulations to essentially mandate EV use ignores the benefits of continued use of renewable biofuels to power our vehicles. South Dakota's primary industry is agriculture, and we are the nation's fifth-largest ethanol producer. Ethanol is clean burning, renewable fuel used in our existing vehicle fleet allowing our citizens to travel across our state safely and reliably. Instead of working to mandate EV use, DANR recommends EPA look for ways to support the continued production and use of renewable biofuels. [EPA-HQ-OAR-2022-0829-0523, p. 3]

South Dakota is a rural state with a small population, wide open spaces, and clean air. South Dakota is in full compliance or attainment with all federal criteria pollutants and the proposed emissions standards will not significantly improve our air quality. However, by essentially mandating EV use, they will limit the ability of our citizens to live and work in rural South Dakota. [EPA-HQ-OAR-2022-0829-0523, p. 3]

Organization: Stellantis

Improve Fuels and Implement a Nationwide Low Carbon Fuel Standard

Stellantis supports cost effective liquid fuel improvements that enable increased fuel efficiency and reduce emissions. To that end, Stellantis fully supports Auto Innovators' comments on improved liquid fuels, proposed changes to Tier 3 test fuel, and request for EPA to take action now on fuels.8 [EPA-HQ-OAR-2022-0829-0678, pp. 22-23]

8 See Alliance for Automotive Innovation comments submitted to docket EPA-HQ-OAR-2022-0829, U.S. Environmental Protection Agency, "Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles"; Proposed Rule, 88 Fed. Reg. 29184 (May 5, 2023)

Auto Innovators states in their comments that out of the 290 million light-duty cars and trucks on the road in the United States,9 98% operate on gasoline or diesel fuel.10 Auto Innovators also points out that the average age of a vehicle in the U.S. has grown to over 12 years.11 It's clear, even with the NPRM's projected BEV penetration rate of 67% of new car sales in 2032, the car parc will continue to rely on liquid fuels for years to come. Liquid fuels will continue to play a significant role in transportation and, ultimately, air quality. Improved liquid fuel can benefit the entire parc with immediate impact once deployed and need not rely on turnover or the introduction of new vehicle technology, which can take decades to become widespread. [EPA-HQ-OAR-2022-0829-0678, pp. 22-23]

Improved liquid fuels will complement, not compete with, other technologies like electrification. Improving liquid fuels can provide significant reductions in GHG and non-GHG emissions from ICE equipped vehicles, engines, and equipment while the EV market grows. For example, implementation of a national low carbon fuel standard could act as a market-based approach to decarbonizing transportation fuel and provide revenue sources to incentivize market adoption of EVs. Eliminating a small fraction of heavy boiling aromatics in gasoline can significantly reduce PM emissions from all spark-ignited vehicles and engines. Capping the sulfur content of gasoline to no more than 10 ppm will enable advanced emissions control technology and will reduce the impact of sulfur on catalyst efficiency. Capping summer vapor pressure of gasoline to 9.0 psi or less, regardless of ethanol content, further reduces evaporative emissions. Additionally, octane is a critical fuel parameter for ICE vehicles, and low octane fuels (sub-87 anti-knock index) remain a barrier to market introduction of more efficient ICE vehicles. Furthermore, transitioning to a higher minimum-octane gasoline (i.e., minimum 95–98 research octane number) would enable increased engine efficiency in new ICE vehicles. EPA should act now to improve liquid fuels, treat vehicle and fuels as a system and leverage the opportunities that improved liquid fuels provide to the approximately 290M vehicles in the car parc. [EPA-HQ-OAR-2022-0829-0678, pp. 22-23]

Organization: Strong Plug-in Hybrid Electric Vehicle (PHEV)

In the longer term, EPA, the DOE or the national labs should conduct an analysis on the value of PHEVs as a platform for low-carbon alternative fuels including whether to allow PHEVs with 85% or more low carbon liquid biofuels blended with gasoline to be treated as zero- emission vehicles (ZEVs) in future EPA regulations. The main issue to be studied is feedstock availability in the long run for both diesel and gasoline substitutes that could be used in PHEVs to make them have lower life cycle emissions. Related environmental issues could be studied. [EPA-HQ-OAR-2022-0829-0646, pp. 9-10]

Justification: Some biomass feedstocks used in gasoline can't or won't be used in diesel or jet fuel powered transportation. This should result in large amounts of unused feedstocks because biomass feedstocks for spark-ignited engines may not be needed in the long run (e.g.,2050) for transportation or industrial uses. However, using some of these existing feedstocks would make future PHEVs have even lower full fuel cycle GHG emissions than they have today. Strong plug-in hybrid cars and light trucks using gasoline already can have lower GHG than long range electric cars and light trucks due to the GHG emissions from battery manufacturing and the slightly poorer fuel economy of long-range BEVs. (See Appendix B in this letter). [EPA-HQ-OAR-2022-0829-0646, pp. 9-10]

CARB-funded research by UC Davis,13 shows a PHEV 60 has the same life cycle GHG emissions as a Tesla model S because of the weight of the Tesla and it has fewer GHG life cycle emissions than a heavier BEV with 400- or 500-mile AER. See the first chart below. Toyota's publicly available tool also correctly shows this result.14 Furthermore, the UC Davis analysis does not include battery manufacturing GHG emissions. Using data from the USDOE cradle to grave analysis,15we estimate that adding 350 miles more of AER adds about 10 grams per mile of GHG emissions to the above analysis for a light duty EV. See the next three charts below. Further, a flex fuel vehicle requirement to enable low carbon fuels for these stronger PHEVs would further lower their life cycle GHG. [EPA-HQ-OAR-2022-0829-0646, pp. 18-20]

Organization: T. Becker Power Systems

1- It is unlawful for EPA to thwart or prevent the implementation of any technology that has the ability to meet the environmental goals of any rule or regulation proposed by EPA. [EPA-HQ-OAR-2022-0829-0567, p. 1]

2- This proposed rule/regulation intentionally thwarts the use of liquid and gaseous fuel technologies that, if implemented, can meet the air quality goals of the proposed rule. [EPA-HQ-OAR-2022-0829-0567, p. 1]

Organization: Toyota Motor North America, Inc.

5. We encourage EPA to consider a role for low-carbon liquid fuels (LCLFs) in future rulemaking. This is the only viable option to reduce GHG emissions from the existing U.S. fleet of 270 million vehicles. Regardless of how quickly the needed shift to electrification occurs, vehicles with internal combustion engines (ICEs) will be on U.S. roads in large numbers for decades to come. Failure to provide a GHG-reduction solution for this massive source of emissions would be missing an enormous opportunity. [EPA-HQ-OAR-2022-0829-0620, p. 2]

5. GHG Program

The Proposed Rule fails to demonstrate the penetration of BEVs assumed for compliance with the proposed standards is feasible. The proposal notes “While emission standards set by the EPA under CAA section 202(a)(1) generally do not mandate use of particular technologies, they are technology-based, as the levels chosen must be premised on a finding of technological feasibility.”17 CAA section 202(a)(1) states “Any regulation prescribed under paragraph (1) of this subsection (and any revision thereof) shall take effect after such period as the Administrator finds necessary to permit the development and application of the requisite technology, giving appropriate consideration to the cost of compliance within such period.”18 [EPA-HQ-OAR-2022-0829-0620, pp. 25-26]

17 88 Fed. Reg at 29232.

18 42 U.S.C. § 7521(a)(2).

The aggressive ramp up of BEVs (see Table 1) required to comply forces a rapid transformation of how vehicles are manufactured, driven, fueled, and serviced. As such, “leadtime and requisite technology” must extend to the availability of critical minerals, the readiness of a sustainable battery supply chain and fueling infrastructure, as well as other market-related factors that will affect the price and consumer demand of BEVs. [EPA-HQ-OAR-2022-0829-0620, pp. 25-26]

[Table 1 Annual BEV Penetration Assume for Compliance w/ Proposed Standards [EPA-HQ-OAR-2022-0829-0620, pp. 25-26]

MY 2027: BEV Share 36

MY 2028: BEV Share 45

MY 2029: BEV Share 55

MY 2030: BEV Share 60

MY 2031: BEV Share 63

MY 2032: BEV Share 67]

Today's PEV support system clearly cannot meet the needs of the future envisioned by the proposal. Our comments explain why the proposal lacks a clear justification for how the support system will be in place over the period of the proposed standards. Neither EPA nor auto manufactures can control the timing or outcomes of these essential support measures. [EPA-HQ-OAR-2022-0829-0620, pp. 25-26]

Therefore, it is disappointing that EPA removed the e-RIN proposal from the RFS set rule as it is one of the few measures for which EPA has direct authority to provide at least some level of assistance in supporting the EV shares required in the GHG proposal. After a muti-year collaboration with the auto industry, a valuable policy tool for establishing PEV markets and promoting clean energy has been lost. [EPA-HQ-OAR-2022-0829-0620, pp. 25-26]

Finally, EPA has taken a more measured view of technology risk and uncertainty in past vehicle emissions rulemakings in which technology costs were lower and automakers had significantly more direct control over managing their technology development, deployment, and sales mix to comply. In this Proposed Rule, EPA appears to be taking a much more cavalier approach to risk, lead time, and ensuring the "requisite technology" is available, despite the high cost of BEVs, the massive uncertainty around mineral supplies, the significant investment needed in charging infrastructure and the power grid, and the uncertain market demand for BEVs. The standards in the Final Rule should be adjusted to better account for market uncertainties. [EPA-HQ-OAR-2022-0829-0620, pp. 25-26]

8. Low Carbon Fuels

EPA needs to return to treating fuels and vehicles as a holistic system to capture the benefits of low carbon fuels. Low carbon liquid fuels are (1) technically feasible today, (2) the only viable decarbonization solution for the legacy vehicle fleet, (3) an important complement to vehicle electrification over a long transition, and (4) factor for a range of consumers whose needs or budgets require different solutions. [EPA-HQ-OAR-2022-0829-0620, pp. 46-48]

Toyota has been working with fuels industry partners to demonstrate the technical feasibility of low carbon fuels today. In April 2023, Toyota announced work with ExxonMobil to test research fuels in Toyota's advanced engines and vehicles. ExxonMobil reports their innovative fuels have potential to reduce greenhouse gas emissions up to 75% compared to conventional fuels available today.36 During that same month, Toyota and Chevron demonstrated a real-world use-case of Chevron's Renewable Gasoline Blend (RGB). Toyota and Chevron drove three Toyota vehicles almost 1,000 miles across parts of Mississippi, Louisiana, and Texas. Chevron reports a 40% lower carbon intensity for Chevron RGB compared to traditional gasoline on a lifecycle basis. These low carbon liquid fuels are compatible with the existing vehicle fleet and existing infrastructure and are technically feasible today. The US ethanol industry continues to make great strides in reducing carbon the carbon intensity of their product. In a 2021 study, researchers from Harvard, Tufts, and EH&E estimated corn ethanol was 46% lower carbon intensity compared to average gasoline.37 The Renewable Fuels Association reports their fuel producing members aim to reduce their lifecycle ethanol GHG by at least 70% on average compared to gasoline by 2030, and achieve net- zero lifecycle GHG by 2050.38 Since the vast majority of the 280 million vehicles on US roads today have an internal combustion engine, decarbonizing liquid fuels on a well-to-wheel basis would yield immediate benefits for lowering the carbon intensity of transportation energy. [EPA-HQ-OAR-2022-0829-0620, pp. 46-48]

36 Reductions in Carbon Intensity (CI) estimates are based on the lifecycle greenhouse gas emission of the fuels tested at Toyota's Research Center, compared to petroleum gasoline. Estimated CI values are based on either GREET 2021 estimates, or feedstock Proof of Sustainability documents. Actual results may vary.

37 Melissa J Scully et al 2021 Environ. Res. Lett. 16 043001.

38 Renewable Fuels Association. (2021, July 27). RFA Pledge to President: Ethanol to Achieve Net Zero Emissions by 2050 or Sooner Link: https://ethanolrfa.org/media-and-news/category/news-releases/article/2021/07/rfa-pledge-to- president-ethanol-to-achieve-net-zero-emissions-by-2050-or-sooner.

Low carbon fuels are an additional pathway for reducing transportation GHG. This pathway offers a hedge against uncertainties that could affect the pace of electrification, such as critical mineral supply and charging infrastructure development. The combination of low carbon fuels with hybrids and PHEVs shows excellent overall GHG performance while optimizing usage of potentially scarce critical minerals. In this way, low carbon fuels would be complementary to vehicle electrification and future GHG goals during the long energy transition. [EPA-HQ-OAR-2022-0829-0620, pp. 46-48]

Low carbon fuels preserve consumer choice on vehicles while still supporting decarbonization of transportation energy. Proposed regulations should factor for a range of consumers whose needs or budgets require different solutions. Vehicle electrification will proceed at different paces in different regions. Full vehicle electrification could take longer in rural areas or other locations lacking sufficient charging infrastructure. If forecasts for future battery costs prove inaccurate, it would have disparate impact on different socioeconomic levels. A diverse set of solutions offers more certainty of both emissions reductions and affordability, which is consistent with environmental justice objectives. Low carbon liquid fuels are an important part of enabling all vehicle owners/users to play a role in reducing emissions. [EPA-HQ-OAR-2022-0829-0620, pp. 46-48]

Organization: Transfer Flow, Inc

Transfer Flow disagrees with EPA's transportation technology biases.

A singular fixation focusing only on tailpipe emissions reduction does not consider important life-cycle emission analysis.1 Vehicular emissions should be considered from the cradle to the grave, from manufacturing and usage to end-of-life disposal of both the vehicle and the energy used to power the vehicle or equipment. Requiring new vehicles sold to either be battery electric vehicles (BEVs), plug-in electric hybrids (PHEV), or fuel-cell battery electric vehicles crowds out other near-zero technologies. Implementation of any and all available near-zero technologies should be encouraged for a multitude of reasons. [EPA-HQ-OAR-2022-0829-0496, pp. 1-2]

1 https://www.youtube.com/watch?v=S1E8SQde5rk

All near-zero technologies should be ramped up and implemented as quickly as feasible in order to help meet the EPA's pollution prevention goals. Encouraging the sales of all new vehicles or equipment to contain some sort of electric vehicle technology and, therefore, also contain a heavy-duty battery instead of encouraging the adoption of the plethora of currently available near-zero technologies is a disservice to the citizens of our great country. [EPA-HQ-OAR-2022-0829-0496, pp. 1-2]

It's going to take a suite of technologies to achieve carbon neutrality.

The EPA's technology bias serves to stymie other clean technologies currently being implemented. The anaerobic practices that create renewable natural gas and biofuels created by keeping organic matter out of landfills should be encouraged. [EPA-HQ-OAR-2022-0829-0496, pp. 5-6]

One of the major contributing factors to the devastating wildfires affecting California over the last several years is, besides climate change, decades of forest mismanagement leading to unhealthy forests filled with rotting biomass. A healthy forest is a carbon sink, and an unhealthy forest is a carbon source. In 2022, UC Berkeley published a study that the best way to clean up these unhealthy forests would be to convert that rotting biomass into renewable drop-in gasoline, which requires no change in behavior from consumers.25 It's simply a different and compatible product being dispensed from the gasoline refueling station. [EPA-HQ-OAR-2022-0829-0496, pp. 5-6]

25 https://bof.fire.ca.gov/media/mn5gzmxv/joint-institute-forest-biofuels_final_2022_ada.pdf

The infrastructure buildout and grid reliability needed to support fleet electrification will take considerable time and funding to achieve. The basic strategy of electrifying transportation delays our dependency on fossil fuels and falls short of immediately reducing greenhouse gas emissions with currently available technologies as well as significantly mitigating short-term criteria pollutants methane, black carbon, and CO2. All near-zero transportation technologies, electric, fuel cell, biofuels, renewable natural gas, biodiesel, renewable diesel, sustainable aviation fuels26, and hydrogen internal combustion engines27'28'29'30'31'32'33 are all needed to drive our great nation towards a sustainable future. [EPA-HQ-OAR-2022-0829-0496, pp. 5-6]

Transfer Flow suggests the EPA encourage usage of all near-zero technologies. [EPA-HQ-OAR-2022-0829-0496, pp. 5-6]

Organization: Transport Evolved LLC (Transportation Consultancy)

3) While calls have been made (mostly from the fossil fuel industry) for the EPA to adopt a "Well to Wheel" calculation, due to the poor quality of data available from the oil and gas industry on the amount of pollution produced, at this point a shift to 'Well to Wheel' calculation would be highly counterproductive.4,5 Should the fossil fuel industry provide accurate, timely and thoroughly researched, independently verified data on the amount of pollution it produces, then it might be more viable, but given the substantial secondary effects (as noted above) it seems incredibly difficult to quantify the harms to society from continuing to allow significant fossil fuel extraction for energy use. [EPA-HQ-OAR-2022-0829-0453, p. 2]

Organization: U.S. Chamber of Commerce

American businesses are playing an essential role in addressing climate change, and the business community is an essential partner in the development of sound policies that protect our environment. We strongly support the continued transition to lower-carbon fuels and vehicles, and are committed to partnering with EPA, the Department of Transportation, and other federal stakeholders to facilitate a successful transition. [EPA-HQ-OAR-2022-0829-0604, p. 1]

EPA Summary and Response

Summary:

Numerous commenters stated that millions of ICE vehicles will remain in widespread use for many years, so it will be beneficial for EPA to incentivize lower-carbon liquid fuels alongside the phase-in of BEVs. Several commenters criticized EPA's proposal for being too narrowly focused on BEVs while ignoring a broader array of options like biofuels and hybrid powertrains. A commenter asserted that EPA has the authority to regulate fuels and vehicles as a holistic system in reducing GHGs.

Some said EPA should put in place a federal low-carbon fuel standard, citing California's program as an example, while others suggested providing certification pathways for higher octane and higher ethanol blends, setting a 95 RON requirement for market fuel, and eliminating fuels with AKI below 87. A commenter encouraged EPA to consider the broad range of fuel-related options that are proven and could be cheaper and faster than widespread rollout of BEVs, including co-processing of biofeedstocks with petroleum, methane production from waste digesters, and carbon capture and sequestration.

Several commenters disagreed with EPA's analyses counting zero CO_2 emissions from EVs, saying that a full lifecycle analysis was needed to evaluate a full range of options, including liquid fuels, and truly make the standards technology-neutral. A commenter stated that Flex-Fuel PHEVs operated on E85 can provide lifecycle GHG performance equivalent to BEVs. Another noted that a proper lifecycle analysis for liquid fuels has not been possible because of the poor quality of data being released by the oil and gas industry, and thus it may be difficult to quantify the harms to society from continued fossil fuel use.

Commenters from biofuel groups highlighted the many hurdles and uncertainties in international supply chains for battery production, meanwhile the domestic ethanol industry has been producing billions of gallons of low-carbon fuel each year while continually reducing their lifecycle emissions. They noted that expansion of ethanol blends can be done with minimal additional infrastructure, something that EPA could further incentivize by establishing carbon intensity factors, FFV multipliers, revising the fuel economy R-factor for E10 test fuel to 1.0, and recognizing ethanol's potential as a high-octane replacement for aromatics. A commenter suggested there is additional potential for net GHG reductions through properly valuing and incentivizing low-carbon agricultural practices where, for example, farmers could earn LCFS credits for acres managed according to certain guidelines. Some ethanol and corn producers stated that they expect rapid vehicle electrification to reduce corn demand and prices, eliminating biofuel jobs and hurting rural communities.

Response:

Implicit (or in some cases, explicit) in many of these comments is that the proposed standards in some manner mandate use of BEVs. They do not. As explained in preamble Sections I and III and RTC 2.3, the final standards are numerical performance-based standards, and can be met in any manner an automaker sees fit that achieves compliance with that numerical standard. In assessing a modeled potential compliance pathway that includes a range of technologies that include ICE vehicles, hybrids, PHEVs, and BEVs, EPA was illustrating one possible approach for compliance as part of its conclusions that the final standards are feasible and appropriate; EPA was not requiring that manufacturers utilize that modeled potential compliance pathway. This is the Agency's approach for all of its CAA Title II standards, following the template set forth initially by the D.C. Circuit in NRDC v. EPA, 655 F. 2d at 332, and echoed many times since in succeeding rules and court opinions.

These standards are vehicle emission standards, and EPA considers all comments asserting that EPA must, or should, set or determine compliance with such standards in a manner other than by reference to emissions from the vehicle as comments asserting that EPA must, or should, consider life cycle assessment. For EPA's response to comments on life cycle assessment, see the next RTC section, 19.2.

EPA recognizes that changes to fuel requirements can result in emission reductions but disagrees that such changes are within the scope of this rulemaking or that EPA is required to consider them as alternatives to this rulemaking, which is concerned with vehicle and engine standards under section 202(a). The CAA has a separate and distinct set of requirements for engaging in fuels regulations and EPA has not at this point undertaken the requisite analyses to regulate GHGs under section 211(c). Indeed, section 211(c)(2)(A) provides that fuel may not be regulated to control harmful air pollution except after "consideration of other technologically or economically feasible means of achieving emissions standards under section [202]." Thus, it is entirely appropriate (if not required) for the Administrator to take the technologically and economically feasible steps of this rule before undertaking further controls on fuels to address emissions reduction.

In light of this statutory structure, with very different regulatory programs for vehicles standards under section 202 and fuels standards under section 211, EPA disagrees that it is required to consider fundamentally altering this rulemaking from a vehicles rulemaking to a fuels rulemaking. "While an agency must consider and explain its rejection of 'reasonably obvious alternative[s],' it need not consider every alternative proposed nor respond to every comment made. Rather, an agency must consider only 'significant and viable' and 'obvious' alternatives." *Nat'l Shooting Sports Found., Inc. v. Jones*, 716 F.3d 200, 215 (D.C. Cir. 2013) (citations omitted). At this point, given that EPA has not met the statutory prerequisites for new fuels controls, much less proposed new fuels controls, the adoption of new fuels controls is not a viable alternative. For these reasons, EPA considers comments in support of adopting changes to fuels requirements as beyond the scope of this rule.

EPA of course continues to separately implement the Renewable Fuel Standard (RFS) program, which provides requirements and incentives to encourage the domestic consumption of low carbon liquid fuels, including cellulosic fuels, under the RFS program pursuant to section 211(o) of the CAA. The most recent renewable fuel standards require the largest volumes to date of renewable fuel use in the U.S. transportation sector. (See 88 FR 44468, July 12, 2023).

19.2 - Life cycle analysis

Comments by Organizations

Organization: 25x'25 Alliance, et al.(25X25)

3) adopts a life-cycle analysis approach to calculating and comparing emissions from different technologies. [EPA-HQ-OAR-2022-0829-0573, pp. 1-4]

Embracing and enabling a pathway to improve fuel quality will increase and accelerate emission reductions, improve public health, help achieve environmental justice goals, provide greater versatility, and improve reliability all at less cost. This pathway is available to EPA and the consideration of it is demanded by the Clean Air Act. The best and most recent data suggests that the adoption of even mid-level ethanol blends would reduce pollution emissions at least as much as EPA's electrification approach, and at far less cost.

Even if EPA's electrification program could be successful—and as explained above, it cannot—a complimentary fuel improvement would double EPA's projected emissions reduction. The current rule takes this option off the table and leaves those pollutants in the air. EPA could do far better. [EPA-HQ-OAR-2022-0829-0573, pp. 1-4]

1 See "Higher Ethanol Blends Support the Transition to a Low-Carbon Future," Brian West, SAE Update, February 2023, pp2-6) National adoption of mid-level ethanol blends is available, feasible, and lower cost than current gasoline. https://www.nxtbook.com/smg/sae/23UPD02/index.php#/p/2

E. Comments on Estimated Social benefits of the CO2 Standards

In this section, Auto Innovators comments on the major categories of estimated social benefits for the CO2 performance standards for model years 2027-2032. [EPA-HQ-OAR-2022-0829-0701, pp. 285-288]

1. Local/Regional Air Quality benefits from Control of Criteria Air Pollutants

The final regulatory impact analysis should acknowledge that the peer-reviewed scientific literature does not generally support the agency's claim that a shift from ICEs to BEVs in the light-duty sector will reduce criteria air pollution across the country. In 2021, Burnham et al. of Argonne National Laboratory (DOE) presented a regional U.S. lifecycle analysis of the impact of BEVs through 2050, accounting for upstream emissions of criteria air pollutants at the powerplant. The abstract of their paper concludes as follows: [EPA-HQ-OAR-2022-0829-0701, pp. 285-288]

We generated state-level emission factors using a projection from 2020 to 2050 for three light-duty vehicle types. We found that BEVs currently provide GHG benefits in nearly every state, with the median state's benefit being between approximately 50% to 60% lower than gasoline counterparts. However, gasoline vehicles currently have lower total NOx, urban NOx, total PM2.5, and urban PM2.5 in 33%; 15%; 70%; and 10% of states, respectively. BEV emissions will decrease in 2050 due to a cleaner grid, but the relative benefits when compared to gasoline vehicles do not change significantly, as gasoline vehicles are also improving over this time. [EPA-HQ-OAR-2022-0829-0701, pp. 285-288]

The results of this study concerning total PM2.5 are especially concerning because the agency's quantified criteria-pollutant benefits in this rulemaking are dominated by an alleged advantage of BEVs with respect to PM2.5 control. Moreover, the lifecycle analysis by Burnham et al. (2021) is published in the peer-reviewed literature, while the agency's lifecycle inputs and analysis have not been peer reviewed by qualified experts. For the final rule, Auto Innovators believes it is unwise for the agency to rely on its lifecycle analysis of criteria air pollutant control as a primary rationale for the final rule. [EPA-HQ-OAR-2022-0829-0701, pp. 285-288]

Insofar as criteria air pollution control is considered a primary rationale for a rule that regulates CO2 emissions, we recommend that the agency go beyond an analysis of average ICE emissions and consider "best-in-class" vehicle emissions in the baseline. For example, in a peer-reviewed contribution, Winker et al. (2018) compared HEVs and BEVs in terms of criteria air pollution emissions. When the upstream emissions from BEVs are included, they find that BEV emissions are 0.06 grams per mile (NOx) while average HEV emissions are 0.004 grams per mile (NOx and HC). The results of Winkler et al. are consistent with an earlier paper by Michalek et al. (2011), which found that HEVs and PHEVs, with small battery packs, are environmentally and economically superior to BEVs. Thus, HEVs may be a superior technological option for criteria air pollution control than BEVs, at least in some regions of the country and until the upstream and manufacturing emissions of BEVs are controlled. [EPA-HQ-OAR-2022-0829-0701, pp. 285-288]

2. Climate Change Benefits

Auto Innovators sees CO_2 emissions control as the primary rationale for the agency's rulemaking. We urge the agency to take great pains to ensure that the CO_2 benefits in the final RIA are not exaggerated significantly, as this will make the entire rulemaking vulnerable to reversal, which will create tremendous regulatory uncertainty for our members. The agency's IPM modeling contains three glaring errors or exaggerations that contribute to an overestimation of the CO_2 emissions benefits of the rule. [EPA-HQ-OAR-2022-0829-0701, pp. 288-289]

First, the state-of-the art lifecycle analyses (LCAs) of BEVs in the scientific literature account for the upstream emissions associated with a BEV's use of the electrical grid and the emissions associated with the supply chain of lithium ion batteries for use in BEVs (e.g., Peters et al, 2017; Hall and Lutsey, 2018; Cox et al, 2020; Koroma et al, 2020; Woody et al 2022). EPA's LCA tries to account for the grid-related emissions within the IPM model but ignores the CO_2 emissions in the supply chain of lithium ion batteries. This is a serious error because the production of lithium ion batteries requires enormous amounts of energy, especially in the mining and processing of raw materials. The MIT group estimates that building a new EV can produce up to 80% more GHG emissions than building a comparably-sized gasoline-powered vehicle. The ICCT study that EPA cites attributes approximately 100 grams per kilogram of CO_2 to a model year 2021 BEV – 60% from grid-related emissions, 40% from battery production (primarily mining and processing of raw materials in the BEV supply chain). [EPA-HQ-OAR-2022-0829-0701, pp. 288-289]

In the structure of EPA's analysis, the battery-production emissions, once added, will be even more important than the grid-related emissions because they occur immediately, in the years that the BEVs are produced (model years 2027 to 2032); they do not gradually decline over the lifetimes of the vehicles as the grid becomes cleaner. The U.S. will not be able to build its own mining and processing sector quickly (e.g., due to permitting obstacles), as standard timelines for new lithium mines in the U.S. are 7 to 12 years. The BEVs sold in the United States from 2027 to 2032 will likely make use of mined and processed materials from countries around the world (e.g., the average grid-associated emissions in 2022 were 530 g/kWh CO_2 in China compared to 368 g/kWh in the United States). Over the long run, the Inflation Reduction Act may reduce the amount of CO_2 emissions in the battery supply chain, but the IRA is unlikely to have much impact on mining and processing in the United States between 2023 and 2027-2032, and the new mining/processing sites in the U.S. may access energy from powerplants using fossil fuels. [EPA-HQ-OAR-2022-0829-0701, pp. 288-289]

Third, as mentioned earlier, the EV deployment induced by the EPA rule will occur predominantly in non-ZEV states while the EPA rule will have little incremental effect on EV deployment in the ZEV states (which account for 30-40% of the new vehicle population). The ICCT study that EPA cites reports that, in 2019, the California grid produced only 225 g/kWh CO2 while the U.S. average grid (even accounting for a gradually cleaner grid from 2021 to 2038) produces 357 g/kWh. Thus, the grids in the non-ZEV states are associated with much larger emissions than the grids in the ZEV states. Funke et al. (2023, p. 43 and Figure B3, Appendix B) make the same point with information on the grids in all ZEV states (not just California). To avoid exaggerating the climate benefits of the rule, the agency should assume that most of the BEVs deployed due to the role will be in non-ZEV states that, today, have more carbon-intensive electricity sectors. Organization: American Free Enterprise Chamber of Commerce (AmFree) et al.

EPA exacerbates that arbitrarily selective approach in the proposed rule's method for measuring compliance. EPA proposes to determine whether man- ufacturers' fleets meet the new standards based solely on their tailpipe emissions—disregarding the other downstream and all upstream emissions caused by producing and operating vehicles. EPA's proposal thus would skew producers' and purchasers' incentives toward electric vehicles even though they may increase emissions overall. [EPA-HQ-OAR-2022-0829-0683, p. 5]

EPA's Analysis Of Net Emissions Is Flawed

EPA estimates that the proposed rule will result in a net reduction of GHG, criteria air pollutant, and air toxic emissions in 2055. See 88 Fed. Reg. at 29,198. That estimate is dubious. In numerous ways, EPA has underestimated the up-stream emissions—i.e., those that do not come from the vehicle itself but can still be attributed to its manufacture and operation—that will result from a widespread shift to electric vehicles. [EPA-HQ-OAR-2022-0829-0683, pp. 55-56]

First, EPA improperly cabins its upstream analysis to only those emissions caused by electricity generating units ("EGUs") and refineries. See 88 Fed. Reg. at 29,198, 29,347, 29,353, 29,355; Draft RIA at 9-32–33. But the emissions as-sociated with powering a vehicle—whether by electricity from an EGU or fuel from a refinery—are far from the only ones reasonably attributed to its opera-tion. Depending on the vehicle, there are also emissions associated with pro-ducing, recycling, and disposing of batteries; operating charging infrastructure; and extracting, refining, transporting, and storing petroleum fuels. These emis-sions can be substantial and, when considered together, may undermine EPA's assumption that swapping internal-combustion-engine vehicles for electric ones will necessarily result in an environmental good. [EPA-HQ-OAR-2022-0829-0683, pp. 55-56]

The International Energy Agency's discussion of emissions from mining il-lustrates this point. According to the IEA, "the production and processing of energy transition minerals are energy-intensive" and involve "relatively high emission[s]." Role of Critical Minerals at 15, 130; see also Charging Infrastructure Challenges for the U.S. Electric Vehicle Fleet, Am. Transp. Rsch. Inst., https://ti-nyurl.com/3ktjd85v ("Mining and processing produce considerable CO2 and pollution issues."). For this reason, producing an electric vehicle is a more car-bon-intensive process than producing a conventional one. Role of Critical Miner-als at 194. [EPA-HQ-OAR-2022-0829-0683, pp. 55-56]

EPA never explains why emissions from EGUs and refineries are the only ones relevant to the analysis. Instead, it acknowledges that "[t]he upstream emissions inventory does not account for all upstream sources related to vehicles, fuels, and electricity generation, such as charging infrastructure, stor-age of petroleum fuels, battery manufacture, etc." Draft RIA at 8-14. But EPA makes no attempt to justify that selective, incomplete approach. [EPA-HQ-OAR-2022-0829-0683, pp. 55-56]

Moreover, EPA's current position marks a change from settled agency prac- tice. In earlier GHG and criteria-pollutant rulemakings, the agency did con- sider additional upstream sources in assessing net emissions. See SAFE Vehicles Rule for Model Years 2021-2026 Passenger Cars and Light Trucks, 85 Fed. Reg. 24,174, 24,872 (Apr. 30, 2020) (noting that emissions "model accounts for up- stream emissions" from "extraction, transportation, refining, and distribution of . . . fuel"); Greenhouse Gas Emissions Standards and Fuel Efficiency Standards for Medium- and Heavy-Duty Engines and Vehicles, 76 Fed. Reg. 57,106, 57,301 (Sept. 15, 2011) ("To project these impacts, EPA estimated the impact of reduced pe- troleum volumes on the extraction and transportation of crude oil as well as the production and distribution of finished gasoline and diesel."); Greenhouse Gas Emissions and Fuel Efficiency Standards for Medium- and Heavy-Duty Engines and Vehicles—Phase 2, 81 Fed. Reg. 73,478, 73,852 (Oct. 25, 2016) ("To project these impacts, Method B estimated the impact of reduced petroleum volumes on the extraction and transportation of crude oil as well as the production and distribution of finished gasoline and diesel."). The agency has not acknowl- edged its change in position here, let alone explained "why the new approach" of ignoring these upstream emissions "better comports with . . . the provisions that Congress enacted." Am. Fed'n of Gov't Emps. v. FLRA, 25 F.4th 1, 12 (D.C. Cir. 2022). That is reason enough to conclude that "the [agency] has not, in fact, engaged in reasoned decisionmaking." Id. (internal quotation marks and brackets omitted). Nor could EPA offer a valid explanation for its change. Up- stream emissions are more important in the current rulemaking than they were in previous regulations given that EPA, for the first time, intends to effectively mandate widespread adoption of electric vehicles, which (as explained above) produce emissions primarily through upstream sources. [EPA-HQ-OAR-2022-0829-0683, p. 56]

Finally, EPA may be substantially overestimating the decrease in refinery emissions. The agency's "central analysis estimates that . . . reduced liquid fuel demand results in reduced domestic refining." 88 Fed. Reg. at 29,358; see also id. at 29,198, 29,353. But at the same time, EPA "recognize[d] that there is significant uncertainty in the impact on refinery emissions due to decreased demand." Draft RIA at 8-12. Indeed, there is a distinct "possibility that reduced domestic demand for liquid fuel would have no impact on domestic refining." 88 Fed. Reg. at 29,358 (emphasis added); see Draft RIA at 8-12 ("If refineries do not decrease production in response to lower domestic demand" and "in- crease exports" instead, total upstream emissions "would be higher," not lower. (emphasis added)). EPA must explain the basis for its assumption that refiner- ies will decrease production before it factors these sizeable reductions into the calculation. See Int'l Harvester Co. v. Ruckelshaus, 478 F.2d 615, 645 (D.C. Cir. 1973) (explaining that EPA must "support its methodology as reliable" with more than "speculation"). [EPA-HQ-OAR-2022-0829-0683, p. 58]

In sum, EPA's analysis of upstream emissions rests on unfounded assump- tions and methodological choices that are skewed in favor of the proposed rule. EPA should withdraw its proposal and conduct a more thorough assessment of the ways in which a widespread shift to electric vehicles will impact overall emissions.7 [EPA-HQ-OAR-2022-0829-0683, p. 58]

7 EPA's superficial analysis of upstream emissions also undermines its discussion of "the envi- ronmental justice impacts of [its] proposal." 88 Fed. Reg. at 29,393; see id. at 29,199, 29,393–97. Although the agency acknowledges that upstream emissions can negatively affect certain populations, it improperly discounts those negative effects by failing to consider emissions as- sociated with anything other than EGUs and refineries, speculating that the emissions from EGUs will decrease over time due to changes in the future generation mix, and overestimating the decrease in refinery emissions.

The Method For Measuring Compliance Is Irrational

Under existing rules, beginning in model year 2027, manufacturers are re- quired to account for upstream emissions as part of their compliance calcula- tion. See 88 Fed. Reg. at 29,197. But under the proposed rule, EPA has explic- itly changed course and would "remove[]" that requirement—meaning that electric vehicles, rather than fairly reflecting their actual total emissions, would "be counted as zero grams/mile in a manufacturer's compliance calculation." Id. In other words, EPA proposes that vehicle compliance with the new stand- ards be measured solely by the grams of pollutants emitted from the tailpipe. Id. To survive arbitrary-and-capricious review, EPA must provide a reasoned explanation for this change and show that there are "good reasons" for its new policy. Encino Motorcars, LLC v. Navarro, 579 U.S. 211, 221 (2016) (internal quo- tation marks omitted). The proposed rule does not do so. [EPA-HQ-OAR-2022-0829-0683, p. 59]

First, EPA attempts to justify its change in position by explaining that it does not include upstream emissions when calculating the compliance of inter- nal-combustion-engine vehicles, contending that the principle of equal treat- ment requires that it take the same approach for electric vehicles. See 88 Fed. Reg. at 29,252. But that compares apples to oranges. These vehicle technologies emit air pollutants in different ways. Internal-combustion-engine vehicles cause emissions mostly from the tailpipe, whereas electric vehicles cause emissions mostly by other means. The timing and manner of their respective emissions is thus fundamentally different. Granularly focusing on tailpipe emissions would mean that almost none of the emissions from electric vehicles are counted, while almost all of the emissions from vehicles with internal-combustion vehicles are. If equal treatment is the goal, EPA must account for both types of emissions when calculating compliance, rather than myopically focusing on tailpipe emis- sions, which prejudges any analysis in favor of electric vehicles. [EPA-HQ-OAR-2022-0829-0683, p. 59]

Second, EPA states that it originally proposed including upstream emissions in compliance calculations at a time when there was “little if any regulation” of those upstream sources for GHGs, noting that this approach was “a depar- ture from its usual practice of relying on stationary source programs to address pollution risks from stationary sources.” 88 Fed. Reg. at 29,252. Now that power-generation emissions are declining, EPA asserts that “manufacturers should not account for upstream utility emissions” any longer. Id. That circular explanation assumes that the only or principal reason to consider upstream emissions is to indirectly regulate the power-generation industry itself—to make each unit of power generated by that industry cleaner. But as EPA acknowledges elsewhere in the proposed rule, it designs vehicle-emissions standards to force vehicle manufacturers to adopt technology that reduces the harmful emissions it is charged with regulating. See, e.g., id. at 29,233. Thus, if a vehicle has no tailpipe emissions but massive upstream emissions—e.g., from producing vehicles and their components, and from generating increased amounts of electricity to operate them—incentivizing manufacturers to incor- porate that vehicle into their fleets would be contrary to the agency’s stated goal. The increased regulation of stationary sources will not solve this problem. Increased reliance on electric vehicles will increase demand for the electricity that the power-generation industry produces, and improvements in emissions per unit of power generated would not address the total increase in emissions. Moreover, regulation of stationery sources will not capture many of the up- stream emissions associated with electric vehicles. As discussed above, operat- ing charging infrastructure and producing, recycling, and disposing of batteries all result in emissions. If upstream emissions are not included in the compliance calculation, these emissions may not be accounted for at all. [EPA-HQ-OAR-2022-0829-0683, pp. 59-60]

EPA itself correctly recognized elsewhere in the proposed rule that up- stream emissions are relevant to its overall effort to address the “well-docu- mented buildup of GHGs due to human activities.” 88 Fed. Reg. at 29,207. For instance, when estimating the proposed rule’s impact on overall emissions, as well as the costs and benefits that it generates, EPA took into account at least some (though far from all) relevant upstream emissions. In doing so, EPA acknowledged that it would be irrational to adopt a rule that decreases down- stream emissions but has the effect of increasing overall emissions. The same principle applies here: It would be irrational to find a manufacturer’s fleet com- pliant if the vehicles within the fleet have lower tailpipe emissions but cause emission of harmful pollutants in other ways that exceeds the levels permitted for tailpipe emissions. EPA offers no explanation for this inconsistent approach to upstream emissions. [EPA-HQ-OAR-2022-0829-0683, pp. 59-60]

Moreover, factoring a broader set of emissions into the compliance calcula- tion will not be difficult or unduly burden EPA. The agency has already devel- oped a method for attributing some of these emissions to manufacturers. In its proposed rule, EPA explained that it initially planned to take emissions from electricity generation into account by “attribut[ing] a pro rata share of national CO2 emissions from electricity generation to each mile driven under electric power minus a pro rata share of upstream emissions associated with . . . gasoline production.” 88 Fed. Reg. at 29,252. That method remains available now. And EPA could develop similarly simple and administrable techniques to account for other key sources of upstream emissions like battery production. [EPA-HQ-OAR-2022-0829-0683, pp. 60-61]

For all of these reasons, EPA's proposed method of calculating compliance is irrational. Any final rule must comprehensively account for the emissions generated by electric vehicles to ensure that EPA's solution (a widespread shift to electric vehicles) bears a rational connection to its regulatory goal of reducing harmful emissions. Cf. Am. Fed'n of Gov't Emps., 25 F.4th at 9 (faulting agency for failing to explain why the standard it adopted will address "the principal problem the new standard is designed to fix"). [EPA-HQ-OAR-2022-0829-0683, pp. 60-61]

Organization: American Fuel & Petrochemical Manufacturers (AFPM)

We are also troubled by EPA's failure to evaluate the lifecycle emissions of various powertrains and the national security implications of the proposal. Focusing exclusively on "tailpipe" emissions paints a distorted picture and perpetuates the false notion that electric vehicles are "zero emitters." EPA must present the public with a complete picture, one that shows how the various powertrains stack up against each other cradle-to-grave and the major carbon reductions that vehicle manufacturers and fuel producers have made over the last few decades and continue to make. EPA's failure to do so would render any final rule arbitrary and capricious. [EPA-HQ-OAR-2022-0829-0733, pp. 1-2]

Even if EPA had Congressional authority to promulgate the proposed standards, the proposal is arbitrary and capricious due to the Agency's reliance on incomplete facts, overly optimistic or outright mistaken assumptions, and failure to use reason-based decision-making. The Agency significantly overestimates environmental benefits and feasibility, underestimates costs, and relies on little more than unsupported hope that consumer preferences will change to enable the Agency's intended policy. EPA's decision to not only ignore lifecycle emissions of ZEVs, but to explicitly propose removing the requirement for automakers to account for them, serves neither consumers nor the environment. EPA's reasoning, that its policy of not accounting for these emissions serves its goal of promoting the use of EVs, is the definition of arbitrary and capricious biased decision-making. Unfortunately, the Agency also ignored significant issues related to energy security and U.S. national security. [EPA-HQ-OAR-2022-0829-0733, p. 2]

The purported benefits in terms of reductions in cost, greenhouse gas emissions, and environmental impacts are based on flawed analyses and will not be realized by consumers. EPA's tailpipe-only approach is flawed, and the Agency needs to evaluate light- and medium-duty vehicles on a full lifecycle basis, regardless of whether those emissions result from electricity generation, battery production, or the combustion of liquid or gaseous fuels. Consumer benefits from the proposal are exaggerated by assuming an unrealistic baseline rate of ZEV-adoption, and inadequate assessments of ZEV purchase and ownership costs, charging costs, and road infrastructure costs. [EPA-HQ-OAR-2022-0829-0733, p. 3]

SEE ORIGINAL COMMENT FOR EVs Require Over 4x the Critical Minerals of an ICE Figure 1: Metal intensity – ICEVs vs. EV8 [EPA-HQ-OAR-2022-0829-0733, p. 5]

8 TURNER, MASON & COMPANY. "Evaluation of EPA's Assumptions and Analyses Used in Their Proposed Rule for Multi-Pollutant Emissions Standards" (June 7, 2023) (Research funded by AFPM and available upon request) [hereinafter "Turner Mason Report"].

C. In the Alternative, EPA Should Set Separate Emissions Standards for Each Vehicle Class.

The Clean Air Act authorizes EPA to establish and revise standards for the emissions of air pollutants from “any class or classes of new motor vehicles or new motor vehicle engines….that endanger public health or welfare”111 Assuming for sake of argument EPA has authority to set emissions standards for EVs, which we posit it does not,112 EPA should promulgate distinct emissions standards for each vehicle class on the basis of the vehicle’s powertrain (e.g., diesel, gasoline, natural gas, electricity). At a minimum, this would obligate EPA to abandon its position that ZEVs are emission-less and account for upstream and other lifecycle emissions as the agency envisioned in its 2012 rule.113 This approach would ensure that EPA is regulating relevant pollutants from specific vehicle classes and would promote a level playing field for different vehicle technologies.114 [EPA-HQ-OAR-2022-0829-0733, p. 26]

111 42 U.S.C.§ 7521(a)(1).

112 As discussed in Section III.A., supra, the CAA sec. 202 does not authorize EPA to regulate ZEV emissions because EPA characterizes them as having “zero” emissions.

113 75 Fed. Reg. 25,324, 25,341 (May 7, 2010).

114 42 U.S.C. § 7521(a)(3)(A)(ii) (“In establishing classes or categories of vehicles or engines for purposes of regulations under this paragraph, the Administrator may base such classes or categories on gross vehicle weight, horsepower, type of fuel used, or other appropriate factors.”). Although this section of CAA Section 202 references “heavy-duty” vehicles, this applies to light-duty vehicles that weigh more than 6,000 lbs gross vehicle weight rating, such as light-duty heavy trucks, and if EPA has authority to set emissions standards for EVs, the Clean Air Act does not otherwise limit EPA’s discretion to expand its classification of vehicles by fuel type.

ZEVs are entirely distinct from other classes of vehicles. Their powertrain design frontloads emissions, meaning the air pollutants associated with these vehicles are emitted before operation (i.e., during vehicle production and recharging). During operation, a ZEV experiences no direct drivetrain emissions. In contrast, most emissions from ICEVs generally occur during operation, not production and refueling. Such different emissions points require different regulatory standards. [EPA-HQ-OAR-2022-0829-0733, p. 26]

AFPM suggests that EPA establish separate emission standards based on the lifecycle emissions of a ZEV and ascribe those emissions to the vehicle over its useful life. Previous regulatory history supports such an approach. [EPA-HQ-OAR-2022-0829-0733, p. 27]

For example, while EPA did not set widely varying emission standards for methanol-fueled vehicles versus “conventionally fueled” vehicles, the Agency discussed how lifecycle emissions were relevant to its determination of Clean Air Act vehicle emission standards: [EPA-HQ-OAR-2022-0829-0733, p. 27]

Methanol vehicles could have an impact on global warming (i.e., the “greenhouse effect”) as well. While increased combustion efficiency may result in lower carbon dioxide (CO2) emissions from methanol-fueled vehicles compared with petroleum-fueled vehicles, the overall impact of a shift to methanol-fueled vehicles on global warming is uncertain. The analysis of the impact must include the effect of not only emissions from the vehicles, but also emissions from methanol production. [EPA-HQ-OAR-2022-0829-0733, p. 27]

In the long-term, the implications of using methanol as a transportation fuel are difficult to predict. Should petroleum and natural gas prices rise substantially, it is probable that methanol would be produced from coal. Assuming vehicle miles traveled, and other factors remain constant and assuming current process technology, a methanol-fueled system using methanol derived from coal could result in as much as a doubling of the motor vehicle contribution to the greenhouse effect relative to the contribution of current petroleum fuels.121 [EPA-HQ-OAR-2022-0829-0733, pp. 27-28]

121 Id. at 14451-2.

EPA's continued reliance on attribute-based regulation of light duty vehicles which focuses solely on the "footprint" of a vehicle cannot be justified in relation to the larger goals expressed in the Proposed Rule. The statute directs EPA to address "class or classes" of vehicles and EVs constitute such a severable class where emissions must be considered based on the full attributes (including lifecycle GHG emissions) of that class of vehicles. [EPA-HQ-OAR-2022-0829-0733, pp. 27-28]

EPA compounds this flaw by making unsupported assumptions regarding the total emissions impacts of its Proposal. While it claims that the overall analysis for combined downstream and upstream emissions "likely underestimates the net emissions reductions that may result" from the Proposed Rule, EPA fails to offer a data-based substantiation. The Proposed Rule failed to assess emissions from battery manufacturing or electricity production. EPA acknowledges that its standards will increase the demand for electricity and that demand will simultaneously increase emissions from the electric generating sector, but by making the unsupported assumption that low carbon electricity will be readily available, it makes no real attempt to quantify those emissions or compare them to alternative options for reducing emissions from this sector. EPA must provide a more comprehensive analysis to comply with its directive under the Clean Air Act and better assess the resulting impact of the Proposed Rule. [EPA-HQ-OAR-2022-0829-0733, pp. 42-44]

In addition, activities associated with mining produce GHG emissions, particulate matter emissions, nitrogen oxide emissions, and other air pollutant emissions from mining equipment. As shown in Figure 8, mining and processing several minerals and metals used for ZEV production are carbon intensive. [EPA-HQ-OAR-2022-0829-0733, pp. 45-46]

SEE ORIGINAL COMMENT FOR Average GHG emissions intensity for production of selected commodities. Figure 8: 210 [EPA-HQ-OAR-2022-0829-0733, pp. 45-46]

210 IEA Report 2022 at 17.

Source: INTERNATIONAL ENERGY ADMINISTRATION

The process for extracting and processing critical minerals can be responsible for approximately 20 percent of the lifecycle GHG emissions from battery production.211 EPA failed to weigh any of these consequences appropriately in the Proposed Rule. [EPA-HQ-OAR-2022-0829-0733, pp. 45-46]

211 H.C. Kim, et al., ENVIRONMENTAL SCIENCE AND TECHNOLOGY (Vol. 50) "Cradle-to-Gate Emissions from a Commercial Electric Vehicle Li-Ion Battery: A Comparative Analysis," (2016), pp. 7715–22.

Another critical aspect of the Proposed Rule not comprehensively considered is that recycling of the battery and related electrical components of ZEVs is in a state of infancy and poses unique materials handling and safety challenges. EPA should consider the environmental profiles of both ZEVs and ICEVs in light of the production, operation, and disposal of the vehicle (its useful life). The following list provides just some of the electric battery disposal-related issues that are likely to impact the environment and need to be addressed by EPA in the Proposed Rule: [EPA-HQ-OAR-2022-0829-0733, pp. 47-48]

- Battery packs could contribute 250,000 metric tons of waste to landfills for every 1 million retired ZEVs.212 [EPA-HQ-OAR-2022-0829-0733, pp. 47-48]

212 Kelleher Environmental, "Research Study on Reuse and Recycling of Batteries Employed in Electric Vehicles: The Technical, Environmental, Economic, Energy and Cost Implications of Reusing and Recycling EV Batteries", (September 2019) available at https://www.api.org/oil-and-natural-gas/wells-toconsumer/fuels-and-refining/fuels/vehicle-technology-studies.

- Less than five percent of Li-ion batteries, the most common batteries used in ZEVs, are currently being recycled "due in part to the complex technology of the batteries and cost of such recycling."213 [EPA-HQ-OAR-2022-0829-0733, pp. 47-48]

213 Gavin Harper, Roberto Sommerville, et al., NATURE, "Recycling lithium-ion batteries from electric vehicles" (Jan. 21, 2020) available at https://www.nature.com/articles/s41586-019-1682-5.

- Economies of scale will play a major role in improving the economic viability of recycling, for which currently cost is the main bottleneck. Increasing collection and sorting rates is a critical starting point.214 [EPA-HQ-OAR-2022-0829-0733, pp. 47-48]

214 IEA Report 2022

- The cathode is where most of the material value in a Li-ion battery is concentrated. Currently, there are numerous cathode chemistries being deployed. Each of these chemistries needs to be known, and then the appropriate method of recycling identified, which poses a challenge, as batteries pass through a global supply chain and all materials are not well tracked. [EPA-HQ-OAR-2022-0829-0733, pp. 47-48]

- Lithium can be recovered from existing Li-ion recycling practices but is not economical at current lithium prices. [EPA-HQ-OAR-2022-0829-0733, pp. 47-48]

- BMI forecasts that near-term recyclers are likely to use scrap material from the increasing number of gigafactories coming online versus used electric vehicle batteries. Scrap is anticipated to account for 78 percent of recyclable materials in 2025.215 [EPA-HQ-OAR-2022-0829-0733, pp. 47-48]

215 Benchmark Minerals Intelligence, "Battery production scrap to be main source of recyclable material this decade" (Sept. 5, 2022) available at https://source.benchmarkminerals.com/article/battery-production-scrap-to-be-main-source-of-recyclable-material-this-decade.

- In 2022, BMI expected over 30 gigawatt hours of process scrap to be available for recycling, growing ten-fold across the next decade. Loss rates vary by region and tend to be higher in earlier years of a gigafactory.216 [EPA-HQ-OAR-2022-0829-0733, pp. 47-48]

216 Id.

- Many 'spent' EV batteries still have 70-80 percent of their capacity left, which is more than enough to be repurposed into other uses such as energy storage and other lower- cycle applications for approximately another 10 years.217 This will extend the time that batteries and raw materials remain in use and therefore increase the demand for virgin critical minerals. [EPA-HQ-OAR-2022-0829-0733, pp. 47-48]

217 Pagliaro, M. and Meneguzzo, F., "Review Article: Lithium battery reusing and recycling: A circular economy insight," Heilyon 5: E01866 (June 15, 2019) available at https://doi.org/10.1016/j.heliyon.2019.e01866

- Clear guidance on repackaging, certification, standardization, and warranty liability of spent ZEV batteries would be needed to overcome safety and regulatory challenges reuse poses at scale.218 [EPA-HQ-OAR-2022-0829-0733, pp. 47-48]

218 IEA Report 2022.

- Recycling ZEV batteries to recover high-value metals has not been proven to a commercial scale. The majority of analysts are aligned that recycling will not become an integral supplier of raw materials until the 2030s, and at that point, only will provide approximately 20 percent of demand.219 [EPA-HQ-OAR-2022-0829-0733, pp. 47-48]

219 Benchmark Minerals Intelligence, supra at n. 105.

- Unlike ICEVs, EPA has recently stated that ZEV batteries may need to be handled as hazardous waste, further driving up the cost of such recycling efforts.220 [EPA-HQ-OAR-2022-0829-0733, pp. 47-48]

220 Letter from Carolyn Hoskinson, Director, EPA Office of Resource Conservation and Recovery, "Lithium Battery Recycling Regulatory Status and Frequently Asked Questions," (May 24, 2023).

- Whether sufficient recycling capacity can be permitted and constructed to facilitate the Proposal. [EPA-HQ-OAR-2022-0829-0733, pp. 47-48]

EPA must, therefore, conduct a full LCA to compare all environmental impacts to reasonably conclude that the Proposal will decrease environmental impacts rather than merely shift them. [EPA-HQ-OAR-2022-0829-0733, pp. 47-48]

Organization: American Petroleum Institute (API)

b. API Supports the Concepts of a Lifecycle Approach to Emissions Reductions.

i. EPA should use a lifecycle assessment (LCA) approach vs. tailpipe only.

To effectively achieve emissions reductions in the transportation sector, technology- neutral solutions are needed, utilizing an approach that addresses fuels, vehicles, and infrastructure systems. This is best accomplished through holistic policy that encompasses the lifecycle emissions of both the fuel and the vehicle. This combination makes for the most effective reduction of transportation GHG emissions, as emissions occur at multiple stages of the lifecycle of internal combustion engine vehicles (ICEVs) and battery electric vehicles (BEVs) and the fuels used in them. Further, utilizing a lifecycle approach would enable quantification of the emissions associated with light- and medium-duty vehicles (LMDVs), and allow technologies to be identified that provide more expeditious and robust GHG emissions reductions. [EPA-HQ-OAR-2022-0829-0641, p. 2]

Use of a lifecycle approach would better achieve the goals of the proposed rule, as it would allow the agency and stakeholders alike to fully identify and reduce transportation sector emissions and to identify and develop meaningful solutions. The reductions achieved by EPA's existing programs – including the Tier 3 Motor Vehicle Emissions and Fuel Standards, Heavy-Duty (HD) GHG Phase 2 standards, and HD engine and vehicle criteria pollutant standards – are due in large part to addressing emissions holistically, and utilizing all available and emerging technology to do so. The myopic focus on tailpipe emissions in the proposed rule essentially means that the rule would only address certain transportation emissions, while ignoring other sources of emissions and potential emissions reduction solutions. A lifecycle approach would allow EPA to quantify all of the emissions associated with LMDVs, and to mitigate those emissions more effectively. [EPA-HQ-OAR-2022-0829-0641, p. 2]

EPA has set the GHG emissions standards as attribute-based, using vehicle footprint as the attribute. As per EPA, "footprint is defined as a vehicle's wheelbase multiplied by its average track width—in other words, the area enclosed by the points at which the wheels meet the ground. The standards are therefore generally based on a vehicle's size." In Draft Regulatory Impact Analysis (DRIA) Section 1.1.2, EPA states that "footprint does not have any relationship with tailpipe emissions from BEVs or any other zero-emission vehicle." Yet, the proposed footprint-based standards are based on a projected penetration rate of BEVs of greater than 50%. A footprint-based tailpipe emission standard where, for the majority of the feet, there is "no relationship" between footprint and tailpipe emissions could drive undesirable behaviors. For example, the weight of BEVs increases as the footprint is increased. This increase in weight impacts the efficiency of larger BEVs. With BEVs on the same footprint curve as internal combustion engines (ICEs) (with a positive slope) in a tailpipe emission banking and trading system, larger BEVs will generate a larger credit relative to their footprint. This could incentivize the production of larger more inefficient BEVs, increasing the upstream electricity generation emissions. The largest potential credit generator based on the proposal would be large BEV trucks which are the most inefficient BEVs. While BEVs have zero tailpipe emissions, the upstream electricity production does generate GHG emissions. Analysis by Argonne National Laboratory2 showed that a current midsize sedan with 200-mile range could achieve 124 mile per gallon gasoline equivalent (MPGge) while a heavier and larger 400-mile range small sport utility vehicle (SUV) could achieve 88 MPGge. This corresponds to cradle-to-grave lifecycle emissions of ~160 and 250 g CO2eq / mile, respectively. For comparison, the same analysis found that a current midsize hybrid ICE would generate ~270 g CO2eq / mile, similar to the 400-mile range SUV. The emissions from the hybrid ICE could be further reduced with lower-emission fuels. Under the current proposal, the hybrid ICE from this example would generate tailpipe emissions of 190 g CO2 / mile, while the BEVs would generate zero tailpipe emissions. EPA should consider a rulemaking that accurately accounts for all emissions in the lifecycle of a vehicle. [EPA-HQ-OAR-2022-0829-0641, p. 2]

2 Kelly, J. et al., "Cradle-to-grave lifecycle analysis of U.S. light-duty vehicle-fuel pathways: a greenhouse gas emissions and economic assessment of current (2020) and future (2030-2035) technologies", June 2022, ANL- 22/27. https://greet.es.anl.gov/publication-c2g_lca_us_ldv.

By EPA's own account,3 transportation pollution has been reduced significantly since the passage of the Clean Air Act – new passenger vehicles are 98-99% cleaner for most tailpipe pollutants compared to the 1960s, new vehicle estimated real-world CO2 tailpipe emissions are at a record low,4 and U.S. cities have much improved air quality, despite ever increasing population and increasing vehicle miles traveled. Criteria pollutant emissions have been mitigated via engine and after-treatment system improvements as well as through fuel quality improvements (e.g., low sulfur gasoline and ultra-low sulfur diesel). As noted in a study prepared for the Transportation Energy Institute, criteria pollutants are well controlled with the existing feet, and ICEV emissions will continue to be reduced into the future as the ICEV feet becomes more efficient (especially as high-emitting vehicles are replaced in the existing feet).5 [EPA-HQ-OAR-2022-0829-0641, p. 2]

4 2022 EPA Automotive Trends Report – Executive Summary, December 2022, EPA-420-S-22-001. https://www.epa.gov/system/files/documents/2022-12/420s22001.pdf.

5 "Decarbonizing Combustion Vehicles: A Portfolio Approach to GHG Reductions," study prepared for the Transportation Energy Institute by Stillwater Associates, July 2023. https://www.transportationenergy.org/research/reports/decarbonizing-combustion-vehicles-a-portfolio-approach- to-ghg-reductions/.

These reductions are due in large part to addressing emissions holistically and utilizing all available and emerging technology to do so. Use of a lifecycle approach would better achieve the goals of the proposed rule, as it would allow the agency and stakeholders alike to fully identify and reduce transportation sector emissions and to identify and develop meaningful solutions. The myopic focus on tailpipe emissions in the proposed rule essentially means that the rule would only address certain transportation emissions, while ignoring other sources of emissions and potential emissions reduction solutions. A lifecycle approach would allow EPA to quantify all emissions associated with light- and medium-duty vehicles6 and more effectively mitigate those emissions. [EPA-HQ-OAR-2022-0829-0641, p. 2]

6 EPA's proposed rule covers light-duty vehicles (i.e., less than 8,500 pounds gross vehicle weight rating) and medium-duty vehicles (i.e., up to 14,000 pounds GVWR), https://afdc.energy.gov/data/10380.

ii. Zero emission vehicles also have emissions impacts.

As with ICEVs, ZEVs7 have carbon emissions impact associated both with their production and throughout their lifetime which EPA should incorporate in its analysis. While ZEVs can be an important part of a diverse transportation future to reduce emissions, they do produce GHG emissions. For instance, BEV production, use, and the disposal of BEV batteries, are not zero-emission activities. Further, all fuels – whether conventional fuels or electricity – have associated carbon emissions regardless of their source. A study conducted by Ricardo, which is included in a report by the Transportation Energy Institute,8 concludes that BEVs "have higher embedded GHG emissions" and therefore carbon intensity of the electricity mix also plays a vital role in defining the magnitude of carbon emissions in this phase. While meaningful reductions have historically been accomplished by focusing on tailpipe emissions from the vehicle, the growing market share of different technologies that include significant upstream emissions warrant inclusion of those emissions in the standard. [EPA-HQ-OAR-2022-0829-0641, pp. 5-6]

7 In these comments, "ZEV" refers broadly to PHEVs, FCEVs and BEV refers specifically to battery electric vehicles.

8 Ricardo, Inc. "Life Cycle Analysis Comparison: Electric and Internal Combustion Engine Vehicles", study prepared for the Transportation Energy Institute (formerly known as the Fuels Institute). January 2022. https://www.transportationenergy.org/research/reports/life-cycle-analysis-comparison-electric-and-internlife- cycle-analysis-comparison-electric-and-intern.

We encourage the agency to not only acknowledge and address the emissions of ZEVs, but to also continue to study the impacts. Failure to do both would be arbitrary and capricious. As noted below in these comments, and in our comments on the Heavy-Duty GHG Phase 3 proposed rule,9 we strongly recommend that EPA include both a readiness assessment prior to program implementation as well as a program review once implementation begins. There will be CO2 emissions associated with the production and use of BEVs,10 and it is important to address these emissions to provide a full picture of the emissions impacts and mitigation needs. [EPA-HQ-OAR-2022-0829-0641, pp. 8-9]

9 API Comments on "Greenhouse Gas Emissions Standards for Heavy-Duty Vehicles—Phase 3", Document ID EPA-HQ-OAR-2022-0985-1423.

10 Kelly, J. et al., "Cradle-to-grave lifecycle analysis of U.S. light-duty vehicle-fuel pathways: a greenhouse gas emissions and economic assessment of current (2020) and future (2030-2035) technologies", June 2022, ANL- 22/27. Figure B.8. https://greet.es.anl.gov/publication-c2g_lca_us_ldv.

While still in the early stages and very small market penetration (in model year 2021 there were three hydrogen FCEV models produced, but they were only available in the state of California and Hawaii and in very small numbers25), hydrogen-based vehicles are a promising technology that many stakeholders are considering.26 As acknowledged by EPA in the DRIA,27 modeled compliance relied on the assumption that 55% of new sales of class 2b and class 3 vehicles would be BEV or FCEV. Furthermore, hydrogen fueling infrastructure is covered by the Bi-partisan Infrastructure Law (BIL) and the Inflation Reduction Act (IRA) funding. API members are engaged in hydrogen projects to support development of hydrogen focused technology. Companies28 are partnering with OEMs to explore commercial business opportunities to build demand for vehicles powered by hydrogen. [EPA-HQ-OAR-2022-0829-0641, pp. 10-11]

26 Morales, M. (April 25, 2023). "Automakers deeply invested in hydrogen-powered cars." TopSpeed. https://www.topspeed.com/automakers-invested-hydrogen-powered-cars/.

27 Ibid.

28 https://corporate.exxonmobil.com/what-we-do/lower-emission-transportation/emerging-vehicle-and-fuel- technology/exxonmobil-and-porsche-strategic-collaboration;https://www.chevron.com/newsroom/2021/q2/chevron-toyota-pursue-strategic-alliance-on-hydrogen; https://www.bp.com/en/global/corporate/news-and-insights/press-releases/bp-and-daimler-truck-ag- to-accelerate-the-deployment-of-hydrogen-infrastructure.html.

As noted by the American Trucking Associations (ATA), in testimony before the U.S. Senate Committee on Environment and Public Works:29 [EPA-HQ-OAR-2022-0829-0641, pp. 10-11]

29 U.S. Senate Committee on Environment and Public Works, hearing on "The Future of Low Carbon Transportation Fuels and Considerations for a National Clean Fuels Program", February 15, 2023. https://www.epw.senate.gov/public/index.cfm/2023/2/the-future-of-low-carbon-transportation-fuels-and-considerations-for-a-national-clean-fuels-program.

When battery electric vehicles are not the answer, federal support should refrain from playing favorites, and instead assist in the buildout of alternative fuel facilities. Proposals for hydrogen infrastructure for trucks need to ensure that the infrastructure is in place where that technology best fits in supply chains. Where lifecycle emissions can be reduced by deploying renewable diesel and renewable natural gas, those fuel stocks need to be available for trucking. [EPA-HQ-OAR-2022-0829-0641, pp. 10-11]

While this statement is in relation to heavy-duty vehicles, the issues are the same for light- and medium-duty vehicles. Infrastructure readiness and reduction of lifecycle emissions without picking one technology over others should be EPA's focus for the proposed program. [EPA-HQ-OAR-2022-0829-0641, pp. 10-11]

d. EPA is Not Taking a Realistic Approach.

i. Further, EPA should consider a lifecycle approach that would accurately capture all the emissions associated with the life of a vehicle and capture the efficiency differences of different technologies in different applications. [EPA-HQ-OAR-2022-0829-0641, p. 11]

ii. Future program incentives and program adjustment of standards.

In the development of the program, EPA needs to consider future program incentives such as adoption of a lifecycle approach, combined with fuel carbon intensity reductions. Such an approach would provide a broad spectrum of industries that power the transportation system (e.g., OEMs, petroleum refiners, power generators, and renewable fuel manufacturers) with incentives to reduce emissions. [EPA-HQ-OAR-2022-0829-0641, p. 23]

Organization: Anonymous

EPA should conduct a rigorous study on the full environmental impacts of a dramatic shift to BEV with respect to other environmental media (i.e., non-air pollutants/contaminants), since the proposed rule is designed to more or less force transition to that vehicle technology. The European Environmental Agency (EEA) issued a report in 2018 that reveals the far higher "Human Toxicity Potential" of BEVs, largely from mining the mineral requirements for EV manufacturing (https://www.eea.europa.eu/publications/electric-vehicles-from-life-cycle). Note especially Figure 6.2 on page 58 that even if BEVs are charged with 100% RE (i.e., eliminating the "In-use phase" segments of the BEV bars in the graph), human toxicity impacts are still over twice as high. Ecotoxicity is also higher even if BEVs are charged with 100% RE (Figure 6.3). This is supported by a publically-available European LCA model "carculator" (https://carculator.psi.ch/). Damages to environmental media other than air should also be taken into account when a shift to a substantially different vehicle technology is expected, even if some of that contamination currently is non- domestic. [EPA-HQ-OAR-2022-0829-0490, pp. 1-2]

A peer-reviewed study in 2018 (https://onlinelibrary.wiley.com/doi/10.1111/jiec.12862, Figure 1) also demonstrated the far higher human toxicity impacts of BEV. Even in extremely clean future electric grid scenarios (denoted by dotted lines (generally corresponding to the RCP2.6 scenario in the IPCC AR5)), "Human Toxicity" remains ~3 times higher for BEV in the same electric grid mix scenario. Note also that "Particle matter formation" is higher for BEV than ICEV in all but the cleanest future grid mix scenarios, disputing the BEV air quality benefits claims. [EPA-HQ-OAR-2022-0829-0490, pp. 1-2]

It should be noted that 3 recent peer-reviewed studies, one by staffers from ANL (https://www.mdpi.com/2073-4433/12/11/1482/htm), one from European (Spanish) researchers (https://www.sciencedirect.com/science/article/abs/pii/S0959652621001037), and a study by U.S. researchers in academia just published in May 2023 (https://journals.plos.org/climate/article?id=10.1371/journal.pclm.0000183) conclude that PM2.5 emissions would generally INCREASE with increasing shift to BEV technology. [EPA-HQ-OAR-2022-0829-0490, p. 2]

The Spanish paper concluded that "electric vehicles will produce an increase in fine particulate matter formation (26%), human carcinogenic (20%) and non-carcinogenic toxicity (61%), terrestrial ecotoxicity, freshwater ecotoxicity (39%), and marine ecotoxicity (41%) relative to petrol vehicles," and will continue to for the foreseeable future. [EPA-HQ-OAR-2022-0829-0490, p. 2]

The 2023 study in California concludes that "…our results indicate that the CVRP [clean vehicle rebate project] has displaced emissions from vehicle tailpipes to electric generating units, leading to a net increase in primary PM2.5 emissions across the state of California….[EPA-HQ-OAR-2022-0829-0490, pp. 2-3]

…Of particular concern for environmental justice and public health is the finding that Disadvantaged Communities, as defined according to CalEnviroScreen 4.0, are disproportionately more likely to experience either larger net increases or smaller net reductions in primary PM2.5, NOX, and SO2 emissions as a result of the CVRP…." That's considering California's current electric grid, which is among the cleanest in the U.S. This is counter to the stated goals of the proposed regulation. [EPA-HQ-OAR-2022-0829-0490, pp. 2-3]

These studies come on the heels of a 2010 study by the National Academy of Sciences (National Research Council - https://www.nationalacademies.org/news/2009/10/report-examines-hidden-costs-of-energy-production-and-use), which concluded... "Electric vehicles and grid-dependent (plug-in) hybrid vehicles showed somewhat higher nonclimate damages than many other technologies for both 2005 and 2030." According to Figure 3-7b in the full report, BEV is projected to be more damaging than most of the ICEV technologies/fuel pathways in 2030. Even if the NRC committee underestimated the pace of the decline in coal-generated electricity, some ICEV technologies/fuel pathways would still be less damaging than BEV or FCV, even in much cleaner grids, most notably diesel/biodiesel and CNG ICEV. [EPA-HQ-OAR-2022-0829-0490, pp. 2-3]

Environmental regulations should be technology neutral with respect to compliance with the goals of the regulations. Forcing a transition to 100% BEV will almost certainly result in much higher contamination of toxic substances, both carcinogenic and non- carcinogenic, in ground water, surface water, and soils near mining sites. BEVs will likely play a prominent role in the future vehicle mix regardless, but categorically excluding ICE vehicle technologies via regulation is a mistake and potentially counterproductive. [EPA-HQ-OAR-2022-0829-0490, pp. 2-3]

Organization: Chevron

1. Lifecycle GHG based standards.

The proposal is focused on tailpipe GHG emissions rather than lifecycle emissions. Therefore, upstream GHG emissions for fuel and vehicle manufacturing are not included in the analysis, favoring "zero tailpipe emission" technologies like Battery Electric Vehicles (BEV). [EPA-HQ-OAR-2022-0829-0553, pp. 3-4]

We recommend EPA revise the proposed standards to incorporate a lifecycle GHG assessment of light and medium duty vehicles and fuel technologies. In an analysis of the California Air Resources Board Advanced Clean Cars II program, a study performed by Ramboll1 in 2022 concluded that a transition to lower carbon intensity (CI) gasoline could provide similar lifecycle GHG emissions compared to zero tailpipe emission alternatives. The Ramboll study utilized a full lifecycle approach to account for emissions associated with vehicle material recovery and production, vehicle component fabrication, vehicle assembly, and vehicle disposal/recycling. EPA should consider alternatives such as low-CI liquid fuels to provide multiple compliance options and avoid a one-size-fits-all solution to reducing transportation sector GHG emissions. Lifecycle assessment is a technology neutral approach that allows for more flexibility in the transition towards reducing transportation GHG emissions in the short and long-term. [EPA-HQ-OAR-2022-0829-0553, pp. 3-4]

1 Ramboll US Consulting Inc "Multi-Technology Pathways to Achieve California Greenhouse Gas Goals Light- Duty Auto Case Study" May, 2022; Available here: www.arb.ca.gov/lists/com-attach/477-accii2022- AHcAdQBxBDZSeVc2.pdf beginning page 59

The proposal does not incentivize GHG reductions from the existing vehicle fleet, thus missing an opportunity to accelerate GHG reduction in the early years of the program. Recent published research from SUNY2 shows that the time value of carbon is important in evaluating technology pathways to maximize emission reductions from the fleet of heavy-duty trucks that includes new and older trucks in-use. GHG emissions generated by the truck fleet accumulate in the atmosphere and dissipate slowly over time. GHG emissions that may be reduced or eliminated today can be more valuable than future emission reductions given the annual accumulation of emissions. While this study focused on heavy-duty vehicle examples, the time value of carbon concept would apply equally to GHG emissions from light and medium-duty vehicles. A GHG reduction strategy that focuses on lifecycle emissions, as opposed to tailpipe emissions only, would incentivize near term emission reductions that would create long term environmental benefits. [EPA-HQ-OAR-2022-0829-0553, pp. 3-4]

2 Quantifying the comparative value of carbon abatement scenarios over different investment timing scenarios - College of Environmental Science (exlibrisgroup.com)

2. Broad technology approach.

There are a wide variety of vehicle technologies and fuel types that can be used to meet consumer needs, employing market-based approaches instead of focusing exclusively on zero tailpipe emission technology options. EPA could allow for innovation within the current market to dramatically reduce GHG emissions, without the systemic risks associated with a single technology solution. It is unlikely that the market would identify a single vehicle technology that would be appropriate for all different customer needs. The proposed rule should be broadened to encourage the use of multiple technologies by establishing a neutral, market-based, lifecycle standard. Light and medium duty vehicles powered by biofuels, hybrid technologies, and renewable natural gas leverage the existing infrastructure and are proven to deliver the power, convenience, and functionality desired by consumers. [EPA-HQ-OAR-2022-0829-0553, pp. 4-5]

Hybrid electric, plug-in hybrid electric, and internal combustion technologies can be paired with lower carbon intensity fuels to result in lower GHG emissions from light and medium duty transportation. These alternative pathways would not require the wholesale transformation of electric energy production and distribution infrastructure on an unprecedented, abbreviated time scale. They would allow battery, hydrogen, and low-carbon intensity gaseous and liquid fueled vehicles to compete to achieve the GHG targets for light-duty transportation in the quickest and most cost-effective manner. [EPA-HQ-OAR-2022-0829-0553, pp. 4-5]

For example, the Ramboll Light Duty Auto Case study showed that a zero-tailpipe strategy did not achieve the maximum emission reductions possible. A fleet mix that deployed a wider range of technologies, including hybrid electric, plug-in hybrid electric, BEVs, and fuel cell electric vehicles, along with a gradual phase-in of low-CI gasoline, out-performed the ZEV only deployment strategy in the near-term and achieved equitable emission reductions in the long-term.3 [EPA-HQ-OAR-2022-0829-0553, pp. 4-5]

3 Ramboll US Consulting Inc "Multi-Technology Pathways to Achieve California Greenhouse Gas Goals Light- Duty Auto Case Study" May, 2022; Available here: www.arb.ca.gov/lists/com-attach/477-accii2022- AHcAdQBxBDZSeVc2.pdf Figure 4-8.

Argonne National Laboratory's "Cradle-to-Grave Lifecycle Analysis of U.S. Light-Duty Vehicle- Fuel Pathways: A Greenhouse Gas Emissions and Economic Assessment of Current (2020) and Future (2030-2035) Technologies" report4, demonstrates that the combination of advancements in lower carbon fuel and higher efficiency vehicles can help all vehicle propulsion types achieve parity for GHG emissions. The Argonne study states, "…large GHG reductions for LDVs are challenging and require consideration of the entire life cycle, including vehicle manufacture, fuel production, and vehicle operation. Achieving a life cycle reduction in GHG emissions is a challenging task and must overcome both technological hurdles as well as cost and market acceptance constraints." [EPA-HQ-OAR-2022-0829-0553, pp. 4-5]

4 Argonne GREET Publication: Cradle-to-grave lifecycle analysis of U.S. light-duty vehicle-fuel pathways: a greenhouse gas emissions and economic assessment of current (2020) and future (2030-2035) technologies (anl.gov)

This conclusion reinforces our belief that a robust vehicle standard, embracing a lifecycle method to quantify vehicle emissions, is the preferred approach to reducing the GHG impact of light and medium-duty transportation. [EPA-HQ-OAR-2022-0829-0553, pp. 4-5]

Organization: Clean Fuels Development Coalition et al. (CFDC)

- Air quality effects. These include the air quality and health impacts from significant increases in tire wear from electric vehicles, as well as the increases in CO2 emissions that will result from manufacturing more electric generation infrastructure, transmission, distribution, and charging equipment, and the manufacturing of electric vehicles themselves, which produce far more upstream emissions than their internal combustion engine counterparts. [EPA-HQ-OAR-2022-0829-0712, pp. 6-7]

D. EPA lacks the statutory authority to ignore upstream emissions for electric vehicles.

EPA has statutory authority to prescribe "standards applicable to the emission of any air pollutant from any class or classes of new motor vehicles or new motor vehicle engines, which in [its] judgment cause, or contribute to, air pollution which may reasonably be anticipated to endanger public health or welfare." 42 U.S.C. § 7521(a)(1). This presents an interpretive dilemma. On the one hand, if electric vehicles are not "vehicles" "which cause[ ] or contribute to" a given type of air pollution, then EPA may not set standards for them. Id. On the other, if electric vehicles are "vehicles" "which cause, or contribute to" a given type of air pollution, then

EPA must set “standards applicable to the[ir] emissions.” Id. [EPA-HQ-OAR-2022-0829-0712, p. 11]

The proposal tries to solve this problem by splitting the baby.8 EPA reasons that electric vehicles are vehicles that “cause or contribute to air pollution,” but EPA just chooses to set their contribution to zero. This cannot be right. Cf. C.S. Lewis, That Hideous Strength 291 (Samizdat ed., 2015) (“Just imagine a man who was too dainty to eat with his fingers and yet wouldn’t use forks!”). If electric vehicles truly emit no emissions, then they are not the sort of vehicle EPA can regulate. [EPA-HQ-OAR-2022-0829-0712, p. 11]

8 Of course, the point of the story about Solomon is that the baby wasn’t split. See 1 Kings 3:16– 28 (“Give the living child to the first woman, and by no means put him to death; she is his mother.”).

Of course, EPA freely admits that electric vehicles do produce upstream emissions, and that these upstream emissions matter. This is true and very important. And the proposal does consider upstream emissions when determining the rule’s impact on total emissions. EPA’s position is that this inconsistent approach to electric vehicles’ upstream emissions is reasonable because it treats upstream emissions of all vehicles, electrified or not, the same way for compliance purposes. 88 Fed. Reg. 29,252 (“EPA proposes to include only emissions measured directly from the vehicle in the vehicle GHG program for MYs 2027 and later (or until EPA changes the regulations through future rulemaking) consistent with the treatment of all other vehicles. Electric vehicle operation would therefore continue to be counted as 0 g/mile, based on tailpipe emissions only.”) [EPA-HQ-OAR-2022-0829-0712, pp. 11-12]

But this “consisten[cy]” is precisely what makes the rule unreasonable. Electric vehicles are not like “all other vehicles.” EPA has previously recognized that “that for each EV that is sold, in reality the total emissions off-set relative to the typical gasoline or diesel powered vehicle is not zero, as there is a corresponding increase in up-stream CO2 emissions due to an increase in the requirements for electric utility generation.” 74 Fed. Reg. 49,454, 49,533 (Sept. 28, 2009). EPA only chose the initial “zero grams/mile compliance value [a]s an incentive,” Response to Comments, EPA-420-R- 10-012a at 5-237 (Apr. 2010),), and explained that in future standards it “would at- tribute a pro rata share of national CO2 emissions from electricity generation to each mile driven under electric power minus a pro rata share of upstream emissions associated with from gasoline production,” 88 Fed. Reg. 29,252. [EPA-HQ-OAR-2022-0829-0712, pp. 11-12]

EPA never had authority to incentivize electric vehicles in this way. Section 202(a) requires the agency to “standards applicable to the emission of any air pollutant from any class or classes of new motor vehicles.” Because it acknowledged that these emissions are “not zero,” it is arbitrary to treat them as such. Indeed, as EPA previously acknowledged, treating upstream emissions of all vehicles, electrified or not, the same way puts a thumb on the scale against conventional vehicles in favor of electric vehicles. An agency’s bare preference for one technology cannot satisfy the requirement that it “reasonably consider[] the relevant issues and reasonably explain[] the decision.” FCC v. Prometheus Radio Project, 141 S. Ct. 1150, 1158 (2021).

At the very least, the agency is not permitted to change its position on the future inclusion of upstream emissions in compliance calculations without explanation. When an agency makes a decision, it must articulate a “satisfactory explanation for its action including a ‘rational connection between the facts found and the choice made.’” Motor Vehicle Mfrs. Ass’n v. State Farm Mut. Auto. Ins. Co., 463 U.S. 29, 43 (1983). If the agency fails to “cogently explain why it has exercised its discretion in a given manner,” its action will be held invalid. Id. at 48. In addition, the agency must “provide a more detailed justification than what would suffice for a new policy created on a blank slate . . . when, for example, its new policy rests upon factual findings that contradict those which underlay its prior policy." FCC v. Fox Television Stations, Inc., 556 U.S. 502, 515 (2009); see also Perez v. Mortg. Bankers Ass'n, 135 S. Ct. 1199, 1209 (2015). EPA previously thought that the zero grams-per-mile compliance value was only viable as a temporary incentive because "in reality" the total emissions were not zero. Failure to consider and adequately explain departure from this finding would render the entire rulemaking arbitrary and capricious. Fox Television Stations, 556 U.S. at 515. [EPA-HQ-OAR-2022-0829-0712, pp. 12-13]

F. EPA lacks authority to Misleads Consumers by Using the Term "Zero-emissions Vehicle."

While it is true that all-electric vehicles have no tailpipe emissions, it is completely false to claim that they are "zero-emissions vehicles." As already noted, EPA acknowledges that what it calls "ZEVs" have significant upstream emissions. 88 Fed. Reg. 29,303. Despite this, the proposal repeatedly describes these vehicles as having no emissions. This is per se unreasonable, and it enables illegal marketing by auto- manufacturers. Seizing on EPA's label, dozens of auto-manufacturers have described their electric vehicles as "zero-emissions." Making false claims in the marketing of products is prohibited by the Federal Trade Commission Act, which prohibits "unfair or deceptive acts or practices in or affecting commerce" 15 U.S.C. § 45. The agency lacks authority to facilitate these deceptive acts or to promote innumerable other false "zero emission" statements. [EPA-HQ-OAR-2022-0829-0712, pp. 14-15]

B. The proposed rule misstates emissions benefits because it neglects upstream electric generating unit emissions, among others.

In addition to underestimating costs, the proposal also overstates benefits. The most egregious of these comes from the way EPA accounts for upstream emissions for electric generating units ("EGU"). See DRIA 8-10, 11. To realize substantial reductions in GHG emissions—and thus benefits from such emissions—the rule relies on the decrease in emissions from petroleum-fueled vehicles replaced by electric vehicles. But these vehicles are themselves still responsible for emissions from the electricity that powers them. Current electricity GHG emissions factors are approximately 442,000 U.S. Tons of CO2 / Terawatt-Hour. How much carbon dioxide is produced per kilo watt hour of U.S. electricity generation, Energy Information Administration, https://www.eia.gov/tools/faqs/faq.php?id=74&t=11 (last accessed July 5, 2023). [EPA-HQ-OAR-2022-0829-0712, pp. 34-35]

This is unrealistic. Emissions reduction on the U.S. electric grid have thus far come primarily from natural gas replacing coal. To continue to lower CO2 emissions in this manner would require an almost complete conversion to low carbon sources. But barriers to wind, solar, and nuclear adoption will not enable these changes on EPA's timeframe. Furthermore, researchers estimate that the 350 million EVs required to decarbonize the fleet in 2050 could use as much as half of US national electricity demand. Thea Riofrancos et al., Achieving Zero Emissions with More Mobility and Less Mining, U.C. Davis Climate + Community Project (Jan. 2023), https://sub- scriber.politicopro.com/eenews/f/eenews/?id=00000185-e562-de44-a7bf-ed7751a00000. [EPA-HQ-OAR-2022-0829-0712, pp. 34-35]

These costs also ignore that realizing these reductions requires the installation of new solar and wind generation, which itself has a cost. Without additional wind and solar generation, upstream emissions from electricity generating units will not decrease as much as EPA expects, diminishing those benefits. In addition to the direct costs of this generation, the proposal also ignores the greenhouse gas emission associated with manufacturing more, less dense, remotely located intermittent generation sources, and the battery back-up; transmission, substation, and transformer investment to integrate these technologies into the power grid; and natural gas peaking capacity necessary to sustain their intermittency. These emissions are significant and must be accounted for in the calculation of any benefits of the proposed rule. [EPA-HQ-OAR-2022-0829-0712, pp. 34-35]

A. EPA has authority to consider the lifecycle emissions from different fuels in its standard setting.

Section 202(a)(3)(A)(ii) authorizes EPA to look beyond the basic engine to set its engine or vehicle emission standards. Specifically, it states that, "[i]n establishing classes or categories of vehicles or engines for purposes of regulations under this paragraph, the [agency] may base such classes or categories on gross vehicle weight, horsepower, type of fuel used, or other appropriate factors." 42 U.S.C. § 7521(a)(3)(A)(ii) (emphasis added). To account for the "type of fuel used," EPA would need to engage in lifecycle emissions analysis. EPA has often eschewed lifecycle analysis because of the nature of the pollutants it regulates, but it is the obvious best fit for greenhouse gas regulations. Section 202(a)(1) gives EPA's authority to issue rules setting emissions standards for "air pollutants" that it finds may reasonably be anticipated to endanger public health or welfare. And while most air pollutants work on the local and regional level, which makes lifecycle analysis a poor fit, greenhouse gases' harms are all at the global level. Except in truly extreme concentrations, CO2 emissions do not lead to adverse health effects if breathed in. [EPA-HQ-OAR-2022-0829-0712, pp. 39-40]

Clean Air Act Section 202(a)(4)(A) and (B) require that EPA consider whether its proposed standards "will cause or contribute to an unreasonable risk to public health, welfare or safety", including whether the proposed standard "causes, increases, reduces, or eliminates emissions of any unregulated pollutants" and to assess "the availability of other devices, systems, or elements of design which may be used to conform to requirements prescribed under this subchapter without causing or contributing to such unreasonable risk." Neglecting lifecycle greenhouse gas emissions incentivizes compliance options that increase upstream carbon emissions at the expense of measured tailpipe emissions. This is exactly the sort of "other … element[ ] of design" that Congress imagined might "increase[ ] emissions." [EPA-HQ-OAR-2022-0829-0712, pp. 39-40]

24 Despite the benefits of renewable fuels, EPA's recent rulemaking decreases total volumes. EPA finalized a multi-year Renewable Fuel Standard that reduces volumes from proposed levels for both advanced biofuels and corn ethanol. Renewable Fuel Standard (RFS) Program: Standards for 2023–2025 and Other Changes, EPA-HQ-OAR-2021-0427. (EPA's final numbers show a 250-million- gallon reduction in total corn-ethanol volumes for 2024 and 2025 from the original proposal, setting those volumes at 15 billion gallons for both years. This is inexplicable given EPA's aggressive decarbonization plans.

Organization: Countymark

The EPA has ignored lifecycle emissions in its environmental impact assessment. The EPA fails to provide a comprehensive picture of a vehicle's environmental impact throughout its lifecycle by focusing solely on tailpipe emissions. It is argued that a ton of carbon emitted during a vehicle's lifecycle has the same climate impact regardless of when or where it is emitted. This means that emissions from the production of batteries for electric vehicles (EVs) should be considered, as they are carbon intensive. A proper lifecycle assessment should consider all emissions associated with a vehicle, including those from production, recharging or refueling, drivetrain or battery replacements, infrastructure modifications, and end-of-life disposal and recycling. By neglecting these factors, the EPA's assessment does not accurately represent the true environmental impact of different vehicle types. In summary, we believe that the EPA's focus on tailpipe emissions alone distorts assessing a vehicle's environmental impact. A more comprehensive approach considering all emissions throughout a vehicle's lifecycle, including production and disposal, is necessary for a more accurate evaluation. [EPA-HQ-OAR-2022-0829-0665, pp. 2-3]

Organization: Cummins Inc. (Cummins)

II. General Principles

Aligned with Cummins' commitments described above, Cummins offer these principles for consideration as EPA develops its Final Rule addressing criteria pollutant and GHG emissions for light-duty (LD) and medium-duty vehicles (MDV) [EPA-HQ-OAR-2022-0829-0645, pp. 2-3]:

- Well-to-wheels emissions should be considered in assessing technology effectiveness to ensure alignment of the standards with the most beneficial path to zero emissions. [EPA-HQ-OAR-2022-0829-0645, pp. 2-3]

Cummins currently certifies heavy-duty (HD) pickup trucks with gross vehicle weight ratings (GVWR) between 8,501 and 14,000 pounds, also known as Class 2b and 3 vehicles, meeting EPA's Tier 3 criteria pollutant emissions standards and Phase 2 GHG standards. Diesel Class 2b and 3 pickup trucks can have significant towing capability and are used in applications going beyond personal use such as construction and agriculture, and as such, do vital work for America. Our additional comments detailed below pertain to those vehicles. [EPA-HQ-OAR-2022-0829-0645, pp. 2-3]

Organization: Dana Incorporated (Dana)

Sustainable Sourcing

As noted above, Dana is heavily focused on steps to drive sustainable best practices in our operations. Sustainable sourcing of materials is still a concern in the production of LD/MD BEVs and suppliers like Dana will face pressures to provide sustainably sourced products at competitive prices. [EPA-HQ-OAR-2022-0829-0538, pp. 2-3]

There is little consideration of the manufacturing side in the NPRM, which is mainly focused on reducing in-use CO2 emissions from LD/MD vehicles. While the NPRM does discuss upstream power-sector emissions driven by increased PEV charging demand, EPA should also consider the impact of manufacturing the full propulsion system when assessing the environmental impact of its proposals. Doing so could help ensure that the cross-over point of combining manufacturing and in-use vehicle CO2 emissions is reasonable for the targeted adoption rate. Dana suggests that EPA include a cross-over point in addition to what is provided on break-even timing for LD/MD ZEVs. [EPA-HQ-OAR-2022-0829-0538, pp. 2-3]

Organization: Darius

The EPA's proposal boosts an electric vehicle supply chain dominated by China, which powers its manufacturing-base through coal-fired power plants and mines minerals for EV batteries with the use of environmental practices that we would never approve of in the United States. Emissions coming out of tailpipe matter, but so do the lifecycle emissions of building a car, constructing and charging a battery, and retiring vehicles. [EPA-HQ-OAR-2022-0829-0519, p. 1]

Organization: Delek US Holdings, Inc.(Delek)

EPA's Proposed Rule is, at best, arbitrary and capricious or otherwise not in accordance with the Clean Air Act because it is based on flawed projections for zero emissions vehicles ("ZEVs"), such as plug-in electric vehicles ("PEVs") and battery electric vehicles ("BEVs"), will increase domestic reliance on foreign supply chains, underestimates the lifecycle GHG emissions associated with PEVs, overstates the benefits of the proposal, severely underestimates the costs, and fails to consider the impacts to other industries. Accordingly, Delek urges EPA to abandon or substantially reconsider its proposal. [EPA-HQ-OAR-2022-0829-0527, p. 2]

III. The Proposed Rule Underestimates the Lifecycle GHG Emissions of BEVs

Contrary to the naming convention, ZEVs—including PEVs and BEVs—are not truly zero-emission vehicles.19 In fact, the lifecycle GHG emissions of BEVs exceed that of ICE- powered vehicles. If EPA is authorized to promulgate such standards, those standards must account for any upstream emissions from electric generating units. The failure to do so creates an uneven playing field that substantially disadvantages ICE engines. [EPA-HQ-OAR-2022-0829-0527, p. 4]

19 Proposed Rule at 29,187 ("As the term 'zero-emission vehicle' suggests, these cars and trucks have zero GHG and criteria pollutant emissions from their tailpipes.").

Organization: Donn Viviani (Viviani)

GHG emissions embedded in the production of vehicles is responsible for ~10% of vehicle carbon footprints. Slowly reducing down the allowable embedded carbon by class will have several outcomes. [EPA-HQ-OAR-2022-0829-0697, pp. 6-7]

Limiting the embedded carbon per ton would result in, e.g., more steel made with green hydrogen, less metal and more plastic parts (already these are replacing metal) which can require less energy to produce, and even parts made with bio-based plastics which count as negative carbon. [EPA-HQ-OAR-2022-0829-0697, pp. 6-7]

Lastly, here, it is important to ensure that imports would be subject to any such embedded carbon restrictions, as that would serve to increase pressure on overseas EGUs to transition away from coal. [EPA-HQ-OAR-2022-0829-0697, pp. 6-7]

Organization: Energy Marketers of America (EMA)

EMA is concerned over EPA's tailpipe emission standards for light-duty and medium-duty vehicles for model year 2027 and later which will effectively discourage investment in lower carbon liquid fuels. EPA projects that a potential outcome of the rule would require nearly 70 percent of all new light duty vehicle sales to be battery electric vehicles (EVs) by 2032. Unfortunately, the focus on EV production will fundamentally eliminate an opportunity to provide clean green liquid fuels such as renewable diesel, biodiesel, renewable gasoline, clean hydrogen and ethanol that immediately lower emissions not only for new vehicles, but for the vehicles currently on the road. In addition, the rule will limit consumer choice on cleaner internal combustion engines and threaten the viability and jobs of small business energy marketers around the country. [EPA-HQ-OAR-2022-0829-0616, pp. 1-2]

EMA urges the EPA to consider lifecycle emissions and a technology neutral approach when considering emission reductions. The proposed rule should consider the lifecycle emissions associated with EV production, usage, and end-of-life disposal including emissions from raw material mining and refining, battery manufacturing, and electricity generation for EV charging. Further EPA needs to consider the logistics, investment, and timing associated with EV and battery production, electric generation and transmission, and EV charging to support a substantial increase in EV production. Achieving a significant ramp up of domestic supply of raw materials for batteries, mineral refining, and battery and vehicle manufacturing as well as upgrades to the electricity generation and transmission will be complex and take time. [EPA-HQ-OAR-2022-0829-0616, pp. 1-2]

Again, EMA urges the EPA to consider lifecycle emissions and a technology neutral approach when it comes to promoting policies to reduce emissions. The most cost-effective and timely way to reduce emissions from transportation is to support multiple technologies that do so for both new vehicles and vehicles currently on the road. [EPA-HQ-OAR-2022-0829-0616, pp. 1-2]

Organization: Exxon Mobil Corporation (ExxonMobil)

ExxonMobil believes that existing transportation sector-based federal policies could be improved to achieve meaningful GHG emissions reductions through complementary fuel and vehicles standards. Specifically, we encourage EPA to consider how it may assist with the development and implementation of a federal low carbon fuel standard that would encourage investment in lowering the carbon intensity of fuels (liquid, compressed/liquefied gas, electricity, hydrogen) and vehicle standards that account for lifecycle GHG emissions, including emissions upstream of a vehicle’s tailpipe. [EPA-HQ-OAR-2022-0829-0632, p. 3]

To encourage investment in technologies to reduce GHG emissions from existing fuels, ExxonMobil is encouraging U.S. policymakers to consider the development of a federal lifecycle and carbon-intensity based fuel standard measured in gCO2e per Mega Joule (MJ) of fuel energy (gCO2e/MJ) that would provide a long-term market signal for the production and use of lower carbon fuels. Such a standard, which could be increased in stringency over time, would establish a market for credit trading that would offer compliance flexibility and would underpin investments in technologies to reduce carbon emissions from gasoline and diesel used for existing vehicles. Examples of lower carbon-intensity fuels that might generate credits under such a standard would include ethanol, biodiesel, renewable diesel, renewable natural gas, hydrogen, electricity produced for EVs, and traditional fuels produced with lower emission technology such as carbon capture and sequestration. Moreover, the standard could be expanded beyond road transportation to the marine and aviation sectors in the future. [EPA-HQ-OAR-2022-0829-0632, p. 3]

EPA should also consider complementary GHG emission standards for new vehicles based on a well-to-wheels (WTW) lifecycle emissions accounting methodology. Such standards would encourage lower CO2e emissions per mile driven (gCO2e/mile) complementing the above-mentioned carbon-intensity based standards for the energy used by the vehicles. Current vehicle GHG standards account only for fuel combustion or tank- to-wheels emissions. A WTW approach, which accounts for lifecycle GHG emissions, allows for a more transparent comparison between the lifecycle emissions associated with vehicle types. In the case of BEVs or plug-in hybrid electric vehicles, such a standard would allow consumers to see the emissions associated with the electricity used to power these vehicles. Moreover, it enables consistent GHG accounting, and thus provides a more holistic approach toward encouraging advancement in vehicle technologies that can reduce GHG emissions. [EPA-HQ-OAR-2022-0829-0632, pp. 3-4]

Linked fuel and lifecycle vehicle CO2 standards offer a preferred, technology-neutral policy pathway relative to BEV-only mandates. A policy that aims to reduce GHG emissions from existing fuels and that recognizes WTW emissions from new vehicles, can help retain consumer choice for the type of vehicle they prefer to drive, would avoid overdependence on foreign critical minerals, would retain high-paying jobs throughout the transportation sector, could grow the role of agriculture in providing energy feedstocks, and ultimately, would be supported through a credit-based system, not taxes. [EPA-HQ-OAR-2022-0829-0632, p. 4]

ExxonMobil respectfully recommends that EPA consider the role it can play in developing and implementing policy to reduce GHG emissions from both new and existing vehicles through the development of WTW emission standards for new vehicles and complementary support for a federal low carbon fuel standard. We would welcome the opportunity to collaborate with the agency and share in greater detail our views on what a comprehensive policy approach might look like. [EPA-HQ-OAR-2022-0829-0632, p. 4]

Organization: Green Diesel Engineering LLC (GDE)

The graph above is from a NASA satellite image which highlights the areas with NOx issues. [See original comment for map of nitrogen dioxide levels throughout the Unites States] Since these areas are predominantly urban vicinities or downstream of power plants, it would be more beneficial to focus on localized efforts to reduce NOx. A good 70% of people live in the urban areas and reducing NOx in these inner cities will provide the most focused assistance. Ideally, most city transportation would be electric to eliminate emissions at source. Cities could build large parking lots outside urban areas for combustion vehicles and mass electric transit into city center. Keep in mind, electric vehicles do not reduce emissions, but rather change where those emissions are produced (battery mining / manufacturing / recycling plants) and electric power-distribution facilities. Moving the emissions away from where most people live would be prudent. Electric transportation does not reduce CO2 emissions over the vehicle life cycle due to battery manufacturing, mining, recycling and charging. Electric vehicles will help reduce smog in LA, Denver, etc. where there is poor airflow, however, they will not reduce carbon emissions when battery recycling/lifespan is incorporated in the well to wheels analysis.

(https://climate.mit.edu/ask-mit/are-electric-vehicles-definitely-better- climate-gas-powered-cars),(https://www.iea.org/data-and- statistics/charts/comparative-life-cycle-greenhouse-gas-emissions-of-a-mid-size-bev- and-ice-vehicle),(https://www.epa.gov/greenvehicles/comparison-your-car-vs-electric- vehicle),(https://www.sciencedirect.com/science/article/pii/S1361920921000614). [EPA-HQ-OAR-2022-0829-0457, p. 4]

Organization: Growth Energy

There are several steps that EPA can and should take to address those deficiencies, both in the final rule and in other contexts: [EPA-HQ-OAR-2022-0829-0580, p. 4]

- First, EPA should fix its system of scoring the emissions from vehicles, which both undercounts EV emissions and overcounts emissions from biofuels used in ICE vehicles. The most accurate way to do so would be by conducting a complete lifecycle analysis for BEVs—using the Argonne laboratory's GREET model or its equivalent—and compare that to a lifecycle analysis for ICE vehicles using various blends of liquid fuels. Alternatively, if EPA does not use a lifecycle analysis, it should at a minimum assign the portion of fuel used in ICE vehicles attributable to biofuels a value of zero g/mi in recognition of the fact that the carbon emitted from combusting biofuels is biogenic carbon sequestered from the atmosphere by crops. [EPA-HQ-OAR-2022-0829-0580, p. 4]

III. EPA Must Compare the Emissions from Electric Vehicles and Biofuels in a Rational Way.

A. The Proposed Rule Dramatically Misconstrues the Relative Lifecycle GHG Emissions of EVs and Biofuels.

The Proposed Rule's emission standard for GHGs is doubly inaccurate—it both severely underestimates emissions from EVs and overestimates emissions from biofuels. EPA has previously acknowledged the severity of its undercounting of GHG emissions from EVs: [EPA-HQ-OAR-2022-0829-0580, p. 6]

C. EPA Can and Should Conduct a Lifecycle Analysis for all Vehicles.

The best way to address the Proposed Rule's inaccurate assessment of emissions would be to conduct a lifecycle analysis for all vehicles covered by the rule. That analysis should fully assess the upstream emissions from production of the vehicle, the upstream emissions associated with the vehicle's fuel source, any upstream sinks of carbon (e.g., uptake of carbon by growing crops), and the emissions from the vehicle itself. Assessing emissions on that type of lifecycle, cradle-to-grave basis would ensure that all components of a vehicle's emissions are appropriately accounted for and compared to other types of vehicles. [EPA-HQ-OAR-2022-0829-0580, p. 10]

In particular, EPA should assess lifecycle emissions based on the Argonne National Laboratory's Greenhouse Gas and Regulated Emissions and Energy Use in Transportation ("GREET") model. GREET is a state-of-the art model for assessing lifecycle emissions that incorporates the latest scientific consensus on modeling and latest data and assumptions on important variables, like induced land-use change ("ILUC"). It is "continually updated by world-class researchers … provides reliable calculations of life-cycle energy and emissions related to transportation, and accounts for a wide range of conventional and emerging energy systems and vehicle technologies."15 Some other models currently in use include estimates for ILUC that are outside the scientific consensus on the "credible range" for land use change induced by crops like corn grown in the United States.16 GREET's ILUC value for corn ethanol of 7.4 gCO2e/MJ is solidly within the credible range of ILUC values identified in a recent meta-analysis by researchers at Harvard University.17 [EPA-HQ-OAR-2022-0829-0580, p. 10]

15 U.S. Department of Energy, GREET: The Greenhouse Gases, Regulated Emissions, and Energy Use in Transportation Model (May 16, 2019), https://www.energy.gov/eere/bioenergy/articles/greet-greenhouse-gases- regulated-emissions-and-energy-use-transportation.

16 Scully, et. al., Carbon intensity of corn ethanol in the United States: state of the science 16 Environ. Res. Lett. 043001 (2021).

17 See id. (identifying the credible range as between -1.0 and 8.7 gCO2e/MJ).

Tellingly, GREET is already used in numerous applications by EPA and across federal and state agencies. For example, it is a central component of the EPA's assessment of lifecycle emissions under the RFS program. And it has been adapted by California's Air Resources Board for use in assessing pathways under California's Low Carbon Fuel Standard ("LCFS") program. [EPA-HQ-OAR-2022-0829-0580, p. 10]

When assessing lifecycle emissions of ICE engines under a GREET-based approach, EPA must appropriately and accurately consider the emissions of biofuels. In particular, to adequately assess the emissions of biofuels going forward, EPA should assume increasing use of biofuel blends in future years. While the prevailing mix of ethanol in the nation's gasoline supply is currently E10, E15 is being increasingly adopted, and efforts to change to Reid Vapor Pressure ("RVP") requirements are likely to further spur its adoption. EPA should also assume that increasing amounts of E30 and E85 can be used in the future. The marginal cost of converting fueling stations and other infrastructure to accommodate E85 is low, so its use could easily be expanded with appropriate incentives. [EPA-HQ-OAR-2022-0829-0580, pp. 10-11]

If EPA is unable to incorporate lifecycle analysis for all vehicles by the time it intends to publish the final rule, an interim alternative would be to simply treat the emissions from the biofuels used in ICE vehicle as zero grams per mile. That solution would be only a partial one because it would not compare, for example, the emissions associated with creating batteries for EVs to the emissions associated with constructing ICE vehicle engines. But it would at least address the glaring inconsistency of the treatment of EVs and the treatment of biofuels. And using such an assumption would be consistent with GREET, which treats the tailpipe GHG emissions from biogenic sources as zero because they net out with the carbon absorbed by crops. It would also be consistent with several of EPA's prior statements on emissions from biogenic sources, like its 2018 policy with respect to the combustion of woody biomass.18 If EPA adopts that short-term fix in this final rule, it should nonetheless finalize a system for conducting a lifecycle analysis as soon as possible, rather than waiting to incorporate it until the time period covered by the current rule ends after 2032. [EPA-HQ-OAR-2022-0829-0580, pp. 10-11]

18 EPA, EPA's Treatment of Biogenic Carbon Dioxide (CO2) Emissions from Stationary Sources that Use Forest Biomass for Energy Production at 6 (Apr. 23, 2018), available at https://www.epa.gov/sites/default/files/2018- 04/documents/biomass_policy_statement_2018_04_23.pdf.

EPA should ensure that its tailpipe rule maximizes emissions reductions and minimize costs. Appropriately accounting for the lifecycle GHG emissions of vehicles would eliminate unintended consequences like incentivizing fossil hydrogen over low-carbon biofuels. And it would align the incentives provided by EPA's tailpipe rule with an accurate calculation of lifecycle GHG emissions so that the market can achieve the greatest emissions reductions in the most efficient way. For some vehicle needs and local markets, that may be investing in EVs, but in others it may be investing in vehicles with efficient ICE engines that can and do use higher biofuel blends. [EPA-HQ-OAR-2022-0829-0580, pp. 11-12]

B. The Proposed Rule is Arbitrary and Capricious and Outside of EPA's Authority.

EPA failed entirely to consider both the upstream emissions of EVs and the emissions reductions of biofuels as part of a rule that will shift new vehicle production dramatically towards EVs. By doing so, EPA "failed to consider an important aspect of the problem," a hallmark of arbitrary and capricious rulemaking under the APA. Motor Vehicle Manufacturers Association v. State Farm Auto Mutual Insurance Co., 463 U.S. 29, 43 (1983). [EPA-HQ-OAR-2022-0829-0580, p. 14]

VII. Conclusion

The proposed rule misses a significant opportunity to reduce GHG emissions through biofuels. EPA should adjust its proposal by: (1) accounting for the upstream emissions of EVs and the upstream carbon sinks of biofuels; (2) considering the potential for higher blends of biofuels in EPA's test fuel and throughout the rule; and (3) developing credit programs and other measures that incentivize greater biofuel use. [EPA-HQ-OAR-2022-0829-0580, p. 17]

Organization: HF Sinclair Corporation (Sinclair)

a. EPA Fails to Properly Account for All GHG Emissions from PEVs

In an attempt to hinder consumer choice and penalize specific forms of technology, EPA's proposed rule fails fully account for the lifecycle GHG emissions that come from PEVs, creating a disparity between how ICE and PEV vehicle emissions are treated. While EPA purports to have considered the GHG emissions attributed to upstream emissions impacts from fuel production at refineries and electricity generating units,27 EPA assumes – without any factual basis – that the power sector will become cleaner over time through the increased use of wind and solar generation and electricity storage (i.e., more batteries). This in turn will purportedly mitigate EPA's recognized concern that, as a result of the proposed rule, "increases in emissions from [Electric Generating Units] . . . would lead to changes in exposure for people living in communities near these facilities."28 But, EPA glosses over this analysis, and instead only focuses on tailpipe emissions. And even if EPA's assumptions on a cleaner electric grid are correct, EPA fails to account for the increased GHG emissions that will come from an increasing effort to mine, process, and manufacture the critical minerals that will be required to both deliver batteries to power an all- electric future fleet as well as deliver "zero-emission" power to the grid. [EPA-HQ-OAR-2022-0829-0579, pp. 7-9]

27 Proposed Rule at 29,252.

28 Proposed Rule at 29,327.

. Ultimately, EPA arbitrarily ignores the full scope of emissions that will come from PEVs, and a full lifecycle analysis of all potential vehicle technologies must be conducted to fully understand the environmental impacts of the Proposed Rule. [EPA-HQ-OAR-2022-0829-0579, pp. 7-9]

III. The Proposed Rule is Arbitrary and Capricious

a. EPA Fails to Properly Account for All GHG Emissions from PEVs

In an attempt to hinder consumer choice and penalize specific forms of technology, EPA's proposed rule fails fully account for the lifecycle GHG emissions that come from PEVs, creating a disparity between how ICE and PEV vehicle emissions are treated. While EPA purports to have considered the GHG emissions attributed to upstream emissions impacts from fuel production at refineries and electricity generating units,27 EPA assumes – without any factual basis – that the power sector will become cleaner over time through the increased use of wind and solar generation and electricity storage (i.e., more batteries). This in turn will purportedly mitigate EPA's recognized concern that, as a result of the proposed rule, "increases in emissions from [Electric Generating Units] . . . would lead to changes in exposure for people living in communities near these facilities."28 But, EPA glosses over this analysis, and instead only focuses on tailpipe emissions. And even if EPA's assumptions on a cleaner electric grid are correct, EPA fails to account for the increased GHG emissions that will come from an increasing effort to mine, process, and manufacture the critical minerals that will be required to both deliver batteries to power an all- electric future fleet as well as deliver "zero-emission" power to the grid. [EPA-HQ-OAR-2022-0829-0579, pp. 7-9]

27 Proposed Rule at 29,252.

28 Proposed Rule at 29,327.

For instance, the power source of a PEV—a battery composed of carbon intensive minerals and the electricity generated to power the battery—produces emissions. The fact such emissions occur 100% upstream of the vehicle's operation and therefore fall outside of the tailpipe emissions calculation stacks the deck in favor of this technology. In fact, according to the International Energy Association, PEVs require six times the raw materials as a traditional ICE vehicle.30 There is no logical basis for this omission because, as EPA is aware, concerns about GHG emissions relate to their longer term global concentrations. Consequently, air pollutant emissions should be an important consideration regardless of where such emissions occur and, by myopically prioritizing PEVs, EPA fails to look at all technologically feasible options that may provide commensurate GHG reductions in a more cost-efficient manner. [EPA-HQ-OAR-2022-0829-0579, pp. 7-9]

30 IEA, "In the transition to clean energy, critical minerals bring new challenges to energy security," (June 2023), available at https://www.iea.org/reports/the-role-of-critical-minerals-in-clean-energy-transitions/executive- summary.

The flaw in EPA's approach is illustrated by the fact that emissions standards easily become meaningless by changing the engine's location. The proposed rule would treat a PEV charged by a diesel-powered generator as if it had zero tailpipe emissions, notwithstanding the fact that it remains "powered" by a diesel engine located outside the vehicle. A light-duty vehicle directly powered by a diesel engine inside the vehicle, however, is credited with the emissions produced by that engine. Thus, the source of the "fuel" matters. [EPA-HQ-OAR-2022-0829-0579, pp. 7-9]

Finally, EPA has not considered the foreseeable, indirect impacts the Proposed Rule will have on ambient air quality. First, with the high purchase price of new PEVs, consumers will likely hold on to their older, higher-emitting ICE vehicles to avoid the increased purchase price of a PEV. Second, PEVs are heavier, and will increase particulate matter emissions through increased brake, tire, and road wear. Ultimately, EPA arbitrarily ignores the full scope of emissions that will come from PEVs, and a full lifecycle analysis of all potential vehicle technologies must be conducted to fully understand the environmental impacts of the Proposed Rule. [EPA-HQ-OAR-2022-0829-0579, pp. 7-9]

Take Virginia as a representative example highlighting the gap between the Proposed Rule's required infrastructure and that which is actually feasible. According to a report by the Consumer Energy Alliance, attached herein, Virginia currently has 7.6 million light-duty vehicles on the road. Assuming Virginia transitions to 100% PEV by 2035, the state would need an additional 35.5 billion kWh of generation – equivalent to the generation required to power almost 70% of the homes in the state. And to maximize the zero-emission benefit of PEVs, this generation would need to come from zero-emitting sources such as nuclear or renewables (ignoring, for a moment, the energy intensity required to construct these resources). But 35.5 billion kWh corresponds to either 4 new nuclear reactors in the state or over 450,000 acres of off-shore windfarms. Neither of which is remotely feasible under the Proposed Rule.42 [EPA-HQ-OAR-2022-0829-0579, pp. 11-12]

42 CONSUMER ENERGY ALLIANCE, "Freedom to Fuel: Consumer Choice in the Automotive Marketplace," August 2023 [hereinafter, "CEA Study"]. Nor has EPA shown that the electric grid itself can meet this increased demand. As highlighted by the North American Electric Reliability Corporation ("NERC"), certain high-risk areas do not today meet resource adequacy criteria, posing significant concern about adding even more demand to the grid.43 This risk is further exacerbated by EPA's new carbon dioxide standards for fossil-fuel fired power plants, proposed shortly after the Proposed Rule and not otherwise considered in the Proposed Rule, that may rapidly phase out affordable base-load generation.44 Far from what the Proposed Rule requires, the infrastructure upgrades to support a U.S. LD fleet that is only 7% PEV would require an additional $75-125 billion, which would be passed on from utilities directly to customers.45 Today, energy insecure households, defined as those that are unable to adequately meet basic household energy needs because of cost, pay 26 cents more per square foot in energy costs as compared to energy secure households.46 This disparity will only increase as infrastructure upgrades to accommodate the increased load from PEVs is passed along to ratepayers.

43 North American Electric Reliability Corporation, 2022 Long-Term Reliability Assessment (Dec. 2022), 21, available at https://www.nerc.com/pa/RAPA/ra/Reliability%20Assessments%20DL/NERC_LTRA_2022.pdf (indicating that increased demand projections may lead to reliability concerns for the electric grid, especially as dual-peaking or seasonal peaking times change with increased electrification).

44 See Proposed Rule, "New Source Performance Standards for Greenhouse Gas Emissions From New, Modified, and Reconstructed Fossil Fuel-Fired Electric Generating Units; Emission Guidelines for Greenhouse Gas Emissions From Existing Fossil Fuel-Fired Electric Generating Units; and Repeal of the Affordable Clean Energy Rule," 88 Fed. Reg. 33,240 (May 23, 2023).

45 CEA Study at 8 (noting that the average price to consumers in New Mexico would be $117-195 per year).

46 EIA, "U.S. energy insecure households were billed more for energy than other households," (May 30, 2023) available at https://www.eia.gov/todayinenergy/detail.php?id=56640.

Organization: International Council on Clean Transportation (ICCT)

Life-cycle comparison of combustion and electric vehicles

The climate benefits of electric vehicles compared to internal combustion engine vehicles are clear and growing. Numerous studies show that BEVs are much cleaner than combustion vehicles over their lifetime. In fact, the most recent ICCT life-cycle analysis shows that only battery electric and hydrogen fuel cell electric vehicles have the potential to achieve the magnitude of life-cycle greenhouse gas emissions reductions needed to meet Paris Agreement goals.40 Specifically, the assessment finds that the life-cycle emissions over the lifetime of BEVs registered in 2021 in the United States are lower than comparable gasoline vehicles by 60%- 68%. For new vehicles registered in 2030, the life-cycle emissions gap between BEV and gasoline vehicles increase to 62%-76%. [EPA-HQ-OAR-2022-0829-0569, pp. 15-16]

40 Bieker, G. (2021). A global comparison of the life-cycle greenhouse gas emissions of combustion engine and electric passenger cars. International Council on Clean Transportation. https://theicct.org/publication/a-global- comparison-of-the-life-cycle-greenhouse-gas-emissions-of-combustion-engine-and-electric-passenger-cars/

SEE ORIGINAL COMMENT FOR Figure 4. Life-cycle GHG emission of average medium-size gasoline internal combustion engine and battery electric vehicles registered in the United States in 2021 and projected to be registered in 2030.41 [EPA-HQ-OAR-2022-0829-0569, pp. 15-16]

41 Bieker, G. (2021). A global comparison of the life-cycle greenhouse gas emissions of combustion engine and electric passenger cars. International Council on Clean Transportation. https://theicct.org/publication/a-global- comparison-of-the-life-cycle-greenhouse-gas-emissions-of-combustion-engine-and-electric-passenger-cars/

There are a few reasons our study finds such high life-cycle GHG benefits of BEVs compared to gasoline passenger vehicles. The foremost reason is that electric motors are far more efficient than internal combustion engines. Another important reason is that we expect continued reductions in the U.S. electricity generation mix as renewables such as solar and wind become more economically competitive (these sources also continue to be supported by fiscal incentives through the IRA). Our analysis accounts for this expected reduction in the GHG emissions from U.S. electricity throughout the 18-year lifetime of a passenger vehicle registered in the U.S. before it is deregistered. A third reason why the life-cycle GHG emissions from BEVs are so low is that estimated GHG emissions from battery production have declined significantly over the past few years as we have collected new data from commercial-scale battery production plants. [EPA-HQ-OAR-2022-0829-0569, pp. 15-16]

These findings are aligned with other life-cycle analysis of electric and combustion vehicles in the U.S. A 2022 UCS study found that electric vehicles produce fewer emissions than new gasoline vehicles everywhere in the U.S., and that on average EVs produce emissions equivalent to 91-mile-per-gallon gasoline cars.42 The same study found that BEVs' higher manufacturing emissions are quickly paid off after about 12,600 to 21,300 miles of driving, which is typically reached in about 1-2 years for most U.S. drivers. [EPA-HQ-OAR-2022-0829-0569, pp. 15-16]

42 Reichmuth, D., Dunn, J., Anair, D. (2022). Driving cleaner: Electric cars and pickups beat gasoline on lifetime global warming emissions. Union of Concerned Scientists. https://www.ucsusa.org/sites/default/files/2022- 09/driving-cleaner-report.pdf

For combustion vehicles, there is no realistic pathway for deep decarbonization, even when the potential for biofuels and biogas are taken into account. For gasoline cars, we account for the current ~10% blend of corn ethanol and its associated GHG emissions. Blending corn ethanol does not significantly reduce the life-cycle GHG emissions from combusting gasoline because the GHG emissions from producing corn ethanol are also quite high when including EPA's estimated GHG emissions from land use change – only around 20% lower than the lifecycle GHG emissions from producing and combusting gasoline. The production and consumption within the U.S. of ultra-low GHG biofuels that can be blended into the gasoline mix (mainly cellulosic ethanol) remains relatively very low.43 Given the greater incentives for second generation biofuels used in aviation compared to the road sector in the IRA, it seems unlikely that biofuels will significantly reduce the overall GHG intensity of the U.S. gasoline mix over the timeframe of EPA's proposal. [EPA-HQ-OAR-2022-0829-0569, pp. 15-16]

Organization: John Graham (Graham)

I. While EPA claims that the NPRM is technologically neutral,1 the structure of the standards for model years 2027 to 2032 is biased in favor of all-electric vehicles and biased against hybrid propulsion systems.

1 Preamble, p. 29342, states, "At the same time, we note that the proposed standards are performance-based and do not mandate any specific technology for any manufacturer or any vehicle."

Rationale: the compliance calculations under the rule assume that BEVs have zero emissions of carbon dioxide, even though it is well established that increasing use of BEVs will increase carbon dioxide emissions at the electric power plant and create more carbon dioxide emissions in the supply chain for BEVs than would be created in the supply chains for hybrids. Based primarily upon ICCT's 2021 lifecycle analysis, we calculate an artificial benefit to BEVs versus hybrids of slightly over $4,500 per vehicle in 2021 and slightly less than $4,500 per vehicle in 2030 towards standard compliance (retail price – artificial benefit in DMC is about $3,000 per vehicle). Had EPA used a lifecycle metric in the CO2 performance standards (rather than the tailpipe metric), the deployment rates of BEVs and hybrids would be more evenly distributed and the overall impact of the standards on CO2 and costs would have been more favorable. [EPA-HQ-OAR-2022-0829-0585, p. 4]

First, the notion that BEVs have zero emissions is a myth; they transfer pollution from the tailpipe to the stack of the electric power plant, where the electricity is produced to power the BEVs. Moreover, the supply chains for BEVs are more polluting than the supply chains for hybrids, principally because of the large amount of energy required to mine and process the raw materials used in batteries and electric motors. The batteries in HEVs are much smaller than batteries in BEVs, typically less than 2% of BEV battery size. Also, upstream emissions from electricity production are usually greater than the energy required to explore, develop, refine, and distribute petroleum resources and ethanol. Thus, environmentally, BEVs and hybrids need to be compared on a lifecycle basis, not simply at the tailpipe. BEVs may be environmentally preferable in some locations (e.g., where electric power is generated from renewables) while hybrids might be environmentally acceptable or even preferable in areas where electric power is dependent on fossil-fuels, especially coal. [EPA-HQ-OAR-2022-0829-0585, p. 9]

Real-World GHG Emissions

In this section, we distinguish the compliance values for greenhouse gas emissions, which address only tailpipe emissions, from real-world lifecycle greenhouse gas emissions, which include induced utility emissions and emissions throughout the BEV manufacturing and supply chain, as well as tailpipe emissions. [EPA-HQ-OAR-2022-0829-0585, p. 33]

The proposed rule states that BEVs are assumed to have zero-GHG emissions for purposes of compliance with the proposed standards. The DRIA includes some flawed IPM modeling of upstream grid emissions that are biased to make BEVs look cleaner than they will be (see below). Even worse, embedded GHG emissions from battery and BEV manufacturing are not only excluded for compliance purposes but are ignored when computing real-world impacts within the IPM model.94 The omission of emissions from the BEV supply chain is especially appalling given that the agency counts some of the environmental benefits of reducing petroleum production (e.g., reduced emissions at refineries). [EPA-HQ-OAR-2022-0829-0585, p. 33]

94 DRIA 8.2.2.5 page 8-14 states, “The upstream emissions inventory does not account for all upstream sources related to vehicles, fuels, and electricity generation, such as charging infrastructure, storage of petroleum fuels, battery manufacture, etc.”

The IPM modeling assumes that the carbon intensity of the electrical grid will decline by 70 percent over the lifetimes of 2032 vehicles, as renewables replace most fossil fuels throughout the United States. The reader is led to believe that the subsidies for renewables in the Inflation Reduction Act will cause this rapid transformation of the US utility industry. However, the Inflation Reduction Act does not include the permitting reforms that are required for the large new transmission lines necessary to bring renewable energy to the markets where they are needed. Recent reports from both Brookings and the R Street Institute show that, without permitting reform, the monies in the Inflation Reduction Act are likely to have minimal impact on the expansion of renewables in the utility sector.95 The IPM modeling also ignores the massive expansion of grid-scale energy storage that would be required to achieve reliability with renewables. That energy storage, which would likely require large numbers of lithium ion batteries, is not included in the agency’s assessment of battery prices, electricity prices, or material supply requirements. For these reasons, it is unrealistic to expect that the electricity currently provided by fossil fuels will be provided by renewables within the average lifetime of the model year 2032 vehicle. Thus, the upstream emissions from BEVs will be significantly larger than the agency assumes. Without this bias, HEVs would look much better in comparison to BEVs, as we illustrate in the simulation below. [EPA-HQ-OAR-2022-0829-0585, pp. 33-34]

95 Rayan Sud, Sanjay Patnaik. How Does Permitting for Clean Energy Work? Brookings Institution. Washington, DC. September 28, 2022; Rayan Sud, Sanjay Patnaik, Robert L. Glicksman. Federal Permitting to Accelerate Clean Energy Infrastructure: A Nonpartisan Way Forward. Brookings Institution. Washington, DC. February 14, 2023; Philip Rosetti. Potential Effects of the Inflation Reduction Act on Greenhouse Gas Emissions. R Street. Washington, DC. September 27, 2022; Philip Rossetti. Written Testimony for the Hearing on “Tax Incentives in the Inflation Reduction Act: Jobs and Investment in Energy Communities.” Committee on Finance. United States Senate. Washington, DC. May 18, 2023.

The attached Table 1 calculates lifecycle and tailpipe emissions for ICEVs, HEVs, and BEVs for 2021 and 2030. Model years 2021 and 2030 are used because it begins with ICCT’s calculation of 101 g/km CO2 for life cycle emissions of a 2021 model year BEV car in ICCT’s 2021 lifecycle emission study.96 The 101 g/km CO2 is composed of 60 g/km due to operation from the U.S. national electric grid at 357 g/kWh CO2 and 41 g/km due to manufacturing and maintenance emissions. These are converted into g/mi CO_2 in Table 1. BEV emissions with the CA grid at 225 g/kWh CO_2 are also shown for 2021. [EPA-HQ-OAR-2022-0829-0585, pp. 33-34]

96 George Bieker, International Council on Clean Transportation, "A Global Comparison of the Life-Cycle Greenhouse Gas Emissions of Combustion Engine and Electric Passenger Cars", July 2021, Figure 4.1. https://theicct.org/sites/default/files/publications/Global-LCA-passenger-cars-jul2021_0.pdf

The ICCT lifecycle study also calculates ICEV life cycle emissions for cars of 252 g/km CO_2 for model year 2021, comprised of 55 g/km from upstream fuel production, 31 g/km due to manufacturing and maintenance, and 166 g/km for tailpipe emissions (also converted into g/mi). [EPA-HQ-OAR-2022-0829-0585, p. 34]

HEV manufacturing and maintenance emissions are assumed to be the same as ICEV since HEVs do not access the grid and the batteries in HEVs are small compared to the batteries in BEVs (see above) Tailpipe emissions are computed by comparing ICEV and HEV fuel consumption from fueleconomy.gov for seven 2022 models offered with optional HEV systems.97 The average reduction was 30%, which was applied to the ICEV upstream and tailpipe CO_2 emissions in Table 1. v [EPA-HQ-OAR-2022-0829-0585, pp. 34-35]

97 The 2022 models are the Kia Sorento, Hyundai Santa Fe, Hyundai Tuscan, Ford Escape, Toyota RAV4, and Toyota Highlander. Calculations were performed for a submitted SAE paper: John D. Graham and Wallace R. Wade, "Reducing Greenhouse-Gas Emissions from Light-Duty Vehicles: Supply- Chain and Cost-Effectiveness Analyses Suggest a Near-Term Role for Hybrids", accepted for publication in SAE International Journal of Sustainable Transportation, Energy, Environment, & Policy (STEEP) and available from the authors upon request.

Table 1 also calculates emissions for 2030 model year vehicles, also based on the 2021 ICCT lifecycle study. ICCT assumes that manufacturing and maintenance emissions will drop from 41 in 2021 to 34 g/km CO_2 in 2030 for car BEVs and from 31 to 26 g/km for car ICEVs; upstream electricity/fuel emissions will drop from 60 to 52 g/km for car BEVs and from 55 to 52 g/km for car ICEVs; and car ICEV tailpipe emissions will drop from 166 to 150 g/km. As for 2021, 2030 car HEV manufacturing and maintenance emissions are the same as 2030 ICEV and 2030 HEV upstream fuel production and tailpipe emissions are 30% lower than 2030 ICEV. All values in Table 1 have been converted to g/mi CO_2. [EPA-HQ-OAR-2022-0829-0585, pp. 34-35]

A key insight from Table 1 is that the emissions advantage of the BEV relative to the HEV is substantially smaller when the BEV is assigned a plausible amount of upstream and embedded emissions. We have understated the upstream emissions of BEVs in Table 1 by using the average carbon intensity of the electrical grid, rather than the marginal emissions that will result from the additional electricity consumed by BEVs. Insofar as BEVs are charged at night, they will often rely on fossil fuel plants that run at night (solar energy is not available at night). [EPA-HQ-OAR-2022-0829-0585, pp. 34-35]

Lifecycle studies that have investigated marginal emissions find that BEVs do not always have a significant advantage over HEVs, especially in some parts of the country where marginal emissions rely on fossil fuels.98 Interestingly, while overall coal use has been steadily declining in the US since 2010, coal use to meet marginal emissions demands has actually been increasing over the same time period.99 [EPA-HQ-OAR-2022-0829-0585, pp. 34-35]

98 J Zivin, M Kotchen, ET Mansur. Spatial and Temporal Heterogeneity of Marginal Emissions: Implications for Electric Cars and Other Electricity-Shifting Policies. Journal of Economic Behavior and Organization. 107 (Part A). 2014, 248-68.

99 Stephen P. Holland, Matthew J Kotchen, Erin T. Mansur, Andrew J. Yate. Why Marginal CO2 Emissions Are Not Decreasing for US Electricity: Estimates and Implications for Policy. PNAS. 119(8). 2022, e2116632119. https://www.pnas.org/doi/10.1073/pnas.2116632119.

Table 1 also shows that the lifecycle emissions advantage of the BEV is larger in the states that have adopted zero-emission vehicle (ZEV) mandates than in states that have not adopted ZEV mandates. This difference reflects that fact that the average reliance on coal and oil for electricity production is much less prevalent in ZEV states (6.9%) than in non-ZEV states (31.2%).100 Since the incremental effect of the EPA rule will be felt predominantly in the non-ZEV states, the most appropriate comparison for this rulemaking is HEV emissions versus BEV emissions in non-ZEV states. [EPA-HQ-OAR-2022-0829-0585, p. 35]

100 EPA. eGRID with 2021 Data. Released January 30, 2023, https://www.epa.gov/egrid/summary-data.

The central case in the DRIA ignores this reality by assuming that no states have adopted zero emission vehicle mandates. There is a sensitivity case where state ZEV mandates are considered in an alternative baseline, but the sensitivity case does not actually assume full implementation of the state-level mandates. Instead, it uses a BEV adopter model with a state-ZEV variable that is not properly specified (this weakness is acknowledged by the authors of the model).101 As a result, even the sensitivity case assumes, incorrectly, that the EPA rule will have a large impact on BEV adoption in the ZEV states. In the final rule, EPA should fix this problem, making sure that the BEV-adoption impact of the rule is concentrated in the non-ZEV states (since the state regulations and ancillary state policies will handle BEV deployment in the ZEV states). We also recommend a specific marginal emissions comparison of BEVs versus HEVs in each of the non-ZEV states. [EPA-HQ-OAR-2022-0829-0585, p. 35]

101 https://www.nrel.gov/docs/fy22osti/81065.pdf (especially p. 18).

The HEV incremental cost (DMC) over ICEV for 2021 of $2,055 in Table 1 was taken directly from the 2021 NAS study.103 The 2030 HEV incremental DMC was reduced using the 0.97 learning factor from PRIA Table 2-26. From the incremental DMC cost and total emissions, the HEV cost per g/mi CO2 avoided was calculated, $19.3 $/g/mi CO2 for 2021 and $20.5 for 2030. (Note: as explained earlier, larger learning factors should be used for HEVs but here we use the agency's assumption for illustrative purposes). [EPA-HQ-OAR-2022-0829-0585, pp. 36-37]

103 National Academies, Assessment of Technologies for Improving Light-Duty Vehicle Fuel Economy; 2025-2035. 2021. https://nap.nationalacademies.org/catalog/26092/assessment-of-technologies-for-improving-light-duty- vehicle-fuel-economy-2025-2035.

The final step was to calculate the incremental BEV DMC over ICEV that matches the cost-effectiveness calculated for the HEV, for lifecycle emissions using the US grid and tailpipe only scenarios (CA grid is also shown for 2021 for comparison). The results are similar for 2021 and 2030. Using lifecycle emissions and US grid, a BEV is more cost-effective than a HEV only if the incremental BEV DMC is less than $4,686 in 2021 and $4,679 in 2030. Using tailpipe emissions only, a BEV is more cost effective than a HEV only if the incremental BEV DMC is less than $7,820 in 2021 and $7,513 in 2030. [EPA-HQ-OAR-2022-0829-0585, pp. 36-37]

The important finding from these calculations is the large difference between BEV cost-effectiveness for the lifecycle and tailpipe scenarios, which is $3,134 for cars in 2021 ($7,820 - $4,686) and $2,834 in 2030 ($7,513-$4,679). Applying EPA's RPE of 1.5 to the DMC cost-effectiveness increases the amount to about $4,500. This is an artificial advantage given to BEVs over HEVs from using tailpipe-emissions standards instead of lifecycle emission standards. To put this in perspective, the artificial incentive for car BEVs of about $3,000 is 50% more than the HEV DMC cost increment over ICEVs of about $2,000 in both 2021 and 2030. It is also about 63% of the $4,725 incremental DMC of a car BEV over a car HEV in 2022.104,105 [EPA-HQ-OAR-2022-0829-0585, pp. 36-37]

104 2022 BEV and HEV DMC calculated from ICCT 2022 BEV cost study: Peter Slowik, Aaron Isenstadt, Logan Pierce, Stephanie Searle, ASSESSMENT OF LIGHT-DUTY ELECTRIC VEHICLE COSTS AND CONSUMER BENEFITS IN THE UNITED STATES IN THE 2022–2035 TIME FRAME. ICCT, Oct. 2022. https://theicct.org/wp-content/uploads/2022/10/ev-cost-benefits-2035-oct22.pdf.

105 Data: 2020 car ICEV DMC from ICCT 2022 BEV cost study (described in footnote 98) Table 3 adjusted to 2022 using Table 4 ($19,956); 2022 car BEV-250 DMC from ICCT 2022 BEV cost study Table 6 adjusted to 300 mile range using Table 5 ($26,736); 2022 car HEV DMC as previously calculated from 2021 NAS study ($2,055).

[See original comment for Table 1: Comparison of tailpipe and lifecycle emissions and cost-effectiveness] [EPA-HQ-OAR-2022-0829-0585, pp. 36-37]

The Preamble states on page 29342:

"At the same time, we note that the proposed standards are performance-based and do not mandate any specific technology for any manufacturer or any vehicle. Moreover, the overall industry does not necessarily need to reach this level of BEVs in order to comply—the projection in our analysis is one of many possible compliance pathways that manufacturers could choose to take under the performance-based standards. For example, manufacturers that choose to increase their sales of HEV and PHEV technologies or apply more advanced technology to non-hybrid ICE vehicles would require a smaller number of BEVs than we have projected in our assessment to comply with the proposed standards. [EPA-HQ-OAR-2022-0829-0585, p. 37]

While EPA is correct that specific technologies are not actually mandated and manufacturers can choose to increase their sales of HEV and PHEV technologies, EPA is NOT correct that the "proposed standards are performance-based". As illustrated in Table 1, EPA has put its thumb on the scale and given BEVs approximately a $4,500 ($3,000 DMC) advantage – in addition to the temporary advantages that Congress gave BEVs in the Inflation Reduction Act of 2022. Given that the incremental cost (DMC) of a HEV is only about $2,000, this is a huge artificial disadvantage to HEVs. Had EPA used a lifecycle metric in the CO2 performance standards (rather than the tailpipe metric), the deployment rates of BEVs and hybrids would be more evenly distributed and the overall impact of the standards on total CO2 emissions and total costs would have been more favorable. The agency should run the OMEGA modeling using our suggested assumptions in the final rule. [EPA-HQ-OAR-2022-0829-0585, p. 37]

EPA's Response to Comments document for the 2023-2026 light-duty standards dismissed lifecycle arguments as irrelevant since the Agency has not proposed to address a possible change in the "form" of the standard. However, lifecycle emissions are not a "form of the standard", they are part of what determines the total amount of CO2 emissions caused by vehicles. It is disingenuous to suggest that, for example, selecting between footprint- and weight-based adjustments to the standards, which is well accepted as a change in the form of the standards, is the same as ignoring CO2 emissions equivalent to 40% of 2021 ICEV emissions. Delaying indefinitely a move to a lifecycle standard is not technology-neutral, as it retards HEV deployment and innovation, while hurting the environment and the economy. [EPA-HQ-OAR-2022-0829-0585, p. 38]

Therefore, we are requesting that EPA also consider our comment as a petition for rulemaking (under the APA and CAA) to adopt a lifecycle emissions standard for vehicles. If necessary, the agency could go final with the 2027 standards with the tailpipe metric and hold on finalization of the 2028-2032 standards until the lifecycle rulemaking is completed. This would ensure that automakers have ample lead time (4-5 years) to adjust to the new lifecycle metric and the new lifecycle performance standards. [EPA-HQ-OAR-2022-0829-0585, p. 38]

Moreover, by ignoring upstream and manufacturing emissions that are higher for BEVs than conventional vehicles, the final rule will generate more total carbon dioxide emissions and larger compliance costs than would occur if the final rule was designed objectively using lifecycle emissions. This is contrary to the intent of the Clean Air Act, which authorizes no special treatment of BEVs. [EPA-HQ-OAR-2022-0829-0585, p. 38]

Organization: KALA Engineering Consultants (KALA)

Comments

1. If I was not an engineer deeply steeped in the subtleties of transportation emission issues and I read your Federal Register (FedReg) text or news reports written by reporters unfamiliar with the actual science basis for your proposed rulemaking for Docket EPA–HQ–OAR– 2022–0829 Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles, I might come away from certain descriptions of vehicles discussed in such text as describing transportation vehicles that have absolutely no emissions coming from them or attributable to them at all. Repeated use by the EPA of the terms Zero Emission and Zero Emission Vehicle (ZEV) could lead some to believe there actually is such a thing, when all of EPA's emission scientists and engineers know this is not the case. We hesitate to charge EPA with putting out deliberately misleading characterizations of Battery Electric Vehicles (BEV) as true ZERO emission vehicles, but it seems that way. Examples from the FedReg text below: [EPA-HQ-OAR-2022-0829-0617, pp. 3-4]

From Section I. A. 2, i: "These industry advancements in the production and sales of zero-and near-zero emission vehicles are already occurring both domestically and globally,… [EPA-HQ-OAR-2022-0829-0617, pp. 3-4]

As the term ''zero-emission vehicle'' suggests, these cars and trucks have zero GHG and criteria pollutant emissions from their tailpipes, which can represent significant reductions over current emissions (particularly for GHG). [EPA-HQ-OAR-2022-0829-0617, pp. 3-4]

[I]t is important to recognize that, despite this anticipated growth in zero-emission vehicles, many internal combustion engine (ICE) vehicles will continue to be sold during the time frame of the rule and will remain on the road for many years afterward." [EPA-HQ-OAR-2022-0829-0617, pp. 3-4]

KALA strenuously objects to what seems to be un-scientific and cavalier use of the "zero emission" terminology when referring to all-electric rechargeable vehicles when all of you know that there may well be fossil-fueled electric generating units (EGU), emitting lots of GHG, supplying the electric power to recharge those vehicle batteries. We implore the EPA to be more scientifically precise in its terminology for BEVs as Zero Operating Emission vehicles and use acronyms of (ZOE and ZOEV). Such proper terminology gives the uninformed reader the idea that there may be no emissions from operation of BEVs, but there might be emissions associated with the electrical refueling, ie, recharging, of those vehicles. Yes, we know that the ZEV terminology used by EPA fits into what we believe is misguided regulatory consideration of ONLY the operating emissions or lack thereof from ZOEVs while entirely ignoring the "Upstream" GHG emissions associated with battery recharge. EPA cannot have this situation represent realistic GHG considerations if you cling to that artifice. We could give you several dandy analogies, but we won't waste your time. [EPA-HQ-OAR-2022-0829-0617, pp. 3-4]

EPA waxes poetic about all the upcoming public and private BEV recharging facilities that have been and are being installed or planned to be installed. It seems odd to us that the GHG emissions associated with all those charging facilities are simply being ignored in any calculations of attributable GHG emissions that could arguably be linked to BEV expansion in the US fleet. [EPA-HQ-OAR-2022-0829-0617, pp. 3-4]

Charging facilities are NOT zero emission when all of the associated GHG emissions are considered. These recharging facilities would not be being installed if there were no BEVs. Therefore, all of these recharging stations and facilities are new to the status quo situation and therefore have GHG emissions directly relatable to the presence of BEVs. All of the copper used in these facilities has GHG emissions associated with mining, haulage, transport, smelting, wire drawing and reeling. The plastic used in these facilities and as wire insulation almost certainly comes from petroleum stocks with GHG emissions associated with the creation of the plastics. Concrete and reinforcing steel used to support the facilities and provide driveways and parking areas have GHG emissions directly associated with the construction of these facilities, plus the fossil fuels used by construction machinery and vehicles doing that construction. We could go on, but it seems that EPA staff is conveniently ignoring the GHG emissions associated with what will become the millions of recharging facilities and stations needed to support the advancement of electric vehicles promulgated under these proposed regulatory rules. Such willful dismissal or ignoring of these types of issues when it comes to GHG emissions associated with rule making that essentially requires vehicle manufacturers to move to BEV adoption as virtually their sole option for compliance smacks of the work of zealots – in this case electrification zealots within the EPA. [EPA-HQ-OAR-2022-0829-0617, pp. 3-4]

Comment

3. The EPA appears to be using a very "special" consideration of emissions that are to be counted as regulated emission from Battery Electric Vehicles (BEV). In unbelievable statements of contorted logic, the EPA has set forth what we describe as a complete artifice designed to promote and "force" a major change to vehicle propulsion starting in model year 2027. While it is true that during operation BEVs produce no criteria pollutants and emit no GHG gasses, the same cannot be said for the probable sources of the electric power used to recharge the batteries of BEVs. We wish this were not so, but we must deal factually with emissions associated with BEV recharging. If the EPA is serious about GHG reductions, they MUST include and consider

the GHG emissions of grid-connected Electric Generating Units (EGU). Much like the water that comes from our faucets, several water sources could be being used to provide that water. So it is with electricity. No one can distinguish or filter out clean electrons coming from wind and solar sources and “dirty” electrons coming from GHG-intensive electric generation. [EPA-HQ-OAR-2022-0829-0617, pp. 8-10]

Power that comes into homes and businesses may well be a mix of so-called clean energy and emission-laden dirty energy produced by burning fossil fuels. In fact, the mix of electricity generation varies greatly by state or region, depending on what the “serving utility” chooses to use for generation. Some regions rely almost entirely on fossil fuel and nuclear generation methods, while others have added or switched to renewable energy production methods, such as wind and solar as part of their generation mix. There are few if any regions of the United States that are completely powered by renewable or GHG-free energy. There are GHG implications for most of the so-called renewable generation methods. Solar panels are often produced with high Global Warming Potential (GWP) chemicals being released and there are GHG emissions associated with the steel, carbon fibers, plastics and copper conductors used in wind turbines. All this is to say there are GHG emissions associated with virtually all forms of electric generation that cannot be ignored when considering whether or not the introduction of a new form of vehicle propulsion that relies on recharging batteries will have associated GHG emissions. The latest figures from the Energy Information Agency for 2022, show the mix of energy production for the US: [EPA-HQ-OAR-2022-0829-0617, pp. 8-10]

[See original attachment for U.S. utility-scale electricity generation by source, amount, and share of total in 20221 Data as of February 2023] [EPA-HQ-OAR-2022-0829-0617, pp. 8-10]

As you can see, 60.2% of overall US electricity generation was still produced by burning fossil fuels with their associated GHG and other pollutant emissions. When we aggregate how much GHG emissions might be attributable to recharging Battery Electric Vehicles we normally do so on a nation-wide scale using the latest available information. Since regional electric power generation is so varied, we cannot say a BEV in Southern California will have lower associated GHG emissions than one recharging in St. Paul, Minnesota. [EPA-HQ-OAR-2022-0829-0617, pp. 8-10]

Therefore, as of 2022, we can say in aggregate, there is a 60% chance that the electrons used to recharge BEVs over the next few years will be from fossil CO2 emitting fossil fuel generating plants. That is why, any scientific calculations made for the GHG contributions that a BEV makes must consider how the recharging power delivered to the BEV was generated. A BEV may have zero operating emissions but they do NOT have zero GHG emissions associated with their use. It is our considered engineering opinion that much of the so-called “low-hanging fruit” for renewable generation in the US has already been implemented and is now on-line or soon will be. [EPA-HQ-OAR-2022-0829-0617, pp. 8-10]

Think about an Electric Utility company that has literally made billions of dollars of investments in coal and/or natural gas fired power plants. In their board room minds, they are doing just fine making electricity in the same old way as they did 50 years ago and feel no compunction at all about charging their customers more for electricity when the cost of the fossil fuels they burn go up. Why would such a business feel compelled to create “stranded assets” of their fossil-fired generating facilities long before their estimated useful life expires and switch over to renewable forms of electricity generation? Might it be because the board of directors and the management suddenly “feel” like it is the “right” thing to do for the planet. Really?? Seriously, businesses have built-in inertia when they have made large investments in what brings in revenue for the business and for their stock holders. They might agree that new generating capacity should be renewable, but there is great impetus to expand their existing fossil fuel-fired facilities with a new generator unit. [EPA-HQ-OAR-2022-0829-0617, pp. 8-10]

So, the 60% fossil fuel number may stubbornly stay close to that figure for some time. The EPA attempted to control both pollutant and GHG emissions from power plants when the “Clean Power Plan” was part of policy thrusts, but they were less than successful in courts and countering the Utility and Fossil Fuel lobbies in Congress. [EPA-HQ-OAR-2022-0829-0617, pp. 8-10]

https://www.nationofchange.org/2022/07/05/the-supreme-court-has-curtailed-epas-power-to-regulate-carbon-pollution-and-sent-a-warning-to-other-regulators/ [EPA-HQ-OAR-2022-0829-0617, pp. 8-10]

Fig. 2. Alternative metrics for evaluating ethanol based on the intensity of primary energy inputs (MJ) per MJ of fuel and of net greenhouse gas emissions (kg CO2-equivalent) per MJ of fuel. For gasoline, both petroleum feedstock and petroleum energy inputs are included. ‘‘Other’’ includes nuclear and hydrological electricity generation. Relative to gasoline, ethanol produced today is much less petroleum intensive but much more natural gas and coal-intensive. Production of ethanol from lignite fired biorefineries located far from where the corn is grown results in ethanol with a high coal intensity and a moderate petroleum intensity. Cellulosic ethanol is expected to have an extremely low intensity for all fossil fuels and a very slightly negative coal intensity due to electricity sales that would displace coal. [EPA-HQ-OAR-2022-0829-0617, pp. 10-15]

The caption explains the units for GHG emissions calculated, which should be easily converted to what ever units EPA would like to use for its purposes. So, please, EPA, don’t tell us such calculations would be a huge burden since someone else has done them for you. [EPA-HQ-OAR-2022-0829-0617, pp. 10-15]

B. EPA may not have legislative authority to make such sweeping changes to the vehicle mix in the 250 million strong US fleet.

Comment

4. We begin this comment by citing passages from A Framework for Federal Scientific Integrity Policy and Practice formulated by The Scientific Integrity Framework Interagency Working Group (SIF-IWG) of The National Science and Technology Council (NSTC). “The Framework,” as we will refer to it, was commissioned by the January 27, 2021 Presidential Memorandum on Restoring Trust in Government Through Scientific Integrity and Evidence-Based Policymaking to create a Scientific Integrity Task Force. [EPA-HQ-OAR-2022-0829-0617, p. 16]

While the creation of a Scientific Integrity Policy is laudable, we wonder why people in the Executive Branch felt it necessary to state or re-state the requirements for Integrity in Federal Government science products. We believe the timing of the Presidential Memorandum, after the administration of Donald Trump had left office, is consequential. We further believe, while not stated per se in The Framework verbiage, the Executive Branch felt it was necessary to re-state and strengthen Scientific Integrity policies for Federal agencies directly due to the unethical behavior of Agency heads and group leaders hand-selected to further the Trump Administration's policy agendas. Those agendas in numerous cases had Federal Agencies coming out with so-called scientific findings that were diametrically opposite or nearly so to science findings made under prior administrations and under prior Congressional commissions for scientific studies. [EPA-HQ-OAR-2022-0829-0617, p. 16]

We would be glad to debate our prior statements with anybody, but that is not why we are here. We are going to introduce science results that appear to be directly in conflict with science findings from and related to EPA Docket ID No. EPA–HQ–OAR– 2022– 0829, specifically projected Greenhouse Gas (GHG) emission reductions, and more specifically projected GHG reductions from Battery Electric Vehicles (BEV) as a result of full adoption of the rulemaking and standards set forth in the cited proposed rulemaking. As such, KALA Consulting is hereby requesting that, at a minimum, the complete content of this Comment's section (Section 4) be referred to the Science Integrity Officer(s) who oversees science integrity conflicts and opposing views by staff or outside commentors. We might also suggest review of negative conclusions drawn by KALA for what we view as misguided regulatory stances made in formulating the subject docket in our full set of comments. [EPA-HQ-OAR-2022-0829-0617, p. 16]

There are those that will argue that this report on the Hidden Costs of Energy is too old to be applicable to today's situation and that things have changed enough that the assumptions made in 2009 are far from the realities of today. We would in part agree with that assessment except for the issue of GHG emissions projected for 2030 in the report. In that case, the changes that became apparent between 2009 and today would not be in your favor when it comes to GHG emissions from fossil-fueled power plants, which are the main source of GHG emissions associated with Grid Dependent BEVs. [EPA-HQ-OAR-2022-0829-0617, pp. 19-27]

Fugitive Methane Emissions: Let's look at those GHG and power plant-related changes that have come up since the NAS Hidden Costs of Energy report was written. The Hydraulic Fracturing of oil and gas shale rocks method of recovering both oil and natural gas (mostly methane) did not really get going until around 2012 when US oil and gas production did a U-turn and both oil and natural gas became more abundant for US consumers. However, as the amounts of natural gas extraction went up, researchers found increasing amounts of methane in the atmosphere that had a carbon signature attributable to fracked gas.

https://news.cornell.edu/stories/2019/08/study-fracking-prompts-global-spike-atmospheric-methane

[EPA-HQ-OAR-2022-0829-0617, pp. 19-27]

It was becoming apparent in research being done in the US that fugitive methane emissions upstream of natural gas electric generating plants was much worse than the power generating industry or the oil and gas industry were reporting. In a landmark study conducted by Purdue University investigators, the "Well to fire-box nozzle" releases of methane may be as much as 120 times higher than previously reported.

https://www.purdue.edu/newsroom/releases/2017/Q1/estimates-of-emissions-from-natural-gas-fueled-plants-much- too-low,-study-finds.html

[EPA-HQ-OAR-2022-0829-0617, pp. 19-27]

It was thought that a switch over to burning natural gas for electricity generation would produce about half of the GHG emissions of a coal-fired power plant (EGU). With the new availability and low price of fracked gas, many electric utility companies switched their coal-fired generating units to natural gas or built new natural gas-fired units. But when upstream methane emissions are considered and the fact that methane is approximately 85 times more potent a greenhouse gas (85x GWP over the first 20 years after release) than CO2, the GHG emissions from natural gas electric generating units is considerably greater than once thought.

https://www.scientificamerican.com/article/methane-leaks-erase-some-of-the-climate-benefits-of-natural-gas/

[EPA-HQ-OAR-2022-0829-0617, pp. 19-27]

These new study revelations would undoubtedly have increased the estimates for GHG emissions from grid-recharged “Electric” vehicles as the Hidden Costs of Energy study calls BEVs. So, in our view, the GHG emissions for BEVs shown in the Hidden Costs of Energy report are undoubtedly UNDERSTATED. [EPA-HQ-OAR-2022-0829-0617, pp. 19-27]

The other major change related to GHG emissions from electric generation that could not have been known to the Hidden Costs of Energy authors has to do with the environmental disaster known as the Trump Administration. That administration attempted to roll back emission standards and promote the use of coal for electric generating. The writing was on the wall for abandoning coal in favor of natural gas for generation during that time, but some utilities may have extended operations of existing coal-fired generating units or added additional coal burners and generators to portfolios under that coal-favorable oversite. For each day of extended coal-fired operation for electricity, the terrible mix of air pollutants and the solid waste problem of coal ash disposal became worse, something those authors could not have foreseen.

https://www.washingtonpost.com/graphics/2020/climate-environment/trump-climate-environment-protections/

[EPA-HQ-OAR-2022-0829-0617, pp. 19-27]

All of these findings and administrative disasters were not known at the time the Hidden Costs of Energy report was being assembled and study authors were not aware of the “Hidden” methane emissions from the natural gas distribution system. [EPA-HQ-OAR-2022-0829-0617, pp. 19-27]

It may seem odd that a report whose name has Costs as a prominent part of its title would have an assessment of GHG emissions as part of its findings in the Transportation section. The Hidden Costs of Energy report actually made projections for 2030 of environmental damage costs on a cents per vehicle mile traveled basis for multiple carbon-containing fuels, hydrogen and electric vehicles (BEVs). In that projection, BEVs were considered to have higher per mile traveled environmental damage costs than conventional gasoline spark Ignition (CG-SI) vehicles in 2030. [EPA-HQ-OAR-2022-0829-0617, pp. 19-27]

From Page 210 of the Hidden Costs of Energy report:

[See original attachment for Table 3-18 Relative Categories of Damages in 2030 for Major Categories of Light-Duty Fuels and Technologies (2005 data deleted)]

Notes: Costs are in 2007 USD. ABBREVIATIONS: VMT = vehicle miles traveled; CNG = compressed natural gas; HEV = hybrid electric vehicle; RFG = reformulated gasoline.; E85 = 85% Ethanol / 15% gasoline fuel blend; E10 = 10% Ethanol / 90% gasoline fuel blend [EPA-HQ-OAR-2022-0829-0617, pp. 19-27]

The authors of the Hidden Costs of Energy report also depicted their environmental damage costs per vehicle mile traveled (VMT) projected to the year 2030 graphically, which makes comparisons by inspection much easier:

[See original attachment for Health and Other Damages by Life-Cycle Component 2030 Light-Duty Automobiles] [EPA-HQ-OAR-2022-0829-0617, pp. 19-27]

Graphic abbreviation notes: RFG=Reformulated Gasoline (used in warmer US regions in summer); SI=Spark Ignition as opposed to Compression Ignition (Diesel); CG=Conventional Gasoline; SIDI=Spark Ignition Direct Injection; CNG=Compressed Natural Gas; E85=85% Ethanol / 15% Gasoline fuel blend; E10=10% Ethanol / 90% Gasoline fuel blend; Electric=Battery Electric Vehicle (BEV); SI HEV= Spark Ignition Hybrid Electric Vehicle; BD20=20% Biodiesel / 80% petroleum diesel fuel blend [EPA-HQ-OAR-2022-0829-0617, pp. 19-27]

It should be obvious to the most casual observer that it was no walk in the park for the authors of the Hidden Costs of Energy report to consider all 22 of the shown vehicle propulsion fuel and technology types and run projected calculations for each. The graphic also shows that the BEV (Electric) cohort is slightly higher in environmental damages, when monetized, than the spark Ignition Gasoline vehicle types. To put a number to it, if the vehicle travels 100,000 miles, the monetary difference in environ- mental damages between gasoline and BEVs ranges from $10 to $1,000 (2007 USD), which would be about 20% higher in 2022. [EPA-HQ-OAR-2022-0829-0617, pp. 19-27]

The takeaway from this environmental damage assessment in the Hidden Costs of Energy report for 2030 vehicle types is that the EPA is now proposing standards that would probably require high percentages of vehicles, namely BEVs, to be sold into the US fleet that are going to cause MORE environmental damage than a good old gasoline vehicle. If the report's assessment for environmental damages is correct, i.e. that BEVS will be more damaging to the environment than conventional gasoline vehicles, why are we expected to want to drive BEVs and damage the environment more so than the gasoline vehicles we have been using? Moreover, why would the EPA want to force, through regulations, a switch over to BEVs if they are going to do more environmental damage, something that is antithetical to the stated mission of the EPA? [EPA-HQ-OAR-2022-0829-0617, pp. 19-27]

We are still scratching our heads over why the EPA would be pushing for a change to vehicles that do more damage to the environment than the gasoline vehicles we have been driving. The environmental damages assessment shown above does not include any attributable damages from GHG emissions for each vehicle type assessed. Fortunately, for those of us who want to see a comparison of estimated GHG emissions between the type of vehicles we have been driving, gasoline vehicles, and BEVs, the Hidden Costs of Energy report did just that projected for the year 2030. [EPA-HQ-OAR-2022-0829-0617, pp. 19-27]

The tabular form of the Hidden Costs of Energy report's table providing ranges of GHG emissions in grams per Vehicle Mile Traveled (VMT) estimates are shown below from Page 215 of the report. (errata note: The final Hidden Costs of Energy report had an error in units for the tabulation of GHG CO2 equivalent emissions by stating gal/VMT, which we would assume to mean Gallons/VMT, when the left axis title in the graphical representation of the same data that will be shown below, correctly indicates the units to be grams of CO2 equivalent per VMT) [EPA-HQ-OAR-2022-0829-0617, pp. 19-27]

It should be noted that the ranges of GHG emissions shown in the table below consider ALL upstream and downstream attributable GHG emissions and we would also remind that the calculations done for attributable BEV GHG emissions were made without the benefit of the recent studies that revealed the extent of methane being released in the US natural gas distribution system and at natural gas-fired Electric Generating Units. [EPA-HQ-OAR-2022-0829-0617, pp. 19-27]

[See original attachment for Table 3-19 Relative Categories of GHG Emissions in 2030 for Major Categories of Light-Duty Fuels and Technologies (2005 data deleted)] [EPA-HQ-OAR-2022-0829-0617, pp. 19-27]

ABBREVIATIONS: GHG = Greenhouse Gas; VMT = vehicle miles traveled; CNG = compressed natural gas; CG = Conventional Gasoline; SI = Spark Ignition; HEV = hybrid electric vehicle; BEV = Battery Electric Vehicle; RFG = reformulated gasoline.; E85 = 85% Ethanol / 15% gasoline fuel blend; E10 = 10% Ethanol / 90% gasoline fuel blend; Cellulosic = Alcohol Fuel made from cellulosic biomass [EPA-HQ-OAR-2022-0829-0617, pp. 19-27]

We hope you will notice that the calculations made for BEV GHG emissions place the BEV in this table within the same range block as conventional gasoline fueled vehicles. The similarity in attributable GHG emissions for both vehicle types can better be evaluated from the graphic representation of the above estimate data, which when looking at the bar heights, we believe those bars represent the actual numbers calculated for each vehicle type. [EPA-HQ-OAR-2022-0829-0617, pp. 19-27]

For completeness, we will show the original graphic of GHG emissions for all 22 types as shown in the Hidden Costs of Energy report. However, there are notations that the authors made indicating that further deductions for GHG emissions need to be made for the Cellulosic alcohol fuel sources bar heights. [EPA-HQ-OAR-2022-0829-0617, pp. 19-27]

Graphic abbreviation notes: RFG=Reformulated Gasoline (used in warmer US regions in summer); SI=Spark Ignition as opposed to Compression Ignition (Diesel); CG=Conventional Gasoline; SIDI=Spark Ignition Direct Injection; CNG=Compressed Natural Gas; E85=85% Ethanol / 15% Gasoline fuel blend; E10=10% Ethanol / 90% Gasoline fuel blend; Electric=Battery Electric Vehicle (BEV); SI HEV= Spark Ignition Hybrid Electric Vehicle; BD20=20% Biodiesel / 80% petroleum diesel fuel blend [EPA-HQ-OAR-2022-0829-0617, pp. 19-27]

It is difficult to accurately gauge the respective bar heights in this very dense graphic, the bar heights of which we believe to represent the actual calculated amounts in each source category in the stacked bars. In the caption for this graphic (Figure 3-8) the following statement and instructions for revising the bar heights was provided: [EPA-HQ-OAR-2022-0829-0617, pp. 19-27]

Going from bottom to top of each bar, damages are shown for life-cycle stages as follows: vehicle operation, feedstock production, fuel refining or conversion, and vehicle manufacturing. One exception is ethanol fuels for which feedstock production exhibits negative values because of CO2 uptake. The amount of CO2 consumed should be subtracted from the positive value to arrive at a net value. [EPA-HQ-OAR-2022-0829-0617, pp. 19-27]

The reason given for having negative bars for cellulosic alcohols was that cellulosic fuels are derived from living plants that use carbon dioxide in the air, the carbon of which is in what we call the “current” carbon cycle and, while some of the atmospheric CO2 used by plants has fossil carbon in it, the plants are incorporating that CO2 into plant biomass and the roots of cellulosic feedstock plants sequester carbon. For example, the switchgrass perennial plant has often been used as an example of one that could be grown and harvested for cellulosic fuel production. Switchgrass can grow to a height of about 5 feet above ground, while the root system of each switchgrass plant can attain a length of up to 15 feet below ground. [EPA-HQ-OAR-2022-0829-0617, pp. 19-27]

While the instructions were given on how and why the stacked bars for cellulosic alcohols should be handled and represented, the Hidden Costs of Energy report never actually made those bar height adjustments in a separate graphic. Not to worry, we have done that while removing many of the vehicle types superfluous to this comment, such as vehicles fueled with Hydrogen. We present that revised graphic below: [EPA-HQ-OAR-2022-0829-0617, pp. 19-27]

[See original comment for Greenhouse Gas Emissions by Life-Cycle Component 2030 Light-Duty Automobiles] [EPA-HQ-OAR-2022-0829-0617, pp. 19-27]

Please notice that we have added a thin red horizontal line that stretches from the top of the Conventional Spark Ignition Gasoline (CG SI) vehicle bar to the “Electric” (BEV) stacked bar. You may also notice that there is no blue bar segment in the BEV bar stack, denoting no GHG emissions from operation of Battery Electric Vehicles, yet there are associated GHG emissions shown for BEVs from attributable upstream sources, namely fossil fuel-fired Electric Generating Units and their upstream emissions. [EPA-HQ-OAR-2022-0829-0617, pp. 19-27]

Please note that the stacked bar for BEV attributable GHG emissions is nearly equal to the stacked bar height of a normal, everyday, conventional gasoline-fueled vehicle as projected to the year 2030. AND, we would repeat that the calculations done for the Fuel component (green bar segment) did NOT include the upstream GHG impacts of fugitive methane, which recent studies have shown is much greater than previously thought. How much greater is something we think EPA should look into immediately to acquire quantitative figures that could be added to the calculations made by the Hidden Costs of Energy report modelling or new modelling made with updated inputs. [EPA-HQ-OAR-2022-0829-0617, pp. 19-27]

The GHG emission comparison just given in the revised graphic above may well be something the EPA did not want the public to be made aware of. Otherwise, the EPA would not have been so circumspect about accounting for upstream emissions, as we are sure EPA is fully aware of the upstream GHG implications of these new fugitive methane studies. The fact that EPA did not address the attributable upstream GHG emissions associated with BEV recharge may well be because they know that after those upstream GHG emissions are accounted for along with fugitive methane accounting, the result will be similar to what the Hidden Costs of Energy report had shown 14 years ago, or, more likely, even worse for BEVs. [EPA-HQ-OAR-2022-0829-0617, pp. 19-27]

We believe that if a full accounting of BOTH downstream and upstream GHG emissions for BOTH gasoline and EGU emissions recharging BEV batteries was made and the results will show, as the Hidden Costs of Energy report results shown above suggests, that GHG emissions from gasoline-fueled vehicles may well be about the same or very possibly LOWER than those attributable to BEVs. We DARE the EPA to make ethical calculations and share with the public the results of accounting for ALL attributable GHG emissions, both upstream and downstream, for conventional/RFG gasoline vehicles and BEVs. If EPA fails to do so after reviewing this comment, the assumption will be in the public's mind and ours that EPA has something to hide. [EPA-HQ-OAR-2022-0829-0617, pp. 19-27]

The other implication of full upstream and downstream GHG accounting is, if the results of such accounting shows that the true associated GHG emissions, both upstream and downstream, for CG-SI and BEV vehicles are nearly the same or, as we suspect, attributable GHG emissions will be HIGHER for BEVs than gasoline-fueled vehicles the GHG reduction claims made in the rulemaking documentation cannot possibly be real. If ethical attributable emissions calculations for both gasoline vehicles and BEVs prove to be nearly the same, the claims made on page 29198 of the Federal Register in Table 2 – Projected GHG Emission Impacts In 2055 From The Proposed Rule, Light-Duty And Medium-Duty of a net 420 Million Metric Tonnes of GHG gasses cannot be supported in any scientific way. If that reduction estimate includes assumed reductions in GHG emissions from stationary EGUs as a result of new EPA regulatory standards being imposed, the EPA is being less than candid by not providing a GHG emissions estimate regulated by new standards and estimated emission reductions with no new GHG EGU standards regulation applied comparison. [EPA-HQ-OAR-2022-0829-0617, pp. 19-27]

[See original attachment for Table 2 – projected GHG emissions impacts in 2055 from the proposed rule, light-duty and medium-duty] [EPA-HQ-OAR-2022-0829-0617, pp. 19-27]

It is our belief that EPA made a simple calculation of their zero GHG counting for BEVs replacing a certain number of gasoline vehicles, with some accounting for increased EGU GHG output and subtracted the gasoline vehicle GHGs to arrive at Table 2 figures. [EPA-HQ-OAR-2022-0829-0617, pp. 19-27]

The Scientific Integrity Policy and procedures adopted by the EPA reflect the model framework's guidance appearing on Page 31 of "The Framework." [EPA-HQ-OAR-2022-0829-0617, pp. 19-27]

II. Ensuring the Free Flow of Scientific Information

Open and timely communication of EPA science plays a valuable role in building public trust and understanding of EPA's work. EPA shall facilitate the free flow of scientific and technological information and support scientific integrity in the communication of scientific activities, findings and products. Scientific and technological information will be disseminated to the extent allowed by and consistent with privacy and classification standards and responsible communication of scientific information. [EPA-HQ-OAR-2022-0829-0617, p. 27]

We believe that EPA has not lived up to these “Open Government” requirements and has been unnecessarily circumspect, secretive and less than open when it comes to revealing all knowable science facts regarding attributable GHG emissions from BEVs and how they would compare to the majority vehicle type in the US fleet, the gasoline- fueled vehicle. The comparative results taken from the Hidden Costs of Energy report shows beyond a shadow of a doubt that the attributable GHG emissions for BEVs, when both upstream and downstream emissions are counted in an ethical manner, may well be nearly the same or larger than those emitted by gasoline-fueled vehicles. If that is true, the claimed GHG reductions from implementing the proposed regulations from this docket simply cannot be true and cannot be scientifically supported and, therefore, cannot be used as a supporting reason for proceeding with implementing these new standards. [EPA-HQ-OAR-2022-0829-0617, p. 27]

Suggested Alternatives

KALA is an engineering firm and would not be making these comments unless we had some alternatives to suggest to EPA. If the EPA does the right thing and makes known the attributable upstream and downstream GHG emissions for both gasoline and BEV vehicles in a straight-forward comparison, the GHG reduction premise for the EPA Docket ID No. EPA–HQ–OAR–2022–0829 would be nullified. That leaves the criteria air pollutant emission reduction premise for the proposed rulemaking. As we stated above, we concur with EPA that BEVs would reduce criteria pollutant levels where they operate. [EPA-HQ-OAR-2022-0829-0617, pp. 27-30]

However, looking at what has been happening with weather events, forest and wildfire emissions and more frequent flooding events over the last 20 years, the number of lives lost from those Climate Change-related calamities may soon overwhelm any life-saving measures that would stem from implementing the criteria pollution standards proposed in this docket, previous dockets and future dockets. [EPA-HQ-OAR-2022-0829-0617, pp. 27-30]

Despite that grim assessment, we feel that continuing to try and reduce criteria pollutants is worthwhile, even though massive forest fires in Canada this year seem to have wiped out any progress in that area for the time being. [EPA-HQ-OAR-2022-0829-0617, pp. 27-30]

Focusing Criteria Pollutant Emission Reductions on Nonattainment Areas

In the Federal Register Text for the EPA–HQ–OAR– 2022–0829, EPA identifies the number of air pollution nonattainment areas around the country. [EPA-HQ-OAR-2022-0829-0617, pp. 27-30]

From Section I. A. 2, i: “There are currently 15 PM2.5 nonattainment areas with a population of more than 32 million people and 57 ozone nonattainment areas with a population of more than 130 million people.” [EPA-HQ-OAR-2022-0829-0617, pp. 27-30]

Each of those PM 2.5 and Ozone nonattainment areas of the country have vehicles that are either registered within the nonattainment area or are registered in surrounding counties that by regularly driving into the nonattainment area contribute to criteria pollutant emissions within the geographic nonattainment area. The vehicles registered outside the nonattainment area itself that contribute to emissions within the actual geographic confines of the defined nonattainment area are probably used to drive to destinations inside the nonattainment area for work or other reasons. [EPA-HQ-OAR-2022-0829-0617, pp. 27-30]

Our reasoning for what we are about to suggest is based on the question we asked ourselves. “If we really want to make the biggest impact on highly air polluted locations, as defined by nonattainment areas, why require nation-wide criteria pollutant standards when requiring low or no operating emission vehicles to be used within or to enter nonattainment areas might obtain acceptable significant reductions?” We really must agree with the comments from South Dakota Department of Agriculture and Natural Resources (DANR), in which they said, [EPA-HQ-OAR-2022-0829-0617, pp. 27-30]

South Dakota is a large state with significant driving distance between many of our communities. Although several new electrical vehicles indicate they have a 200 mile or greater range (note – it is 224 miles one way from Pierre to Sioux Falls), a recent study shows electric vehicles (EVs) do not consistently achieve EPA' s range estimates. In addition, all batteries degrade over time. Reports indicate EV vehicle batteries will degrade between 10 and 40 percent over a 10-year life span. To maintain the battery's life, manufactures recommend batteries are not frequently depleted below 10 percent capacity or charged above 90 percent capacity. This means that an electrical vehicle should be limited to 80 percent of its capacity range to maintain the battery's life. In addition, cold, hot, and windy weather conditions may reduce an EV vehicle's range between 20 to 40 percent and may further impact the reliability of EV. South Dakota is known to have cold and windy winters and hot and windy summers, which, with current EV ranges, batteries conditions, and availability of charging stations, makes widespread use of EV s impractical in South Dakota. [EPA-HQ-OAR-2022-0829-0617, pp. 27-30]

We believe that a regulatory scheme targeted at vehicles that regularly operate within nonattainment areas, requiring vehicle registrants to use low or no operating emission vehicles if they wish to operate those vehicles inside the nonattainment area on a regular basis would be one approach to reduce criteria emissions in those designated areas. Such a regulatory scheme would require cooperation with the automobile registration agencies, the air quality or resources agencies and potential enforcement agencies within the state where the nonattainment areas are located. [EPA-HQ-OAR-2022-0829-0617, pp. 27-30]

By shifting focus to nonattainment areas, the efforts underway to add charging stations all over the country could be re-focused to install many more charging stations within nonattainment areas and get more bang for the Federal buck spent. [EPA-HQ-OAR-2022-0829-0617, pp. 27-30]

Here is how we see such a plan could work. [EPA-HQ-OAR-2022-0829-0617, pp. 27-30]

A. Vehicle registrants who reside inside the non-attainment area would receive notices that their vehicle(s) do not meet newly promulgated EPA regulations for lowering air pollutant emissions in the local nonattainment area. These of course, would include fleet owners of delivery vans, service vehicles, school busses and other owners of large numbers of vehicles that operate principally inside or very nearby the nonattainment area boundaries. These notices would inform them that one or more of the vehicles they own may no longer be used to drive within the local area because the emissions from the vehicle(s) are too high. The notice would inform the registrants that they can ask for monetary assistance with purchase of a compliant vehicle (sort of like Cash for Clunkers, i.e. high polluting vehicles) or ask for a waiver due to the age of the registrant and/or very low use of the non-complying vehicles (you know, that little old lady who just drives her car to church and the grocery store). [EPA-HQ-OAR-2022-0829-0617, pp. 27-30]

B. Since vehicles are re-registered every year, state registration bureaus would ask registrants if they work or travel to destinations inside the nonattainment area on a regular basis. If so and their vehicles are non-compliant, they would receive the same notice that the non-compliant vehicle they drive into the nonattainment area must be changed out to a compliant vehicle by a date certain. [EPA-HQ-OAR-2022-0829-0617, pp. 27-30]

C. Enforcement could be carried out by application of modern technology. With the advancement of Artificial Intelligence, cameras, many of which are now in place, could be connected to computer systems using software that reads the license plate numbers for vehicles entering the nonattainment area. As time goes by and the same license plates, which of course have vehicle information tied to them including engine type and possibly latest emissions testing data, are read over and over again, the registrant for that vehicle would be notified that the vehicle they are using has been spotted entering the nonattainment area multiple times, enough times to meet criteria for regular entry, and they must switch to a compliant vehicle by a date certain. Warnings and then fines could be levied in stepped amounts against repeat offenders who regularly operate non-compliant vehicles in the nonattainment area. Impoundment would be the final step. [EPA-HQ-OAR-2022-0829-0617, pp. 27-30]

D. The states where these focused programs would be operating could set up a vehicle connection service similar to or connected to Craig's List in which non-compliant vehicle owners could sell or swap their vehicles with interested parties within the state or outside of the state. The description of such vehicles would be required to notify potential buyers that the vehicle does not comply with nonattainment area emission requirements and buyers should not attempt to register the vehicle if they will be entering a nonattainment area with it regularly. There should also be a website that will show car buyers where nonattainment areas and possible candidates for nonattainment areas are located and the qualifying vehicles for each, which could be tailored to the particular criteria pollutant group, such as PM2.5 or Ozone, the area falls under. [EPA-HQ-OAR-2022-0829-0617, pp. 27-30]

E. EPA might require large over-the-road trucks to drive to a central off-loading location where their cargo would be removed in a timely manner from their trailers into covered or enclosed staging platforms where pallets or other items would be re-loaded onto heavy-duty all-electric urban delivery vehicles that would then distribute the goods to various destination points within the nonattainment area (about a 75 mile round trip distance). These truck off-loading facilities would be located downwind of the prevailing winds for the area so that PM and diesel soot would be blown away from the nonattainment area most of the time and be dispersed through dilution. Moving trucks and special loads that require heavy lift machinery to off-load would be exempt from these requirements. [EPA-HQ-OAR-2022-0829-0617, pp. 27-30]

We believe this sort of regulatory scheme could work better than applying universal, nation-wide criteria pollutant standards for all vehicles, especially in those locations where such standards are not actually required to meet local air quality goals. If the proposed rulemaking standards were revised to apply to nonattainment areas, and major urban corridor areas, such as the more dense parts of the I-95 corridor, the complaints seen in the comments to this rulemaking would be lessened or mitigated. We think most people can agree that vehicle requirements that address the worst air pollution areas in the country should be acceptable to protect the health of those who live and work in those areas. [EPA-HQ-OAR-2022-0829-0617, pp. 27-30]

We have some things to say about Electrification Step 3 later. In many of the comments EPA has received for the EPA–HQ–OAR– 2022–0829 Docket, many claim that the existing grid is simply not capable of handling (conductor ampacity) the increased power demands for recharging millions of electric vehicles that will replace much of the 250 million vehicle US fleet. [EPA-HQ-OAR-2022-0829-0617, pp. 31-34]

We have some thoughts on that grid capability issue if we may digress for a moment. The problem with many analyses of electric vehicle switch-out scenarios has been not understanding and taking into account what we call the Most Probable Time-of-Day for Recharge (MPTODR). The scenario put forth by electric vehicle advocates for recharging is everyone who has a BEV will come home from work to their single family home that has been retrofitted with a high-amperage (50 – 70 amps) charging station or stations if the family has more than one BEV. The BEV owner will plug their BEV into the charge station, go inside and enjoy a relaxing evening. That of course, is the elitist part of the whole electrification mythos that other people are like you, being upper middle class people that can easily afford a BEV and the other expenses associated with owning a BEV. [EPA-HQ-OAR-2022-0829-0617, pp. 31-34]

If we take Tesla as a typical BEV example, the Tesla Wall Charger is an outlet that requires more amperage at 240 Volts than most home outlets for an electric dryer or stove can supply. We found a cost estimate for installing a Tesla Wall Charger in the Denver, CO metro area that came in at about $5,000. [EPA-HQ-OAR-2022-0829-0617, pp. 31-34]

[See original attachment for photo of EV calculator] [EPA-HQ-OAR-2022-0829-0617, pp. 31-34]

Remember that the large wire gauge conductors needed for the Tesla charger are usually run in metal or plastic conduit and the straight-line distance between the electric distribution box and a garage is not the installed length because the conduit must be routed around your house to the garage, where the new wires will enter that space and be connected to the wall charger or chargers (if you need multiple chargers, the conduit size and cost is increased to run multiple sets of wires for each charger). [EPA-HQ-OAR-2022-0829-0617, pp. 31-34]

If you want to travel with your Tesla they recommend you should carry recharging gear that will provide flexibility for charging from various outlet types. [EPA-HQ-OAR-2022-0829-0617, pp. 31-34]

[See original attachment for picture of various types of TESLA recharging gear] [EPA-HQ-OAR-2022-0829-0617, pp. 31-34]

It looks to us like that “flexibility” is another $450 or so just to reduce what we call “Recharge Anxiety” for BEV owners. [EPA-HQ-OAR-2022-0829-0617, pp. 31-34]

Notwithstanding the larger initial cost of the vehicle associated with owning a typical BEV, we would argue that for people who live paycheck to paycheck who might be in the middle to lower income economic strata, such expenses are probably out of reach. [EPA-HQ-OAR-2022-0829-0617, pp. 31-34]

Now, back to the Most Probable Time-of-Day for Recharge (MPTODR) issue. If most BEV owners will choose to recharge overnight, this is the time when utility companies are generating what is called Base Load. Base Load is the minimum power output load that a utility company has for its daily load swings. This is the time when most people are asleep and not using a lot of electric power, as opposed to increased power needs when people are up and using more electricity. Most utility companies use the Base Load time period to do maintenance on their Intermediate and Peaking generators. With a massive increase in BEV recharging needs in the overnight Base Load time frame, utility companies may have to run their Intermediate generating units during that time, as well as for meeting daytime loads. [EPA-HQ-OAR-2022-0829-0617, p. 34]

Many utility companies use coal-fired generation for Base Load power needs because they cannot switch coal-fired generators on and off like they could a natural gas-fired turbine generator. It can take days for a large coal generating station to come up to temperature from cold start and start making electricity. We believe that some utility companies will choose to add coal-fired or natural gas-fired generating capacity to meet increased Base Load demand, rather than adding renewables, which would need to be wind power because solar power is not available at night. Whatever generating mix utility companies decide to use to meet BEV recharging demand, the proportion of fossil-fueled generation will be larger because solar will not be available during the MPTODR. This is another aspect of making the upstream calculations for fossil-fired pro rata GHG accounting that we are urging EPA to do for attributable BEV GHG emissions. [EPA-HQ-OAR-2022-0829-0617, p. 34]We now present several graphics that show results of butanol blending tests and fuel properties. [EPA-HQ-OAR-2022-0829-0617, pp. 44-53]

[See original attachment for comparison of fuels] [EPA-HQ-OAR-2022-0829-0617, pp. 44-53]

In the Comparison of Fuels chart above, you can see that Butanol comes the closest to E10 gasoline in energy density than any other non-petroleum fuel. But because it is an alcohol with higher Heat of Vaporization (the ability of a liquid to absorb heat and turn into a vapor - the lower the HOV the more readily the fuel will vaporize on its way into an engine) we will need to add some gasoline to Butanol fuel blends, just as we do for E85 to make cold starting easier, bringing the energy density to 27.8 MJ/L, very close to the 31.8 MJ/L (mega Joules per Liter) of E10. Butanol's stoichiometry at 11.2 : 1 is also far closer to that of E10 gasoline (14.3 : 1) than any other candidate fuel. [EPA-HQ-OAR-2022-0829-0617, pp. 44-53]

Argonne National Laboratory performed FTIR species characterization for butanol blends in their 2010 work on butanol as a fuel using a direct injection ecotec stationary engine. [EPA-HQ-OAR-2022-0829-0617, pp. 44-53]

[See original attachment for graphic of Speciated Hydrocarbons] [EPA-HQ-OAR-2022-0829-0617, pp. 44-53]

This graphic shows emissions prior to entering a catalytic converter and depicts a number of selected "species" for different ratios of both ethanol and butanol compared to both gasoline and E10. The two higher alcohol blend ratios are based on equal percent oxygen by mass, meaning that an 83% butanol-gasoline blend has as much oxygen content as a 50% ethanol blend or about 18 mass%. The vertical bars represent the percent of each species by volume when all of them are added together for each blend's emissions. Note that the percentage of Acetaldehyde for the Bu83 blend is about the same as that for E50, even though there is 66% more alcohol in the Bu83 blend. Obviously, there is an increase in Formaldehyde for the Bu83 blend compared to E50.

That is why we are suggesting lower blend percentages up to 48% butanol with 52% or more of gasoline derived from cellulosic butanol as a potential maximum blend ratio for maximum GHG reductions while reducing formaldehyde emissions indicated for the higher ratio blends. [EPA-HQ-OAR-2022-0829-0617, pp. 44-53]

We also show the Argonne chart of Acetaldehyde emissions below, comparing only 50% ethanol with 83% butanol (66% more alcohol in the butanol blend but same oxygen mass%).

[See original attachment for chart of acetaldehyde emissions] [EPA-HQ-OAR-2022-0829-0617, pp. 44-53]

Clearly, the Bu83 blend is producing far less aldehydes than an equal Oxygen % blend ratio of ethanol would produce. The three aldehydes expected to increase with alcohol fuels, Acetaldehyde, Formaldehyde and Acrolein (Acrylic-aldehyde) are among the EPA's group of six "priority" Mobile Source Air Toxics compounds. [EPA-HQ-OAR-2022-0829-0617, pp. 44-53]

From this confirmation, we can conclude that butanol is a far better fuel at equal blend ratios as to emission of aldehydes when compared to ethanol. If we look at oxides of nitrogen (NOx), the Argonne data show that both ethanol and butanol will reduce NOx, but butanol tends to reduce NOx more as the mass percent of oxygen increases. Argonne also indicates that Carbon Monoxide (CO) is also reduced with increasing ratios of both ethanol and butanol. [EPA-HQ-OAR-2022-0829-0617, pp. 44-53]

While emissions of Acetaldehyde and, perhaps, Acrolein may decrease with butanol in comparison with ethanol for the same blend ratio with gasoline, Formaldehyde (HCHO) emissions will increase. But, unlike Benzene that is in and can evaporate from gasoline, and is also formed by burning other aromatic constituents of gasoline, Formaldehyde is only produced as a combustion product. Formaldehyde is now classified by the EPA as an "A" carcinogen and also has other non-carcinogenic health effects. [EPA-HQ-OAR-2022-0829-0617, pp. 44-53]

[See original attachment for graphs of regulated and formaldehyde emissions] [EPA-HQ-OAR-2022-0829-0617, pp. 44-53]

It is known that VOC emissions from volatile fuels escape into the air and combine with NOx compounds in the presence of sunlight (photochemical) to form Ozone. The volatility of fuels is measured using the Reid Vapor pressure (RVP) scale. [EPA-HQ-OAR-2022-0829-0617, pp. 44-53]

In the vapor pressure effect graphic below for blends of ethanol and butanol, the Bu16 blend, equivalent in oxygen to 10% ethanol will lower the RVP of that blend by about 0.6 psi. A 10% ethanol blend would have increased the blend's RVP by anywhere from 0.6psi to 1.2 psi, or an average of 0.9 psi. To compare the two effects, we must look at the difference between the addition of the two oxygenates to understand the complete effect. [EPA-HQ-OAR-2022-0829-0617, pp. 44-53]

[See original attachment for graph of vapor pressure of ethanol and n-butanol in gasoline] [EPA-HQ-OAR-2022-0829-0617, pp. 44-53]

As shown in the graphic above, vapor pressure is reduced as soon as any butanol is added to gasoline blends, while ethanol additions to gasoline increase vapor pressure and, thus, the tendency for fuel molecules to enter the air more readily. Ethanol at 10% V/V produces the greatest increase in vapor pressure. The vapor pressure difference between the two gasoline additives at equal oxygen content for E10 and Bu16 is 1.5 psi. [EPA-HQ-OAR-2022-0829-0617, pp. 44-53]

By reducing fuel blend vapor pressure using butanol, the effect is likely to be reduced VOC releases from butanol blended fuels. [EPA-HQ-OAR-2022-0829-0617, pp. 44-53]

For PM 2.5 considerations, decreasing the amount of aromatics in diesel fuel, especially polynuclear or poly-aromatic hydrocarbons (PAH) could lead to reduced PM emissions and possibly lower mutagenicity (ability to cause genetic mutations) and carcinogenicity risks. [EPA-HQ-OAR-2022-0829-0617, pp. 44-53]

Testing of blends of butanol with diesel fuel with no attempt to maintain Cetane Number (CN) has been performed by Argonne National Laboratory (ANL). In tests on a light-duty vehicle with a diesel engine, ANL was able to show that increasing ratios of n-butanol with a native CN of about 25, blended at various ratios with a CN 42 diesel fuel (presumably with an initial aromatic content of 35 volume% or less) could significantly reduce diesel smoke with its accompanying PM content. Soot and smoke content is measured by the Filter Smoke measurement where diesel exhaust is run through a filter designed to capture almost all of the PM materials in the exhaust and a Filter Smoke Number (FSN) is obtained. [EPA-HQ-OAR-2022-0829-0617, pp. 44-53]

[See original attachment for graph of smoke and NO Emissions] [EPA-HQ-OAR-2022-0829-0617, pp. 44-53]

While 100% n-butanol would not operate properly in an engine designed and calibrated for diesel fuel, Argonne found that low to medium blends of 1-butanol and ultra-low sulfur diesel (ULSD) provide acceptable Cetane along with the potential advantage of oxygen in the fuel. Broadly, the study found that on the urban drive cycle, both total hydrocarbon (THC) and carbon monoxide (CO) emissions increased as larger quantities of butanol were added to the diesel fuel. THC increased significantly as the percentage of butanol increased for cold-start UDDS drive cycle and only modestly for the hot-start UDDS cycle. Oxides of nitrogen (NOx) were not significantly affected by the 20% butanol blend and decreased with the 40% butanol blend. For the highway drive cycle, THC and CO emissions were not significantly impacted but NOx showed a slight increase as the butanol blend ratio increased. For the steady-state tests, they found a reduction in filter smoke number with increasing butanol quantity—an 80% reduction in filter smoke number was observed for the 40% butanol blend. The lowest fuel economy reduction (~9%) occurred for the HWFET drive cycle. [EPA-HQ-OAR-2022-0829-0617, pp. 44-53]

Comments 4. (Cont.) http://pure-oai.bham.ac.uk/ws/portalfiles/portal/54062490/Hergueta_Santos_Olmo_et_al_Impact_bio_alcohol_fuels_Applied_Energy.pdf [EPA-HQ-OAR-2022-0829-0617, pp. 44-53]

For PM 2.5 considerations for butanol/gasoline blends, we refer EPA to newer research performed at University of Birmingham, United Kingdom in 2018. In this study, both particulate size and overall particulate quantity released from combustion were characterized for neat gasoline, E25 and Bu33 (not equal in oxygen content). [EPA-HQ-OAR-2022-0829-0617, pp. 44-53]

[See original attachment for average primary particle diameter] [EPA-HQ-OAR-2022-0829-0617, pp. 44-53]

The study showed nearly equal PM particle size for both gasoline and Bu33 (B33 in the graph), while particle size for E25 was lower than either. The study text states: “The average primary particle size dp0 is 29.42 nm, 28.60 nm and 25 nm from the combustion of gas- oline, B33 and E25, respectively…E25 [EPA-HQ-OAR-2022-0829-0617, pp. 44-53]

emitted the highest concentration of smaller particles in the range between 7 nm and 40 nm.” Not good news for advocates of higher ethanol blends when those Exx blends appear from these results to produce smaller particle sizes, which might be more deeply inhaled into the lungs. The research further looked at overall PM reductions. [EPA-HQ-OAR-2022-0829-0617, pp. 44-53]

[See original attachment for graph of particle size distribution for gasoline and DN/DlogDp] [EPA-HQ-OAR-2022-0829-0617, pp. 44-53]

The study stated, “The most significant reduction of 80% in the PM peak concentration was achieved in the combustion of B33, when compared to gasoline. The maximum particle concentration was 30% lower from the combustion of E25 when compared to gasoline.” [EPA-HQ-OAR-2022-0829-0617, pp. 44-53]

We don’t know how EPA feels about an 80% reduction in PM concentration just by adding 33% V/V of butanol to gasoline, but we think that is pretty darned good. [EPA-HQ-OAR-2022-0829-0617, pp. 44-53]

The major issue in this Comment #4 has been a discussion of how to dramatically lower GHG emissions from the liquid fuels that will still be being used in all those millions of gasoline vehicles that EPA in the Federal Register document admits will still be on the road emitting GHG and criteria pollutants. From the foregoing research hints at what benefits may be obtained by adding higher blend ratios of butanol to the nation’s gasoline supply, the reduction of fossil carbon emissions we believe to be the most important for Climate Change solutions, solutions that will actually work. [EPA-HQ-OAR-2022-0829-0617, pp. 44-53]

We are asking the EPA to start thinking differently about GHG emissions. Tail pipe emissions from a vehicle that has a blend of say 48% cellulosic butanol and 52% “Green” gasoline made from that same butanol will show CO2 emissions. But, the carbon in that CO2 will have an extremely small percentage of FOSSIL CARBON in those emissions, because the carbon in the CO2 was inside green plants growing just a few months before being processed into butanol and “Green” gasoline. The measured CO2 emissions will certainly contain carbon, but that carbon will not be fossil carbon. [EPA-HQ-OAR-2022-0829-0617, pp. 44-53]

We ask that EPA begin to formulate methods of calculating actual fossil and non-fossil GHG emissions from exotic blends of advanced biofuels made from biomass, where the carbon incorporated into the fuels is from the “current” carbon cycle. The emission of CO2 from such fuels will cycle that CO2 back into the bodies of growing plants, which are later harvested and converted into carbon-neutral fuels in an endless cycle. [EPA-HQ-OAR-2022-0829-0617, pp. 44-53]

We believe efficient production of the advanced biofuel, cellulosic butanol, can and will produce major reductions in FOSSIL carbon emissions from the US transportation fleet. Our calculations for potential GHG reductions use the UC Berkeley RAEL (Farrel, et. al.) calculations done for ethanol GHG emissions compared to gasoline burned in ICEs. Our interpretation of those GHG computations for cellulosic butanol are shown below:

[See original attachment for Effects of Producing Cellulosic Butanol Rather than Ethanol] [EPA-HQ-OAR-2022-0829-0617, pp. 44-53]

The main reason cellulosic butanol can achieve such high GHG reduction numbers has to do with the opportunity to cycle butanol in a much larger way than ethanol ever could back into the production train, where farm and ranch production, harvesting and transport of cellulosic biomass can be made with machinery and vehicles fueled by butanol/diesel blends and high butanol/gasoline blends. We don't know how EPA feels about a potential for 91.5% reductions in GHG emissions from fuel compositions using high ratios of cellulosic butanol in gasoline and, perhaps "Green" gasoline made from butanol, but we are pretty excited. [EPA-HQ-OAR-2022-0829-0617, pp. 44-53]

So, let's review. We offer a qualitative review of GHG and liquid fuel combustion air pollutants when cellulosic butanol and analog hydrocarbon fuels made from it are incorporated into the fuel mix for US transportation use. Probable movement: [EPA-HQ-OAR-2022-0829-0617, pp. 44-53]

1. GHG emissions

a) Reduced (KALA calculations show that for pure cellulosic butanol and gasoline or diesel made from cellulosic butanol and blends thereof could reduce GHG emissions by 91.5%)

2. Criteria and other air pollution components likely direction

[See original attachment for list or air pollutants and their reductions and increases] [EPA-HQ-OAR-2022-0829-0617, pp. 44-53]

Another way of looking at the severity of the pollutants and how reductions or increases might affect human health would be to look at a grouping of the highest rated Human Carcinogen Potential (HCP) rating these pollutants have. Therefore, we offer tables of those compounds that are likely to decrease with butanol induction into common fuels and those that would increase in amounts emitted and their associated HCP below. [EPA-HQ-OAR-2022-0829-0617, pp. 44-53]

[See original attachment for Likely-to-be-Reduced Compounds] [EPA-HQ-OAR-2022-0829-0617, pp. 44-53]

[See original attachment for Inclusive list of Probable Increased EPA Master List & Non-Listed Butanol Fuel Emissions] [EPA-HQ-OAR-2022-0829-0617, pp. 44-53]

Listing Notes: * Based on IARC Determination ↓ Likely to be produced in small quantities & consumed in a catalytic converter

We might note that the HCP A-rated compound in the above "Increased" list, Formaldehyde, has a half-life in air in the absence of nitrogen dioxide, of approximately 50 minutes during the daytime; in the presence of nitrogen dioxide, this drops to 35 minutes (source WHO), while the other HCP A-rated compound that will be reduced, Benzene, has a half-life in air of 13.4 days (source: Spectrum Chemical Fact Sheet: Benzene). We would much rather increase an A-rated carcinogen, Formaldehyde, that degrades and decomposes over a matter of hours than keeping an A-rated carcinogen, Benzene, that will only decompose after a matter of tens of days in the air pollutant mix. [EPA-HQ-OAR-2022-0829-0617, pp. 44-53]

We believe the observable benefits of adding butanol into the US fuel mix outweighs the minimal drawbacks of some increased emission species. This tradeoff, of course, is what we have been doing for a long time in this country, trading the health degrading aspects of vehicle air pollution for the speed and convenience modern vehicles provide. [EPA-HQ-OAR-2022-0829-0617, pp. 44-53]

Comment 5. The Law of Unintended Consequences or Reactions [EPA-HQ-OAR-2022-0829-0617, pp. 54-60]

A. We believe public sentiment toward the obvious potential results of adoption of the Docket ID No. EPA–HQ–OAR– 2022–0829 rulemaking of “forcing” manufacturers to predominately produce BEVs in order to meet the proposed standards may well have a host of unintended consequences.

Despite the glowing polling results reported in the Federal Register rulemaking document regarding eager acceptance of BEVs and polls of PHEV and BEV owners that would be willing to purchase such vehicles again, we believe that most of those respondents fall into several categories such as ‘Early Adopters,’ electric car zealots and wealthy people who can afford BEVs and want to impress their friends and neighbors with how “Green they are. Seriously, a person who buys an obscenely ostentatious Lucid 1,000 horsepower electric vehicle cannot be considered represen-tative of the majority of people who will be presented with BEVs as, essentially, their only choice in new car showrooms in a few years. We think there may well be elderly people who buy a new car after 2027 that will get the BEV home and be wondering, “Where do I put in the gas for this thing?” [EPA-HQ-OAR-2022-0829-0617, pp. 54-60]

We looked at several polls, as did several other commenters, but the one we chose to discuss here has international representation in several developed countries in Europe as well as the US. The poll was conducted by UK-based Kantar Public in their Journal-04 publication of polling data on public attitudes towards the environment, sustainability, and climate change. If you go to ResearchGate and request the actual PDF of the research, you will get the graphics and discussion we are about to share with EPA. https://www.researchgate.net/publication/355734467_European_attitudes_to_climate_change_i mplication s_for_citizens_institutions_and_governments [EPA-HQ-OAR-2022-0829-0617, pp. 54-60]

The Guardian also published excerpts from the polling in 10 countries here:

https://www.theguardian.com/environment/2021/nov/07/few-willing-to-change-lifestyle-climate-survey [EPA-HQ-OAR-2022-0829-0617, pp. 54-60]

From those sources we present the second of two graphics below from the survey and then comment on the results. The most interesting results we found were from the following question “How would you rate in terms of importance, the following measures aimed at preserving the environment and the planet?: [EPA-HQ-OAR-2022-0829-0617, pp. 54-60]

Replacing fossil fuels with renewable energy – 45% say important Reducing people's energy consumption – 32% say important Favoring the use of public transport over cars – 25% say important And most pertinent to this comment's discussion: [EPA-HQ-OAR-2022-0829-0617, pp. 54-60]

Banning fossil fuel vehicles – 22% say important [EPA-HQ-OAR-2022-0829-0617, pp. 54-60]

[See original attachment for poll on how people ranked, in terms of importance, the following measures aimed at preserving the environment and the planet] [EPA-HQ-OAR-2022-0829-0617, pp. 54-60]

Only 22% felt that banning fossil fuel vehicles (22%) was important to preserve the planet. We would characterize this level of response to that question as dismal at best, people do not want to use electric vehicles. [EPA-HQ-OAR-2022-0829-0617, pp. 54-60]

In the US, Transportation accounts for slightly more Greenhouse Gas (GHG) emissions than does electricity generation. However, in most other large emitter countries, the opposite is true with Electricity generation being far greater than Transportation. This is especially true of China (the largest global GHG emitter), where much of the country is still rural in nature, most electrical generation is by exceedingly dirty coal-fired power plants and the thought of a personal vehicle being a birthright is a foreign (i.e. US) notion. The most frightening aspect of what we call the "Lifestyle Gap" is the desire by most people in other countries to have a similar lifestyle to what they observe in the US. Having personal transportation (something bigger and more enclosed than a motor scooter) is very high on that desire list. That implies that as other countries catch up to a US lifestyle, Transportation GHG emissions will continue to rise from that sector. [EPA-HQ-OAR-2022-0829-0617, pp. 54-60]

Most other countries that do not have oil reserves, look to the US for what to do about Climate Change. The reasoning goes, the US is the most technically advanced country in the world and whatever solutions the US comes up with must be the "correct" solutions. These facts make it doubly important for the US to act as the leader of the world on Climate Change with truly "correct" and nearly universally applicable solutions. Yet, we do not have a set of National Climate Change Solution Plans that the Federal Government has endorsed as policy and has committed funding and regulations to implement. So far, there have been "Band Aid" measures on Transportation GHG emissions such as the Biden plan to place electric vehicle charging stations all across the country, a partial solution that KALA disagrees with, not on the viability of electric vehicle charging stations, but the lack of focus on deployment in locations that desperately need reductions in emitted vehicle pollution (these are known as EPA's nonattainment areas such as large cities where most of the pollution that creates the nonattainment condition is from vehicles). The opposite is true in China where big city pollution is mostly from nearby electrical generation. [EPA-HQ-OAR-2022-0829-0617, pp. 54-60]

These dichotomies between nations and their levels of technology and emission profiles also makes it important for the solutions developed by the US be largely applicable to nations with lower levels of technology and wealth. The battery electric vehicle solution so often touted as "THE" solution to transportation GHG emissions, will NEVER apply to the hundreds of millions of motor bikes, motor scooters, motor trikes, motorized boats and various other transport modes, which all use petroleum-based liquid fuels, found all across Asia, India, Indonesia, the

Philippines, the Middle East, Africa and South America. Many countries that are considered "Developed" (I'm thinking Russia and the former USSR vassal states) may not have citizenry that can easily afford a transition to an entirely different vehicle propulsion method, such as battery electric, and will struggle to maintain their existing fleets of vehicles that still use fossil petroleum fuels. In fact, the less developed and lower income nations around the world will balk at implementing the so-called "solution" that seems to be prevalent in the thinking of the United States for Transportation GHG emissions, i.e. Battery Electric Vehicles (BEV). Oil producing states, such as Russia and Saudi Arabia, where oil income is the principal national revenue will be outright hostile to the notion of changing the vehicle propulsion method. [EPA-HQ-OAR-2022-0829-0617, pp. 54-60]

In response to the Kantar polling as to why they would be hesitant to make drastic changes to help with Climate Change: "I need more resources and equipment from public authorities" (69%) together with "I can't afford to make those efforts" (60%) were major responses. [EPA-HQ-OAR-2022-0829-0617, pp. 54-60]

Any policy makers who see these results, especially in the US, MUST rethink where policy making should go on Transportation GHG reductions. When someone says, "I can't afford to make those efforts" what are they most likely talking about? In our view, for most people, they are referring to the cost of replacing their current gasoline vehicle with an electric vehicle. In the US, vehicles are usually the second most costly item of personal ownership, with a home being in first place. For those who cannot afford home ownership, a large percentage of the Democratic Party's base, a vehicle is their most costly personal possession. If those individuals are middle to lower income, their budgets are usually very tight and the thought of being forced to purchase a vehicle that is 20% to 50% more costly than a gasoline vehicle is generally out of the question even with generous tax rebates that actually mostly apply to more wealthy individuals with high personal incomes. We believe that they will instead, choose to buy a replacement vehicle, when needed, from the existing stock of gasoline-burning used cars for as long as they can. [EPA-HQ-OAR-2022-0829-0617, pp. 54-60]

This analysis brings up the issue of how little time we have left to actually make the most significant changes to GHG emissions. We simply do not have time for people to run out of gasoline-burning used car choices, which could amount to 20 years or more, for them to finally buy the supposed "solution" to transportation GHG emissions, a BEV. Related to this lower to middle income demographic is the issue of their vehicle being able to provide "Dual Duty." A Dual Duty vehicle is one that can provide short-distance (short time frame) transportation for daily needs such as grocery getting and the back and forth to work commute AND provide a way to take long trips for such things as vacations and family gatherings. Let me relate an interesting response to a question I posed to a Nissan representative at a Denver car show about the Leaf All-Electric vehicle (BEV). I asked what about trips up into places like Wyoming where they will not be welcoming to electric vehicles in that oil producing state? Incredulously, the Nissan rep said, "Oh, you don't use the Leaf for longer trips – you use your 'Other car' for that." [EPA-HQ-OAR-2022-0829-0617, pp. 54-60]

Such a response shows an unbelievable elitism about lower cost BEVs, such as the Leaf and the Chevrolet Bolt, that the owner of such BEVs will have the financial means to have two or more vehicles, one of which is capable of long-distance trips without the bother of waiting 3 to 7 hours for a recharge after the car's battery is exhausted. This has become known as "Recharge

Anxiety." It is a real thing and represents the problem all BEVs have in public perception of: What happens when you run out of battery charge on a long trip or in a traffic jam? Will it take hours to recharge even if I can find an open and working recharge outlet? Why would I ever try to take a BEV on a long trip when I can "recharge" (i.e. refuel) my gasoline vehicle in less than 10 minutes? BEV makers have tried to address this problem, Tesla for example, by providing a Supercharging option at special recharge stations designed to recharge a half-discharged battery in about 15 minutes. But, even Tesla admits that rapid recharge is not good for the individual cells in the battery pack and should not be done too often. [EPA-HQ-OAR-2022-0829-0617, pp. 54-60]

B. If the EPA attempts to "force" people into BEVs, there may be an unexpected and unforeseen political reaction among people who have traditionally been the base of the Democratic Party who may switch their political allegiance to the other Party who won't force them to drive BEVs. [EPA-HQ-OAR-2022-0829-0617, pp. 54-60]

So, what choices do the lower and middle income people that comprise a large percentage of the Democratic Party base have when it comes to the supposed Transportation GHG emission "solution," the BEV. The answer is not much, because for the ONE car they can afford, they need the Dual Duty vehicle that is represented best by a gasoline-fueled vehicle that can be refueled on longer trips in less than 10 minutes and then they are on their way again. If the Democratic party at the behest of a Democratic president through a regulatory agency attempts to force those people to purchase and deal with all the recharge problems that BEVs have, they might well not be Democrats anymore. Republicans will NEVER support forcing people to buy BEVs (they are in the back pockets of the oil companies after all) and that may well drive people who were reliable Democratic voters into the Republican camp over this single issue. [EPA-HQ-OAR-2022-0829-0617, pp. 54-60]

So, the question to EPA administrators is simple. Do you want to risk political reprisals in the form of election of Republican legislators and the head of the executive branch, the president, because you felt this was your chance to "force" the adoption of a vehicle type, the BEV, down peoples throats that, frankly, we believe we have shown conclusively will not perform the GHG reduction function that the EPA claims it will. [EPA-HQ-OAR-2022-0829-0617, pp. 54-60]

Didn't you see what happened when Donald Trump was president and the EPA was rendered powerless and, now that the Supreme Court is constituted the way it is with ultra-conservative judges, how do you think court cases that make it to SCOTUS will turn out for EPA on this and other regulatory Docket issues? Now look, we are not saying to the EPA to be fearful and hunker down and not do anything about GHG and criteria pollutants from transportation. PLEASE review our set of alternatives in Comment Section 4, which we think makes more sense, especially from a GHG reduction standpoint than trying to "force" adoption of BEVs into the US fleet at unreasonable numbers. Making people buy and drive very different vehicle types may not be the answer, especially for GHG reductions. We think the "Fuel Change Out" approach with high GHG reduction potentials and better criteria emissions profiles is a better way to meet the needs for health risk reductions and more importantly, as we have argued above, for dramatic reduction in GHG emissions by substituting fossil carbon containing fuels for carbon-neutral fuels made from biomass. [EPA-HQ-OAR-2022-0829-0617, pp. 54-60]

We have the technology to make these carbon-neutral fuels that come very close to the properties of gasoline and dramatically reduce GHG emissions if we just have the will and foresight to do so. [EPA-HQ-OAR-2022-0829-0617, pp. 54-60]

C. The consequences that may arise from full implementation of Docket ID No. EPA–HQ–OAR– 2022–0829 rulemaking standards and requirements may produce something that could be described as a quiet rebellion against what many people would view as government overreach via regulation. [EPA-HQ-OAR-2022-0829-0617, pp. 54-60]

To give you a better "feel" or Flavor for the reaction to the docket's provisions, we would invite EPA to look at a YouTube video by long-time YouTube maven on automotive issues, Scotty Kilmer. https://www.youtube.com/watch?v=j1R0wTBsK3I [EPA-HQ-OAR-2022-0829-0617, pp. 54-60]

In this video presentation, Kilmer starts out blaming President Biden and by association the Democratic Party as the villains who want to take your gasoline car away from you and limit your buying choices in the future. Here are some of the comments elicited from the video with many of the obvious Trumpian attitudes filtered out: [EPA-HQ-OAR-2022-0829-0617, pp. 54-60]

"How do we do this when 90% of Americans cannot afford a new car?" [EPA-HQ-OAR-2022-0829-0617, pp. 54-60]

"As someone who has never bought a new car. I can assure you I will never be buying a used electric car." "We can barely get enough minerals to power our phones, and now we want 60%of cars to run on batteries." [EPA-HQ-OAR-2022-0829-0617, pp. 54-60]

"They can build all they want, but you cannot force people to buy them." [EPA-HQ-OAR-2022-0829-0617, pp. 54-60]

"Just where am I supposed to get $61,500 for a car? That is absolutely insane! This is legislation through regulation. Who voted for those EPA bureaucrats? There is exactly ZERO percent probability that I will buy an EV." [EPA-HQ-OAR-2022-0829-0617, pp. 54-60]

"This is the closest thing to government mandating what people get to choose and eliminating a free market based on consumer demand." [EPA-HQ-OAR-2022-0829-0617, pp. 54-60]

"We just need a group of people with the know-how and the financial ability to sue the EPA to stop infringing on our rights to purchase what we want. They're just basically taking our freedom away through regulation without actually saying we don't have the freedom to choose what we want." [EPA-HQ-OAR-2022-0829-0617, pp. 54-60]

"Thanks to Scotty's advice we just bought a 2023 Camry V-6. We're good for 20 years or 300,000 miles." "I have a Tesla but forcing everyone to get an EV is insane. Many don't have the capability to charge at home and a lot of homes need panel upgrades to make room for a EV charger. All of this costs a lot of money for people to afford." [EPA-HQ-OAR-2022-0829-0617, pp. 54-60]

"In our office people are buying hybrid cars instead of EV cars. It make more sense, 500 miles of range, fill the tank in 6 minutes and probably last longer and they are about the same price or less and are proven technology." [EPA-HQ-OAR-2022-0829-0617, pp. 54-60]

“This sounds like used vehicle prices are going to skyrocket worse than before -probably not a good sign for those of us stuck as pizza drivers.” [EPA-HQ-OAR-2022-0829-0617, pp. 54-60]

“The EPA doesn't have the authority to change the law or the regulations. The people through congress will make that decision thank you.” [EPA-HQ-OAR-2022-0829-0617, pp. 54-60]

“American people remember you have the power to choose your president and who makes the laws, if it’s affecting you who cannot afford to change your car then get someone who sides with the working classes and will help you make your own choices, the fact that making batteries pollutes more than gasoline engines produce doesn’t matter to these politicians who don’t know what it’s like to have to work for a living.” [EPA-HQ-OAR-2022-0829-0617, pp. 54-60]

“Is it at all possible for congress to stop this insane man [presumably Pres. Biden]? [EPA-HQ-OAR-2022-0829-0617, pp. 54-60]

So, does the EPA get some of the rebellion flavor in those comments? It is our opinion that one of the unintended consequences of implementing this Docket may be to create a rebellion of sorts among millions of Americans. We think that people may decide to hold on to their gasoline vehicles much longer than they otherwise might. We also think that once BEVs are about the only vehicles on dealer’s showroom floors, the price of used gasoline vehicles may well increase dramatically. If that happens, millions of low income people may be priced out of the used car market. What may happen is “Cubanization” of the US used car market. Cuba has long been banned from importing vehicles from the US and elsewhere. With the parts Cubans are able to smuggle in and automotive machine shops making some hard-to-get parts, the car owners in that country are driving around in cars from the Fifties and Sixties with no end in sight. Fortunately, Cuba is a small island, but the idea is that there could be new “cottage industries” like the ones in Cuba pop up all across our country that would be mechanics, auto machine shops, and detailers and upholsterers who keep those old cars in good shape. The very same thing could conceivably happen here in a “Resistance” movement against the regulations the EPA is advocating for. [EPA-HQ-OAR-2022-0829-0617, pp. 54-60]

The temporal upshot of these possible consequences is that the gasoline part of the US fleet will continue to use gasoline and spew the usual GHG and criteria pollutants as time goes by. The problems we foresee are that as engines in those older vehicles that people in the Resistance Movement are holding onto will get tired and transmissions get less efficient, the amount of pollutants and GHGs could go up – exactly what the efforts to implement these new regulations are meant to avoid. [EPA-HQ-OAR-2022-0829-0617, pp. 54-60]

George H. W. Bush stated it best when he said, “The American life-style is non-negotiable.” And in this context, that means that stubborn Americans are not going to be told what they can and can’t drive and they will resist what they might view as an intrusive government trying to alter their “life-style.” [EPA-HQ-OAR-2022-0829-0617, pp. 54-60]

Organization: Kentucky Office of the Attorney General et al. (KY-AG)

What is more, demand for these rare materials will spike outside the automotive context as quickly as the Proposed Rule will spike it within. EPA recognizes this: It acknowledges that critical minerals for EV component production “are also experiencing increasing demand across many other sectors of the global economy . . . as the world seeks to reduce carbon emissions.” 88

Fed. Reg. at 29,313. The Proposed Rule also concedes that other "uncertain issues" like "permitting, investor expectations of demand and future prices, and many others" make it "difficult to predict with precision the rate at which new capacity will be brought online in the future." Id. Yet the proposed solution is just a short "transition period" so that "a robust supply chain" can develop for these products, including new material mining and expanded processing capacity. Id. These obstacles should slow a project with even a conservative timetable; for an overhaul as rushed as the Proposed Rule, they are reason to return to the drawing board. Proceeding without more concrete, realistic projects for expanded supply chains—and more realistic timetables—is another mark of arbitrary and capricious decision-making. [EPA-HQ-OAR-2022-0829-0649, pp. 13-15]

Other concerns about the minerals' supply and their extraction processes raise still more hurdles. The Proposed Rule had to recognize that it would take an estimated "five to ten" or more years "to develop a new [lithium] mine or mineral source"—and that delay is despite "very high" industry motivation from a "very robust" demand outlook. 88 Fed. Reg. at 29,313. Yet even that estimate is likely far too rosy. Last year, one geometallurgy professor looked at what it would take to shift away from fossil fuels entirely and to these and other rare materials for a single generation. Based on 2019 mining production rates, he predicted that the necessary extraction of "battery metals like lithium, cobalt, and graphite" would take over 9,900 years, 1,700 years, and 3,200 years, respectively. Simon P. Michaux, The quantity of metals required to manufacture just one generation of renewable technology units to phase out fossil fuels, YouTube (Aug. 18, 2022), https://bit.ly/42w7Fcx; see also Simon P. Michaeux, Assessment of the Extra Capacity Required of Alternative Energy Electrical Power Systems to Completely Replace Fossil Fuels (Aug. 18, 2022), https://bit.ly/3qCU1qU. Indeed, in 2022, the global reserves of those same three metals amounted to "less than five percent of what we need [for] one generation." Id. And among those reserves, not every discovery deposit becomes a mine. Only 1 or 2 for every 1000 does, and it takes between 15 and 20 years for those few mines to become fully functional. Id. And of those, 20–30% of the mines that get up and running will eventually "go out of business because of market conditions." Id.; see also The Raw-Materials Challenge: How The Metals And Mining Sector Will Be At The Core Of Enabling The Energy Transition, McKinsey & Co. (Jan. 10, 2022), https://tinyurl.com/2ne5jt37. Throw in the fact that each of these materials has a limited life-cycle after which they must be "decommissioned and replaced," and it becomes clear that we may well need to "make batteries out of something else." Michaux, The quantity of metals required to manufacture just one generation of renewable technology units to phase out fossil fuels, supra. That whole endeavor "is not going to be easy." Id. Quite right. The Proposed Rule needs to deal with real projections for the real demand it creates. [EPA-HQ-OAR-2022-0829-0649, pp. 13-15]

The view further down the supply chain is no better. The Proposed Rule can say only that supply capacity is "rapidly forming," not that it exists now or in the near-enough future. 88 Fed. Reg. at 29,323. EPA recognizes that it is still only "a goal of the U.S. manufacturing industry to create a robust supply chain for these products." Id. (emphasis added). EPA also says that, "[i]n general, the structure of the proposed standards allows an incremental phase-in to the MY 2032 level and reflects consideration of the appropriate lead time for manufacturers to take actions necessary to meet the proposed standards." Id. at 29,239. But there is nothing "incremental" about an edict for an eight-fold increase in EV sales in eight years. See id. at 29,189, 29,329, 29,346. And there is nothing simple about the amount of time and money needed to get the still-illusory supply chain running at massive new scale. According to former auto executive-turned-industry adviser Larry Burns, "[t]he transition automakers are perusing requires building totally new factories, assembly lines and supply chains, a years-long process." Puko, supra. Automakers will have to apply "major re-engineering" that "usually takes anywhere from three to five years" per model to dozens of vehicle models in under a decade. Id. [EPA-HQ-OAR-2022-0829-0649, pp. 13-15]

Battery factories, in particular, take years to build. See Eli Leland, So You Want To Build A Battery Factory, Medium: Batteries are Complicated (July 16, 2021), https://tinyurl.com/mv4vhh3x. It takes longer still to create and sharpen production processes that yield quality and safe products that can satisfy consumer demand and federal regulators. Mistakes are too costly for it to be any other way. See Bradley Berman, Battery Experts Provide Deeper Explanations for Chevy Bolt Fires, Autoweek (Nov. 15, 2021), https://tinyurl.com/3r7879u6 (describing recall of 141,000 EVs following 16 reported fires). The Proposed Rule, however, will have "automakers rac[ing] to supplement material shortages," and risking far more than prudence allows, just to "scal[e] these facilities and operations quickly." Paige McKirahan, United States: EV Supply Chain Disruption To Ignite Disputes Over IP, M&As, And More, Mondaq (Dec. 9, 2022), https://bit.ly/3p6eXpI. This demand, in turn, "put[s] at risk the stability of mines and refineries with possible unskilled workers," and "[h]uman rights violations . . . run rampant if safe and proper processes are not identified." Id. None of this is acceptable. All of it can be avoided. [EPA-HQ-OAR-2022-0829-0649, pp. 13-15]

The Proposed Rule should also account for the reality that too-fast and too-aggressive regulation can stifle the very innovation it relies on. Even with increased governmental subsidies toward rapid EV development, mandates like the Proposed Rule will almost certainly "prompt automakers to make bigger bets on a narrower set of options for complying, which might limit innovation and progress because technology now is changing so rapidly." Puko, supra. Programs like the Renewable Fuel Standards are whittled down, contrary to Congress's intent. See WV Amicus Br., at 24-27. And changing contexts that should command our attention end up ignored, including that EV "battery technology is still evolving," which means "the U.S. may be at risk of building mines and factories to produce batteries that wind up being obsolete in a decade." Joann Muller & Jael Holzman, Why the U.S. Can't build EVs without China, Axios (Apr. 12, 2023), https://bit.ly/42iaoWS. [EPA-HQ-OAR-2022-0829-0649, pp. 13-15]

The second- and third-order consequences of choosing rushed production based on today's technologies over innovation are weighty, too. Take nickel, for example. It is possible—even likely—that later battery technologies will render it unnecessary. See 88 Fed. Reg. at 29,314 (citing battery applications that "an iron phosphate cathode which has lower energy density but does not require . . . nickel"). And that may prove to be a very good thing: "Reaching the nickel means cutting down swaths of rainforest," and "[r]e?ning it is a carbon-intensive process that . . . produc[es] waste slurry that's hard to dispose of." Jon Emont, EV Makers Confront the 'Nickel Pickle,' WSJ (June 4, 2023), https://bit.ly/3PdIoRH. Nickel, then, exposes "a larger contradiction within the EV industry: Though EVs are designed to be less damaging to the environment in the long term than conventional cars, the process of building them carries substantial environmental harm." Id. Rather than letting market demand and innovation explore other paths forward, the Proposed Rule locks automakers and the rest of our economy into this impossible option. EPA should slow down this endeavor and allow both safety and innovation to drive decision-making in this critically important area. [EPA-HQ-OAR-2022-0829-0649, pp. 13-15]

Organization: Marathon Petroleum Corporation (MPC)

Renewable liquid fuels can play a critical role in a multifaceted solution for reducing carbon emissions, particularly those from the transportation sector. The renewable liquid fuel industry is well-positioned to produce the renewable fuels needed to help attain the EPA's emissions goals. However, EPA has ignored the emission-reduction benefits provided by renewable liquid fuels in its proposed vehicle emissions standards because EPA did not account for the assumption that the CO2 emissions from renewable liquid fuel combustion are zero. [EPA-HQ-OAR-2022-0829-0593, pp. 1-2]

EPA should consider changes to its emissions standards to address total lifecycle emissions of vehicles rather than focusing specifically on tailpipe emissions. EPA's historic methodology no longer meets the needs of the complex vehicle market. Cradle- to-grave lifecycle analysis allows all technologies to be evaluated using consistent criteria. [EPA-HQ-OAR-2022-0829-0593, p. 2]

A. To Properly Compare ICE Vehicles to EVs, EPA Needs to Evaluate the Lifecycle GHG Emissions, and Not Just the Tailpipe Emissions, of These Types of Vehicles.

EPA's approach to vehicle emissions standards includes a strict interpretation that centers on the vehicle's tailpipe in determining standards and compliance. EPA takes this approach because EPA's historic framework for the vehicle emission program only contemplated internal combustion engine ("ICE") vehicles. [EPA-HQ-OAR-2022-0829-0593, pp. 2-3]

With the significant changes in vehicles and vehicle power trains, MPC believes that EPA's approach should include lifecycle analysis ("LCA") and modeling, which would quantify the breadth of vehicle emissions. Use of LCA shows that all vehicle types have emissions impacts across their supply chains and ensures that certain technologies are not disproportionately advantaged or disadvantaged simply based on power train. Adopting an LCA approach to vehicle categorization would present a science-based, technology-neutral solution to adequately capture the differences between electric vehicles ("EVs") and ICE vehicles, as well as future vehicle technology advancements. [EPA-HQ-OAR-2022-0829-0593, pp. 2-3]

LCA most accurately quantifies total EV emissions, which include emissions-intensive operations such as critical mineral mining, electricity generation, and battery production as well as disposal and recycling. These activities can generate significant CO2 emissions and should be fully quantified before setting a standard that effectively mandates an increase in the production of EVs. Full lifecycle impacts, cradle to grave, for all vehicles should be itemized. Then emissions standards based on equivalent metrics among similar vehicle technologies could be applied. [EPA-HQ-OAR-2022-0829-0593, pp. 2-3]

MPC supports efforts to reduce emissions from the transportation sector. However, EPA has failed to recognize in this rule a way to achieve an immediate and significant reduction in transportation emissions by excluding the benefit that renewable liquid fuels provide when used in transportation vehicles. EPA's calculation of tailpipe emissions from ICE vehicles presumes that the vehicle is operating on petroleum fuel. In comparison, renewable liquid fuel use can result in vehicle emissions reductions that are equal to or greater than the reductions EPA is claiming from converting the fleet to electric vehicles. Renewable liquid fuels are readily available and compatible with the current vehicle fleet. Renewable liquid fuels can provide emissions reductions immediately at the scale required to meet emissions reduction targets and do so more economically than EVs or other nascent technologies. [EPA-HQ-OAR-2022-0829-0593, pp. 3-4]

Other emissions reduction programs, including the EPA's Renewable Fuel Standard ("RFS"), as well as LCA models, including the Greenhouse gases, Regulated Emissions, and Energy use in Technologies (GREET) model, do not include CO2 emissions from renewable liquid fuels combustion in their lifecycle analyses. As EPA explained in its RFS rulemaking, "the CO2 emitted from biomass-based fuels combustion does not increase atmospheric CO2 concentrations, assuming the biogenic carbon emitted is offset by the uptake of CO2 resulting from the growth of new biomass."1 Similarly, EPA adopts the Intergovernmental Panel on Climate Change ("IPCC") Tier 1 approach to CO2 emissions from biofuels, including renewable liquid fuels, in its Greenhouse Gas ("GHG") Inventory. IPCC Tier 1 methods are based on default emission factors and define a methodology to track shifts in carbon stocks due to biofuel combustion. When using Tier 1 methods, CO2 emissions from biofuel combustion are attributed to the Agriculture and Land Use sector, where it is assumed that the biofuel emissions are balanced by carbon uptake prior to the feedstock's harvest, resulting in net combustion emissions of zero.2 [EPA-HQ-OAR-2022-0829-0593, pp. 3-4]

1 2010 Renewable Fuels Standard Program (RFS2) Regulatory Impact Analysis, EPA-420-R-10-006, Pg 444.

2 2006 IPCC Guidelines for National Greenhouse Gas Inventories, General Guidance and Reporting, Volume 1, pg. 1.6.

Despite the science-based approach used by these authoritative sources, EPA chose not to assign zero CO2 emissions from renewable fuel combustion in an ICE vehicle to its vehicle emissions standard. With the ever-increasing volume of renewable fuel available in the market, EPA's failure to attribute zero CO2 emissions to renewable fuel results in an over-estimation of CO2 emissions from ICE vehicles. Consistency in the treatment of renewable liquid fuels and their CO2 emissions across programs is key to ensuring that data are treated similarly, and that no technology is favored over another. [EPA-HQ-OAR-2022-0829-0593, pp. 3-4]

Alignment of EPA's tailpipe emissions standards with other programs that promote domestic renewable liquid fuels, such as the RFS is needed. Mandating the blending and use of renewable liquid fuels in vehicles in one program while simultaneously ignoring the positive impacts of their use in another results in rules that are at cross purposes. Renewable liquid fuels can be a part of a multifaceted solution for reducing carbon emissions and similar treatment of their benefits from program to program would be a significant step forward for the EPA. This change would lead to significantly more investments in renewable liquid fuels, providing an option for meeting EPA's goals that is compatible with ICE vehicles and does not require a wholesale shift in vehicle manufacturing and infrastructure, with its concomitant effects on U.S. drivers who would bear the costs. [EPA-HQ-OAR-2022-0829-0593, p. 4]

A continued push from the Agency to further narrow regulations in regard to renewable liquid fuels results in lost opportunities for investments and places additional burden on the transportation and fuels industry, as well as consumers. In addition, these lost opportunities for decarbonization are impactful, as renewable liquid fuels can be deployed quickly, at a large scale, and with significant carbon reductions in the transportation fuel sector. The renewable liquid fuel industry is well-positioned to produce the fuels needed to contribute to the EPA's goals because renewable liquid fuels are widely accepted throughout the country. [EPA-HQ-OAR-2022-0829-0593, p. 4]

Organization: Matthew DiPaulo (DiPaulo)

The EPA's proposal boosts an electric vehicle supply chain dominated by China, which powers its manufacturing-base through coal-fired power plants and mines minerals for EV batteries with the use of environmental practices that we would never approve of in the United States. Emissions coming out of tailpipe matter, but so do the lifecycle emissions of building a car, constructing and charging a battery, and retiring vehicles. [EPA-HQ-OAR-2022-0829-1514, p. 1]

Organization: Mazda North American Operations (Mazda)

As a global automaker that sells in over 120 countries around the world, Mazda is already working to reduce the carbon footprint of our vehicles and our corporate operations. In January 2021, Mazda announced its Endeavor for Carbon Neutrality by 2050. To achieve this, we will first strive to realize carbon neutrality at Mazda manufacturing facilities around the globe by 2035. Mazda sees reducing emissions of CO2 and other greenhouse gases over a vehicle's entire lifecycle - including manufacturing, use and disposal - as one of its top priorities. Life Cycle Assessment (LCA) is a method for calculating and evaluating the environmental influence of vehicles across their entire life cycle through the purchase of materials, manufacture, use, recycling, and final disposal. Since 2009, Mazda has adopted LCA as a means of determining the time required to reduce the environmental impact of vehicles in their life cycle and has been actively working to reduce the environmental impact at each stage of the life cycle. [EPA-HQ-OAR-2022-0829-0595, p. 1]

Organization: Michalek and Bruchon

Thank you for the opportunity to provide comments on the proposed rule for Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehi- cles. We are researchers at Carnegie Mellon University with experience in life cycle as- sessment of plug-in electric vehicles (PEVs). We recently conducted a study, currently in peer review, analyzing how to reduce electric vehicle life cycle emissions during the transition to PEVs (Bruchon et al., 2023). We are attaching the working version of that study for your reference. An interactive app to explore the results is also available at https://mbruchon.shinyapps.io/PJM_EV/ [EPA-HQ-OAR-2022-0829-0514, pp. 2-4]

Our study was motivated by a prior finding, using 2010 grid data of the PJM grid region, that a battery electric vehicle (BEV) would produce an estimated 2x to 3x the consequential air emissions externalities of an ordinary gasoline vehicle, largely due to SO2 emissions from coal fired power plants operating on the margin. In the updated study, using the most recent data available, we find that PEV consequential emissions externalities have dropped by 17-18% as natural gas has replaced coal. Using data on expected generator retirements, we expect consequential life cycle PEV emissions to continue to drop through 2025, bringing PEV emissions in line with those of gasoline vehicles (Figure 1). However, base case projections suggest that consequential PEV emissions externalities will bottom out and remain comparable to gasoline vehicles through at least 2035. These projections reflect a trend that even though the power system is expected to become cleaner on average during that period, marginal generation that responds to changes in load at the times that PEVs charge will remain primarily a mix of fossil fuel sources in this timeframe. Increased renewable capacity will reduce total grid emissions in the near and long term, but it will not substantially reduce consequential PEV emissions in PJM over the period of the proposed policy—only in the long term (later than 2035) if renewables are routinely curtailed and available to supply additional load on the margin. We find that the three largest levers available for reducing PEV emissions externalities during the period of the proposed policy are [EPA-HQ-OAR-2022-0829-0514, pp. 2-4]

1. Shifting electric vehicle batteries away from nickel-based chemistries. We estimate that nickel production emissions contribute a substantial portion of consequential PEV emissions, depending on the source, and a shift away from nickel-based lithium-ion battery chemistries toward lithium iron phosphate (LFP) would reduce electric vehicle life cycle emissions below those of gasoline vehicles and hybrid electric vehicles in PJM (Figure 1). We are already observing this shift in the electric vehicle market. [EPA-HQ-OAR-2022-0829-0514, pp. 2-4]

2. Reducing emissions from fossil generators. Because fossil fuel generators like coal and natural gas power plants will continue to dominate operational responses to changes in load during the period of the proposed policy, emission rates from fossil generators are key to determining the consequential emissions of electric vehicles. EPA's new proposed rule on "New Source Performance Standards for Greenhouse Gas Emissions from New, Modified, and Reconstructed Fossil Fuel-Fired Electric Generating Units; Emission Guidelines for Greenhouse Gas Emissions from Existing Fossil Fuel- [EPA-HQ-OAR-2022-0829-0514, pp. 2-4]

[See original attachment for: Figure 1: Estimated consequential life cycle emissions externalities as PJM's generator fleet evolves over time. ICEV = internal combustion engine vehicle, HEV = gasoline hybrid electric vehicle, BEV300 = battery electric vehicle with a 300-mile range, LFP = lithium iron phosphate BEV battery chemistry, NMC = nickel manganese cobalt lithium ion BEV battery chemistry. For BEV300 the base case includes uncontrolled (convenience) charging, NMC622 battery chemistry, 10% renewables in 2035, and no accelerated coal retirements or natural gas installations. The y-axis is truncated to make trends visible. From Bruchon et al. (2023)] [EPA-HQ-OAR-2022-0829-0514, pp. 2-4]

Fired Electric Generating Units; and Repeal of the Affordable Clean Energy Rule"1 has the potential to address this factor directly. [EPA-HQ-OAR-2022-0829-0514, pp. 2-4]

1 Federal Register v88 n99 p33240-33420

3. Revising vehicle fleet emissions standards. Past work has found that when PEVs are adopted this triggers slack in the light duty vehicle greenhouse gas standards that increases permitted emissions from the rest of the fleet (Goulder et al., 2012) and that this "leakage" effect is amplified when the standards count PEVs favorably in compliance calculations by counting each PEV sale as though it were more than one sale and by excluding electric vehicle charging emissions (Jenn et al., 2019, 2016). In our new study we find that this effect is still substantial today, and the emissions consequences of adopting PEVs are higher because of the design of existing light-duty vehicle greenhouse gas emissions standards (Figure 2). [EPA-HQ-OAR-2022-0829-0514, pp. 2-4]

The proposed rule does two things that mitigate this effect.

(a) First, the multipliers used in prior standards to count individual PEV sales as more than one sale in compliance calculations have been discontinued, which reduces the amplification of the emissions leakage effect. [EPA-HQ-OAR-2022-0829-0514, pp. 4-6]

(b) Second, while prior light-duty vehicle greenhouse gas standards were not primary drivers of vehicle electrification, the proposed rule is sufficiently stringent that it is expected to act as a binding constraint, pushing automakers to electrify more than they would without the rule. When the GHG standard is the driver of electrification, the leakage question changes. Specifically, prior concerns about leakage were based on other policies (e.g.: California's ZEV policy, tax incentives) and consumers driving electric vehicle adoption and triggering an increase in permitted fleetwide emissions. When the GHG standard is a primary driver of electrification, this type of leakage is less relevant. [EPA-HQ-OAR-2022-0829-0514, pp. 4-6]

Both of these changes in the proposed rule reduce consequential emissions of PEV adoption. However, the proposed rule continues to exclude PEV charging emissions in compliance calculations, and thus the extent of consequential GHG reductions implied by the proposed rule hinges on reduced emissions from marginal generators in the power system. Ideally, regulation would be based on the full consequential life cycle emissions of each vehicle technology so that incentives and constraints would be directly aligned with the target externalities (National Academies of Sciences and Medicine, 2022). When practical and regulatory authority limitations restrict the scope of policy, it is important to assess the consequential implications of the restricted policy on overall emissions, which EPA does in the draft regulatory impact analysis. [EPA-HQ-OAR-2022-0829-0514, pp. 4-6]

Overall, with this proposed rule for vehicles together with EPA's proposed rule for limiting fossil fuel generator emissions, EPA is acting on two of the top three levers we identified for reducing life cycle emissions of PEVs during the transition to electric vehicles (and during the period of the proposed policy). We also note that EPA's regulatory impact analyses, which computes predicted emissions in scenarios both with and without the proposed policy to estimate the effect of the proposed policy, is (at least in this sense) consistent with [EPA-HQ-OAR-2022-0829-0514, pp. 4-6]

[See original attachment for: Figure 2: Range of estimates for consequential life cycle emissions externalities in our Base Case (ignoring policy interactions) and our Policy Interaction Case (including the effect of EV sales on permitted fleetwide emissions in the light duty GHG standard). From Bruchon et al. (2023)] [EPA-HQ-OAR-2022-0829-0514, pp. 4-6]

the National Academies report on methods for life cycle assessment of transportation fuels (National Academies of Sciences and Medicine, 2022). Specifically, from that report [EPA-HQ-OAR-2022-0829-0514, pp. 4-6]:

Recommendation 3-2: Public policy design based on LCA should ensure through regulatory impact assessment that, at a minimum, the consequential life-cycle impact of the proposed policy is likely to reduce net GHG emissions and increase net benefits to society... –National Academies of Sciences and Medicine (2022) [EPA-HQ-OAR-2022-0829-0514, pp. 4-6]

We recommend citing the National Academies of Sciences and Medicine (2022) report and describing the regulatory impact analysis in consequential terms for clarity. [EPA-HQ-OAR-2022-0829-0514, pp. 4-6]

PERFOMANCE BASED/TECHNOLOGY NEUTRAL RULEMAKING NEEDED

A recent study4 by Argonne National Lab, in cooperation with coauthors from the automotive and energy industries, shows a BEV with 400-mile range (BEV400) has lifecycle GHG emissions of about 250 g/mi. This is an improvement from a conventional internal combustion engine vehicle (ICEV) which is about 430 g/mi. However, the lifecycle GHG emissions of a BEV are far from zero. In fact, lifecycle GHG emissions of a BEV400 are comparable to other low-emission options such as E85 or PHEV. Regulations based only on tailpipe emissions are clearly inadequate for comparing BEVs to other pathways for reducing GHG emissions. [EPA-HQ-OAR-2022-0829-0612, pp. 4-5]

4 Kelly et al., "Cradle-to-Grave Lifecycle Analysis of U.S. Light-Duty Vehicle-Fuel Pathways: A Greenhouse Gas Emissions and Economic Assessment of Current (2020) and Future (2030-2035) Technologies", report ANL-22/27, June 2022.

The Argonne report demonstrates that other “vehicle-fuel pathways” can compete with BEVs. For example, a conventional gasoline hybrid (HEV) achieves about 310 g/mi and E85 in a non-HEV FFV achieves 260 g/mi. The future potential of HEVs combined with FFV technology, utilizing E85, is comparable to future BEVs with wind and solar power. [EPA-HQ-OAR-2022-0829-0612, pp. 4-5]

The proposed rulemaking does not allow other vehicle-fuel pathways to compete with BEVs. By regulating only tailpipe emissions, and ignoring the rich literature of lifecycle analysis, EPA would create artificial incentives for auto manufacturers to pursue only BEVs. This could have disastrous impacts on both the cost and the GHG emissions of future vehicles. The same Argonne report found the cost and GHG emissions of a BEV are strongly affected by the driving range. A BEV with 400-mile range is dramatically more expensive than one with 200-mile range, and its lifetime GHG emissions are substantially worse. In fact, a BEV with 400-mile range has only a slight GHG benefit compared to a HEV or an E85 FFV. But the proposed rule counts all BEVs as zero GHG emissions, regardless of battery size – and regardless of vehicle size and weight. [EPA-HQ-OAR-2022-0829-0612, pp. 4-5]

It is essential for EPA to utilize life cycle analysis to create a “level playing field” which encourages speedy adoption of HEVs, PHEVs, FFVs, and other technologies (in addition to BEVs) to achieve the most rapid, affordable, robust, and practical GHG emissions reductions in a wide range of vehicle segments, while satisfying diverse customer needs and preferences. Europe is already making progress towards regulation based on life cycle analysis.10 11 [EPA-HQ-OAR-2022-0829-0612, p. 6]

11 Sala et al., "The evolution of life cycle assessment in European policies over three decades", International Journal of Life Cycle Assessment, December 2021; https://doi.org/10.1007/s11367-021-01893-2.

UPSTREAM EMISSIONS

EPA's proposal continues to treat EVs as carbon neutral, without regard to the source of electricity powering the vehicles. Depending on the sources of electricity – whether coal, natural gas, wind or nuclear and the mix of those sources - full lifecycle emissions of EVs vary widely, masking the true GHG emissions from these vehicles. Without accounting for upstream emissions from these vehicles, full lifecycle emissions are not considered. Furthermore, EPA notes in the proposal that increases in electricity demand will result in increased non-GHG emissions for some upstream pollutants. EPA does a disservice to emissions reduction goals by accounting for upstream emissions from some fuels and vehicle technologies but not others, providing an advantage to the sources for which "wells-to- wheels" upstream emissions are excluded and concealing emissions from coal power generation, mineral extraction, and other high-carbon sources. [EPA-HQ-OAR-2022-0829-0612, p. 6]

Adopt Argonne's GREET Model

Argonne's Greenhouse Gases, Regulated Emissions, and Energy Use in Transportation (GREET) model is the federal government's most accurate tool for evaluating biofuel and energy lifecycle emissions. Adopting a true "wells-to- wheels" methodology will help to ensure an accurate accounting of total carbon intensity so that all low carbon fuels and technologies are compared on full and accurate lifecycle emissions on a technology and feedstock neutral basis. [EPA-HQ-OAR-2022-0829-0612, p. 13]

Organization: National Association of Convenience Stores (NACS) et al.

The Proposed Rule is also arbitrary and capricious because it fails to accurately and fairly account for the greenhouse gas emissions impacts of both EVs and biofuels. EPA should use the best available science to accurately account for the full lifecycle carbon intensity associated with each fuel and technology, but the Proposal ignores the significant upstream emissions from electricity generation associated with EVs. Incentives for alternative fuel technologies should be tied to those technologies' full lifecycle environmental attributes rather than a single segment of the lifecycle (i.e., tailpipe emissions). The Agency should revise the Proposal to adopt a more market-oriented, technology-neutral, and consumer-focused approach to decarbonizing light-duty vehicle transportation. [EPA-HQ-OAR-2022-0829-0628, p. 2]

III. The Proposed Rule Fails to Account for the Lifecycle Emissions of Electric Vehicles.

Under the Proposal, electric vehicles effectively serve as the only means of compliance with the standards in part because the Agency focuses solely on tailpipe emissions rather than the full lifecycle emissions of light- and medium-duty EVs. This is a flawed approach. To ensure an accurate accounting of the lifecycle carbon intensity associated with each technology, EPA should incorporate lifecycle emissions into its analysis. This will facilitate continued investment in all decarbonization technologies alongside deployment of electric vehicles. [EPA-HQ-OAR-2022-0829-0648, pp. 10-12]

Though EVs do not directly have tailpipe emissions, other segments along the lifecycle of the EV do. The fuel source of an EV—a battery composed of carbon intensive minerals and the electricity generated to power the battery—produces meaningful emissions to which the Proposal turns a blind eye. Addressing the impact of climate change, however, requires mitigating emissions irrespective of whether they originate from a tailpipe, a mining operation, a power plant, or a battery plant. Consequently, emissions standards should account for the entire lifecycle emissions. [EPA-HQ-OAR-2022-0829-0648, pp. 10-12]

EPA's analysis examines only logistical challenges to EV manufacturing and does not account for carbon impacts of critical mineral mining, the use of natural resources for refining and processing, engine and battery manufacturing, and other confounding variables such as prolonged ICE turnover rates and vehicle end-of-life consequences. Importantly, a lifecycle analysis of EV emissions impacts will better equip EPA to understand the varying costs and emissions reductions associated with all technologies and best inform manufacturers and consumers of their options. [EPA-HQ-OAR-2022-0829-0648, pp. 10-12]

EPA also makes flawed assumptions regarding the total emissions impacts of the Proposal. Despite claiming that "upstream emissions impacts from fuel production at refineries and electricity generating units are considered in EPA's analysis of overall estimated emissions impacts and project benefits," 31 this analysis uses overgeneralizations and assumes cleaner and less expensive generation over time—incorrectly assuming as a certainty that the power sector will become cleaner through the increased use of wind and solar generation as well as electricity storage (e.g., batteries) despite opposition from the power sector.32 Although the Agency concedes these assumptions will still result in "some increases in ambient pollutant concentrations" and that "the specific locations of increased air pollution are uncertain," EPA fails to meaningfully engage with the consequences of even its own flawed analysis.33 [EPA-HQ-OAR-2022-0829-0648, pp. 10-12]

31 Proposed Rule at 29,252.

32 See, e.g., David Pomerantz, The New York Times, "Guess Who's Been Paying to Block Green Energy? You Have." (Jul. 5, 2023) available at https://www.nytimes.com/2023/07/05/opinion/utility-bills-clean-energy.html; Susan Cosier, "Why Electric Utilities Are Resorting to Dark Money and Bribes to Resist Renewables," Audubon, March 16, 2021, available at https://www.audubon.org/news/why-electric-utilities-are-resorting-dark-money-and-bribes-resist- renewables ("Many utility companies cling to old business models and dirty fuels rather than go through the tough energy transition that climate change demands.") Comment from Southern Company on EPA Proposed Rule, Docket No. EPA-HQ-OAR-2022-0723, Comment ID EPA-HQ-OAR-2022-0723-0029 (Dec. 21, 2022) available at https://www.regulations.gov/comment/EPA-HQ-OAR-2022-0723-0029 (advocating for continued construction of new EGU infrastructure for fossil fuels and cautioning against unattainable limits for existing coal and natural gas EGUs); Valerie Volcovici and Nichola Groom, Reuters, "U.S. utilities want protection from Biden's tight timeline in clean energy mandate" (Apr. 14, 2021) available at https://www.reuters.com/business/sustainable-business/us- utilities-want-protection-bidens-tight-timeline-clean-energy-mandate-2021-04-14/.

33 Proposed Rule at 29,361.

The Proposed Rule fails to adequately evaluate local ambient air quality impacts from increased power generation. Though EPA modeled changes to power generation anticipated by the Proposed Rule as part of its upstream analysis, the Agency does not consider the potential degradation of air quality in areas in the direct vicinity of existing or new power plants.34 This is further complicated by the fact that emissions associated with electricity generation are not consistent across the U.S. In contrast to EPA's generalized emissions benefits, the emissions advantages of EVs are much lower in states with relatively high carbon profiles for electricity generation than those states with relatively low carbon profiles. Indeed, the Fuels Institute analyzed these differences and concluded that in states with high-carbon intensity electric generation, such as West Virginia, ICE vehicles produced decidedly less carbon emissions relative to EVs over the entire 200,000-mile life of the vehicles.35 Of course, the Report recognizes emissions advantages to EVs in those low-carbon states as well, but these differences further illustrate the importance of accurately accounting for full lifecycle emissions. Instead of comprehensively accounting for these emissions in compliance calculations, the Agency proposes to continue providing EVs with a discounted emissions rate by allowing these vehicles to be counted as producing 0 g/mile of CO2, and solidifying preferential treatment of one mode of technology: electric vehicles. [EPA-HQ-OAR-2022-0829-0648, pp. 10-12]

34 Proposed Rule at 29,361.

35 Ricardo Inc., FUELS INSTITUTE, "Lifecycle Analysis Comparison" (Jan. 2022) available https://transportationenergy.org/wp-content/uploads/2022/10/FI_Report_Lifecycle_FINAL.pdf.

While ICE-powered vehicles generally emit more carbon dioxide during operation, the emissions associated with the manufacturing of ICE-powered vehicles are significantly lower than those emitted from battery-electric vehicles.36 There is no climate rationale for EPA to pursue this rulemaking from a state of willful blindness over these distinctions. A recent examination conducted by Volvo provides a directly applicable case study. Volvo concluded that the "accumulated emissions from the [m]aterials production and refining, [Lithium-ion] battery modules and Volvo Cars manufacturing phases of C40 Recharge are nearly 70 percent higher than for XC40 ICE."37 Volvo explains, "[e]lectrification of cars causes a shift of focus from the use phase to the materials production and refining phase."38 [EPA-HQ-OAR-2022-0829-0648, pp. 10-12]

36 See IEA, "The Role of Critical Minerals in Clean Energy Transition" (May 2021) available at https://www.iea.org/reports/the-role-of-critical-minerals-in-clean-energy-transitions; see also David Biello, SCIENTIFIC AMERICAN, "Electric Cars Are Not Necessarily Clean,"(May 11, 2016) available at https://www.scientificamerican.com/article/electric-cars-are-not-necessarily-clean/ ("Your battery-powered vehicle is only as green as your electricity supplier"); see also Nina Lakhani, THE GUARDIAN, "Revealed: How US Transition to Electric Cars Threatens Environmental Havoc," the Guardian, (January 24, 2023) available at https://www.theguardian.com/us-news/2023/jan/24/us-electric-vehicles-lithium-consequences-research. ("The US's transition to electric vehicles could require three times as much lithium as is currently produced for the entire global market, causing needless water shortages, Indigenous land grabs, and ecosystem destruction.").

38 Id. at pg. 5.

Further, the Proposed Rule overlooks the emissions impacts from the substantial expansion of the electrical grid. While EPA credits emissions reductions from assuming the power sector will become cleaner over time using renewable generation and electricity storage (e.g., batteries), it ignores the impacts of building out that associated infrastructure. New power generation, renewable power generation, and energy storage require the same critical minerals necessary for manufacturing EV batteries. Increased electricity demand will only further compound the stress on critical minerals. Indeed, copper and aluminum—both needed for EVs—are also the two main materials in wires and cables. Battery storage equipment for solar and other renewable energy sources rely on similar battery chemistries as EVs.39 Again, EVs may be the most environmentally compelling solution, but it does neither the climate nor American consumers any favors for the Agency to pretend the solution is more compelling or achievable than it actually is. [EPA-HQ-OAR-2022-0829-0648, pp. 10-12]

39 And, as described above, higher prices on these materials could have a major impact on future grid investments. INTERNATIONAL ENERGY AGENCY, The Role of Critical Minerals in Clean Energy Transitions (Mar. 2022), 77–80, available at https://iea.blob.core.windows.net/assets/ffd2a83b-8c30-4e9d-980a- 52b6d9a86fdc/TheRoleofCriticalMineralsinCleanEnergyTransitions.pdf.

The simultaneous spike in demand for materials such as copper and aluminum for both the grid and EV manufacturing will increase extraction and refining efforts globally, potentially exacerbating consequences on a regional level.40 By failing to consider geographic electricity generation differences and the potential benefits of a non-homogenized vehicle population, the Proposal misses the opportunity to most effectively respond to emissions concerns and, more importantly, could indirectly lead to increased emissions in certain regions. A full accounting of the relative advantages and disadvantages of the different vehicle technologies is necessary to ensure the Proposal harnesses the benefits of competition among different current and potential future vehicle technologies. [EPA-HQ-OAR-2022-0829-0648, pp. 10-12]

40 The U.S. is almost entirely dependent on other countries, especially China, for materials essential to manufacturing EVs, meaning the Proposal may potentially raise national security concerns.

Organization: National Corn Growers Association (NCGA)

NCGA urges EPA to advance a much-needed rulemaking addressing fuel quality to cut emissions from the millions of liquid fuel vehicles on the road now and the new vehicles that will be sold through the compliance period. Greater lifecycle emission reductions are available from sustainable, affordable low carbon ethanol through a clean, high-octane standard, by removing barriers to higher ethanol blends and by equitably incentivizing all alternative fuels and vehicles. [EPA-HQ-OAR-2022-0829-0643, p. 1]

A recent study 4 by Argonne National Lab, in cooperation with coauthors from the automotive and energy industries, shows a BEV with 400-mile range (BEV400) has lifecycle GHG emissions of about 250 g/mi. This is an improvement from a conventional internal combustion engine vehicle (ICEV) which is about 430 g/mi. However, the lifecycle GHG emissions of a BEV are far from zero. In fact, lifecycle GHG emissions of a BEV400 are comparable to other low-emission options such as E85 or PHEV. Regulations based only on tailpipe emissions are clearly inadequate for comparing BEVs to other pathways for reducing GHG emissions. [EPA-HQ-OAR-2022-0829-0643, p. 3]

4 Kelly et al., "Cradle-to-Grave Lifecycle Analysis of U.S. Light-Duty Vehicle-Fuel Pathways: A Greenhouse Gas Emissions and Economic Assessment of Current (2020) and Future (2030-2035) Technologies", report ANL-22/27, June 2022

The Argonne report demonstrates that other “vehicle-fuel pathways” can compete with BEVs. For example, a conventional gasoline hybrid (HEV) achieves about 310 g/mi and E85 in a non-HEV FFV achieves 260 g/mi. The future potential of HEVs combined with FFV technology, utilizing E85, is comparable to future BEVs with wind and solar power. [EPA-HQ-OAR-2022-0829-0643, pp. 3-4]

The proposed rulemaking does not allow other vehicle-fuel pathways to compete with BEVs. By regulating only tailpipe emissions, and ignoring the rich literature of lifecycle analysis, EPA would create artificial incentives for auto manufacturers to pursue only BEVs. This could have disastrous impacts on both the cost and the GHG emissions of future vehicles. The same Argonne report found the cost and GHG emissions of a BEV are strongly affected by the driving range. A BEV with 400-mile range is dramatically more expensive than one with 200-mile range, and its lifetime GHG emissions are substantially worse. In fact, a BEV with 400-mile range has only a slight GHG benefit compared to a HEV or an E85 FFV. But the proposed rule counts all BEVs as zero GHG emissions, regardless of battery size – and regardless of vehicle size and weight. [EPA-HQ-OAR-2022-0829-0643, pp. 3-4]

It is essential for EPA to utilize life cycle analysis to create a “level playing field” which encourages speedy adoption of HEVs, PHEVs, FFVs, and other technologies (in addition to BEVs) to achieve the most rapid, affordable, robust, and practical GHG emissions reductions in a wide range of vehicle segments, while satisfying diverse customer needs and preferences. Europe is already making progress towards regulation based on life cycle analysis. 10 11 [EPA-HQ-OAR-2022-0829-0643, p. 4]

10 https://www.goldmansachs.com/intelligence/pages/briefly/from_briefings_21-Jan-2020/new-era-in-co2-regulation.pdf

11 Sala et al., "The evolution of life cycle assessment in European policies over three decades", International Journal of Life Cycle Assessment, December 2021; https://doi.org/10.1007/s11367-021-01893-2

EPA’s proposal continues to treat EVs as carbon neutral, without regard to the source of electricity powering the vehicles. Depending on the sources of electricity – whether coal, natural gas, wind or nuclear and the mix of those sources - full lifecycle emissions of EVs vary widely, masking the true GHG emissions from these vehicles. Without accounting for upstream emissions from these vehicles, full lifecycle emissions are not considered. Furthermore, EPA notes in the proposal that increases in electricity demand will result in increased non-GHG emissions for some upstream pollutants. EPA does a disservice to emissions reduction goals by accounting for upstream emissions from some fuels and vehicle technologies but not others, providing an advantage to the sources for which “wells-to-wheels” upstream emissions are excluded and concealing emissions from coal power generation, mineral extraction, and other high-carbon sources. [EPA-HQ-OAR-2022-0829-0643, p. 4]

Corn-based ethanol can reach net zero emissions with continued on-farm improvements and soil carbon sequestration, along with carbon capture technology and new efficiencies in ethanol production. Corn farmers are proud of our leadership in adopting conservation and best management practices. NCGA’s recently released Corn Sustainability Report 21 details corn farmers’ history of improvements and our commitment to further sustainability achievements by 2030. [EPA-HQ-OAR-2022-0829-0643, pp. 6-7]

21 National Corn Growers Association Corn Sustainability Report: chrome-extension://efaidnbmnnnibpcajpcglclefindmkaj/https://dt176nijwh14e.cloudfront.net/file/392/NCGA%20Sustainability%20Report_final_digital_07_29_21.pdf

Sustainable production means corn farmers today are producing more corn using less land and fewer resources. For example, planted corn acres in 2022, at 88.6 million acres, were less than planted acres in 2007, the year the RFS was expanded, at 93.5 million acres. USDA data also shows the area planted to principal crops in the United States is not expanding overall. Corn production has increased primarily because crop yields have increased from an average of 150 bushels per acre in 2007 to 173 bushels in 2022. With the average yield in 1980 at just 91 bushels per acre, productivity growth is a long-term trend. [EPA-HQ-OAR-2022-0829-0643, pp. 6-7]

Using the expertise of Argonne's scientists and the U.S. Department of Agriculture's data, we believe Argonne's Greenhouse Gases, Regulated Emissions, and Energy Use in Technologies (GREET) model is the federal government's most accurate tool for evaluating biofuel and energy lifecycle emissions. Because GREET is regularly updated, this model captures GHG emissions reductions from farmers' improved production practices and will incorporate the ongoing, voluntary climate-smart improvements in agriculture production this Administration supports, ensuring further carbon intensity reductions are accounted for in the LCA. [EPA-HQ-OAR-2022-0829-0643, pp. 6-7]

Corn production has improved across all measures of resource efficiency, including higher crop yields per acre, resulting in greater corn production using less land and fewer inputs, further fortifying ethanol as a sustainable, low-carbon renewable fuel. This progress is reflected in Argonne's most recent analysis, which builds on and is consistent with other recent reviews. [EPA-HQ-OAR-2022-0829-0643, p. 7]

For example, a 2018 USDA study shows that ethanol then resulted in 39 to 43 percent fewer GHG emissions than gasoline. 22 Building on this progress, additional improvements on farms and in ethanol production supported by expanding markets for low carbon fuels could result in ethanol with up to 70 percent fewer GHG emissions than gasoline, according to USDA's analysis. Furthermore, according to California Air Resources Board (CARB) data, the CI of ethanol is more than 40 percent lower than the CI of gasoline. 23 [EPA-HQ-OAR-2022-0829-0643, p. 7]

22 Lewandrowski, Jan, and et. al, "The Greenhouse Gas Benefits of Corn Ethanol - Assessing Recent Evidence," (202) Biofuels, 11:3, 361-375. https://www.tandfonline.com/doi/full/10.1080/17597269.2018.1546488

23 California Air Resources Board, Low Carbon Fuel Standard Reporting Tool Quarterly Summaries, based on data through Q3 2020 at https://ww3.arb.ca.gov/fuels/lcfs/lrtqsummaries.htm

These increasing benefits have occurred without accounting for corn's ability to sequester carbon in the soil. Corn as a crop can serve as a carbon sink. As a photo-synthetically superior C4 plant, corn has an extraordinary ability to sequester carbon and move fertilizer nutrients back to the surface for plant growth rather than polluting ground water. Corn's extensive, deep root system makes it one of the few plants with this important capability to make crop production sustainable. [EPA-HQ-OAR-2022-0829-0643, p. 7]

High-yield corn—combined with the steady adoption of best practices such as reductions in tillage intensity—is sequestering carbon from the atmosphere into the soil. This sequestration is increasing soil carbon levels and reducing atmospheric CO2. Although GHG lifecycle models do not currently account for this direct GHG reduction from corn production, NCGA believes the effect of corn crops on soil carbon sequestration, among other considerations, should be incorporated into current lifecycle analysis. This increase in soil carbon from corn production, when included, could result in a 20 gram/MJ carbon credit for corn-based ethanol. 24 Fully accounting for corn's carbon sequestration would further demonstrate significant low-carbon advantages of a high-octane midlevel ethanol blend. [EPA-HQ-OAR-2022-0829-0643, p. 7]

24 American Coalition for Ethanol, The Case for Properly Valuing the Low Carbon Benefits of Corn Ethanol, 2018

Argonne's Greenhouse Gases, Regulated Emissions, and Energy Use in Transportation (GREET) model is the federal government's most accurate tool for evaluating biofuel and energy lifecycle emissions. Adopting a true "wells-to-wheels" methodology will help to ensure an accurate accounting of total carbon intensity so that all low carbon fuels and technologies are compared on full and accurate lifecycle emissions on a technology and feedstock neutral basis. [EPA-HQ-OAR-2022-0829-0643, p. 10]

Organization: National Farmers Union (NFU)

Unfortunately, the large GHG benefits of ethanol and other low-carbon fuels are not adequately accounted for in the proposed rulemaking. EPA should use lifecycle analysis to properly account for and incentivize their use. [EPA-HQ-OAR-2022-0829-0581, p. 6]

Numerous studies have used lifecycle analysis to quantify GHG benefits of BEVs compared to other options including hybrid electric vehicles (HEVs) and renewable fuels. As these studies show, BEVs are not zero emissions. Further, they are not the most cost-effective way to reduce GHG emissions. [EPA-HQ-OAR-2022-0829-0581, p. 6]

For example, below is a plot from a study released by Argonne National Laboratory.12 It shows that a BEV with 400 mile range (BEV400) has lifecycle GHG emissions of about 250 gCO2e/mi. This calls into question the term "zero emissions vehicle." According to this study, lifecycle GHG emissions of a BEV400 are not much better than other options such as E85 or PHEV. Regulations based only on tailpipe emissions are insufficient to compare BEVs to other ways of reducing GHG emissions. The report found that "these results demonstrate that large GHG reductions for LDVs are challenging and require consideration of the entire life cycle, including vehicle manufacture, fuel production, and vehicle operation. Achieving a net life cycle reduction in GHG emissions is a challenging task and must overcome technological, cost, and market acceptance hurdles."13 [EPA-HQ-OAR-2022-0829-0581, pp. 7-8]

12 Jarod C. Kelly, et al., Cradle-to-Grave Lifecycle Analysis of U.S. Light-Duty Vehicle-Fuel Pathways: A Greenhouse Gas Emissions and Economic Assessment of Current (2020) and Future (2030-2035) Technologies, Argonne National Laboratory, ANL-22/27, at xxi (2022), available at https://publications.anl.gov/anlpubs/2022/07/176270.pdf.

13 Id.

[See original comment for Figure ES-1.C2G GHG emissions of various vehicle-fuel pathways for small SUVs assuming high technology progress. Analysis was performed using GREET2020] [EPA-HQ-OAR-2022-0829-0581, pp. 7-8]

The Argonne report shows that other "vehicle-fuel pathways" can compete with BEVs. For example, a conventional gasoline hybrid (HEV) achieves about 310 gCO2e/mi and conventional corn-based E85 in a non-HEV achieves 260 gCO2e/mi. The grey arrows in the plot indicate that the future potential of HEVs with advanced E85 or E-Fuels is comparable to future BEVs with wind and solar power. [EPA-HQ-OAR-2022-0829-0581, pp. 7-8]

The proposed rulemaking would not allow other vehicle-fuel pathways to compete with BEVs. By regulating only tailpipe emissions, EPA would create artificial incentives for only BEVs. This could have disastrous effects on both the cost and the GHG emissions of future vehicles. As shown in Figure 37 from the same Argonne report (reproduced below),14 the cost and GHG emissions of a BEV are strongly affected by the driving range. A BEV with a 400-mile range is dramatically more expensive than one with a 200-mile range, and its lifetime GHG emissions are substantially worse. A 400-mile-range BEV has only a slight GHG benefit compared to a HEV or an E85 internal combustion engine vehicle (ICEV). But the proposed rule would count all BEVs as zero GHG emissions, regardless of battery size, vehicle size, or weight—all of which can have an impact on lifecycle GHG emissions and costs. [EPA-HQ-OAR-2022-0829-0581, p. 8]

14 Id. at 114.

[See original comment for graph of Lifetime Cost vs. GHGs, Current Tech] [EPA-HQ-OAR-2022-0829-0581, p. 8]

It is important that EPA utilize lifecycle analysis to create a "level playing field" which encourages speedy adoption of HEVs, PHEVs, flex-fuel vehicles, and other technologies (in addition to BEVs) to achieve the most rapid, affordable, robust, and practical GHG emissions reductions in a wide range of vehicle segments, while satisfying diverse customer needs and preferences. Europe is already making progress towards regulation based on lifecycle analysis.30 Furthermore, EPA should revise the proposed standards to a level which can be achieved using more realistic estimates for future penetration of vehicle technologies and that incorporates low carbon fuels. [EPA-HQ-OAR-2022-0829-0581, p. 13]

30 See Goldman Sachs, New era in CO2 regulation: EVs to be tested across life cycle, not only on running performance, Dec. 5, 2019, available at https://www.goldmansachs.com/intelligence/pages/briefly/from_briefings_21-Jan-2020/new-era-in-co2-regulation.pdf; Serenella Sala, et al., The evolution of life cycle assessment in European policies over three decades, The International Journal of Life Cycle Assessment 26, 2295-2314 (2021), available at https://doi.org/10.1007/s11367-021-01893-2.

Organization: Natural Gas Vehicles for America (NGVA)

Introduction

Natural Gas Vehicles for America (NGVAmerica) respectfully submits these comments in response to the above captioned notice. NGVAmerica supports EPA finalizing regulations that achieve needed emission reductions and incorporate a strong fuel- and technology- neutral performance standard. Future standards must incorporate realistic expectations about the pace, cost, and deployability of technology, and to ensure success must encourage engine makers and vehicle manufacturers to deploy a variety of available, scalable, and cost-effective technologies. To achieve these objectives and drive manufacturers toward zero-emission technology, EPA must incorporate well-to-wheel emission or life-cycle assessments into its regulations. We therefore request that EPA develop and approve a method of calculating and certifying emission reductions related to the use of low-carbon and carbon-negative biofuels. [EPA-HQ-OAR-2022-0829-0597, p. 3]

Two compelling developments have occurred in recent years that require EPA to reevaluate its past conclusion that only electric vehicle technology is a “game-changer” and therefore only electric vehicles warrant special regulatory incentives to assist in their development and commercialization. These developments are the certification and sale of low-NOx natural gas trucks, which achieve reductions surpassing the 2027 standards finalized by EPA1 and the increasing uptake of renewable natural gas as a transportation fuel. [EPA-HQ-OAR-2022-0829-0597, pp. 3-4]

1 See https://www.govinfo.gov/content/pkg/FR-2023-01-24/pdf/2022-27957.pdf

Renewable natural gas currently consumed in California achieves a lower carbon intensity score than electricity. In fact, based on the latest data submitted to CARB under the low- carbon fuel standard program, bio-CNG in 2022 had an average carbon intensity value of negative 99. [EPA-HQ-OAR-2022-0829-0597, pp. 3-4]

The time has come for EPA to fully embrace all low-carbon technologies and provide a level playing field in its regulations. EPA staff previously stated to NGVAmerica in meetings that the Renewable Fuel Standard Program already incentivizes low-carbon fuels like RNG and that its vehicle regulations are not intended for that purpose. EPA staff also has acknowledged in meetings with NGVAmerica that when it comes to greenhouse gas emissions, moving to a life cycle analysis (LCA) or well-to-wheels (WTW) approach would be preferable, and previously indicated as part of the proceedings for the 2012 light-duty GHG regulations that it would move away from the tailpipe only approach once automakers surpass sales of 200,000 vehicles. EPA under the Biden Administration, however, has abandoned that prior commitment. [EPA-HQ-OAR-2022-0829-0597, pp. 5-6]

There are ample studies that support the importance of evaluating well-to-wheel emissions. A September 2022 study published in the Journal Sustainable Energy & Fuels included the following: [EPA-HQ-OAR-2022-0829-0597, pp. 5-6]

The results show that in both the U.S. and EU markets, waste-streams-to-energy technologies, such as CNG production via AD of wet waste resources, offer the biggest opportunities to reduce WTW GHG emissions. …Drop-in renewable diesel fuels, produced from forest residues or wood waste feedstock via thermochemical conversion technologies, including FT and pyrolysis technologies, could potentially reduce GHG emissions more than 75% in both the U.S. and the EU, despite the varying energy efficiency of the conversion routes and feedstocks used.3 [EPA-HQ-OAR-2022-0829-0597, pp. 5-6]

3 Journal of Sustainable Energy & Fuels, Decarbonization potential of on-road fuels and powertrains in the European Union and the United States: a well-to-wheels assessment, (Published Sept. 1, 2022)(Decarbonization potential of on-road fuels and powertrains in the European Union and the United States: a well-to-wheels assessment - Sustainable Energy & Fuels (RSC Publishing).

This report looks at benefits in the U.S. and Europe, references numerous other studies, and its authors include several prominent experts on greenhouse gas emissions. A White Paper entitled Smart CO2 Standards for Negative Emissions Mobility published by the European Biogas Associations references nearly a dozen studies with similar findings regarding emission reduction benefits and cost-effectiveness of RNG reductions. A copy of that document is included in Appendix A. [EPA-HQ-OAR-2022-0829-0597, pp. 5-6]

Another excellent report on the importance of accounting for well-to-wheel emissions and life-cycle emissions was prepared in 2021 by Frontier Economics for NGVA Europe. That report was specifically prepared with the intention of highlighting the need for regulatory standards that account for well-to-wheel emissions. The frontier economics evaluation included a comparison based on conventional natural gas, 100 percent biomethane, and a mixture of 40 percent conventional natural gas and 60 percent biomethane. This study supports the contention that a mixture of biomethane of 60 percent biomethane is cost- competitive from a purchase perspective with electric vehicle technology while also delivering greater emission CO2 equivalent emission reductions. A copy of this report is included in Appendix B. [EPA-HQ-OAR-2022-0829-0597, pp. 6-7]

A report4 prepared by Ramboll US Consulting, Inc. for the Western States Petroleum Association provides additional evidence on the cost-effectiveness and well-to-wheel benefits of natural gas vehicles and other low-emission technologies. The report evaluated California's plans to focus almost exclusively on electrification as the solution to address transportation related emissions including NOx emissions and greenhouse gas emissions. [EPA-HQ-OAR-2022-0829-0597, pp. 6-7]

4 Ramboll Multi-Technology Pathways Study - Western States Petroleum Association (wspa.org)

The report's executive summary includes the following:

- Expanded implementation of zero-emission and Low-NOx vehicles, coupled with increased introduction of renewable liquid and gaseous fuels, can deliver (as shown in Figures ES-1) and more cost-effective benefits than a zero-emission vehicle (ZEV)-only approach. [EPA-HQ-OAR-2022-0829-0597, pp. 6-7]

- As advanced low-emitting trucks are commercially available (citation omitted) to deliver benefits to communities sooner, multi-technology pathways can help achieve emission reductions without reliance on infrastructure and technology upgrades that will take years to resolve. [EPA-HQ-OAR-2022-0829-0597, pp. 6-7]

- There is growing potential for renewable fuels, including those with negative carbon intensity, to [sic] achieve GHG reductions, which CARB has not acknowledged fully in the MSS nor assessed the potential for early and cost-effective GHG reductions through these multi-technology vehicle pathways. [EPA-HQ-OAR-2022-0829-0597, pp. 6-7]

- Low-emission heavy-duty trucks are cost-competitive with (or cheaper than) battery electric vehicles (BEVs). This is true even though battery technology promises (such as greater energy density/lower cost) have not been adequately demonstrated and related transmission/distribution infrastructure cost have not been included in the state's analyses. [EPA-HQ-OAR-2022-0829-0597, pp. 6-7]

In addition to the greenhouse gas emission benefits, it is important to note that virtually all new natural gas engines already achieve emission reductions of nitrogen oxides that surpass the reductions required by EPA recently finalized low-NOx rule for medium and heavy-duty vehicles. All new natural gas trucks and buses regardless of whether they operate on conventional natural gas or RNG therefore provide meaningful reductions of this important pollutant. EPA's regulations provide averaging, banking, and trading credits to manufacturers that exceed emission requirements (i.e., deliver lower emitting engines). [EPA-HQ-OAR-2022-0829-0597, p. 7]

The new regulations are expected to further encourage the development and sale of natural gas engines. The incentive for lower polluting natural gas engines however could be offset by this rulemaking if EPA does not amend its proposal to incorporate well-to-wheel, greenhouse gas emission benefits of NGVs. [EPA-HQ-OAR-2022-0829-0597, p. 7]

Two automakers opposed the use of 0 g/mi. Honda ‘‘believes that EPA should separate incentives and credits from the measurement of emissions. Honda believes that without accounting for the upstream emissions of all fuels, inaccurate comparisons between technologies will take place * * *. EPA's regulations need to be comprehensive and transparent. By zeroing out the upstream emissions, EPA is conflating incentives and credits with proper emissions accounting.'' EcoMotors International ‘‘encourages EPA to drop the 0 g/mile tailpipe compliance value.'' Environmental advocacy groups also opposed the 0 g/ mi compliance treatment. The Natural Resources Defense Council claimed that 0 g/mi ‘‘undermines'' the pollution and technology benefits of the program. Along with other environmental groups, the American Council for an Energy Efficient Economy also opposed 0 g/mi, but added that ‘‘[m]ost important, however, is that a zero-upstream treatment of plug-in vehicles not be continued indefinitely, and that full upstream accounting be applied to these vehicles by a date certain. EPA's proposed treatment of EVs largely accomplishes this, so we strongly support that aspect of the proposal.'' The American Petroleum Institute argued that ‘‘[i]gnoring the significant contribution of (and extensive compilation of published literature on) upstream CO2 emissions from electricity generation, defies principles of transparency and sound science and distorts the market for developing transportation fuel alternatives. It incentivizes the electrification of the vehicle fleet with a pre- defined specific and costly set of technologies whose future potential is not measured with the same well-to-wheels methodology against that of advanced biofuels or other carbon mitigation strategies.'' Organizations advocating fuels other than electricity also opposed the use of 0 g/mi. [EPA-HQ-OAR-2022-0829-0597, pp. 10-11]

Despite the expressed views, EPA nevertheless retained the 0 g/mi standard. In defense of continuing to retain the 0 g/mi treatment and providing multiplier credits, EPA stated that:

EPA believes that it is both reasonable and appropriate to accept some short- term loss of emissions benefits in the short run to increase the potential for far- greater game-changing benefits in the longer run. The agency believes that these multipliers may help bring some technologies to market more quickly than in the absence of incentives. [EPA-HQ-OAR-2022-0829-0597, pp. 10-11]

The European Biogas Association eloquently explained why the EU Commissions rules should account for well-to-wheel emissions and their explanation is worth including here:

The current “tank-to-wheel” approach does not compare the different technologies appropriately because it ignores emissions associated with the production of the fuel. It does not recognise the positive contribution of renewable fuels such as biomethane to climate protection, and thus biases one technology over others without a climate protection rationale. [EPA-HQ-OAR-2022-0829-0597, pp. 10-11]

The revised CO2 regulation should propose technology-neutral solutions to reduce emissions in an accelerated and cost-effective way. It should avoid one-size-fits-all options that could prove insufficient in the long-term and may lead to a slow, unfair and costly emissions reduction process. [EPA-HQ-OAR-2022-0829-0597, pp. 10-11]

The CO2 regulation should be amended to ensure an integrated transition that picks no single green technology over others and leaves no-one behind. All alternative fuels are necessary if transport decarbonisation is to be delivered at pace.11 [EPA-HQ-OAR-2022-0829-0597, pp. 10-11]

11 SMART CO2 STANDARDS FOR LEAN MOBILITY (europeanbiogas.eu)

The Frontier Economics report similarly offers an excellent case for ensuring proper treatment and inclusion of biomethane.

Our analysis shows that gas mobility can help to contribute to reducing GHG emissions in road transport at comparably low system cost. As gas mobility – in contrast to other drivetrain technologies which are less mature – is readily available on vehicle, infrastructure and fuel supply levels and thus quickly scalable now, it can contribute to ambitious early GHG emission reduction by 2030 at low cost. [EPA-HQ-OAR-2022-0829-0597, pp. 11-12]

- Technological diversification. The immense challenge and high urgency for the mobility sector to achieve emissions reductions does not allow for cherry picking of individual technologies. Rather, we have to go “all-in” by enabling as many options to contribute as possible. [EPA-HQ-OAR-2022-0829-0597, pp. 11-12]

- Freedom of choice and competition of technologies. The heterogeneity of mobility applications with many individual factors determining the most efficient technology in each case rules out any central planning approach – there is no “one size fits all” solution. [EPA-HQ-OAR-2022-0829-0597, pp. 11-12]

- Keeping options open. There is a high degree of uncertainty around the optimal technology options in the future. Regulation therefore should avoid prematurely ruling out any pathway (e.g. by banning combustion engines which may in the future be fuelled by renewable or low-carbon fuels or gases). [EPA-HQ-OAR-2022-0829-0597, pp. 11-12]

We fervently believe that the Administration’s decarbonization and clean air goals will only be achieved by focusing on a multi-technology approach that includes cost-effective carbon-negative solutions like RNG trucks that can begin accruing and compounding significant clean air and carbon reductions right away. We, therefore, respectfully request that EPA provide credits for natural gas vehicles based on the well-to-wheel benefits of the consuming natural gas which increasingly includes larger amounts of RNG. We also believe that any additional incentives finalized in this rulemaking to offer aid in the commercialization of electric vehicles or fuel-cell vehicles should be extended to NGVs based on the extraordinary emission reduction potential of these vehicles. [EPA-HQ-OAR-2022-0829-0597, pp. 11-12]

Organization: Nebraska Corn Board (NCB) and Nebraska Corn Growers Association

On behalf of the nearly 2,500 Nebraska Corn Growers Association (NeCGA) dues paying members and the over 21,000 corn farmers in Nebraska who contribute to the state’s corn checkoff program through the Nebraska Corn Board (NCB), we appreciate the opportunity to comment on the Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles. [EPA-HQ-OAR-2022-0829-0583, p. 1]

Nebraska corn farmers and ethanol producers have worked diligently in reducing greenhouse gas emissions while supplying the fuels industry with a low carbon, high octane alternative. However, the EPA seemingly overlooks the contribution that biofuels, such as ethanol, can provide to reducing carbon emissions through tailpipes and internal combustion engines. [EPA-HQ-OAR-2022-0829-0583, p. 1]

This proposal gives EVs an unfair advantage when the EPA upstream emissions. [EPA-HQ-OAR-2022-0829-0583, p. 1]

As most Americans will continue driving their current vehicle, it is crucial to ensure they have access to an affordable and environmentally friendly product such as gasoline with 15% ethanol, known as E15. This is a fuel that is acceptable for vehicles 2001 and newer which are 97% of the vehicles on the road. If made available to every consumer in the country, this would reduce carbon emissions by 280 million tons in the next decade. We ask the EPA to consider the University of California, Riverside's study on the Comparison of Exhaust Emissions between E10 and splash blended E15 as it demonstrates the opportunity that E15 has at reducing emissions. This study states around 54% reduction in carbon emissions compared to E10. We strongly believe in the role biofuels have as a critical step in reducing carbon emissions and being a cost-effective fuel for consumers. [EPA-HQ-OAR-2022-0829-0583, p. 2]

Organization: North Dakota Farmers Union (NDFU)

Benefits of Renewable Fuels

NDFU continues to believe that high octanes fuels are the cheapest method for reducing GHG emissions. Improved engines and high octane fuels, specifically mid-level ethanol blends, are technologically feasible and economically reasonable means to achieve reduced GHG emissions. Increased ethanol volume increases the octane level of gasoline across grades. In addition to its higher octane level, ethanol also boosts engine efficiency.2 Higher ethanol blends can increase fuel octane without expensive refinery upgrades. [EPA-HQ-OAR-2022-0829-0586, p. 2]

2 Ricardo, Inc. (2016, September 20). The draft technical assessment report: Implications for high octane, mid- level ethanol blends, Final report. Prepared for Renewable Fuels Association. Retrieved from https://d35t1syewk4d42.cloudfront.net/file/1607/ATTACHMENT-A_Ricardo-TAR-Report-for-RFA_2016_09-20.pdf.

Ethanol is substantially cleaner than petroleum-based octane additives. It reduces emissions of particulate matter and air toxics, such as benzene, toluene, and xylene. Ethanol further provides GHG emissions reductions, which is increasingly important as the carbon intensity of gasoline is increasing with greater use of unconventional fossil fuels. "Emissions from fossil fuel combustion comprise the vast majority of energy-related emissions," with an increase in emissions from the transportation sector largely attributed to increased vehicle miles travelled and motor gasoline consumption by light-duty vehicles.3 At the same time, energy use in ethanol production and lifecycle GHG emissions have decreased with changes in farming practices and higher yields. As EPA has found, the land use, lang-use change, and forestry sector generated a net increase in carbon stocks.4 [EPA-HQ-OAR-2022-0829-0586, p. 2]

3 Environmental Protection Agency (2023). Inventory of U.S. greenhouse gas emissions and sinks: 1990-2021. U.S. Environmental Protection Agency, EPA 430-R-23-002. https://www.epa.gov/system/files/documents/2023-04/US-GHG-Inventory-2023-Main-Text.pdf.

4 Id.

EPA should not focus on one technology. While BEVs may be part of the solution, a balanced approach to emissions reductions using BEVs and other technologies is needed.11 It is important that EPA utilize lifecycle analysis to create a level playing field that encourages speedy adoption of flex-fuel vehicles, hybrid electric vehicles, plug-in hybrid electric vehicles and other technologies, to achieve the most rapid, affordable, robust, and practical GHG emissions reductions in a wide range of vehicle segments, while satisfying diverse customer needs and preferences. Furthermore, EPA should revise the proposed standards to a level which can be achieved using more realistic estimates for future penetration of vehicle technologies and that incorporates low carbon fuels. [EPA-HQ-OAR-2022-0829-0586, p. 5]

11 Pratt, G. (2021, August 23). (More) straight talk about Toyota's electric vehicle strategy. Medium. Retrieved from https://medium.com/toyotaresearch/more-straight-talk-about-toyotas-electric-vehicle-strategy- f0aba4be40.

Biofuels have an important role to play in supporting family farms and rural communities. Renewable fuels can also significantly contribute to EPA's emissions reduction goals. However, we are concerned that EPA's proposal is biased in favor of BEVs and against renewable fuels. [EPA-HQ-OAR-2022-0829-0586, p. 6]

NDFU believes EPA should take into account lifecycle analysis to provide a fairer and neutral comparison of technologies available to reduce emissions, including consideration of biofuels. BEVs are not zero emissions in this context and would not necessarily provide the most cost-effective, practical or fastest way to achieve EPA's emission reduction goals. [EPA-HQ-OAR-2022-0829-0586, p. 6]

Organization: Novozymes North America (Novozymes)

Novozymes' Innovative Technologies Result in Lower Biofuel Lifecycle Emissions

Novozymes' enzymatic catalyst solutions, also known as biocatalysts, make the production of biofuels more efficient and environmentally friendly. Enzymes increase yield, reduce waste, reduce raw material input, and produce higher energy savings. Enzymes enable biofuel producers to convert corn kernel, corn stover, wheat straw, wood chips, sawdust, waste, and sugarcane bagasse into fuel, while collectively increasing yield and energy efficiency throughout the sector. Our enzymes help biofuel producers get more energy out of every harvest. These technologies have already helped the U.S. replace about 10% of liquid fuels with renewable alternatives. [EPA-HQ-OAR-2022-0829-0650, pp. 2-3]

Fiberex is a platform designed by Novozymes to utilize waste cellulosic material found in agricultural products. These cellulase enzymes can convert the cellulosic fiber found in, for example, corn kernel fiber, into high-value, low-CI products including cellulosic ethanol and increases corn oil yield that may be utilized as a raw material for renewable diesel production. This process is critical in maximizing fermentation efficiency and generating the low carbon products the markets (and consumers) are demanding. This technology has been instrumental in generating the roughly 120 million gallons of cellulosic ethanol that is currently being shipped to

California every year. With a CI score 70 percent lower than gasoline, this cellulosic ethanol made from the corn kernel is helping to lower carbon emissions, drive sustainability in our transportation sector and create economic impacts from coast to coast. It is vital that, moving forward, this cellulosic technology can be applied not only to the production of low carbon ethanol, but increasingly to low carbon biochemicals as well as Sustainable Aviation Fuel (SAF). This includes supporting large-scale production of critical enzymes and yeast used in fiber conversion as well as ensuring that modeling (i.e. Argonne GREET) accurately accounts for the benefits being seen via this advanced technology. [EPA-HQ-OAR-2022-0829-0650, pp. 2-3]

Novozymes Innova yeast products deliver unparalleled robustness, help increase ethanol yield, and reduce fermentation time and operational costs. Novozymes launched its first yeast product in North America in 2018, and it has now launched 11 yeast products across the globe. Novozymes' yeast allows producers to consistently reduce corn and chemical inputs and power through the most challenging conditions. Most of Novozymes' yeast products express enzymes required to hydrolyze starch to produce glucose. Delivering enzymes via yeast decreases exogenous enzyme requirements resulting in a more sustainable, and lower CI fermentation process. Novozymes also developed the Cellerity® yeast platform for second generation biomass refineries. Cellerity enables increased ethanol yield and improved xylose conversion and inhibitor tolerance. [EPA-HQ-OAR-2022-0829-0650, pp. 2-3]

Above the inherent efficiencies and savings achievable with Novozymes' enzymes alone, the company's yeast technologies provide additional benefits. Many of our yeasts express critical enzymes needed for the lowest emissions biofuel production, in addition to converting available sugars to ethanol. These enzymes reduce the need for exogenous enzyme addition, further enabling overall lower CI values for today's biofuels. [EPA-HQ-OAR-2022-0829-0650, pp. 2-3]

EPA Should Issue a Final Rule That is Technology Neutral and Promotes All Available Lower Emissions Transportation Fuels

Whether intended or not, the practical effect of the proposed rule in its current form would be to pick winners and losers and would fail to help encourage and facilitate the continued growth, production and use of vehicles that run on all lower emissions transportation fuels, including low CI biofuels. This effect would make it harder for the United States to attain its necessarily ambitious goal to achieve net zero emissions by 2050. This conclusion is especially true considering that many in the auto and other industries have predicted as overly ambitious and impractical the myriad policy goals to phase out the sale and production of light and medium duty vehicles with internal combustion engines by 2030 to 2040. [EPA-HQ-OAR-2022-0829-0650, pp. 2-3]

Although, through this proposal, EPA appears to be essentially directing the auto industry to sell approximately 67 percent of new cars and trucks as EVs by 2032, there are real questions whether that many consumers will want to buy them and whether the necessary infrastructure and grid enhancements to handle that many EVs on the road will be available by that time. Meantime, the federal government has formulated laws and policies to encourage the increased investment in and production and use of the cleanest biofuels that have been and continue to be responsible for massive emissions reductions in the transportation fuel sector over the last two decades. These policies and laws, including the federal Renewable Fuel Standard (RFS), have worked together to encourage these outcomes and the ongoing innovation within the biofuels industry that has and continues to improve the carbon and other GHG emissions reduction capabilities of the biofuels used in transportation fuel. [EPA-HQ-OAR-2022-0829-0650, pp. 2-3]

We respectfully urge the EPA to revise the proposed rule, so that when it is issued in its final form, the regulation will not only help facilitate the wider production, sale and use of EVs, but will simultaneously recognize and build on the enormous emissions reduction success and potential of biofuels. Both of these outcomes will be needed to meet the transportation fuel need in this country at least over the next two decades. Moreover, they will be necessary for this country to achieve net zero emissions by 2050, especially given the realities of legacy ICE vehicles expected to be on the road at least through the 2040s. Put another way, to achieve this country's collective net zero by 2050 emissions reduction goals, U.S. policies and laws will need to recognize and encourage every potential source of clean energy. Biofuels must continue to be on top of this list for the foreseeable future, and the final rule must reflect this fact so as to avoid inadvertently leaving behind millions of tons of avoided emissions reductions, or discouraging the continued investment, innovation and use of low carbon and other GHG emissions fuels in this country. [EPA-HQ-OAR-2022-0829-0650, pp. 2-3]

Organization: Oryxe International Inc. (Oryxe)

Oryxe is a strong supporter of balanced environmental stewardship and shares the Biden Administration's commitment to increasing vehicle efficiency and reducing carbon dioxide and criteria pollutant emissions from the transportation sector. In fact, Oryxe built and operates its business in the pursuit of these goals. However, if finalized as proposed, the Proposed Rule would have a very significant negative impact on producers of low emission fuel additives such as Oryxe. For this reason, as discussed further below, Oryxe respectfully requests that EPA ensure that the final rule (1) recognizes the ability of vehicle manufacturers to use fuel additives to comply with the standards and (2) accounts for the upstream and lifecycle emissions impact of electrified vehicles in the light-duty and medium-duty vehicle sectors. Oryxe also offers comment in response to EPA's announcement that the Agency is considering proposing changes to the gasoline fuel property standards in order to further reducing PM emissions. [EPA-HQ-OAR-2022-0829-0752, p. 2]

2. EPA Should Account for the Upstream and Lifecycle Emissions Impact of Electrified Vehicles

Oryxe further urges EPA to fully account for the upstream and lifecycle emissions impact of electrified vehicles in the light-duty and medium-duty sectors. The Proposed Rule will effectively force a transition to electrified vehicles while disregarding the emissions impact associated with sourcing, production, and use of electrified vehicles. These include the carbon impacts associated with mineral extraction and battery manufacturing, fueling with electricity made from coal or natural gas, battery disposal and recycling, and potential higher tire and brake wear from electric vehicles. Manufacturing batteries for use in electric vehicles can contribute between 10 and 30 percent of lifecycle emissions due to the significant amount of energy needed to extract and process critical materials.3 [EPA-HQ-OAR-2022-0829-0752, p. 3]

3 See "Slow Down: The Case for Technology Neutral Transportation Policy," ConservAmerica, at 4-5, https://static1.squarespace.com/static/5d0c9cc5b4fb470001e12e6d/t/5fd1580999fe644e8a504a54/1607555090612/C A+Tech+Neutral+Paper+-+12.20+%281%29.pdf.

A national strategy that forces a dramatic transition from ICE vehicles to electrified vehicles in the domestic light-duty and medium-duty vehicle sectors deserves and demands that EPA undertake a lifecycle analysis for each vehicle technology. To determine the impact on emissions of each vehicle technology, EPA should conduct a lifecycle analysis to evaluate the manufacture, materials, disposal, and transport for all needed vehicle components and provide a grams/ton-mile comparison of the emissions of ICE vehicles and electrified vehicles. Accounting for the upstream and lifecycle emissions impact of electrified vehicles in any final rule will ensure a level playing field for all vehicles, including ICE vehicles using fuel additives. In addition, a technology-neutral strategy that supports multiple options will promote innovation and increase near-term carbon dioxide and criteria pollutant emission reductions. [EPA-HQ-OAR-2022-0829-0752, pp. 3-4]

Organization: Plains All American Pipeline, L.P. (PAAP)

In general, we have serious concerns about the Proposal. It will render America more dependent on foreign- controlled supply chains and create irreparable harm to our energy security, while missing the mark on well- intentioned emission reductions. By focusing solely on tailpipe emissions, the Proposal would only address certain transportation emissions and fail to quantify the full lifecycle of emissions for all vehicles, including materials resourcing, production, operation, battery replacement, recycling and end-of-life disposal. [EPA-HQ-OAR-2022-0829-0713, p. 1]

Organization: POET, LLC (POET)

POET thanks the Environmental Protection Agency ("EPA") for the opportunity to submit this comment on the proposed rule, "Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles" (the "Proposed Rule"). POET generally supports standards, like those in the Proposed Rule, that will significantly curb greenhouse gas ("GHG") emissions from cars and light- and medium-duty trucks covered by the Proposed Rule. However, EPA must broaden the range of technologies the Proposed Rule relies upon to include renewable fuels, such as bioethanol, in setting standards for reducing GHG and other emissions. Renewable fuels will be critical to decarbonizing and reducing other air pollutant emissions from these vehicles. POET urges EPA to credit renewable fuels, including their significant lifecycle carbon emissions reductions, and adopt POET's other recommendations in these comments. [EPA-HQ-OAR-2022-0829-0609, p. 1]

I. Summary of Comments

A. Greenhouse Gas Emission Reductions.

Renewable fuels, such as bioethanol, significantly reduce lifecycle carbon emissions relative to fossil fuels and are a key pathway to achieving the Proposed Rule's goals. Yet, the Proposed Rule provides no mechanism for low-carbon fuels to contribute to decarbonizing the light- and medium-duty vehicle fleet. Bioethanol can achieve net-zero, or even net-negative, lifecycle emissions within the Proposed Rule's 2032 timeframe by employing technologies and methods such as carbon capture, climate-smart farming, and using renewable power or process energy and biomass for process heat at bioethanol plants. Renewable fuels will be particularly critical in decarbonizing internal combustion engines ("ICE") in light-duty vehicles ("LDVs") that will remain on the road for at least the next several decades. EPA's proposed GHG standards should credit vehicles that use renewable fuels to reduce their net GHG emissions. [EPA-HQ-OAR-2022-0829-0609, p. 4]

Renewable fuels are a proven technology. Expanding their use is consistent with federal and state programs. Many federal and state programs, such as the federal Renewable Fuel Standard ("RFS") and California's Low Carbon Fuel Standard ("LCFS"), support the production of significant quantities of low-carbon renewable fuels. Renewable fuels such as bioethanol receive congressionally approved funding and tax credits under the recently enacted Bipartisan Infrastructure Law ("BIL") and Inflation Reduction Act ("IRA").1 Renewable fuels are also key to the Administration's renewable energy policies. The U.S. National Blueprint for Transportation Decarbonization, which EPA co-authored, calls for more renewable fuels as one of its many decarbonization strategies.2 EPA's Proposed Rule must align with those policies by incentivizing vehicles that run on higher bioethanol blends and thus can achieve significant lifecycle GHG emissions reductions. [EPA-HQ-OAR-2022-0829-0609, p. 4]

1 135 Stat. 429 (2021); 136 Stat. 1818 (2022).

2 The U.S. National Blueprint for Transportation Decarbonization (Jan. 2023), available at https://www.energy.gov/sites/default/files/2023-01/the-us-national-blueprint-for-transportation-decarbonization.pdf.

EPA's proposal to address reducing GHG emissions is arbitrary and capricious in only addressing tailpipe emissions and ignoring the real-world GHG lifecycle impacts of vehicles. EPA's approach could have significant adverse consequences with respect to GHG emissions because it inaccurately assumes that electric vehicles have no "upstream" emissions while failing to incentivize crucial technologies such as bioethanol with significant lifecycle GHG emissions benefits. EPA thus pushes out of the market highly beneficial but disincentivized bioethanol-compatible vehicles. To most efficiently reduce greenhouse gases, EPA must establish compliance crediting for the lifecycle GHG emissions reductions from bioethanol. [EPA-HQ-OAR-2022-0829-0609, pp. 4-5]

Even if EPA does not adopt the lifecycle approach to assess GHG emissions from all light-duty vehicles, its vehicle GHG program must still distinguish between biogenic and fossil carbon sources and credit the former (biogenic) as carbon neutral. This approach would recognize the carbon neutrality and significant benefits of replacing petroleum with renewable liquid fuels. As President Biden has correctly indicated, "you simply can't get to net zero by 2050 without biofuels."3 [EPA-HQ-OAR-2022-0829-0609, pp. 4-5]

3 See The White House, Remarks by President Biden on Lowering Energy Costs for Working Families (Apr. 12, 2022), available at https://www.whitehouse.gov/briefing-room/speeches-remarks/2022/04/12/remarks-by-president- biden-on-lowering-energy-costs-for-working-families/.

Under EPA's own justification for the Proposed Rule, bioethanol is an essential strategy that must be recognized and given due credit under the GHG standards. EPA justifies the proposal based on (i) GHG emission reduction benefits, (ii) manufacturer cost and consumer cost, (iii) energy security, (iv) "criteria" and toxic air pollutant reductions, and (v) environmental justice.7 EPA inadequately addresses each of these key factors because EPA fails to consider the benefits of bioethanol for each. By taking this narrow approach that effectively pushes biofuels out of the market, EPA undermines its own criteria for undertaking the Proposed Rule. [EPA-HQ-OAR-2022-0829-0609, pp. 5-6]

7 See e.g., 88 Fed. Reg. at 29347.

The Proposed Rule's analytical gaps regarding the failure to credit real-world biogenic lifecycle emission benefits and BEV feasibility call into question the legality of the Proposed Rule as currently structured. As EPA knows, courts will invalidate rules if the agency has "entirely failed to consider an important aspect of the problem" or "offered an explanation for its decision that runs counter to the evidence before the agency."8 Additionally, the United States Supreme Court in West Virginia v. EPA faulted EPA for exercising Clean Air Act authority to "substantially restructure the American energy market" in a way that "Congress had conspicuously and repeatedly declined to enact itself."9 By pressing for the extraordinarily rapid deployment of light-duty BEVs without thoroughly evaluating the lifecycle drawbacks of BEVs and BEV feasibility, supply chain and infrastructure challenges, and by failing to credit the lifecycle benefits of biofuels, the Proposed Rule is similarly deficient. [EPA-HQ-OAR-2022-0829-0609, pp. 5-6]

8 Motor Vehicles Mfrs. Ass'n v. State Farm Mutual Automobile Ins. Co., 463 U.S. 29, 43 (1983).

9 142 S. Ct. 2587, 2610 (2022) (quotation omitted). Similarly, under the "major questions" doctrine, agencies may not construe a statute to authorize them to exercise powers of "vast economic and political significance" unless the statute does so in clear terms. Alabama Ass'n of Realtors v. HHS, 141 S. Ct. 2485, 2489 (2021) (quoting Utility Air, 573 U.S. at 324 (2014)).

Finally, POET strongly supports EPA's proposal to set gasoline fuel property standards to reduce particulate matter ("PM") emissions from gasoline-fueled LDVs and medium-duty vehicles.11 Bioethanol must play a major role in any future regulatory proposal. Bioethanol has been shown to significantly reduce PM and other toxic air emissions relative to alternative aromatics and other blending compounds. It will also boost octane levels in gasoline to make up for any loss in octane from standards requiring removal of certain high-boiling, heavy aromatics. Bioethanol also has the added benefit of significantly reducing lifecycle GHG emissions unlike other, carbon-intensive alternatives. EPA should propose standards that tackle two problems at once, by promoting increased bioethanol blends, such as E15, that both reduce PM emissions and help combat climate change. [EPA-HQ-OAR-2022-0829-0609, pp. 6-7]

11 See Proposed Rule at Section IX, 88 Fed. Reg. at 29397-29404.

III. EPA Must Revise the Proposed Rule to Credit Real-World Lifecycle Emissions Reductions from Renewable Fuels, including Bioethanol.

The Proposed Rule must credit renewable fuels such as bioethanol and their lifecycle GHG emissions reductions as an additional technology pathway for meeting EPA's emissions reduction standards. ICE vehicles are expected to remain on the road for decades. The Proposed Rule recognizes this. It states that "some portion of their light-duty sales will remain ICE-based for the foreseeable future, predominantly in large SUVs and pickup trucks."15 Other sources, such as the U.S. government's leading energy forecaster, show much larger numbers of ICE vehicles will be on the road for decades to come.16 Renewable liquid fuels offer one of the best solutions to decarbonizing those legacy ICE vehicles. [EPA-HQ-OAR-2022-0829-0609, p. 8]

15 See 88 Fed. Reg. at 29187.

16 U.S. Energy Information Administration, AEO2023 Issues in Focus: Inflation Reduction Act Cases in the AEO2023, at 11 (2023).

A. Incentivizing Renewable Fuels in the Vehicle GHG Program Will Have Myriad Benefits.

1. Renewable fuels significantly reduce carbon emissions on a lifecycle basis and may soon achieve net-zero or net-negative emissions.

The carbon-reducing benefits of renewable fuels are immense. Bioethanol, for instance, reduces lifecycle GHG emissions by at least 46 percent relative to fossil transportation fuels.17 POET and others are also pursuing ways to reduce lifecycle emissions of renewable fuels even further. By deploying carbon capture and storage technologies, switching to renewables such as wind and solar for process energy at production facilities, utilization of renewable biomass rather than natural gas for process heat, and encouraging farmers to implement climate-smart farming practices, renewable fuel producers are working to reduce the carbon footprint of their processes even further and may even achieve net-negative lifecycle emissions—removing carbon from the total atmospheric carbon load. [EPA-HQ-OAR-2022-0829-0609, pp. 8-9]

17 See Scully MJ, Norris GA, Alarcon Falconi TM, MacIntosh DL. 2021a. Carbon intensity of corn ethanol in the United States: state of the science. Environmental Research Letters, 16(4), pp. 043001. The 46 percent reduction figure relates to typical corn starch ethanol on an energy-adjusted basis. Cellulosic ethanol that is currently being produced is associated with even greater reductions, and corn starch ethanol may also have greater benefits when its octane value is accounted for.

By POET's calculations, bioethanol production could achieve significant emissions reductions from such measures, and could even achieve net-negative emissions. The latest scientific assessments assign bioethanol a carbon intensity of 51.4 gCO2/MJ.18 POET estimates that sequestering the biogenic carbon dioxide byproduct of bioethanol production would reduce bioethanol's carbon intensity by 30 gCO2/MJ. Switching to renewable electricity for process energy at bioethanol plants would reduce bioethanol's carbon intensity by another 5 gCO2/MJ. And climate-smart farming practices could lower bioethanol's carbon intensity by at least an additional 30 gCO2/MJ. The Proposed Rule should encourage these developments by crediting renewable fuels for vehicles. [EPA-HQ-OAR-2022-0829-0609, pp. 8-9]

18 Id. See also Lewandrawski et al., The greenhouse gas benefits of corn ethanol (March 2019), for a study with USDA input that while earlier nevertheless finds "opportunities to produce corn ethanol" with emissions that are 70% lower than gasoline, available at https://www.tandfonline.com/doi/full/10.1080/17597269.2018.1546488.

B. EPA Has the Authority to Set GHG Emissions Standards Based on Lifecycle GHG Emissions Reductions.

EPA has broad authority under Clean Air Action § 202 to set vehicle emissions standards that extends beyond tailpipe emissions reductions to other emissions in the fuel and vehicle manufacturing lifecycle. Clean Air Act § 202(a) requires EPA to set vehicle emissions standards for any air pollutant the Administrator determines may reasonably be anticipated to endanger public health or welfare. EPA may regulate emissions of such a pollutant "from any class or classes of new motor vehicles or new motor vehicle engines."30 The statute does not expressly limit EPA to regulating emissions only from vehicle tailpipes or the engines themselves. Instead, it is broadly worded to include emissions of any air pollutant that "cause[s], or contribute[s] to, air pollution."31 Lifecycle (upstream) emissions, especially for GHGs, fit that description.32 And in Massachusetts v. EPA, the Supreme Court confirmed EPA's broad authority to regulate additional, non-specified pollutants, provided the agency determines they endanger the public health or welfare.33 [EPA-HQ-OAR-2022-0829-0609, pp. 8-9]

30 42 U.S.C. § 7521(a)(1).

31 Id.

32 Other constraints in § 202(a) do not bar EPA from considering lifecycle emissions. The statute states that EPA's standards must apply to vehicles and engines during their useful life, cannot take effect until after a time that the EPA Administrator determines is necessary for the development and application of the technologies needed to meet EPA's standards, and must consider costs. Id. § 7521(a). None of those provisions prohibit EPA from crediting bioethanol vehicles for their positive lifecycle GHG emissions benefits.

33 See Massachusetts v. EPA, 549 U.S. 497, 506-07 (2007).

The best reading of Clean Air Act § 202(a) is that it mandates that EPA consider lifecycle GHG emissions as part of considering GHG emissions "from" motor vehicles. Otherwise, EPA would be failing "to consider an important aspect of the problem" in violation of U.S. Supreme Court precedent in Motor Vehicle Manufacturers Association v. State Farm.34 Emissions of GHGs, which are a globally mixed pollutant, from any phase of a LDV's lifecycle should be equally subject to § 202(a). Biofuels address the hazards caused by GHG emissions by reducing emissions on a lifecycle basis. As a result, the benefits generated by bioethanol in reducing lifecycle GHG emissions must be recognized through a crediting mechanism or other compliance flexibility benefits. [EPA-HQ-OAR-2022-0829-0609, pp. 12-13]

34 See Motor Vehicle Mfrs. Ass'n v. State Farm, supra. If EPA considers accounting for upstream emissions inappropriate under 202(a), query if 202(a) is inappropriate for addressing GHGs at all since GHGs are a globally mixed pollutant not a "tailpipe" pollution issue. Such a question is timely now since EPA proposes in this rulemaking to affirmatively ignore EV upstream emissions (as opposed to temporarily excluding upstream emissions when EVs were only an emerging and de minimis share of the vehicle market).

Courts interpreting § 202 have also found that EPA has the type of discretion sufficient to allow crediting bioethanol compatible vehicles for their lifecycle benefits. The D.C. Circuit has observed that "[m]anufacturers produce a wide variety of motor vehicles of different sizes, some using different engine technologies resulting in unusual emission characteristics."35 If EPA's authority to set emissions standards is flexible enough to address those varying vehicle characteristics, it should be similarly flexible to allow EPA to credit lifecycle emissions reductions from bioethanol. Under a common sense reading of section 202(a), EPA's ability to regulate GHGs from vehicles includes those lifecycle emissions. [EPA-HQ-OAR-2022-0829-0609, pp. 12-13]

35 Nat. Res. Def. Council, Inc. v. U. S. Envtl. Prot. Agency, 655 F.2d 318, 322 (1981).

EPA's statements in the Proposed Rule are consistent with the need for the vehicle GHG program to address lifecycle GHG emissions beyond a narrow focus on tailpipe emissions. EPA observes that, "[s]ince the earliest days of the CAA, Congress has emphasized that the goal of section 202 is to address air quality hazards from motor vehicles, not to simply reduce emissions from internal combustion engines to the extent feasible."36 While EPA is referring to electric vehicles, that sentiment also applies to the need for EPA to credit the lifecycle benefits of bioethanol. EPA's goal is to address air quality hazards from carbon dioxide emissions associated with classes of vehicles. One ton of GHG emissions causes the same harm whether it is released from a vehicle tailpipe or further upstream. [EPA-HQ-OAR-2022-0829-0609, pp. 12-13]

36 88 Fed. Reg. at 29233.

The Proposed Rule's discussion of the legislative and regulatory history regarding automotive emissions under the Clean Air Act repeatedly refers to alternative power sources and fuels, which further supports EPA's authority to establish a crediting program that accounts for bioethanol's lifecycle emissions benefits.37 Nothing in the record suggests that alternative power sources exclude other low-carbon alternatives, such as liquid renewable fuels. [EPA-HQ-OAR-2022-0829-0609, pp. 12-13]

37 Id.

The Proposed Rule, in fact, confirms that EPA believes it can regulate upstream emissions under § 202. EPA notes that its own current regulations would require "upstream emissions accounting for BEVs and PHEVs as part of a manufacturer's compliance calculation" to begin in MY 2027.38 EPA is now proposing, for the very first time, to permanently eliminate that upstream emissions accounting.39 But the fact that the current regulations do account for upstream emissions demonstrates that EPA knows it has the power to account for them in this Proposed Rule as well. [EPA-HQ-OAR-2022-0829-0609, pp. 12-13]

38 Id. at 29197.

39 Id.

Incorporating lifecycle emissions reductions into the Proposed Rule is the best reading of § 202 for carbon dioxide as an air pollutant, because, unlike other regulated substances, carbon dioxide (as a GHG) is a global, rather than a local, pollutant, meaning that it does not necessarily cause adverse effects in the specific places where emitted. GHGs instead result in adverse effects at a global scale, such as rising sea levels and eroding coastlines, flooding, more frequent and intense storms, melting polar icecaps, and droughts. A GHG emissions rule that focuses only on tailpipe emissions when emissions at all lifecycle stages have equal import is the very definition of arbitrary and capricious.40 [EPA-HQ-OAR-2022-0829-0609, pp. 12-13]

40 See Section III.e of these comments regarding absurd results in terms of emissions increases that may arise from the Proposed Rule as currently structured.

Speed and significance of GHG reductions. Bioethanol significantly reduces carbon emissions on a lifecycle basis and may soon achieve net-zero, if not or net-negative emissions, within the timeframe covered by the Proposed Rule.43 As described elsewhere in these comments, FFVs with low carbon bioethanol can derive significant GHG reductions on par or greater than BEVs, MLEB-compatible vehicles can provide a key means compliance alternative, and renewable gasoline can provide a key drop-in fuels and vehicle solution. Agencies are required, as part of reasoned decision making, to consider "significant and viable and obvious alternatives" to their proposed action.44 Here, EPA violates this basic requirement with respect to bioethanol. [EPA-HQ-OAR-2022-0829-0609, pp. 14-15]

- Cost effectiveness. Ethanol is a widely used, proven technology that can be cost effective in reducing GHGs. Again, EPA fails to assess ethanol as a "significant and viable and obvious alternative[]" including by incentivizing the lifecycle benefits of ethanol to obtain real-world emission reductions. [EPA-HQ-OAR-2022-0829-0609, pp. 14-15]

- Energy security. EPA acknowledges the energy security benefits of bioethanol in the technical support document for the proposed rule, noting the "U.S. is less dependent on imported oil … due in part to … increased production of renewable fuels such as ethanol and biodiesel."45 However, the Proposed Rules ignores bioethanol's significant energy security benefits, while failing to fully assess the supply chain and critical mineral drawbacks of the dramatically increased use of BEVs on which the Proposed Rule relies. [EPA-HQ-OAR-2022-0829-0609, pp. 14-15]

- Criteria pollutant reductions. Ethanol can replace toxic and PM-generating aromatics in gasoline blends, further reducing criteria and other toxic air pollutant emissions.46 [EPA-HQ-OAR-2022-0829-0609, pp. 14-15]

- Environmental justice. Bioethanol provides a proven solution for low-income communities compared BEVs, which, due to high costs, lack of charging infrastructure, and other factors, have yet to be successfully deployed at scale in those communities.47 Bioethanol also reduces air toxics emissions near roadways that disproportionately impact minority and low-income communities.48 [EPA-HQ-OAR-2022-0829-0609, pp. 14-15]

43 See generally, Section III.a.1 of these comments regarding the significant GHG emission reduction benefits of bioethanol.

Total Environ., 812, at 151426; Kazemiparkouhi, F., Karavalakis, G., Alarcon Falconi, T.M., Macintosh, D.L., and Clark, N. 2022b, Comprehensive U.S. database and model for ethanol blend effects on air toxics, particle number, and black carbon tailpipe emissions, Atmospheric Environment: X, 16, 100185.

D. EPA Should Credit Renewable Fuels for Their Lifecycle Emissions Reductions or By Treating the Biogenic Emissions from Renewable Fuels as Zero-Emissions Sources.

Because carbon dioxide differs from other air pollutants, a different regulatory approach is warranted. The Proposed Rule should include a crediting program for liquid renewable fuels because they reduce fossil fuel use and the need to extract and burn fossil fuels. Although liquid renewable fuels emit carbon when burned, those emissions are biogenic: the carbon dioxide naturally recirculates when the plants and other biomass sources absorb the carbon dioxide as they grow. The result is no net increase in atmospheric carbon. The more we can rely on fuels utilizing biogenic carbon, the less we will need to use fossil fuels that increase the atmosphere's total carbon load. [EPA-HQ-OAR-2022-0829-0609, pp. 15-17]

The lifecycle benefits of biofuels, including bioethanol, are widely recognized by GHG models such as the GREET model developed and maintained by Argonne National Laboratory. EPA regularly utilizes lifecycle greenhouse gas modeling in its implementation of the RFS. EPA could utilize the Argonne GREET model and its own experience with lifecycle assessments to establish nationwide average carbon intensity scores for renewable fuels. Vehicles that utilize those fuels could be credited based on the degree of GHG reductions compared to fossil fuels and a factor that represents real-world use of renewable fuels in the vehicle—i.e., using an "F Factor" representing real world biofuel use similar to what EPA currently applies to FFVs, as discussed below. [EPA-HQ-OAR-2022-0829-0609, pp. 15-17]

The crediting mechanism POET recommends closely resembles the "Volumetric Conversion Factor" (VCF) that EPA established in the vehicle GHG program through model year 2015. Mathematically, the VCF multiplied the carbon compliance value for E85 by 0.15 to account for the fact that such fuel nominally contained only 15% petroleum.49 In 2012, EPA declined to extend use of a VCF beyond model year 2015, stating GHG compliance must be based on "demonstrated GHG emissions performance."50 However, EPA has learned much regarding lifecycle emissions in the ensuing 10+ years, and the VCF should be reinstituted for FFVs at 0.15 or some similar value that EPA considers appropriately represents the lifecycle benefits of ethanol using the latest GHG lifecycle models such as the widely used GREET model. Without the VCF (or some comparable crediting value) re-instituted in EPA's vehicle GHG regulations, automakers will stop making FFVs, thus eliminating a key pathway to compliance and real-world GHG emissions.51 [EPA-HQ-OAR-2022-0829-0609, pp. 15-17]

49 See National Academy of Sciences, Cost, Effectiveness, and Deployment of Fuel Economy Technologies for Light- Duty Vehicles (2015), p. 60, available at https://nap.nationalacademies.org/catalog/21744/cost-effectiveness-and- deployment-of-fuel-economy-technologies-for-light-duty-vehicles. This statutory .15 VCF derives from the Alternative Motor Fuels Act of 1988, Public Law 100-494, section 6.

50 2017 and Later Model Year Light-Duty Vehicle Greenhouse Gas Emissions and Corporate Average Fuel Economy Standards, 77 Fed. Reg. 62624, 62823 (Oct. 15, 2012).

51 After EPA's GHG program VCF discontinuation in Model Year 2015, FFV production dropped from 20% of all 2014 light-duty vehicles to only 8% of 2016 vehicles. See EPA, 2020 EPA Automotive Trends Report (January 2021), pp. 83-84, available at https://nepis.epa.gov/Exe/ZyPDF.cgi?Dockey=P1010U68.pdf. FFV production has dropped even further since 2016 due to EPA's failure to recognize the real-world lifecycle benefits of bioethanol used in FFVs.

If EPA does not wish to examine lifecycle emissions in detail, an alternative approach could be to assign zero tailpipe emissions to renewable fuels because their biogenic emissions are canceled out by the carbon intake of biofuels feedstocks. Such an approach would be consistent with EPA's lack of consideration of lifecycle emissions associated with electric vehicles. EPA already largely assumes zero tailpipe emissions for renewable fuels when determining whether to approve new RFS production pathways for biofuels.52 EPA also considers "biogenic CO2 emissions resulting from the combustion of biomass from managed forests at stationary sources for energy production as carbon neutral," per the agency's 2018 statement of policy.53 Similarly, the California Air Resources Board ("CARB") treats biogenic emissions as carbon neutral under its cap-and-trade regulations. Under CARB's regulations, CO2 emissions from certain biomass-derived fuels (biogenic solid waste; waste pallets, crates, dunnage, manufacturing and construction wood wastes, tree trimmings, mill residues, and range land maintenance residues; all agricultural crops and waste; and certain wood and wood wastes) do not count towards an entity's compliance obligations.54 If EPA fails to add any other incentives under its vehicle GHG program to credit the lifecycle benefits of biofuels, to avoid an arbitrary and capricious favoring of one technology over another EPA must apply the same assumptions of zero tailpipe emissions here for that component of a biofuels-compatible vehicle deemed to operate (per an F factor) on those biofuels. [EPA-HQ-OAR-2022-0829-0609, pp. 15-17]

52 See, e.g., ENVIA Energy, LLC, Landfill Biogas to Diesel, Naphtha for D-Code 3 or D-Code 7 RINs (May 8, 2015), available at https://www.epa.gov/sites/default/files/2015-08/documents/envia-energy-merged-deter-ltr.pdf; Oberon Fuels, Inc., Waste-derived Biogas to Demethyl ether ("DME") (Aug. 12, 2014), available at https://www.epa.gov/sites/default/files/2015-08/documents/oberon-fuels-determination.pdf.

54 Cal. Code Regs. tit. 17, § 95852.2.

E. Failing to Account for Lifecycle Emissions Would Lead to Absurd Results.

EPA risks implementing a rule that leads to absurd results if it omits the lifecycle emissions benefits of biofuels. The rule could end up incentivizing transportation fuels that greatly increase upstream carbon emissions in the near- and medium-term. Because electricity generation remains largely fossil-based, EPA concedes that increasing electricity demand in the near-term would drive up fossil fuel use while the country tries to solve the many challenges associated with developing renewable electric generating facilities and the transmission capacity to support them.58 BEVs will also require extracting certain metals at a far larger scale. That extraction can be energy-intensive and much of it occurs in countries where mining can severely degrade the environment, including by clear-cutting rainforests that store vast amounts of carbon.59 [EPA-HQ-OAR-2022-0829-0609, pp. 18-19]

58 EPA forecasts that "GHG and criteria pollutant emissions from EGUs would increase as a result of the increased demand for electricity associated with the proposal." 88 Fed. Reg. at 29198.

59 J. Emont, EV Makers Confront the 'Nickel Pickle,' Wall Street Journal (June 4, 2023), https://www.wsj.com/articles/electric-vehicles-batteries-nickel-pickle-indonesia-9152b1f (describing the EV makers shift from cobalt mining in the Democratic Republic of Congo to nickel mining by clear-cutting Indonesian rainforests) ; N. Lahkni, Reveaeled: how US transition to electric cars threatens environmental havoc, The Guardian (Jan. 24, 2023), available at: https://www.theguardian.com/us-news/2023/jan/24/us-electric-vehicles-lithium- consequences-research.

EPA concedes the absurd results of its regulatory approach by noting a "Fleet of all BEVs would emit 0 g/mi, regardless of their footprints."60 In other words, an electric Lincoln Navigator, GM Hummer, or "monster truck" has the same GHG emissions (zero) as a sub-compact Chevy Bolt. This is of course not the case. Larger BEVs have much larger battery packs (which significantly increase lifecycle emissions) and require much more electricity, which as discussed above, is still largely fossil-generated. Thus, larger BEVs have much higher upstream GHG emissions, but EPA's Proposed Rule considers all BEVs as equally having no emissions at all, regardless of size. Worse still, by granting a zero upstream benefit for BEVs while providing no credit for the lifecycle benefits of bioethanol or other biofuels, EPA would push real-word GHG solutions out of the marketplace in favor of potentially more carbon-intensive vehicles. [EPA-HQ-OAR-2022-0829-0609, pp. 18-19]

60 88 Fed. Reg. at 29235.

Incorporating renewable fuels could also shore up the rule against a challenge that it violates precedent of the U.S. Supreme Court in West Virginia v. EPA. That case overturned EPA's

Clean Power Plan because the Court determined that EPA's regulatory program went too far toward requiring a shift from conventional sources of electricity generation to renewables, which in the Court's view would have substantially restructured the American energy market.61 Crediting biofuels in the Proposed Rule would have the opposite effect. Biofuels are already a key component of the American transportation sector. This is not the case in which, as the Supreme Court stated in West Virginia v. EPA, the "history and the breadth of the authority that [EPA] has asserted, and the economic and political significance of that assertion, provide a reason to hesitate before concluding that Congress meant to confer such authority."62 Congress has given EPA plain authority to incentivize biofuels under the Clean Air Act and RFS. Those preexisting programs have encouraged producers to make billions of gallons of renewable fuels every year. Congress' mandate was clear. The RFS was meant to encourage the production of renewable fuels that are "used to replace or reduce the quantity of fossil fuel present in a transportation fuel."63 EPA must interpret its § 202 authority in a manner that is consistent with the other directives that Congress has imposed on the transportation sector. [EPA-HQ-OAR-2022-0829-0609, pp. 18-19]

61 See West Virginia, 142 S. Ct. at 2616.

62 Id. at 2595 (quotations omitted).

62 42 U.S.C. § 7545(o)(1)(J).

63 42 U.S.C. § 7545(o)(1)(J).

F. Plug-in Hybrid Electric FFVs (PHEV FFVs) Provide a Key Compliance Solution that Must be Incentivized.

EPA has recognized the need to incentivize emerging technologies under its vehicle GHG program. With the proper incentives, PHEVs can rapidly scale up to dramatically reduce GHGs while providing consumer friendly fuel flexibility to adjust low carbon fuel choices to market conditions. For instance, a PHEV FFV allows consumers to maximize the bioethanol blend used in a vehicle or rely more heavily on the vehicle battery, depending on the varying costs and availability of biofuels, electricity, and electric charging infrastructure. [EPA-HQ-OAR-2022-0829-0609, pp. 19-20]

Various technical analyses show that bioethanol flex-fuel paired with hybrid electric technology can reduce lifecycle emissions just as effectively as comparable BEVs.64 At a minimum, PHEVs provide a supplemental means to meeting the Proposed Rule's significant GHG reduction targets. [EPA-HQ-OAR-2022-0829-0609, pp. 19-20]

64 See ePure, New research confirms important role for renewable ethanol in reducing car emissions (September 1, 2022), finding that "plug-in hybrid vehicles running on E85 ethanol blend are at least as climate-friendly as battery electric vehicles," available at https://www.epure.org/press-release/new-research-confirms-important-role-for- renewable-ethanol-in-reducing-car-emissions/. See also, Mueller and Unnasch, High Octane Low Carbon Fuels: The Bridge to Improve Both Gasoline and Electric Vehicles (March 22, 2021), p. 1, available at https://erc.uic.edu/wp-content/uploads/sites/633/2021/03/UIC-Marginal-EV-HOF-Analysis-DRAFT- 3_22_2021_UPDATE.pdf. Here, this Mueller and Unnasch study found that "High octane fuel vehicles with ethanol provide very similar GHG savings compared to EVs (within 5 gCO2e/MJ of each other) for many states" and "E85 and HOF-plug-in hybrids are the lowest GHG emitting technology as these vehicles are both able to take advantage of the low carbon intensity of ethanol in their combustion engine and the low carbon intensity of the electricity grid in hybrid mode of operation."

The Proposed Rule correctly explains, “PHEVs may help provide a bridge for consumers that may not be ready to adopt a fully electric vehicle.”65 The Proposed Rule specifically “requests comment on the types of PHEVs EPA could consider in our analysis for the final rulemaking.”66 The same emissions credit for FFVs discussed above (e.g., the 0.15 Volumetric Conversion factor or a comparable incentive based on the real-world lifecycle benefits of bioethanol) could apply to PHEV FFVs for that portion of those hybrid vehicles that operate on bioethanol E85, MLEBs, or other higher-level ethanol blends. [EPA-HQ-OAR-2022-0829-0609, pp. 19-20]

65 See 88 Fed. Reg. at 29298.

66 Id.

Regarding PHEV pickup trucks, the Proposed Rule correctly notes that “PHEV pickup architecture would provide several benefits” including among others “zero-emission electric range,” “increased total vehicle range during heavy towing and hauling,” and “job-site utility with auxiliary power capabilities.”67 Also, pickup trucks have been a difficult-to-decarbonize class of vehicles. Even under the Proposed Rule’s extremely aggressive electrification scenarios, medium-duty pickup trucks only obtain a 19% BEV deployment rate in 2032.68 [EPA-HQ-OAR-2022-0829-0609, p. 20]

67 Id.

68 Id. at 29331.

EPA should specifically incentivize PHEV FFV pickup trucks with additional incentives, which could go even further beyond incentives for other FFVs. FFV architecture has been broadly used with pickup trucks, so consumers are familiar with the role biofuels can play. [EPA-HQ-OAR-2022-0829-0609, p. 20]

Pickup trucks are also broadly used in Midwestern states where bioethanol is readily available. Various precedent exists for specially incentivizing pickup trucks given the difficulties in decarbonizing pickup trucks and other work vehicles where consumers need high towing capacity, reliability and extended range. 69 [EPA-HQ-OAR-2022-0829-0609, p. 20]

69 California Hybrid and Zero-Emission Truck and Bus Voucher Incentive Project (see more information at: https://californiahvip.org/); California Innovative Small E-Fleet Pilot (see more information at: https://californiahvip.org/purchasers/#isef); Oregon Advanced Clean Trucks Rule 2021, Permanent Administrative Order DEQ 17-2021 (available at: https://lpdd.org/wp-content/uploads/2022/01/DEQ_17-2021.pdf).

B. EPA Has Relied on Unreasonable and Unsupported Assumptions in Its Assessment of GHG Emissions Reductions.

The Trinity report also addresses certain unfounded assumptions in EPA’s assessment of GHG emissions reductions and has identified the following flaws. [EPA-HQ-OAR-2022-0829-0609, pp. 24-25]

First, EPA ignores upstream emissions from BEVs other than emissions from electricity generation.105 EPA’s assessment assigns 710 metric tons of GHG emissions from the increased electricity needed to power BEVs incentivized by the Proposed Rule. However, the Trinity report demonstrates that EPA’s assessment significantly undercounts those emissions. The report cites a recent study showing that between “56 to 494 kilograms of CO2eq emissions per kWh of battery pack capacity which translates to between about 5 and 50 metric tons of GHG emissions per 100 kWh battery pack."106 Using this study and EPA's estimate of 80 million BEVs on the road by 2055, Trinity calculates additional upstream emissions between 400 and 4,000 metric tons.107 That is in addition to the 710 metric tons EPA calculates for electricity generation. [EPA-HQ-OAR-2022-0829-0609, pp. 24-25]

105 Attachment 2 at 10.

106 Id.

107 Id.

Finally, the Proposed Rule overstates the GHG emissions reductions the Proposed Rule could achieve by failing to account for emissions reductions from bioethanol and other biofuels that are currently blended into transportation fuels for existing conventional vehicles.110 EPA must take those emission reductions into account in its baseline when calculating GHG emissions reductions attributable to the Proposed Rule. Lifecycle emission reductions are at the core of EPA's own RFS program incentivizing the production of biofuels. EPA should not consider those reductions in the RFS program only to ignore them here in order to inflate this Proposed Rule's GHG benefits. [EPA-HQ-OAR-2022-0829-0609, p. 25]

110 Id. at 12.

EPA should address these flawed assumptions in its GHG emissions assessment. [EPA-HQ-OAR-2022-0829-0609, p. 25]

V. OMEGA Modeling Highlights the Feasibility Challenges of EPA's Proposed Rule and How Biofuels Could Make the Rule More Workable.

After conducting a series of runs using EPA's OMEGA model, OnLocation in the attached report concludes that EPA's Proposed Rule on light-duty vehicle emissions "has significant shortcomings in achieving its stated goal of reducing GHG emissions."111 OnLocation finds that compliance with the Proposed Rule "can only be achieved through a narrow range of BEV vehicle penetration pathways."112 While EPA relies on BEV penetrations around 67% of new light-duty vehicle sales in 2032, OnLocation finds that if a production limit of 60% is imposed on BEVs in that general timeframe, compliance with the target emission goals is prevented through 2034.113 When a BEV production limit of 50% is similarly imposed, compliance is generally not achieved throughout the timeframe covered by the Proposed Rule and not even through the year 2050.114 Furthermore, ICE vehicles cannot make up the difference in GHG emissions reductions.115 This result occurs because EPA does not consider the lifecycle benefits of biofuels while artificially assigning zero emissions to BEVs (ignoring the upstream emissions of BEVs), and for other reasons that may include EPA assigning unduly low battery costs to BEVs. [EPA-HQ-OAR-2022-0829-0609, p. 26]

111 Attachment 1, at 2, 16.

112 Id. at 1.

113 Id. at 7 & Fig. 4.

114 Id. 4 & Fig. 1.

115 OnLocation found "no amount of technological improvements for ICE vehicles incorporated by EPA for their supporting analysis with the OMEGA model for ICE vehicles can compensate for even a relatively small reduction in the penetration rate of BEVs." See id. at 3.

OnLocation also finds that if BEV upstream emissions are considered, “real-world” emissions to the atmosphere from covered vehicles would be at levels significantly higher than the proposed compliance standards. More specifically, if upstream fuel production emissions are accounted for regarding BEVs, the Proposed Rule’s 86 gram per mile target in 2032 cannot be met when using electric grid GHG emission intensities from EIA, the leading U.S. governmental source for independent energy statistics and analysis.116 Note that OnLocation’s analysis does not seek to account for battery manufacturing lifecycle emissions, which is addressed in Trinity’s report, as described above. As Trinity has shown, “actual BEV lifecycle emissions would be even higher if battery manufacturing impacts are considered.”117 [EPA-HQ-OAR-2022-0829-0609, pp. 26-27]

116 Id. at 1, 10.

117 Id. at 10.

OnLocation further finds that “using only tailpipe emissions provides inconsistent incentives between BEV and ICE vehicles, while optimistic projections for the grid carbon intensity and BEV penetration could reduce the effectiveness of the Proposed Rule in reducing carbon.”118 Regarding electric grid intensity, OnLocation finds that EPA’s Draft Regulatory Impact Analysis (DRIA) using its model shows a 70% reduction of power sector-related CO2 emissions from current levels by 2055, while EIA’s reference case “shows closer to a 50% reduction from current levels and substantially less CO2 reduction if renewable costs do not decline as quickly as in the Reference scenario.”119 While ICE vehicles have incentives under the proposal to reduce their tailpipe GHG emissions, BEVs and the electric grid lack GHG reduction incentives since the Proposed Rule effectively assumes that all electricity used by BEVs is zero carbon.120[EPA-HQ-OAR-2022-0829-0609, pp. 26-27]

118 Id. at 14.

119 Id.

120 Id. at 16.

OnLocation also finds EPA considering the lifecycle benefits of biofuels (like bioethanol) would have various benefits. For instance, OnLocation considers a scenario where biofuels reduce ICE vehicle carbon intensity by 75%. In this scenario, “greater total emission reductions (i.e., those that consider upstream emissions) are achieved by deploying low-carbon ICE vehicles” and “with lower-carbon ICE fuels (such as low carbon bioethanol), and considering upstream emissions, compliance within the range of EPA’s proposed target is possible.”121 However, as OnLocation highlights, the OMEGA model is likely undercounting actual biofuel benefits for a number of reasons. [EPA-HQ-OAR-2022-0829-0609, p. 27]

Manufacturing emissions differ between EV and ICE

[See original attachment for Figure 14. Vehicle Manufacturing Emissions] [EPA-HQ-OAR-2022-0829-0609, pp. 49-50]

Emissions for BEV200, BEV300, and BEV400 compared with midsize gasoline ICEV. Source: Cradle-to-Grave Lifecycle Analysis of U.S. Light-Duty Vehicle-Fuel Pathways: A

Greenhouse Gas Emissions and Economic Assessment of Current (2020) and Future (2030-2035) Technologies, Argonne National Lab, 2022 [EPA-HQ-OAR-2022-0829-0609, pp. 49-50]

As shown in Figure 14, compared with a midsize gasoline ICEV, a BEV has higher emissions from vehicle manufacturing under current technologies, ranging from approximately 10 gCO2e/mi in a BEV200, to 25 gCO2e/mi in a BEV300, and 35 gCO2e/mi in BEV400, according to the lifecycle analysis by the Argonne National Lab (battery emissions are embedded in Figure 14 within "vehicle" emissions, and are most significant in the data in Figure 14 labelled "Current Tech"). [EPA-HQ-OAR-2022-0829-0609, pp. 49-50]

Relative to the ~80 gCO2e/mi EPA proposed compliance value, where the alternatives are +-10 gCO2e/mi, these are substantial incremental emissions that are neglected when upstream emissions are ignored. [EPA-HQ-OAR-2022-0829-0609, pp. 49-50]

VIII. POET Strongly Supports EPA's Suggestion in Section IX of the Proposed Rule to Institute a Future Regulatory Action to Further Limit PM Emissions from Vehicles and Nonroad Equipment.

POET strongly supports EPA's consideration of a possible future rulemaking aimed at further PM emissions reductions for vehicles and nonroad equipment.134 POET agrees with the EPA's assessment that reducing certain high-boiling compounds in gasoline could further reduce vehicle PM emissions.135 However, removing those heavy aromatic compounds will lower gasoline octane levels. To most effectively reduce tailpipe PM emissions while retaining high-octane gasoline, POET urges EPA to support a future rule that would limit the use of high-boiling compounds while encouraging those compounds to be replaced with higher bioethanol blends, such as E15. Bioethanol boosts octane while decreasing PM emissions. Bioethanol also significantly reduces lifecycle GHG emissions compared to more carbon-intensive alternative octane-boosting compounds, such as heavy aromatics.136 Bioethanol should be EPA's preferred solution because it both reduces toxic air pollutants and helps combat climate change. [EPA-HQ-OAR-2022-0829-0609, pp. 29-31]

134 88 Fed. Reg. at 29397.

135 Id. at 29398.

136 See generally Attachment 3.

In support of POET's position, POET retained Environmental Health & Engineering, Inc. ("EH&E"), who prepared a report on the potential changes to EPA gasoline fuel property and GHG standards for light- and medium-duty vehicles in the Proposed Rule, attached hereto as Attachment 3. EH&E's report confirms that heavy aromatics have significant negative impacts on PM emissions.137 The report assesses EPA's position that high boiling compounds are associated with increased tailpipe emissions, reviews the impact of removing high boiling compounds on gasoline and refineries, analyzes the suitability of EPA's Haverly model, studies the importance of octane for gasoline, and evaluates increased ethanol blending as an alternative for octane contributions in gasoline. [EPA-HQ-OAR-2022-0829-0609, pp. 29-31]

137 88 Fed. Reg. at 29398.

EH&E's report uses the particulate matter index, or "PMI," to predict the propensity of PM in various gasoline compounds. PMI values are correlated with emissions of PM: the higher a compound's PMI value, the higher the tailpipe PM emissions for gasoline containing that compound.138 Studies have found that high-boiling compounds—and particularly heavy aromatics—have significantly higher PMI values than other, lower-boiling compounds in gasoline blends.139 And while heavy aromatics are only a small portion of the compounds making up gasoline, about 2.4% of gasoline by volume, they contribute disproportionately to the PMI of gasoline, making up about 38 percent of gasoline's PMI value.140 In comparison, ethanol has proven to be the most favorable component in gasoline in terms of PMI contribution: it represents 10% of gasoline volume but contributes less than 1% to PMI.141 Because the PMI value of ethanol is so low, the PM emissions associated with gasoline blended with higher levels of ethanol are significantly lower than gasoline containing heavy aromatics.142 [EPA-HQ-OAR-2022-0829-0609, pp. 29-31]

138 Attachment 3 at 3.

139 Id. at 1, 3.

140 Id. at 6.

141 Id.

142 Id. at 3-8.

Despite the negative air quality impacts of heavy aromatics, they do serve to increase octane in gasoline. Sufficiently high octane levels are necessary for the efficient operation of vehicles with internal combustion engines.143 Specifically, octane supports high compression ratios, turbocharging, and advanced spark and valve timing and downsizing.144 If EPA moves forward with a rulemaking to limit heavy aromatics in gasoline, EPA should also identify an alternative to maintain octane levels and develop its standards with that alternative in mind. [EPA-HQ-OAR-2022-0829-0609, pp. 29-31]

143 Id. at 10-11.

144 Id. at 11.

Bioethanol's criteria pollutant emission benefits are well documented. Two studies published by EH&E's team, the Kazemiparkouhi et al. (2022a) and Kazemiparkouhi et al. (2022b) studies, establish the air quality benefits of adding increasing ethanol blends to E15 or higher. Those studies represent the "first large-scale analyses of data from light-duty vehicle emissions studies to examine real-world impacts of ethanol-blended fuels on air pollutant emissions, including PM, NOx, CO, and THC, as well as BTEX (benzene, toluene, ethylbenzene, xylene) and 1,3-butadiene."152 These significant benefits include: [EPA-HQ-OAR-2022-0829-0609, pp. 32-33]

152 EPA Docket EPA-HQ-OAR-2022-0513, comment submitted by POET LLC, Attachment 1 at 3; see also Kazemiparkouhi, F., Alarcon Falconi, T.M., Macintosh, D.L., and Clark, N. 2022a, Comprehensive U.S. database and model for ethanol blend effects on regulated tailpipe emissions, Sci. Total Environ., 812, at 151426; Kazemiparkouhi, F., Karavalakis, G., Alarcon Falconi, T.M., Macintosh, D.L., and Clark, N. 2022b, Comprehensive U.S. database and model for ethanol blend effects on air toxics, particle number, and black carbon tailpipe emissions, Atmospheric Environment: X, 16, 100185.

- Aromatic levels in market fuels decreased by ~7% by volume for each 10% by volume increase in ethanol content.

- PM emissions decreased by 15-18% on average for each 10% increase in ethanol content under cold-start conditions.

- Emissions of CO and THC generally decreased with increasing ethanol fuel content under cold running conditions, while NOx emissions did not change.

- Air toxic emissions showed lower BTEX, 1-3 butadiene, black carbon, and particle number emissions with increasing ethanol fuel content.153 [EPA-HQ-OAR-2022-0829-0609, pp. 32-33]

153 EPA Docket EPA-HQ-OAR-2022-0513, comment submitted by POET LLC, Attachment 1 at 3-4.

Using bioethanol blending as an alternative for octane in gasoline would also promote EPA's goal of reducing GHG emissions. As discussed above, bioethanol reduces lifecycle GHG emissions by at least 46 percent relative to fossil fuel.154 Thus, EPA's potential rulemaking could tackle two goals at once—decreasing tailpipe PM emissions and reducing lifecycle GHG emissions. [EPA-HQ-OAR-2022-0829-0609, pp. 32-33]

154 See Scully MJ, Norris GA, Alarcon Falconi TM, MacIntosh DL. 2021a. Carbon intensity of corn ethanol in the United States: state of the science. Environmental Research Letters, 16(4), pp. 043001. The 46 percent reduction figure relates to typical corn starch ethanol on an energy-adjusted basis. Cellulosic ethanol that is currently being produced is associated with even greater reductions, and corn starch ethanol may also have greater benefits when its octane value is accounted for.

EPA has broad authority under Section 211(c)(1)(A) of the Clean Air Act to issue regulations controlling fuels or fuel additives that cause and/or contribute to air pollution that may endanger public health.155 This authority permits EPA to limit high-boiling compounds/heavy aromatics because these fuel additives contribute to PM emissions which endanger public health. Pursuant to Section 211(c)(2)(A), EPA must consider all relevant scientific evidence available to the agency when setting these standards, including the significant evidence that bioethanol blending is the most practicable replacement for heavy aromatics, and that bioethanol has particularly significant emissions benefits for PM, other criteria pollutants, and GHGs.156 The further reduction of aromatics in gasoline would also be consistent with EPA's mandates and authority under the Mobile Source Air Toxics Program.157 [EPA-HQ-OAR-2022-0829-0609, p. 33]

155 42 U.S.C. § 7545(c)(1)(A).

156 Id. § 7545(c)(2)(A).

157 See Control of Hazardous Air Pollutants from Mobile Sources, 72 Fed. Reg. 8428 (Feb. 26, 2007).

Bioethanol does not receive the credit it deserves as a powerful tool in reducing both criteria pollutant and GHG emissions. Replacing heavy aromatics with bioethanol blending would maintain octane levels, reduce tailpipe PM emissions, and reduce lifecycle GHG emissions, furthering many of EPA's Clean Air Act mandates. EPA should carefully consider the benefits of bioethanol blending as a key solution in any potential rulemaking to further reduce tailpipe PM reductions. [EPA-HQ-OAR-2022-0829-0609, p. 33]

Introduction

Peter Whitman and Michael Schaal of OnLocation ("Authors") have been asked to review the assumptions and modeling in support of the U.S. Environmental Protection Agency's ("EPA's") proposed "Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles," under Docket ID No. EPA–HQ–OAR–2022–0829–0451 ("Proposed Rule"), that addresses standards for criteria pollutants and greenhouse gases (GHG) for light-duty vehicles and Class 2b and 3 (''medium-duty'') vehicles for model years 2027 through 2032. [EPA-HQ-OAR-2022-0829-0609, pp. 35-36]

OnLocation's Analysis

In this analysis, we reviewed EPA's assumptions and then we performed a series of test scenarios to observe the robustness of the results obtained using EPA's OMEGA (Optimization Model for reducing Emissions of Greenhouse Gases from Automobiles) model. This OMEGA model is the same model that EPA used in the Proposed Rule for its analysis of compliance scenarios.1 [EPA-HQ-OAR-2022-0829-0609, pp. 35-36]

1 Available at https://www.epa.gov/regulations-emissions-vehicles-and-engines/optimization-model-reducing-emissions- greenhouse-gases

EPA's Assumptions

We focus on two interrelated aspects of the rulemaking: using only tailpipe emissions for compliance with the MY 2027 – 2032 standards and only a narrow range of BEV penetration trajectories that will allow compliance to be achieved. [EPA-HQ-OAR-2022-0829-0609, pp. 35-36]

Our key insight is that compliance can only be achieved through a narrow range of BEV vehicle penetration pathways. We demonstrate this through a set of runs using EPA's OMEGA model described below. [EPA-HQ-OAR-2022-0829-0609, pp. 35-36]

In addition, we note that upstream emissions are a significant contributor to GHG emissions and ignoring them has implications for aligning the incentives for compliance to the Proposed Rule with its intent, reductions in GHG emissions. This leads to the following observations: [EPA-HQ-OAR-2022-0829-0609, pp. 35-36]

- Should upstream emissions for all fuels, including electricity, be incorporated in compliance, projections of grid carbon emissions vary widely, and according to our modeling using the OMEGA model, EPA's proposed standard of 86 grams/mile in 2032 cannot be met when using EIA's projected electric grid carbon intensities. [EPA-HQ-OAR-2022-0829-0609, pp. 35-36]

- Upstream manufacturing emissions are an important differentiator between vehicles but are not accounted for. Using only tailpipe emissions provides inconsistent incentives between BEVs and ICE vehicles, while EPA's optimistic projections for the grid carbon intensity and BEV penetration could reduce the effectiveness of the Proposed Rule in reducing carbon. [EPA-HQ-OAR-2022-0829-0609, pp. 35-36]

- Because upstream emissions are ignored in the Proposed Rule, the shape of the GHG footprint-based compliance curve depends on the assumed BEV penetration, even though it is only applicable to ICE vehicles. If BEVs penetration is different than EPA projections, then EPA's proposed compliance curves are likely to be inconsistent with the analysis used in their development and penalize larger footprint vehicles. [EPA-HQ-OAR-2022-0829-0609, pp. 35-36]

Per the Summary at the end of this report, our analysis of the EPA's Proposed Rule on light-duty vehicle emissions finds it has significant shortcomings in achieving its stated goal of reducing GHG emissions. [EPA-HQ-OAR-2022-0829-0609, pp. 35-36]

Finally, we look at three scenarios showing the effect of upstream emissions and low-carbon fuels on meeting the Proposed Rule.

Scenario 4: Adding Upstream Emissions to the Compliance Values Scenario 5: 10% Reduction in Carbon Intensity of Gasoline, Scenario 6: 75% Reduction in Carbon Intensity of Gasoline [EPA-HQ-OAR-2022-0829-0609, p. 37]

The first three OMEGA runs show a narrow range of BEV penetration pathways will allow sufficient reductions to support compliance with the Proposed Rule, and that reductions in BEV market share cannot be compensated for by ICE technology improvements. The latter three runs show that low carbon fuels could potentially play an important role in GHG emission reductions. [EPA-HQ-OAR-2022-0829-0609, p. 37]

Testing the Robustness of the Proposed Rule using OMEGA

OnLocation executed numerous runs of the OMEGA model to test the boundaries of its domain and the robustness of the supporting analysis. The following scenarios explore some of the limitations of the modeling and the lack of robustness of the Proposed Rule to changes in market assumptions. [EPA-HQ-OAR-2022-0829-0609, pp. 37-41]

Scenario 1: Production Limit on BEV Production [EPA-HQ-OAR-2022-0829-0609, pp. 37-41]

[See original attachment for Figure 1 Compliance Path with Production Limit]

[See original attachment for Figure 2 Market Shares]

In Scenario 1, only tailpipe emissions were included for compliance purposes, while potential BEV penetration was limited to 30% in 2025, 40% in 2030, and 50% from 2035 onwards. Figure 1 shows the effects of BEV production limits. From 2027 through 2051, the target is not reached. Figure 2 below shows the evolution of the market share of different vehicle categories for this scenario, where the BEV production limits are binding at 30%, 40%, and then 50%. It is clear that the BEV penetration constraints limit the ability of manufacturers to meet the target, as the fuel efficiency improvements available for ICE vehicles are insufficient to compensate for the zero tailpipe emissions of the BEV vehicles. [EPA-HQ-OAR-2022-0829-0609, pp. 37-41]

In Figure 1 and in each of the following figures labeled "Compliance Path," the blue line indicates the target emissions while the red line indicates achieved emissions. Yellow circles indicate banked credits from previous periods, while the green lines indicate inter-temporal credit trades. The red circles indicate fleet does not reach compliance in that year. [EPA-HQ-OAR-2022-0829-0609, pp. 37-41]

Scenario 2: Relaxed Production Limit on BEV Production [EPA-HQ-OAR-2022-0829-0609, pp. 37-41]

[See original attachment for Figure 3 Compliance Path with Relaxed Production Limit]

[See original attachment for Figure 4 Market Shares with Relaxed Production Limit]

Scenario 2 follows the CO2 targets in the Proposed Rule, with no upstream emissions. In this scenario, production limits on BEVs were relaxed relative to Scenario 1. BEV penetration was initially limited to 40%, rising to 50% in 2030 and 60% in 2035 for the remainder of the scenario. Even these relaxed production limits on BEV market penetration were binding throughout the simulation (Figure 3), preventing compliance with the target emission goals through 2034 (Figure 4). [EPA-HQ-OAR-2022-0829-0609, pp. 37-41]

The effect of low-carbon fuels

The first three scenarios all identified the risks of developing a new set of rules which are highly dependent on a high BEV market share being achieved. In the next three scenarios, we examine the effect of upstream emissions and low-carbon fuels in achieving the targets of the Proposed Rule. The first scenario evaluated in this regard follows on the next page. [EPA-HQ-OAR-2022-0829-0609, pp. 42-44]

Scenario 4: Adding Upstream Emissions [EPA-HQ-OAR-2022-0829-0609, pp. 42-44]

[See original attachment for Figure 7 Compliance Path with Upstream Emissions]

[See original attachment for Figure 8 Market Shares with Upstream Emissions]

In Scenario 4, upstream emissions were added to the compliance calculations for gasoline, diesel, and electricity (these upstream emissions for BEVs include grid impacts, but BEV battery manufacturing impacts are not included). The AEO2023 EIA Reference Scenario was used to calculate upstream emissions of grid electricity. As shown in Figure 7 and Figure 8, with the addition of upstream emissions, the BEV market share rises to over 80%, much greater than the 67% market share in the central case of the Proposed Rule. To achieve this BEV market share, the domestic infrastructure would have to grow at an accelerated rate. [EPA-HQ-OAR-2022-0829-0609, pp. 42-44]

This figure shows that using the OMEGA model, EPA's proposed standard of 86 grams/mile in 2032 cannot be met if upstream emissions are also included. Furthermore, actual BEV lifecycle emissions would be even higher if battery manufacturing impacts are considered. [EPA-HQ-OAR-2022-0829-0609, pp. 42-44]

In this scenario, the LDV fleet does not reach the modelled target emission until 2036, and compliance is intermittent throughout the model forecast. EPA's having such stringent target emission goals. which rely to such a degree on the implementation of BEVs into the market, ignores the importance of upstream emissions, as model runs indicate upstream emissions generally render any achievable fleet of BEVs and ICE vehicles (within the current technology packages of the model, which don't include biofuels carbon intensity reductions) out of compliance with EPA's proposed standard. [EPA-HQ-OAR-2022-0829-0609, pp. 42-44]

Scenario 5: Low Carbon Fuel [EPA-HQ-OAR-2022-0829-0609, pp. 45-46]

[See original attachment for Figure 9 Compliance Path with Low Carbon Fuel (gasoline with 10% lower Carbon Intensity)]

[See original attachment for Figure 10 Market Shares with Low Carbon Fuel]

In Scenario 5, starting in 2030, gasoline combustion emissions were reduced by 10% to represent the introduction of low-carbon biofuels such as bioethanol. No upstream emissions were included within the model. This scenario effectively provides compliance flexibility for the Proposed Rule, leading to a 0.2% to 0.4% reduction in the absolute market share of BEVs from 2035-2050. Greater reductions in the need for high BEV shares could potentially result if the model is revised to (i) assess a broader range of battery learning curve algorithms, and (ii) the "zero emissions" treatment assigned to BEVs is refined. Further evaluation of these issues is warranted by EPA to ensure that small changes in BEVs under this scenario 5 (e.g., lower carbon intensity gasoline) are not a result of artifacts of the modelling. [EPA-HQ-OAR-2022-0829-0609, pp. 45-46]

Scenario 6: Adding Low Carbon Fuel and Upstream Emissions [EPA-HQ-OAR-2022-0829-0609, pp. 47-48]

[See original attachment for Figure 11 Compliance Path with Low Carbon Fuel and Upstream Emissions]

[See original attachment for Figure 12 Market Shares with Low Carbon Fuel and Upstream Emissions]

Scenario 6 presents a 75% reduction in fuel carbon intensity for gasoline, though including upstream emissions including those for BEVs. Figure 11 and Figure 12 show that using the model compliance with the Proposed Rule's targets still could be achievable, though outside of 2027 – 2032 timeframe when considering both upstream emissions and the impact if biofuels reduce ICE vehicle carbon intensity by 75%. In this scenario, the market share of BEVs only changes slightly from the Proposed Rule, however in the model greater total emission reductions (i.e., those that consider upstream emissions) are achieved by deploying low-carbon ICE vehicles. This scenario shows that with lower-carbon ICE fuels (such as low carbon bioethanol), and considering upstream emissions, compliance within the range of EPA's proposed target is possible. [EPA-HQ-OAR-2022-0829-0609, pp. 47-48]

Ignoring Upstream Emissions is Inconsistent with Incentivizing GHG Emission Reductions

The following section demonstrates that using only tailpipe emissions provides inconsistent incentives between BEV and ICE vehicles, while optimistic projections for the grid carbon intensity and BEV penetration could reduce the effectiveness of the Proposed Rule in reducing carbon. [EPA-HQ-OAR-2022-0829-0609, p. 48]

Upstream Emissions are Uncertain

While EPA's Draft Regulatory Impact Analysis (DRIA) using its model shows a 70% reduction of power sector- related CO2 emissions from current levels by 2055. As shown in Figure 13, EIA's reference scenario shows closer to a 50% reduction from current levels and substantially less CO2 reduction if renewable costs do not decline as quickly as in the Reference scenario. If included in the CO2 targets, differences between grid emissions and projections used in the Proposed Rule could have a significant impact on the ability of manufacturers to achieve compliance. [EPA-HQ-OAR-2022-0829-0609, p. 48]

[See original attachment Figure 13. Grid Intensity]

Source: AEO 2023 Reference, High Technology Cost Tables 8, 18 [EPA-HQ-OAR-2022-0829-0609, p. 48]

Manufacturing emissions differ between EV and ICE

[See original attachment for Figure 14. Vehicle Manufacturing Emissions] [EPA-HQ-OAR-2022-0829-0609, pp. 49-50]

Emissions for BEV200, BEV300, and BEV400 compared with midsize gasoline ICEV. Source: Cradle-to-Grave Lifecycle Analysis of U.S. Light-Duty Vehicle-Fuel Pathways: A

Greenhouse Gas Emissions and Economic Assessment of Current (2020) and Future (2030-2035) Technologies, Argonne National Lab, 2022 [EPA-HQ-OAR-2022-0829-0609, pp. 49-50]

As shown in Figure 14, compared with a midsize gasoline ICEV, a BEV has higher emissions from vehicle manufacturing under current technologies, ranging from approximately 10 gCO2e/mi in a BEV200, to 25 gCO2e/mi in a BEV300, and 35 gCO2e/mi in BEV400, according to the lifecycle analysis by the Argonne National Lab (battery emissions are embedded in Figure 14 within "vehicle" emissions, and are most significant in the data in Figure 14 labelled "Current Tech"). [EPA-HQ-OAR-2022-0829-0609, pp. 49-50]

Relative to the ~80 gCO2e/mi EPA proposed compliance value, where the alternatives are +-10 gCO2e/mi, these are substantial incremental emissions that are neglected when upstream emissions are ignored. [EPA-HQ-OAR-2022-0829-0609, pp. 49-50]

Shape of footprint curve depends on BEV penetration rate

As noted in the Proposed Rule, "The slope that corresponded with a neutral response for ICE vehicles only (overall, no change in the average footprint of ICE vehicles) was 0.8 g/mi/square foot. This slope was then scaled down accordingly-for example, based on a nominal BEV sales penetration of around 50%, this 0.8 slope would be scaled down to 0.4 (based on the remaining 50% of ICE vehicles)."6 [EPA-HQ-OAR-2022-0829-0609, pp. 49-50]

6 Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles Draft Regulatory Impact Analysis, 1-7.

The targets defined in the Proposed Rule are a function of vehicle footprint. That is, the compliance target depends upon the footprint of the vehicle. Figure 15 shows the EPA's proposed footprint for cars. If the penetration of BEV is much below the proposal, the footprint target function is too flat relative to the actual market share of non-BEV vehicles, penalizing ICE vehicles. [EPA-HQ-OAR-2022-0829-0609, pp. 49-50]

[See original attachment for Figure 15] [EPA-HQ-OAR-2022-0829-0609, pp. 49-50]

Source: "Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles," Federal Register Vol. 88, No. 87, pg. 29237. [EPA-HQ-OAR-2022-0829-0609, pp. 49-50]

Ignoring upstream emissions has other negative effects on incentivizing reductions of GHG emissions from LDVs, including disregarding the substantially greater GHG manufacturing footprint of BEVs over conventional vehicles and decreasing incentives for clean electricity (since EPA assumes, under the Proposed Rule's compliance scheme, that all electricity used in EVs is effectively zero carbon). This analysis also shows that a rulemaking that also considers low-carbon ICE vehicles (such as enabled by low-carbon bioethanol) can facilitate compliance with EPA standards while decreasing the larger system emissions (including upstream emissions) in the atmosphere. [EPA-HQ-OAR-2022-0829-0609, p. 50]

The first of these concerns is that U.S. EPA has ignored upstream sources of GHG emissions other than electricity generation. This is of particular concern given that there are significant upstream emissions associated with the manufacturer of batteries for BEVs that do not occur with conventional vehicles. A paper published by ICCT4 notes that estimates of these GHG emissions range from 56 to 494 kilograms of CO2eq emissions per kWh of battery pack capacity which translates to between about 5 and 50 metric tons of GHG emissions per 100 kWh battery pack. Using U.S. EPA's assumption that the Proposed Rule will result in an additional 80,000,000 BEVs on the road in the U.S. by 2055 relative to the no- action case, and these estimates of GHG emissions from battery production, the cumulative increase in GHG emissions by would be between 400 and 4000 metric tons. This value can be compared to U.S. EPA's 710 metric ton estimate of the cumulative GHG emissions increase due to electricity generation for BEVs and the 8,000 ton reduction from conventional vehicles (see DRIA Table 9-21) to show the importance of accounting for battery production emissions. U.S. EPA might respond by noting that they have not accounted for upstream GHG emissions associated with the production of gasoline and diesel, but those are small compared to the GHG emissions from fuel combustion and accounting for them would assume a net global reduction in the use of those fuels which would likely, even with the Proposed Rule, still be used in other parts of the developing world. [EPA-HQ-OAR-2022-0829-0609, p. 62]

4 https://theicct.org/sites/default/files/publications/EV-life-cycle-GHG_ICCT-Briefing_09022018_vF.pdf.

U.S. EPA Fails to Account for the Potential of Increased Use of Ethanol to Achieve GHG Reductions as an Alternative to BEVs

Although BEVs have zero tailpipe emissions of CO2, they are still sources of CO2 emissions because of the emissions associated with fossil fuels used to produce the electricity used to power them. It then follows that the magnitude of the effective CO2 emissions from these BEVs will, in general, not be zero but will in fact vary depending on the source of that electricity. GHG emissions associated with the manufacture of batteries are another significant source of upstream emissions for BEVs. As noted above, based on a paper published by ICCT,7 upstream emissions associated with battery production vary considerably depending on the region in which they are manufactured as well as the size of the battery pack and selected a value on the order of 50 gCO2eq per mile as being representative. This value is obviously large when compared to the standards of the Proposed Rule (see Table 8) which range from 134 gCO2eq per mile in MY 2027 and 73 gCO2eq per mile in MY 2032 and thereafter. Despite the significant upstream emissions associated with BEVs, U.S. EPA is, as part of the Proposed Rule, planning to change existing requirements that would account for these "upstream" emissions in determining GHG associated with BEVs for purposes of regulatory compliance (FR Vol. 88, No. 87 at 29197). [EPA-HQ-OAR-2022-0829-0609, pp. 64-96]

7 https://theicct.org/sites/default/files/publications/EV-life-cycle-GHG_ICCT-Briefing_09022018_vF.pdf.

In contrast, while ICE vehicles fueled by ethanol-gasoline or neat ethanol will have tailpipe CO2 emissions, they may have lower overall effective CO2 emissions than BEVs. This is because there may be less fossil fuel used in their production and/or carbon capture and sequestration may be applied as well as the fact that the CO2 emitted at the tailpipe will ultimately be removed from the atmosphere by the growing of the next generation of feedstock plants. In addition, and unlike BEVs, the expanded use of ethanol would not result in any appreciable increase in upstream GHG emissions associated with vehicle manufacture. It is important to note that U.S. EPA claims that the purpose of the Proposed Rule is to generate "…substantial additional reductions in criteria pollutants and GHG emissions from the transportation sector" in order to achieve public health and welfare goals (FR Vol. 88, No. 87 at 29186). Given this, it is unclear why the Proposed Rule is effectively a mandate forcing automakers to produce and attempt to sell BEVs rather than a mechanism providing vehicle manufacturers with a range of options to reduce GHG emissions from new vehicles. Clearly, increased use of renewable ethanol as a direct substitute for petroleum-based gasoline would achieve this goal. For example, the widespread use of 20 percent gasoline-ethanol blends rather than the current 10 percent blends in new light-duty vehicles would double the associated GHG reductions. Further, the use of biofuels such as ethanol-gasoline which offer high octane ratings in combination with advanced combustion technologies that can offer substantial improvements in fuel efficiency as evidenced by the results of the U.S. Department of Energy's "Co-Optimization of Fuels & Engines" program8 and other research. [EPA-HQ-OAR-2022-0829-0609, pp. 64-96]

8 https://www.energy.gov/sites/default/files/2022-06/beto-co-optima-fy15-fy21-impact.pdf.

Overall, it is not clear why U.S. EPA has chosen to completely ignore the potential for the use of renewable biofuels to substantially reduce GHG emissions from light- and medium-duty vehicles in developing the Proposed Rule and instead myopically focused on a single unproven technology that will require a complete transformation of the vehicle industry – BEVs. U.S. EPA should consider the addition of provisions in the Proposed Rule that would lead to greater substitution of ethanol and other renewable fuels for gasoline and diesel used in conventional vehicles These provisions would include creating appropriate tailpipe GHG credit provisions for new vehicles designed to operate on ethanol blends above E10 and up to E99 that recognize the renewable nature of ethanol. An obvious advantage of this approach is that it would provide vehicle and engine manufacturers with compliance options other than overreliance on BEV technology that may or may not be available and/or accepted in the marketplace and help to ensure that substantial reductions in GHG emissions are actually realized by the Proposed Rule. [EPA-HQ-OAR-2022-0829-0609, pp. 64-96]

Organization: Renewable Fuels Association (RFA)

To ensure the final tailpipe standards have the desired effect of truly reducing GHG emissions from transportation, RFA strongly urges EPA to adopt a full lifecycle GHG accounting approach for all vehicles in the final rule. [EPA-HQ-OAR-2022-0829-0602, pp. 6-8]

VI. EPA Should Adopt a Full Lifecycle Analysis Approach for All Vehicle Options that Includes Upstream GHG Emissions Associated with Vehicle Fuel/Energy Use

Vehicles and fuels operate together as integrated systems. This is true whether the system is a battery electric vehicle operating on electricity, or an ICE vehicle operating on liquid fuel. To effectively regulate emissions associated with the operation of light- and medium-duty vehicles, EPA must adopt approaches that most accurately assess the overall climate impacts of various transportation options. Specifically, EPA should examine the full scope of lifecycle GHG emissions associated with each vehicle/fuel system and allow automakers to use g/mile compliance values that reflect the overall GHG impacts of various vehicle/fuel options. [EPA-HQ-OAR-2022-0829-0602, pp. 11-12]

In the proposal, EPA requests comments on its proposed treatment of electrified vehicles in manufacturer compliance calculations (i.e., the use of a 0 g/mile compliance value for EVs). As part of its rationale for proposing to maintain the 0 g/mile value for EVs, the Agency states that "[i]f EPA deviated from this tailpipe emissions approach [i.e., using 0 g/mile] by including upstream accounting, it would appear appropriate to do so for all vehicles, including gasoline-fueled vehicles."28 [EPA-HQ-OAR-2022-0829-0602, pp. 11-12]

28 88 Fed. Reg. 29252 (May 5, 2023).

RFA agrees with this statement by EPA and recommends that the Agency should indeed adopt an approach that accounts for full lifecycle emissions for all fuel and vehicle combinations. In fact, this is the only scientifically defensible approach for regulating emissions from light- and medium-duty vehicles. Implementing an approach that accounts for all lifecycle emissions would not only open the automotive market to greater competition and lower costs for consumers, but it would stimulate investment in lower- carbon technologies and practices across the entire fuel/vehicle supply chain. [EPA-HQ-OAR-2022-0829-0602, pp. 11-12]

RFA believes the final rule should take a market-based approach that sets clear and predictable annual full lifecycle GHG reduction requirements for automakers (in g/mile values), then allows the marketplace to determine the most cost-effective means for achieving the reductions. [EPA-HQ-OAR-2022-0829-0602, pp. 11-12]

Robust, peer-reviewed methodologies already exist for conducting full lifecycle emissions analysis for current and future vehicle and fuel options. Specifically, EPA should use the Department of Energy Argonne National Laboratory GREET model, which is accepted worldwide as the most robust and authoritative tool for lifecycle GHG accounting for a wide array of transportation fuels. The GREET model is also updated annually to incorporate the latest data. [EPA-HQ-OAR-2022-0829-0602, pp. 11-12]

EPA's proposed rule is also arbitrary and capricious because it fails to accurately account for the GHG emissions reductions achieved by both EVs and biofuels. EPA should use the best available science to accurately account for the lifecycle carbon intensity associated with particular fuels and technologies, but its proposed approach ignores the upstream emissions and emissions from electricity generation associated with EVs. Specifically, EPA proposes to assign a value of 0 grams/mile to EVs, which in effect assumes that electricity and battery minerals powering EVs are always 100% renewable and free of any CO2 emissions impacts. This assumption is flawed because the CO2 emissions associated with producing and transmitting electricity, as well as the emissions linked to critical mineral extraction and battery production, are significant. Indeed, lifecycle analysis studies show that some EVs (using coal-generated electricity and battery minerals from intensive mining practices) may have a larger carbon footprint than conventional vehicles using internal combustion engines. At the same time, EPA's proposal fails to recognize or account for the meaningful CO2 emissions savings that can be achieved through greater use of low-carbon ethanol in vehicles designed to accommodate higher blends (e.g., flex fuel vehicles). [EPA-HQ-OAR-2022-0829-0602, pp. 13-14]

In sum, we urge EPA to revise its proposal to create a technology neutral rule that accounts for all lifecycle emissions of the vehicles it regulates. A technology neutral rule will not only avoid some of the legal issues EPA's current proposal will face, but incentivizing multiple technologies is also the best way for EPA to achieve its ambitious goals. [EPA-HQ-OAR-2022-0829-0602, pp. 13-14]

b. Lifetime cost of the vehicle versus GHG reduction

The proposed rulemaking would not allow other vehicle/fuel pathways to compete with BEVs. By regulating only tailpipe emissions, and ignoring the rich literature of lifecycle analysis, EPA would create artificial incentives for auto manufacturers to pursue only BEVs. This could have disastrous effects on both the cost and the GHG emissions of future vehicles. As shown in the figure below from Argonne National Laboratory, the cost and GHG emissions of a BEV are strongly affected by the driving range. A BEV with 400- mile range is dramatically more expensive than one with 200-mile range, and its lifetime [EPA-HQ-OAR-2022-0829-0602, pp. 15-16]

GHG emissions are substantially worse. In fact, a BEV with 400-mile range has only a slight GHG benefit compared to a hybrid EV or an FFV operating on E85. But the proposed rule would count all BEVs as "zero emissions," regardless of battery size – and regardless of vehicle size and weight. [EPA-HQ-OAR-2022-0829-0602, pp. 15-16]

[See original comment for Lifetime Cost vs GHG, Current Tech] [EPA-HQ-OAR-2022-0829-0602, pp. 15-16]

Organization: Specialty Equipment Market Association (SEMA)

While the draft rule will adversely impact automotive businesses, their employees, and the millions of automotive enthusiasts whose careers, businesses, and passions are threatened by this proposal, it will also have considerable unintended consequences for individuals and families who will have fewer choices when looking to purchase a new vehicle in the coming years. The agency's proposal is also problematic when digging into its actual environmental impact, as the draft rule considers only the emissions coming out of the tailpipe rather than the lifecycle emissions of producing and operating a vehicle. The move to a cleaner vehicle fleet is critical to our future, but it cannot be done in a way that picks winners and losers while also strengthening China and other geopolitical foes. It is imperative that the EPA factors-in automotive industry and consumer concerns and amend this proposed rule to help facilitate a technology-neutral transition to reducing vehicle emissions that thoughtfully positions multiple technologies to be part of a market-based solution. [EPA-HQ-OAR-2022-0829-0596, p. 2]

Tailpipe Emissions vs. Lifecycle Emissions

SEMA is disappointed that this proposal exclusively looks at tailpipe emissions and not the full carbon footprint surrounding the manufacture of BEVs, including their batteries and components. The EPA's calculations should include the environmental impacts associated with mining for battery minerals, manufacturing batteries, and the resources from the power grid to power a full fleet of BEVs. Of note, the U.S. Energy Information Administration reported that fossil fuels are the largest sources of energy for electricity generation in the United States with an estimated 61% of all the electricity generated in 2021 coming from a combination of coal, natural gas, and petroleum.4 While BEVs do not have tailpipe emissions, it is naï ve to assume that they are carbon neutral given the fossil fuels that the U.S. and other countries around the world rely upon to produce the power to operate these vehicles. An analysis from S&P Global Mobility found that for the sixth consecutive year in a row the average age of a vehicle on the road today is 12.5 years old. Conversely, the “average age of battery electric vehicles in the U.S. fell to 3.6 years down slightly from 3.7 years in 2022.”5 According to a 2022 EPA report on greenhouse gas emissions, new vehicle fuel economy has increased 32% since model year 2004.6 SEMA believes that tailpipe emissions can continue to be reduced without shifting to a zero-based tailpipe emissions model. A diverse approach to addressing GHG emissions through a multifaceted approach of cleaner fuels, alternative fuels and electrification provides consumers with a choice in how they reduce their carbon footprint. [EPA-HQ-OAR-2022-0829-0596, p. 4]

5 S&P Global Mobility: US consumers keep vehicles for a record 12.5 years on average (Link: https://www.reuters.com/business/autos-transportation/us-consumers-keep-vehicles-record-125-years-average-sp-2023-05-15/).

6 The 2022 EPA Automotive Trends Report (Link: https://www.epa.gov/system/files/documents/2022-12/420s22001.pdf).

Conclusion

While the automobile's roots are tied to the internal combustion engine, SEMA prides itself on maintaining a forward-looking vision that embraces innovative technology, including EVs and other zero-emissions vehicles. The specialty automotive aftermarket has led the way on alternative fuel innovations from replacing older engine technologies with newer, cleaner versions to converting older ICE vehicles to new electric, hydrogen, and other alternative-fuel vehicles. Sadly, the EPA's plans to reduce greenhouse gases and criteria pollutants do not factor this in. SEMA and its members have serious concerns with this proposal, which aggressively seeks to lower carbon emissions under timelines that effectively make electric vehicles the de facto choice for automakers to meet the requirements. [EPA-HQ-OAR-2022-0829-0596, p. 6]

Clean air and the reduction of greenhouse gases are goals everyone can acknowledge. That said, when governments arbitrarily pick technology winners and losers, the marketplace is deprived of choices and the public suffers. Instead of forcing this transition, the EPA should put in place incentives to support a diversified, zero-emissions approach that takes advantage of breakthrough technologies across the spectrum. [EPA-HQ-OAR-2022-0829-0596, p. 6]

Organization: Steven G. Bradbury (Bradbury)

Worsening air quality and increasing global carbon emissions. As the EPA touts the environmental benefits it hopes to achieve from the production of more EVs, it ignores the fact that as consumers turn away from new models and the overall U.S. fleet ages, the older cars left on America’s highways will produce more smog and other traditional air pollutants that degrade local air quality. And if there truly were an explosion in the sale of EVs, those EVs would need to be charged using elec- tricity produced mostly from fossil-fuel-fired power plants, increasing the national emissions of carbon dioxide.47 EPA largely dismisses this reality based on the wish-ful claim that America’s future power generation will soon shift en masse to wind and solar.48 [EPA-HQ-OAR-2022-0829-0647, p. 17]

47 See Roger Pielke Jr., “The Energy Transition Has Not Yet Started: Global fossil fuel consumption is still increasing,” The Honest Broker, June 29, 2023, https://rogerpielkejr.substack.com/p/the-energy-transition-has-not-yet; Robert Bryce, “The Energy Transition Isn’t: Despite $4.1 trillion spent on wind and solar, they aren’t even keeping pace with the growth in hydrocarbons,” July 1, 2023, https://robertbryce.substack.com/p/the-energy-transition-isnt.

48 See 88 FR at 29303-04.

Furthermore, EPA has deliberately left out of its cost-benefit equation entirely the upstream carbon dioxide emissions associated with EV production.49 The minerals and components used in EV batteries are mostly processed or manufactured in China using power generated from coal. While the U.S. has achieved huge reduc- tions in carbon dioxide emissions by converting coal-fired power plants to natural gas, China’s and other Asian nations’ carbon emissions are growing rapidly because of their heavy reliance on coal, and EPA’s rules will only accelerate that dynamic.50 An automotive engineering analysis published in 2022 estimated that the carbon dioxide emissions from producing the battery used in one small EV (the Nissan Leaf) were equivalent to driving an ICE vehicle 24,000 miles (two years of driving), and those from producing the battery used in a large EV (the Tesla Model S) were equivalent to driving an ICE vehicle 60,000 miles (five years of driving).51 In these rulemaking proposals, EPA has completely ignored the fact that EVs start out their lives on the road with such a huge head start (two to five years worth) in carbon dioxide emissions over their ICE counterparts. [EPA-HQ-OAR-2022-0829-0647, pp. 17-18]

49 See id. at 29197, 29254.

50 See Robert Bryce, “The Iron Law of Electricity Strikes Again as Vietnam Boosts Coal Burn,” June 17, 2023, https://robertbryce.substack.com/p/the-iron-law-of-electricity-strikes.

51 See Tristan Burton, et al., Convergent Science, Inc., “A Data-Driven Greenhouse Gas Emission Rate Analysis for Vehicle Comparisons,” SAE Int’l Journal of Electrified Vehicles, April 13, 2022, https://doi.org/10.4271/14-12-01-0006 (also available at https://www.sae.org/publications/technical-papers/content/14-12-01-0006/).

EPA’s benefits analysis is flawed and arbitrary.

On the benefits side of the ledger, EPA claims sky-high monetized benefits from the asserted reductions in carbon dioxide emissions—to the tune of upwards of a trillion dollars.64 These estimates are based on predicted reductions in the amount of gasoline and diesel fuel that would be burned if the U.S. auto fleet converts to EVs at the rates projected by EPA. But they completely ignore the very large increase in carbon dioxide emissions that would necessarily occur from the projected expansion in the production of EV batteries. They also ignore the upstream emissions of carbon dioxide from the increased electricity generation that would be needed to charge the projected fleet of EVs. [EPA-HQ-OAR-2022-0829-0647, pp. 22-23]

64 See id. at 29200, 29344.

EPA’s refusal to account for these huge offsetting emissions of carbon dioxide fundamentally distorts its analysis of net benefits in a manner that arbitrarily favors the Agency’s preferred regulatory outcome. It is, in fact, false and misleading to label EVs “zero-emission vehicles” when the production of EV batteries and the charging of the batteries over the life of the vehicles both generate enormous amounts of carbon dioxide. [EPA-HQ-OAR-2022-0829-0647, pp. 22-23]

Organization: Strong Plug-in Hybrid Electric Vehicle (SPHEV)

The chart below for light-duty PHEVs and BEVs show the benefit of PHEVs in reducing the use of critical minerals and accounts for the difference in electric miles between BEVs and different types of PHEVs. Strong PHEV battery utilization maximizes the value of battery manufacturing and materials capacities and helps address the need for fast scale up of battery manufacturing and mineral extraction by better utilizing resources. PHEV cars and trucks, especially, Strong PHEV cars and trucks, can electrify most daily commuting miles while occasionally using some gasoline, while BEVs have a lot of battery capacity that only gets "used" on very long trips. We assert that this could be considered wasted or underutilized lithium and other battery minerals. Thus, because PHEVs use their batteries more, the USA gets more EV miles per tonne of lithium by driving PHEVs and Strong PHEVs as shown in the chart below. PHEV's smaller batteries reduce the lifecycle environmental burdens associated with battery materials, production, and end-of-life.16 [EPA-HQ-OAR-2022-0829-0646, pp. 20-21]

Organization: TCW Inc. (TCW)

The current tunnel vision approach to ZEV's fails to consider the significant opportunities that are likely to come with hydrogen. Perhaps equally important is the recent use of R99, a renewable diesel fuel that is a direct replacement for petroleum based fuel. Studies have shown R99 emissions at 30-40% that of petroleum based fuel. When comparing the total lifecycle carbon footprint of a BEV (production, electricity generation, disposal), R99 has actually been shown to have less of a carbon footprint than BEV and does not rely on Russia, The Democratic Republic of Congo, or China to source materials for production. (Reference ATRI study at the link below) [EPA-HQ-OAR-2022-0829-0452, p. 1]

Organization: Tesla, Inc. (Tesla)

EPA has long considered BEVs to be the most effective mobile source pollution mitigating technology, stating over a decade ago, "From a vehicle tailpipe perspective, EVs are a game-changing technology."38 Additionally, study after study shows BEVs are a superior technology for reducing air pollution and GHG emissions over their lifetime.39 On a well to wheels analysis including upstream emissions, the U.S. Department of Energy (DOE) has repeatedly found BEVs to be far superior in emission performance than internal combustion engine (ICE) technology.40 For example, a Tesla Model 3 or Model Y charging on the U.S. grid has average lifecycle emissions almost 3.5 times less than an average premium ICE vehicle.41 As a result, over a 17- year lifetime, a Tesla vehicle driver can avoid emitting over 55 tons of CO2e.42 [EPA-HQ-OAR-2022-0829-0792, pp. 6-7]

Further, California’s recent adoption of the ACC II rule, setting a 100 percent zero-emission vehicle (ZEV) sales standard by 2035, will also accelerate BEV adoption. As EPA recognizes, a number of states have already adopted ACC II and the list is growing.85 New research assessing the impact of additional states adopting California’s standards (accounting for the IRA’s tax credits) finds that adoption by California and 16 other states would accelerate electric vehicle adoption, cut 1.3 gigatons of carbon emissions (equivalent to closing 13 coal plants), create 300,000 new jobs, save households $230 per year, and prevent 5,000 deaths in 2050.86 [EPA-HQ-OAR-2022-0829-0792, pp. 12-13]

Furthermore, the seemingly sharp former distinctions between regulatory strategies to address criteria pollutant emissions and GHG emissions have continued to erode in view of the appropriate control strategies and technologies and the increasingly smaller margins for improvement from conventional ICE emissions. States have noted that zero emission vehicles (ZEVs) produce no tailpipe emissions, reduce brake wear PM emissions, and have lower upstream emissions to contribute to their State Implementation Plan (SIP) strategies.133 EPA's 2017 Tier 3 standards, for example, achieved reductions of methane (CH4) and nitrous oxide (N2O), each of which are GHGs that were part of EPA's endangerment finding.134 [EPA-HQ-OAR-2022-0829-0792, pp. 21-22]

In order to produce supplies of renewables, China is increasing its construction of coal- fired power plants. This increases carbon emissions and reduces EPA's benefits from U.S. emissions reduction. America has 225 coal-fired power plants, and China has 1,118 (half of all the coal-fired plants in the world).31 That is one reason why China has increased carbon emissions by over 5,000 million metric tons over the past 16 years.32 In contrast, America's carbon emissions have declined by over 1,000 million metric tons over the same period due to the use of clean natural gas.33 (See Figure 1.) China has not committed to reducing emissions until 2027. Research has shown that even completely eliminating all fossil fuels from the United States would result in less than 0.2 degrees Celsius in temperature mitigation by 2100.34 Americans, particularly poor and middle class, would be bearing major costs in higher electricity prices, higher food prices, and a forced switch to costly electric vehicles without benefits for the environment. They would pay the price for President Biden’s energy agenda. [EPA-HQ-OAR-2022-0829-0674, pp. 7-8]

6.2. Technology Assessments Should Incorporate Critical Mineral Supply and Lifecycle Emissions

The modeling should also include a sensitivity analysis of BEV/PHEV mix on critical mineral usage for any assumed overall PEV penetration. PHEVs can make the most efficient use of the limited battery supply and constrained infrastructure network forecast through the period of the rulemaking. The below example compares different vehicle powertrain emissions for a mid-size SUV using peer-reviewed data from carghg.com. The same amount of lithium in the battery of one 300-mile plus BEV can be used for up to six PHEVs –or more than eighty conventional hybrids. See Figure 10 for the CO2 saved from replacing a mid-sized SUV powered by a conventional gasoline engine with electrified alternatives under a constrained lithium supply. This analysis assumes average US electric grid emissions for BEVs and the electric operation of PHEVs. [EPA-HQ-OAR-2022-0829-0620, pp. 31-32]

[See original for attachment for Figure 10 CO2 Saving from Replacing ICEs Under Constrained Mineral Supply]

PHEVs can rival the emissions performance of BEVs under many real-world operating conditions. PHEVs are not always the best-performing option but can have as good or better lifecycle performance because of lower manufacturing emissions for smaller batteries and lower well-to- tank emissions while still covering a significant fraction of daily trips in electric drive. Given most average daily trips are under 50 miles, this results in a significant portion of all-electric miles like a BEV. [EPA-HQ-OAR-2022-0829-0620, pp. 31-32]

Organization: Valero Energy Corporation

EPA should evaluate the merits of all fuels and vehicle technologies on a full lifecycle basis. For example, EPA states that “[i]n December 2022, Toyota announced plans to introduce 30 BEV models by 2030”.125 But EPA’s Proposed Rule should also meaningfully consider following statements from Toyota in the same announcement:126 [EPA-HQ-OAR-2022-0829-0707, pp. 25-27]

125 EPA's Proposed Rule at 29191 (citing to Toyota Motor Corporation, ''Video: Media Briefing on Battery EV Strategies,'' Press Release, December 14, 2021. Accessed on December 14, 2021).

126 Toyota Motor Corporation, "Video: Media Briefing on Battery EV Strategies,'' Press Release, December 14, 2021 (emphasis added).

- "We are living in a diversified world and in an era in which it is hard to predict the future. Therefore, it is difficult to make everyone happy with a one-size- fits-all option. That is why Toyota wants to prepare as many options as possible for our customers around the world." [EPA-HQ-OAR-2022-0829-0707, pp. 25-27]

- "If the energy that powers vehicles is not clean, the use of an electrified vehicle, no matter what type it might be, would not result in zero CO2 emissions." [EPA-HQ-OAR-2022-0829-0707, pp. 25-27]

IV. The proposed rule should be technology- and fuel-neutral.

A. The proposed rule should evaluate all fuels and technologies on a lifecycle basis.

Although the preamble describes the proposed standards as being achievable by manufacturers using a variety of strategies that may include varying degrees of electrification among vehicle offerings, elements of the program have been skewed to favor electric vehicles. A glaring example of this is EPA's refusal to recognize the upstream emissions associated with EV power and battery production, on the one hand, or on the other hand, to provide a mechanism for appropriately quantifying and crediting reductions in GHG emissions attributable to low-carbon fuels used in ICE vehicles. [EPA-HQ-OAR-2022-0829-0707, pp. 61-62]

The National Bureau of Economic Research has acknowledged that "…despite being treated by regulators as 'zero emission vehicles', EVs are not necessarily emissions free."330 In fact, the Hummer EV using U.S. average grid electricity is reported as generating higher carbon dioxide emissions per mile than many smaller, more efficient gasoline-powered cars.331 [EPA-HQ-OAR-2022-0829-0707, pp. 61-62]

330 See http://www.nber.org/papers/w21291.

331 See https://qz.com/2154558/big-electric-trucks-and-suvs-are-the-new-gas-guzzlers.

A lifecycle analyses conducted by Southwest Research Institute finds that GHG emissions from a light-duty internal combustion engine ("ICE") vehicle that runs on renewable diesel with a carbon intensity of 25 g/MJ results in 25% fewer lifecycle GHG emissions when compared to a comparable battery electric vehicle ("BEV") using U.S. average grid electricity, as illustrated below. [EPA-HQ-OAR-2022-0829-0707, pp. 61-62]

[See original for graphic titled "Figure 2: U.S. Light-Duty Vehicle Lifecycle Emissions (Sept. 2022 Valero Investor Relations Presentation)"] [EPA-HQ-OAR-2022-0829-0707, pp. 61-62]

Organization: Western Energy Alliance

Further, it is not at all clear that the proposed rule will reduce GHGs as planned. Pure plug-in battery- powered vehicles can create more emissions than hybrid EVs (HEV) and even more than some traditional ICEVs for a variety of reasons including the fuel mix of the electrical grid where the EV is being charged and the large GHG footprint for producing the battery. The manufacture of a battery can produce GHGs equivalent to driving 24,000 miles, in the case of a Nissan Leaf up to 60,000 miles in the case of a Tesla Model S.4 Those numbers are before a single mile is driven by the supposed ZEV with its associated GHGs from the electricity used. When CO2 emissions linked to the production of batteries and the energy mix are considered, a study in Germany found EVs emit 11% to 28% more than their diesel counterparts.5 Volvo reports that in comparing a gas-burning model with its fully electric equivalent, with both vehicles built in the same factory, on the same assembly line, and sharing a large number of components, it found the electric version results in 70% more emissions.6 [EPA-HQ-OAR-2022-0829-0679, p. 3]

6 “Building An EV Produces 70% More Emissions Than ICE, Says Volvo,” InsideEVs, Andrei Nedelea, November 20, 2021.

EPA needs better analysis of the GHG reductions by EVs. The assumption that they are “zero emission” must be tested using a more comprehensive analysis of full lifecycle emissions sources from EVs. [EPA-HQ-OAR-2022-0829-0679, p. 3]

EPA Summary and Response:

Summary:

A number of commenters maintained that lifecycle GHG emissions should be reflected in the emission standards themselves as well as in the compliance regime for the standards (i.e., certification) or within a GHG credit program. These commenters included fuel suppliers, fuel producers, several fleets and dealers, non-governmental organizations, and a few environmental groups. In addition, no commenter questioned the appropriateness of EPA considering upstream emissions as part of its overall assessment of CO_2 emission impacts, non-CO_2 emission impacts, or use in cost-benefit calculations.

The remainder of this section addresses exclusively the issue of life cycle analysis in the standard setting process and in determining compliance with standards. Comments relating to EPA’s consideration of upstream emissions in calculating emission impacts are addressed in sections 11.3 and 12.1.3 of this document.

A threshold issue addressed by some of the commenters is whether EPA has the legal authority to use some type of lifecycle approach in standard setting. Some of these commenters cited the broad discretion afforded by CAA section 202 (a) (1). Other commenters cited CAA sections 202 (a)(3)(A) and 202 (a)(4)(A) and (B).

Most of these commenters’ arguments were based on considerations of policy. They point out that PEVs in fact have greenhouse gas emissions associated with their production and their fuel source, i.e., emissions upstream of the vehicle tailpipe (and some commenters would consider downstream emissions as well, such as emissions attributable to battery disposal). Given these emissions, they maintain, it is more consistent with the Act’s emission reduction goals, and the technology-neutral basis of this rule, to account for those emissions in the standards. Certain proponents of alternative fuel use presented studies and other information which they characterized as showing that ICE vehicles powered by various types of biofuels would emit less than a comparable BEV vehicle, and, in any case, alleged that emission reductions from alternative fuel-powered vehicles would accrue immediately rather than after fleet turnover. Some commenters went further and argued that EPA would be acting arbitrarily by ignoring lifecycle impacts in the standards, since this would amount to just moving pollution around rather than reducing it, and would otherwise arbitrarily fail to solve the problem the rule is addressing.

Commenters were divided as to how a lifecycle approach could be reflected in the standards. Indeed, it was not always clear if the commenters intend for the approach only to apply to standards for PEVs, or for all vehicles. With respect to PEVs, suggestions ranged from accounting only for GHG emissions from the electricity generating source (potentially including an accounting for electricity lost in transmission and distribution), to emissions from battery manufacture, battery disposal, electricity supply chains, and mining of materials critical to battery production (including from overseas mining venues). Commenters were unclear as to whether their suggestions applied to GHG emissions only, or to other pollutants as well (although some pointed out that GHGs are exceptional, being global pollutants, such that a lifecycle accounting was justified).

Several commenters noted that EPA also did not consider emissions from mining and resource extraction processes as well as from battery production.

Response:

EPA is adhering to the approach for measuring compliance that every light and medium vehicle has used to date: compliance is based on emissions from the vehicle. As EPA stated in the Response to Comments in the 2021 final rule:

EPA disagrees that it is required to perform a life cycle analysis of vehicle and fuel production before setting vehicle standards, or to treat emissions of air pollutants attributable to electricity generation, or the mining, production or disposal of batteries for electric vehicles, as emissions "from" new motor vehicles. The Clean Air Act's entire structure evidences a clear divide between stationary sources (regulated under Title I) and mobile sources (regulated under Title II). There may be indirect impacts of stationary source regulation on mobile sources and vice versa, and it may be appropriate to consider those impacts in some circumstances, but it would be inappropriate and contrary to the plain text of the Clean Air Act to conflate the consideration of indirect impacts, when appropriate, with actually treating stationary source emissions as mobile source emissions. *Cf. Coal. for Responsible Regul., Inc. v. E.P.A.,* 684 F.3d 102, 128–29 (D.C. Cir. 2012), *aff'd in part, rev'd in part sub nom. Util. Air Regul. Grp. v. E.P.A.,* 573 U.S. 302 (2014), *and amended sub nom. Coal. for Responsible Regul., Inc. v. Env't Prot. Agency*, 606 F. App'x 6 (D.C. Cir. 2015) ("EPA was not arbitrary and capricious by not considering stationary-source costs in its analyses"). Congress directed EPA to address emissions from manufacturing fuels and vehicles under EPA's authority to reduce pollution from stationary sources and to address emissions from the operation of light duty vehicles under its authority to reduce pollution from mobile sources. It would be contrary to the purpose of the Clean Air Act if EPA declined to adopt otherwise-appropriate standards to reduce emissions from new light duty vehicles because additional reductions in pollution could be, but had not yet been, achieved by refineries, electric generating units, or vehicle manufacturers (due to vehicle production facilities). EPA interprets the Clean Air Act as directing EPA to consider regulation of emissions for each sector according to the applicable statutory requirements for each program. Congress has established and EPA intends to continue to undertake regulation of GHG consistent with those statutory requirements.[630]

Thus, EPA disagrees it is required to treat lifecycle emissions (such as those attributable to the production of vehicle fuel) as emissions “from” new motor vehicles or new motor vehicle engines for purposes of CAA 202(a), and even assuming EPA has authority to do so, EPA finds it would not be appropriate to do so.

EPA also finds that at this time there would be enormous, likely insuperable, practical difficulties in trying to incorporate a lifecycle approach into the standard setting process. As EPA has previously explained,[631] there are two fundamental problems with incorporating lifecycle analysis into standard setting: 1) having sufficient data for every technology; and 2) life cycle emissions are dependent on factors outside the scope of the rulemaking that may change in the future.

First, we doubt the data is adequate to undertake reliable life cycle analysis for any technology, but even if it is available for one technology, that is of little benefit unless it is available for every technology, or else there is no way to compare technologies. And as discussed elsewhere, sometimes the industry innovates in unforeseen ways and it is unclear how a lifecycle-based approach can be applied on an ongoing basis. Commenters advocating for life cycle analysis did not provide adequate data to support such an analysis. Although some commenters cited studies performing LCA for certain fuel or vehicle types, we also did not find those studies sufficiently robust for reasons we explain later in this section.

Second, this rule is not regulating manufacturing processes, distribution practices, or the locations of manufacturing facilities. And yet each of these factors could impact life cycle emissions. So while we could theoretically take a snapshot of life cycle emissions at this point in time for specific manufacturers, it may or may not have any relation to life cycle emissions in 2027 or a later year, or for other manufacturers.

With respect to comments from alternative fuel providers, EPA disagrees that it would be appropriate to provide a credit for renewable-fueled vehicles to reflect the lifecycle emissions of renewable fuels as compared to a baseline fuel. There already is a statutory program which encourages use of renewable fuels in transportation, including light- and medium-duty vehicles and heavy-duty engines, which moreover requires EPA to consider lifecycle greenhouse gas emissions. Id.; see also 76 FR at 57124 (Sept. 15, 2011) (Renewable Fuel Standards provisions, not section 202 (a)(1), are the appropriate means of evaluating and encouraging use of alternative fuels). The RFS program is the Congressionally mandated and appropriate means of evaluating

[630] 2021 Rule RTC at 16-41; see also Motor & Equip. Mfrs. Ass'n, Inc. v. E.P.A., 627 F.2d 1095, 1118 (D.C. Cir. 1979) (“there is no indication that Congress intended section 202's “cost of compliance” consideration to embody “social costs” of the type petitioners advance. Every effort at pollution control exacts social costs. Congress, not the Administrator, made the decision to accept those costs. Section 202's “cost of compliance” concern, juxtaposed as it is with the requirement that the Administrator provide the requisite lead time to allow technological developments, refers to the economic costs of motor vehicle emission standards and accompanying enforcement procedures. … It relates to the timing of a particular emission control regulation rather than to its social implications.”).

[631] 81 FR 73478, 73528 (Oct 25, 2016).

lifecycle implications of biofuels, and of encouraging their use, as appropriate.[632] There is no legal mandate or otherwise compelling reason to achieve the same purpose through Section 202 (a) (1) -- a provision directed at reducing emissions "from … motor vehicles." EPA notes that Congress established two distinct regimes for reducing pollution from vehicles—section 202, which is directed at vehicle and engine emissions, and section 211, which is directed at fuels. Congress was clearly aware that fuels and engines work in tandem to produce emissions[633] and yet the two sections, as discussed above, have very distinct structures and requirements. EPA finds that in light of this careful Congressional design, it would be inappropriate to adopt a fuels rule in the guise of a vehicle standard. Just as section 202 standards should be based on vehicle emissions, and not stationary source emissions, so too they should be based on vehicle emissions, as opposed to the lifecycle emissions of fuels.

Lifecycle emissions, especially those related to resource extraction, affect the total environmental footprint of all vehicles, including ICE vehicles with a range of electrification and BEVs. However, considering all such emissions in the context of modeling emission inventory impacts attributable to the final GHG standards is fraught and presents scope challenges. For example, resource extraction is a very large worldwide industry that supports many other manufacturing industries. Attributing any activity specifically to the standards is very difficult and highly uncertain. Another challenge is that the emissions from the mining sector are constantly changing as processes evolve, power grids become cleaner, and the areas of the mining itself change.[634] Therefore, calculating future emissions for this sector, especially in later years such as through the 2030s and 40s, is exceedingly difficult. These arguments also exist in the context of battery production itself. We note further that for a comparison to be valid, there would need to be an accounting of emissions associated with all aspects of petroleum extraction, all aspects of mineral extraction needed for catalytic converters (rhodium, palladium, platinum), and all aspects of lead acid battery production and subsequent management, which the commenters appear to disregard.

One commenter stated that EPA did not explain why, in assessing the air quality impacts of the rule, EPA limits its analysis of upstream emissions. It is true that, as discussed in RIA chapter 7.2, EPA's analysis of upstream emissions is limited to EGUs, refineries, and well sites and pipeline pumps for crude oil and natural gas production. EPA's judgment is that this approach represents a reasonable balance between considering indirect effects of the rule on air quality and limiting that consideration to reasonably proximate and predictable effects. Because we lack the data and capacity to predict every indirect effect of the rule throughout the supply chain and the broader economy, we judge that by examining the upstream emissions of EGUs and refineries we have taken into consideration the most significant indirect effects of the rule on

[632] To the extent the RFS statute is of any relevance in understanding section 202(a)(1), but see CAA section 211(o)(12) (savings clause), it indicates that when Congress wanted the agency to consider lifecycle emissions, it knew how to say that clearly. See also 26 USC 45V (providing a credit for clean hydrogen considering certain lifecycle emissions). Sections 202(a)(1)-(2) do not contain any such language, and particularly in light of the Act's overall division between mobile and stationary source regulation, any mandate to consider lifecycle emissions ought not to be implied.

[633] See, e.g., section 211(c)(1)(B) (authorizing EPA to regulate fuels that will impair emissions control devices); section 211(f)(1) (prohibiting the introduction into commerce of any fuel not substantially similar to the fuel used in certification testing of vehicles).

[634] Even the minerals being mined are likely to change as new battery chemistries are developed.

air quality, such that our air quality analysis is sufficiently complete for consideration in the rulemaking.

EPA also notes that accounting for these upstream emission processes in the context of an increase in PEV production while failing to do equivalent accounting for a reduction in the production of other vehicles, including ICE with a range of electrification, would unreasonably skew the emission impacts estimates. Many of the same metals that are in demand for PEV production would also be in demand for ICE production, so whether the standards would truly result in an increase in all mining, resource extraction, and production emissions is not clear. And, because such a broad accounting of these emission processes for the range of vehicles would include emissions from around the world, accounting for these emissions presents scope challenges.

EPA notes further that the emission benefits of certain alternative fuels are recognized at the tailpipe (in addition to whatever credit may be obtained under the RFS program). In response to comments that alternative fuel vehicles can provide CO_2 emission reduction benefits immediately and without the need for new supporting infrastructure, to the extent that is true, EPA notes that this potential compliance pathway remains an option.

EPA notes further that the commenters maintaining that use of alternative fuels producing GHG emission benefits sooner (on a lifecycle basis) than PEV deployment did not address the temporal issue of emissions associated with producing the additional quantities of agricultural biofuels. When crop production is expanded to produce more biofuels, a carbon debt is incurred through land use change emissions, by releasing carbon stored in vegetation and soil as one clears land and prepares it for cropping. That carbon debt must be "paid back" over time by displacing fossil fuel consumption with biofuels using the crops grown on that land. This 'debt' can require decades to pay back.[635]

Certainty of emission benefits (again, on a lifecycle basis) is by no means clear cut either. For example, in its recent RFS volume-setting rulemaking (the "Set Rule"), EPA analyzed the GHG-saving potential of soybean biodiesel, which is both the most widely used domestic biofuel in the diesel pool. EPA's analysis of the existing literature and comparison of biofuel modeling tools documented significant uncertainty regarding the GHG emissions profile of soybean oil biodiesel, including some uncertainty as to whether this fuel's GHG emission profile is favorable compared to diesel.[636]

EPA also notes the irony that many of the commenters raising concerns about lifecycle accounting are the same ones who claimed EPA's standards implicate the major questions doctrine because they represent a significant and novel expansion of EPA's regulatory

[635] For discussion of the carbon debt and payback time see for example: Fargione, J., Hill, J., Tilman, D., Polasky, S., & Hawthorne, P. (2008). Land clearing and the biofuel carbon debt. Science, 319(5867), 1235-1238. For more recent modeling of the temporal profile of biofuel GHG emissions see Sections 6.7 and 7.7 of the EPA Model Comparison Exercise Technical Document (EPA-420-R-23-017): https://nepis.epa.gov/Exe/ZyPDF.cgi?Dockey=P1017P9B.pdf

[636] See Chapter 4 of the Regulatory Impact Analysis (EPA-420-R-23-015) accompanying 88 FR 44468 and also EPA's Model Comparison Technical Document (EPA-420-R-23-017) accompanying this FRM. https://www.epa.gov/renewable-fuel-standard-program/final-renewable-fuels-standards-rule-2023-2024-and-2025

authority.[637] Despite their putative concern about the expansion of agency power, these commenters seem to suggest the agency should further extend its regulatory ambit under section 202(a)(1) to include a broad range of stationary sources, including not only major point sources, but area sources and agricultural operations, both domestic and foreign. A comprehensive lifecycle analysis of motor vehicle control technologies could be extraordinarily far ranging, including assessment of factors ranging from practices for clearing agricultural land for farming palm oil in Malaysia, to the environmental standards for cobalt mines in the Democratic Republic of Congo, to spills of diesel fuel at countless retailers across the United States. And while a lifecycle analysis could potentially be less far-reaching, the commenters requesting lifecycle accounting uniformly failed to advance a coherent basis for why the statute requires or permits the lifecycle accounting line to be drawn at a particular industry or degree of nexus. It would be remarkable if EPA's authority to regulate "the emissions of any air pollutant from any class or classes of new motor vehicles or new motor vehicle engines" encompassed consideration of emissions attributable to the manufacture of fertilizer for growing corn but excluded consideration of the emissions performance of BEVs. Regardless of whether the agency has authority to account for these or other lifecycle emissions in the manner advocated for by these commenters, we think that so extending the agency's authority is neither necessary nor appropriate for administering a statutory program focused on reducing vehicular emissions.

Finally, in response to comments suggesting that tailpipe emissions of biogenic and non-biogenic CO2 should be treated differently, we disagree. EPA notes that ever since the section 202 Endangerment Finding was made, it has considered GHG pollution as being comprised of six well-mixed gases (one of which is CO2), based on their properties and behaviors in the atmosphere that are relevant to the climate change problem, including characteristics and attributes related to radiative forcing, chemical reactivity, and atmospheric lifetime. As EPA stated, in reiterating this position in the 2016 Endangerment Finding for GHG Emissions from Aircraft, "[i]n the record for the 2009 Endangerment Finding, the Agency stated that 'all CO_2 emissions, regardless of source, influence radiative forcing equally once it reaches the atmosphere and therefore there is no distinction between biogenic and non-biogenic CO_2 regarding the CO_2 and the other well-mixed GHGs within the definition of air pollution that is reasonably anticipated to endanger public health and welfare.'"[638] EPA finds it appropriate to continue this policy of treating all tailpipe CO_2 emissions equivalently, since once they have been emitted to the atmosphere the CO_2 molecules have equivalent impacts on the climate, regardless of the origin and constitution of the fuel prior to combustion.

<u>Responses to specific comments:</u>

<u>Summary:</u>

EPA has legal authority to consider life cycle emissions in the standard setting process under CAA section 202 (a)(1) given the breadth of discretion afforded by that provision. Further, the provision does not specify regulation from vehicles. Rather, it refers to standards applicable to

[637] We explain in the RTC 2.3 why this rule is not an extraordinary exercise of agency power that would justify invocation of the major questions doctrine.

[638] 81 FR 54422, 54446.

emissions of air pollutants from a class or classes of motor vehicles which contribute to that air pollution.

Response:

First, these commenters' reading of section 202(a)(1) is problematic. The provision refers to emissions "from any class or classes of new motor vehicles" and EPA's endangerment determination identified new motor vehicles – specifically, passenger cars, light-duty trucks, motorcycles, buses, and medium and heavy-duty trucks – as the class contributing to the air pollution which endangers. EPA's contribution finding respecting this class considered only the emissions from the vehicles in the class. See 74 FR at 66537-540 (Dec. 15, 2009.)[639] Therefore, EPA does not perceive that the reference to 'class' in section 202(a) advances the commenter's argument.

If the provision is read as discretionary, as the commenters urge, EPA has explained above why it is inappropriate to exercise that discretion to include lifecycle-based standards. As noted and referenced above, there is both a clear demarcation in the CAA between stationary and mobile sources, and an entire statutory program devoted to consideration of alternative vehicular fuel use. There is no compelling reason to import all of those considerations into the section 202 (a)(1) standard setting process for light- and medium-duty vehicles. This would turn an emissions program into a fuel program, and obliviate the distinction between the two now codified in the Act.

Summary:

CAA sections 202(a)(3)(A)(ii) and 202(a)(4)(B) authorize or require consideration of lifecycle emissions in the standard setting process.

Response:

Section 202(a)(3)(A)(ii) does not compel EPA to establish standards based on lifecycle emissions. First, that provision only applies to certain criteria pollutant standards (including certain criteria pollutant standards for medium-duty vehicles established in this final rule), not to GHG standards or any light-duty standards. In any event, the reference to subcategorizing based on "type of fuel use" does not compel lifecycle standards. The natural meaning of that provision is that EPA may subcategorize based on the fuel used by a vehicle, for example, gasoline versus diesel, recognizing for example that vehicles of different fuel types may have different emissions characteristics. That provision does not mean that the Administrator must establish standards based on lifecycle emissions relating to fuel type. Moreover, section 202(a)(3) (A) (ii) is discretionary ("the Administrator *may* base such classes or categories"), and so cannot be read to compel any particular approach. Finally, given that the standard-setting provisions in section 202(a)(1) and 202(a)(3)(A)(i) speak to addressing emissions from classes of motor vehicles, we do not think a subsidiary provision on how such classes can be subdivided indicates that EPA is in fact compelled to establish standards based on lifecycle emissions from a wide range of stationary and agricultural sources. Congress does not hide elephants in mouseholes.

---

[639] See, e.g. 74 FR at 55538/1 (contribution finding relates to the "emissions from the source category"); id. at 55540/2 (contribution finding relates to "[e]missions from the CAA section 202(a) source categories constitute the major part of the emissions from the transportation sector"); id. (showing transportation and electricity sector contributions separately).

Sections 202(a)(4)(A) and (B) are directed to whether emission control devices used to comply with the vehicular emission standards in vehicles might pose unreasonable risks. See section 202 (a)(4) (A) (“devices …used in a new motor vehicle”; “if such device … contributes to … unreasonable risk … in its operation or function”); and section 202(a)(4)(B) (“whether … the use of any device” affects emissions of unregulated pollutants, and whether any risk posed by “the use of such device” can be eliminated). These provisions consequently are directed at risks posed by devices used in the vehicle, not to upstream emissions. EPA has carefully evaluated the potential safety risks of PEV technologies in RTC 22. We note, moreover, the significant expansion of regulatory authority the commenter’s approach suggests: to conform to section 202(a)(4) EPA must evaluate the public health, welfare, and safety risks associated with gasoline refining and distribution, electricity generation and transmission, mining, and agriculture, in the US and in foreign nations. It would be odd, to say the least, for such a capacious command to lie hidden in an ancillary provision of the statute.

Summary:

Given that there are upstream and downstream emissions associated with BEVs, terming them zero emission vehicles is misleading. Without accounting for such emissions, EPA is improperly assessing the environmental impacts of its standards, and potentially just transferring pollution from one source to another. This can be demonstrated by an example: if a BEV were to be fueled by electricity from a stationary diesel generator, it would count as a zero emission vehicle, yet its overall impact would be the same as an ICE operating on diesel fuel. EPA’s distinctions are consequently arbitrary, and potentially counterproductive.

Response:

EPA is not ignoring emissions from upstream sources. See Preamble section VI and VII, and RTC section 11.3 and 12.1.3. These analyses show that the net GHG and criteria pollutant emission impacts of this rule are overwhelmingly positive, taking into account GHG emissions from both vehicles and upstream sources. We also find substantial positive $PM_{2.5}$ health benefits while accounting for both vehicular and upstream emissions. Thus, EPA does not accept the assertion in some of the comments that this rule fails to positively address the problem which prompts the need for the rule.

Second, the commenters ignore that upstream, and for that matter, downstream potential emission impacts from stationary sources are controlled via other EPA regulatory programs. Thus, electricity generation, battery manufacture, and recycling and disposal of spent batteries are all comprehensively regulated under other EPA programs. For example, EPA regulates electric generating units under many programs such as the Mercury and Air Toxics Standards (CAA), the Cross State Air Pollution Rule (CAA), the Cooling Water Intake Systems Rule (CWA), the Coal Combustion Residuals Rule (RCRA), the Steam Electric Power Generating Effluent Guidelines (CWA), as well as under various actions of particularly applicability such as State and Federal Implementation Plans to implement the National Ambient Air Quality Standards and the visibility protection program. See also 88 FR 24854 (proposing further controls on hazardous air pollutants emitted by steam electric power units), and 88 FR 33240 (May 11, 2023) (proposing GHG emission standards for existing coal- and oil-fired steam generating units, and for new and some existing gas fired steam electric generating units). With respect to the commenters’ example of PEVs being charged by electricity from a stationary source diesel generator, we note that notwithstanding some viral social media videos,[640] there is no evidence that this is happening in a way that significantly affects the emissions reductions achieved by the standards. Moreover, EPA notes that there are emission standards for such generators under the NESHAP for Reciprocating Internal Combustion Engines. 40 CFR subpart ZZZZ. Disposal of lithium-ion batteries is regulated comprehensively under EPA rules implementing the Resource Conservation and Recovery Act, see 40 CFR Part 173, and their transport is regulated comprehensively under DOT Hazardous Material Rules in 49 CFR Parts 171-180 (see RTC Section 22 "safety" responses, and RTC section 12.2.5 "recycling" responses.) Moreover, on October 23, 2023, EPA announced plans to propose further regulations adding to the safety standards for management of spent lithium-ion batteries.[641] Many of these same activities are regulated by other jurisdictions as well, including by U.S. states and foreign governments and their local jurisdictions. The preamble and RIA also discuss anticipated emissions reductions from the power sector attributable to the IRA.

As noted above, the delineation between mobile and stationary source standard setting is in keeping with the structure of the Act, whereby Congress directed EPA to control stationary sources under Title I of the Act, and mobile sources under Title II. For these reasons, EPA rejects the assertion of commenters that it has ignored these issues and consequently arbitrarily failed to consider an issue of importance in the rulemaking.

Summary:

Commenters had various suggestions as to which lifecycle emissions should figure into the standard setting process. All recommending the approach would include emissions associated with electricity generation. Others would include emissions associated with battery production. Commenters also mentioned inclusion of electricity supply chain-related emissions, associated with battery "disposal", and mining of materials critical to battery manufacture, including cobalt and other minerals presently supplied primarily from overseas.

Response:

The differing perspectives of commenters on where to draw the line for what is included in a lifecycle analysis illustrates the difficulties of importing a lifecycle approach into the section 202(a) GHG standard setting and compliance process, and reinforces EPA's long-established choice not to do so. Aside from the practical difficulties of making reliable accounting for emissions from overseas extractive activities, these commenters are not advocating consideration of emissions associated with extraction of precious and semi-precious metals used in ICE emission control systems, or extraction of lead used for lead-acid batteries.

As noted above, these commenters do not appear to be advocating a similar approach for fossil fuels, whereby all emissions and other impacts of locating, extracting, and processing fossil fuels, or all emissions associated with growing, harvesting, and transporting biofuels, would be accounted for in the vehicular standard setting process. Nor have the commenters

[640] See, e.g., https://www.usatoday.com/story/news/factcheck/2023/11/15/ev-charger-is-solar-and-diesel-powered-not-247-diesel-fact-check/71568937007/ (determining that video showing "EV charging station with diesel generator that 'runs 24 hours of the day, seven days a week'" was "false").

[641] The Unified Regulatory Agenda Entry reads, in relevant part, "EPA is proposing universal waste standards specially tailored for lithium batteries, separate from the existing general battery universal waste category. This change in the RCRA regulations would benefit those generating and managing waste lithium batteries by improving the safety standards and reducing fires from end-of-life lithium batteries, while continuing to promote recycling."

urging consideration of end-of-life battery disposal and recycling emission issues addressed emissions relating to disposal and recycling of lead acid batteries, or of wastes from petroleum refining. [642]

As noted above, EPA does not consider a partial life cycle analysis, which focuses only on certain technologies to be a sufficient analytical basis for standard setting.

Summary:

Various commenters submitted quantified analyses or cited journal papers, technical papers or reports purporting to show that ICE vehicles operating with biofuels, or HEVs, or PHEVs would actually emit less GHGs (or comparable amounts of GHGs) than comparable BEV vehicles when their respective lifecycle GHG emissions, including raw material extraction and processing, component and vehicle manufacturing, use-phase emissions, and end-of-life are accounted for.

Response:

None of the commenters citing journal papers, technical papers, or reports presented any evidence of having conducted a thorough literature review of automotive LCA in general, or for prospective/comparative LCA of BEV relative to other energy sources in particular. Commenters cherry-picked from among a small number of LCA studies, some extremely dated (e.g., a 2009 National Academies study) and that contain data and results that are of little or no relevance with respect to current or prospective life cycle emissions inventories (LCI) and LCA. In some cases, specific examples were then cherry-picked from within specific studies or generated from extreme cases among current automotive offerings using findings of a single study. For example, some commenters selected a single vehicle example from within a single study, e.g., an ICEV or HEV light-duty passenger car, and made direct comparisons to a BEV with substantially different use and capability, e.g., a 400-mile range BEV SUV; and then further attempted to apply conclusions from such a comparison to the broad diversity of the U.S. light- and medium-duty vehicle fleet. One commenter calculated emissions using a Hummer EV, as if a limited production, large, off-road-capable truck is somehow representative of the future U.S. vehicle fleet. Other commenters selected a single power sector scenario with higher carbon emissions from among the scenarios in the ICCT/Bieker et al (2021) LCA study instead of showing the full range of results.

In some cases, these studies pose methodological issues, or scope issues, that make them of limited value for comparison with this final rule, e.g., not referencing and adhering to international standards for conducting LCA (e.g., the ISO 14040 and ISO 14044 Standards) or not using transparent, traceable life-cycle inventories of sufficient data quality (see "Guidance on Data Quality Assessment for Life Cycle Inventory Data", EPA/600/R-16/096 June 2016). Since this rulemaking occurs in the future, the use of prospective LCA is key to understanding life-cycle emissions impacts at future dates. Some analyses included power sector and other analytical tools that are wholly unsuited for prospective LCA use, for example, Graham's use of EPA's own eGRID model for modeling prospective secondary power sector LCI.

[642] Among other things, petroleum refining results in the generation of a number of hazardous wastes, listed as hazardous wastes K048-K052 under the regulations (40 CFR Part 261.32) implementing subtitle C of the Resource Conservation and Recovery Act.

Even relatively recent and fully ISO compliant studies may have shortcomings with respect to prospective LCA if they do not include sensitivity analyses sufficient to cover the full range of fast-changing inputs. For example, battery cathode chemistries for automotive applications are rapidly evolving and different chemistries predominate to meet differing conditions and priorities in different regions of the world. Energy policies and policies to address the growing climate crisis are also rapidly evolving. The geographic regions for extraction and processing of raw materials, component manufacturing, battery manufacturing, and whole vehicle manufacturing are also evolving as new legislation such the BIL and IRA are put into place. Stationary emissions regulations, especially U.S. electric power sector emissions regulations, have evolved significantly over the past decade. One example of a recent study that did not, and frankly could not, account for the full range and rapid pace of changes impacting key LCI used for LCA was the ANL/Kelly et al. 2022 study cited by the Alliance, API, Chevron, Growth Energy, MCGA, NCGA, NFU, POET, RFA and others. The study relied on EIA 2017 power sector forecasting, which is now significantly out of date but was still fairly recent at the time that the work for the study was underway. The power sector analysis thus did not take into account implementation of recent EPA EGU emissions regulations or newer regulations finalized since 2017 (for example, the Mercury and Air Toxics or "MATS" rule or the Good Neighbor Plan's FIP requirements) that significantly impact coal thermoelectric retirement. Thus the prospective LCI from the study would reflect criteria pollutant emissions exceeding EGU standards implemented under the CAA. The study was also published just after and immediately prior to the BIL and the IRA, respectively, and thus includes none of the power sector investment in clean technologies encompassed within those laws. One of the primary reasons that EPA continues to use the Integrated Planning Model for developing prospective power sector LCI is that it incorporates all final EPA CAA actions impacting the power sector and it is regularly updated to incorporate new legislation. For example, EPA's Power Sector Modeling Platform Post-IRA 2022 Reference Case included updates to incorporate impacts from both the BIL and IRA.

To address some of these shortcomings with respect to the preponderance of LCA data and what it may say regarding comparative and prospective LCA of BEV relative to other energy carriers, EPA commissioned Eastern Research Group, Incorporated, (ERG) to conduct a thorough and comprehensive review of recently published (2019-2023 publication dates) automotive life cycle assessments (LCA) focusing on attributional LCA of battery electric vehicles (BEV) and competing technologies that included internal combustion engine vehicles (ICEV) as well as other electrified vehicles such as hybrid electric vehicles (HEV), plug-in hybrid electric vehicles (PHEV), and fuel cell electric vehicles (FCEV).

In addition to a thorough review of the literature, ERG conducted a meta-analysis of available automotive LCA studies. The final report for the literature review and meta-analysis identified approximately 10,000 potentially relevant automotive LCA studies for review. Of these studies, 91 studies were identified by ERG as relevant for detailed review, with 74 studies further identified as meeting acceptance criteria of both peer review and full compliance with ISO LCA standards. Of those 74 ISO-compliant studies, 31 studies were further identified as having sufficiently consistent assumptions and context, and sufficient level of detail regarding LCI and other parameters to allow intra-study comparison. A total of 23 LCA studies within the intra-study comparison found GWP impacts that were lower for BEVs relative to ICEVs, while 5 studies found that BEVs were higher than ICEVs. Those 5 studies represented a portion of the BEV use cases in parts of Asia and Eastern Europe that employ electricity grid mixes predominantly reliant on coal and/or natural gas to generate power. Results for U.S.-based use cases all found BEVs to have a lower GWP relative to ICEV, with a minimum of 20 percent GWP reduction, a maximum of 65% GWP reduction, and a median of 37% GWP reduction for BEV impacts relative to ICEV. While the Agency's analysis of upstream and tailpipe emissions for the final rule does not constitute a full LCA, the reduction in GWP reported after 2040 for the final rule (see RIA Chapter 8.6) falls within the bounds of ISO-compliant comparative automotive LCA literature for BEV GWP reductions. The preponderance of ISO-compliant LCA literature is supportive of GHG reductions for BEV when the full life-cycle is taken into account.

It should be noted, however, that there remain serious limitations to the use of LCA for determining life-cycle emissions from passenger cars and trucks. EPA received many comments with statements like "EPA should just use GREET". GREET is a major LCA platform that is frequently used by EPA for fuels and other analyses. It is important to take into consideration, however, that GREET is a platform that still must be populated with valid LCI input data in order to construct a valid LCA for prospective and comparative purposes. LCI for many key processes for both electrified and conventional automotive component and whole vehicle manufacturing, including LCI for extractive, manufacturing, and critical material recycling, lacks sufficient transparency and data quality, and may not be relevant for differing geographic locations and thus differing resulting energy/power sector LCI.

ERG's final report outlined a number of significant LCI data gaps and provided a summary of recommendations necessary for valid comparative and prospective automotive LCA. Please refer to the ERG report for a complete summary of the literature review, meta-analysis of BEV and other automotive energy carriers, data gaps, and recommendations. It is important to note that one key set of data gaps identified by ERG and also identified by the Automotive Life Cycle Assessment Informal Working Group of the United Nations Economic Commission for Europe World Forum for Harmonization of Vehicle Regulations[643] is with respect to component manufacturing processes (in particular batteries, semiconductors, and levels of automation), vehicle manufacturing processes, and their respective LCI.

Summary:

EPA itself has used a lifecycle approach for light-duty electric vehicles, whereby emissions associated with the source of electricity are considered for compliance once there is a given volume of sales in a model year. EPA should not ignore those upstream emissions, since doing

[643] EPA currently represents the U.S. as a contracting party to the United Nations Economic Commission for Europe World Forum for Harmonization of Vehicle Regulations (UN ECE WP.29). Recognizing the limitations and shortcomings of automotive LCA with respect to comparative and prospective LCA of different energy carriers, the UN ECE WP.29 established the Automotive Life Cycle Assessment Informal Working Group (A-LCA IWG). The role established for the A-LCA IWG is to serve as an international forum to develop common methodology and accepted practices for comparative and prospective automotive LCA for policymakers, LCA practitioners, and other stakeholders. The A-LCA IWG is currently working towards preparation of an initial set of draft recommendations tentatively scheduled for UN ECE WP.29 review by the end of 2025.

so dilutes the rule's benefits and exaggerates the difference in emission impacts of ICE and BEV vehicles. Nor is the zero emission needed any longer as an incentive.

Response:

The commenter notes correctly that past light-duty vehicle rules included a provision capping the number of BEVs whose tailpipe emissions count as zero. EPA adopted the cap to balance the competing concerns of promoting highly promising (then) relatively new technologies with concerns about decreasing overall emission reductions associated with the program at a time when neither the IRA nor EPA regulations were in existence to reduce upstream emissions. 77 FR at 62817, 62818 (Oct. 15, 2012). However, EPA postponed the implementation of the cap before any manufacturer became subject to it and returned to "its historical practice of basing compliance with vehicle emissions standards on tailpipe emissions." 85 FR 24174, 25208. As proposed, EPA is finalizing provisions that would continue to base manufacturer compliance calculations for tailpipe standards on tailpipe emissions. See preamble III.C.7 and section 3.1.5 of this RTC. With respect to accounting for electricity production emissions, EPA does so in its analysis of emissions impacts. Moreover, as the commenter notes, GHG emissions associated with electricity generation are decreasing with the increased use of renewables. Such a decline was a key factor for EPA in deciding to return to basing compliance on actual tailpipe emissions in 2020, 85 FR 25208, and confirms the reasonableness of the approach currently as well. EPA reiterates its view expressed above, and in the 2021 rule, that the appropriate means of addressing those emissions is through the Act's stationary source provisions.

Summary:

Several commenters said a lifecycle standard-setting approach was important for protecting disadvantaged communities.

Response:

EPA notes that BEVs not only have zero tailpipe GHG emissions, but zero tailpipe emissions of all other pollutants. Their operation consequently has very significant benefits, including for disadvantaged communities. See generally section 9 of this for addressing issues of environmental justice. As described in preamble section VI and VII, EPA has undertaken an analysis of the upstream and downstream emission impacts of the final rule's standards, which were set consistent with EPA's historic approach to standard setting, and EPA considers that analysis of the net impacts as supportive of the final standards.

Summary:

NGV America cites undocumented conversations with unspecified agency staff which the commenter characterizes as EPA staff support for a lifecycle approach to GHG vehicular standard setting.

Response:

Given the absence of documentation of these contacts – indeed, not even a year when the purported conversations occurred -- it is impossible to assess the accuracy of the commenter's characterization of them. In any case, agency staff are not the agency decisionmaker. The EPA Administrator is. For the commenter to speak of a 'breached commitment' by the administration is consequently both incorrect and inappropriate. Furthermore, as discussed in other comment responses, EPA's views have evolved as circumstances (e.g., the RFS program, power sector emissions, and PEV market development) have developed and changed. EPA has fully explained the basis for its decisions.

Summary:

Some comments suggest that EPA ignores the upstream emissions of CO_2 from the increased electricity generation that would be needed to charge the projected fleet of EVs and that it is false and misleading to label EVs "zero-emission vehicles" when the production of EV batteries and the charging of the batteries over the life of the vehicles both generate emissions, including CO_2.

Response:

This comment is incorrect. While EPA uses the name "zero-emission vehicle" to reference vehicles with no tailpipe emissions by convention, EPA never asserts or models the vehicles as having no emissions attributed to their activity. In this rulemaking, EPA largely uses the term "BEV" to denote battery electric vehicles. EPA's emission impacts analysis includes EGU emissions resulting from the charging demand in Chapter 5 of the RIA.

Summary and Response:

KALA Consulting ("KALA") filed a late comment.

KALA criticizes EPA for referring to BEVs as "zero emission vehicles" when there are upstream emissions associated with fueling them. As noted in the previous response, EPA has accounted for upstream emissions associated with both electricity generation and petroleum refining and has monetized those reductions in assessing the phase 3 rule's costs and benefits. In this regard, we note that KALA states mistakenly that EPA failed to account for electricity transmission losses in its analysis (Comment p. 13). See RIA chapter 5 noting that the 2022 post-IRA version of the Integrated Planning Model accounts for both energy generation and transmission. KALA is also incorrect in asserting that EPA has failed to consider issues associated with time-of-day recharging (Comment p. 34). Assessment of time-of-day charging is in fact is a critical part of EPA's analysis of both emission impacts and costs of this rule. See RIA Chapter 5.1 (load profiles reflecting total daily demand from BEV charging for each vehicle type).

Like a number of other commenters, KALA believes the section 202(a) GHG emission standards (although not standards for criteria pollutants or toxics) should reflect upstream emissions along with tailpipe emissions. KALA would draw the line at upstream GHG emissions associated with electricity generation, and it would do the same for gasoline and diesel-fueled vehicles. Comment p.14. Among the bases for the commenter's suggestion is its assumption that EGU GHG emission profiles are unlikely to improve (Comment p.10), failing to account for the effect of the IRA or any of the other factors reflected in EPA's IPM modelling showing renewables becoming an increasingly large portion of the EGU power-generating energy source. See RIA Chapters 5.4. Nor does KALA discuss why its upstream analysis stops at the EGU or refinery. For example, there is no discussion of whether to consider methane emissions associated with petroleum extraction.

KALA acknowledges EPA's statement that the Clean Air Act clearly delineates between mobile and stationary sources, but disagrees with EPA's further statement that stationary source GHG emissions can be and are being controlled by EPA regulatory programs addressing stationary sources. We respectfully disagree. KALA also does also does not speak to any potential legal impediments to including stationary source emissions as part of a mobile source section 202(a) standard (e.g., "from any class … of new motor vehicle").

20 - Employment

Comments by Organizations

Organization: Alliance for Automotive Innovation

1. Consideration of Labor Costs in Battery Cost Projections

EPA uses default BatPaC model labor costs. Presumably those costs reflect global production of batteries today. Yet given the agency's assumption that all batteries in all electric vehicles sold in the United States will be domestically produced, it seems likely that default labor values currently hard coded into the BatPaC model would need some degree of reconsideration. Neither of these issues, nor other potential issues pertaining to default assumptions applied elsewhere in the model, are addressed, or even acknowledged by the agency in its proposal. [EPA-HQ-OAR-2022-0829-0701, p. 56]

Organization: American Free Enterprise Chamber of Commerce (AmFree) et al.

First, EPA asserts that the proposed rule will likely have a net positive employment effect within the automotive industry by 2032—and even its worst- case scenario projects only a few thousand job losses. See 88 Fed. Reg. at 29,392. But a wealth of contrary research in recent years shows that a shift to electric vehicles is likely to have a substantial negative effect on employment in key automotive-related sectors. For instance, the Economic Policy Institute es- timates that "a rise in BEVs to 50% of domestic auto sales by 2030 could see losses of roughly 75,000 jobs by 2030." Jim Barrett & Josh Bivens, The Stakes for Workers in How Policymakers Manage the Coming Shift to All-Electric Vehicles, Econ. Pol'y Inst. (Sept. 22, 2021). Likewise, a Princeton analysis estimates that jobs in the fossil-fuel industry may decline by 131,000 to 210,000 jobs by 2030 as a result of the move to electric vehicles. See Net-Zero America: State-Level Health, Employment, and Land Use Impacts (Oct. 2021). And the California Air Resources Board projects that by 2040, nearly 32,000 (13.8 percent of baseline employment) auto-mechanic jobs will be lost in that State alone. See Advanced Clean Cars II Proposed Amendments to the Low Emission, Zero Emission, and Associ- ated Vehicle Regulations: Standardized Regulatory Impact Assessment (Mar. 29, 2022). Although EPA acknowledges some of this research, see 88 Fed. Reg. at 29,390, it has made no effort to distinguish it or explain why it is wrong—and thus failed to justify its optimistic employment predictions. [EPA-HQ-OAR-2022-0829-0683, pp. 61-62]

Worse, many of the jobs that are created by the shift to electric vehicles likely will not be located in the United States. Virtually all of the dominant battery producers that will need to ramp up production, for instance, are in Asia. Daniel Kupper et al., Shifting Gears in Auto Manufacturing, Bos. Consulting Grp. (Sept. 28, 2020), https://tinyurl.com/5a9w33ph. As EPA concedes, the proposed rule could well result in domestic "job loss" if "the United States does not become a major producer" of electric-vehicle components like "batteries, electric motors, regenerative braking systems and semiconductors." 88 Fed. Reg. at 29,390. [EPA-HQ-OAR-2022-0829-0683, pp. 61-62]

Organization: American Freedom and America First Policy Institute (AFPI)

EV Manufacturing Requires Fewer Workers

EVs are technologically different from conventional vehicles. They are significantly more expensive than gas-powered vehicles because their batteries require costly minerals (Mills, 2022, pp.7-8; Frazin, 2022) (Link: https://thehill.com/policy/3607123-heres-why-many-electric-vehicles-are-so-expensive/). Nonetheless, EVs are mechanically less complex. Conventional vehicles have many interconnected moving parts that convert the energy from burning gasoline to motion while processing exhaust. These parts include catalytic converters, gears, clutches, and torque converters. None of these parts are needed in electric vehicles, which consist of relatively simple motors and a battery. Ernst and Young report that conventional vehicles have 2,000 moving parts in their powertrains, while Tesla EV drivetrains have only 17 (Canis, 2019, p. 2) (Link: https://sgp.fas.org/crs/misc/IF11101.pdf). [EPA-HQ-OAR-2022-0829-0699, pp. 3-4]

Consequently, EVs require fewer workers to assemble. Automakers like Ford and Volkswagen report that EV manufacturing requires 30% to 40% less labor than gasoline-powered vehicles (United Auto Workers, 2020, p. 13; Bushey, 2022) (Link: https://www.ft.com/content/8df00b42-4e3f-4a45-b665-2726720105e0). Moreover, parts suppliers—not final assembly plants—employ almost three-quarters of auto manufacturing workers.3 About one- quarter of those parts workers produce gasoline engines and parts or powertrain and transmission parts—jobs that would be largely eliminated by a shift to EVs (U.S. Bureau of Labor Statistics, 2021) (Link: https://www.bls.gov/cew/data.htm). [EPA-HQ-OAR-2022-0829-0699, pp. 3-4]

> 3 As shown in Table 1, data from the Bureau of Labor Statistics Quarterly Census of Employment and Wages shows that 219,000 employees worked in automobile and/or light-duty motor vehicle manufacturing facilities in 2021, while 539,000 workers were employed in motor vehicle part manufacturing facilities.

EV Mandates Will Eliminate Manufacturing Jobs

Auto industry analysts have accordingly noted that EV mandates will eliminate many existing auto manufacturing jobs. As Brett Smith, director of technology at the Center for Automotive Research, explained "[t]he industry is going through a transition unlike anything we've ever seen. There's a pretty strong chance that there will be fewer people building these cars, fewer people building the parts to these cars, and that will create challenges in some automotive communities" (Levin, 2022) (Link: https://www.yahoo.com/now/going-electric-could-cost-auto-105500604.html). [EPA-HQ-OAR-2022-0829-0699, pp. 3-4]

Analysts across the ideological spectrum project substantial job losses. In 2018, analysts projected EVs would account for about one-fifth of new U.S. vehicle sales by 2030 (International Energy Agency, 2018, p. 80; Cooper & Schefter, 2018, p. 2) (Link: https://www.edisonfoundation.net/-/media/Files/IEI/publications/IEI_EEI-EV-Forecast-Report_Nov2018.ashx). That year, the United Auto Workers (UAW) union estimated that the shift to electric vehicles would eliminate 35,000 of its members' jobs (Bogage, 2022) (Link: https://www.washingtonpost.com/business/2022/12/08/ev-union-gm/). That figure accounts for nearly 1 in 10 UAW members. [EPA-HQ-OAR-2022-0829-0699, pp. 3-4]

UAW research director Jennifer Kelly has publicly predicted that “[t]he workers who are making engines and transmissions today, their jobs will be eliminated when we make a transition to electric vehicles” (Beene & Coppola, 2018) (Link: https://www.ttnews.com/articles/electric-vehicles-seen-imperiling-us-jobs-uaw-says?itx%5bidio%5d=5856017&ito=792&itq=7d3aa1df-ab57-4b41-adf2-d079d9c1a42f). She warns that “electric, to me, is where the real risk is to our membership” (Dawson et al., 2019). [EPA-HQ-OAR-2022-0829-0699, pp. 3-4]

In 2021 President Biden set a target of EVs accounting for half of all new vehicle sales by 2030 (The White House, 2021) (Link: https://www.whitehouse.gov/briefing-room/statements-releases/2021/08/05/fact-sheet-president-biden-announces-steps-to-drive-american-leadership-forward-on-clean-cars-and-trucks/). The left-wing Economic Policy Institute (EPI) estimated that, without substantial government intervention, hitting this target would eliminate 75,000 auto manufacturing jobs (Barrett & Bivens, 2021) (Link: https://www.epi.org/publication/ev-policy-workers/). EPA’s even stricter proposed new mandate—two- thirds of all vehicles sold by 2032—would cost even more jobs. [EPA-HQ-OAR-2022-0829-0699, pp. 3-4]

Foreign analysts similarly project that EV mandates will eliminate many auto-related jobs overseas. For example, the European Union has advanced aggressive EV mandates. The European Association of Automotive Suppliers estimated that, by 2040, these measures will eliminate a net of 275,000 jobs in automotive suppliers (Sigal, 2021) (Link: https://europe.autonews.com/suppliers/ev-transition-could-cost-500000-jobs-supplier-group-says). Japanese analysts expect EVs to eliminate more than 80,000 auto-related jobs in their country by 2050 (Yamada & Abe, 2021) (Link: https://asia.nikkei.com/Business/Automobiles/EV-shift-puts-engine-jobs-on-chopping-block-in-Japan-and-Germany). [EPA-HQ-OAR-2022-0829-0699, pp. 3-4]

Great Lakes Region Will Be Particularly Affected

EV mandates will particularly affect the industrial Midwest. The tri-state region of Indiana, Michigan, and Ohio is the heartland of U.S. automobile production, particularly for gas-powered vehicles, transmissions, and related parts manufacturing. More than two-fifths of U.S.-built vehicles and three-fifths of U.S.- built transmissions are manufactured in these three states (Massachusetts Institute of Technology, 2022, p. 2) (Link: https://energyjustice.indiana.edu/doc/2022-the-roosevelt-project-industrial-heartland-case-study.pdf). These states account for 43% of U.S. autoworkers, including more than 70,000 workers who produce parts for motor vehicle powertrains, transmissions, or gasoline engines (U.S. Bureau of Labor Statistics, 2021) (Link: https://www.bls.gov/cew/data.htm). [EPA-HQ-OAR-2022-0829-0699, pp. 4-5]

Industry analysts have noted that an EV transition will be particularly painful to the Midwest (Massachusetts Institute of Technology, 2022, pp. 21-22) (Link: https://energyjustice.indiana.edu/doc/2022-the-roosevelt-project-industrial-heartland-case-study.pdf) . As Lawrence Burns, former vice president for research and development at General Motors, told reporters, “If you play this out in a five- to 10-year time frame, employment ramifications for states like Michigan and regions like southeast Michigan and northwest Ohio are really going to be a big deal" (Grzelewski, 2020) (Link: https://www.govtech.com/fs/transportation/in-the-shift-to-evs-some-worry-workers-could-suffer.html). [EPA-HQ-OAR-2022-0829-0699, pp. 4-5]

Table 1 shows motor vehicle manufacturing employment in the tristate area and in the U.S. as a whole, including both employees on primary assembly lines and employees in parts production. Michigan, Ohio, and Indiana have significantly more jobs—and thus economic disruption—at stake from EV mandates than any other region of the country. [See original comment for Table 1: Motor Vehicle Manufacturing Employment in Indiana, Michigan, Ohio, and the Entire United States (2021) [EPA-HQ-OAR-2022-0829-0699, pp. 4-5]

Estimated Job Losses

While EV mandates are widely expected to eliminate existing auto manufacturing jobs—especially in the Midwest—few public estimates are available for how EV mandates will affect individual states. EPA did not project the economic impact of its proposed rule on individual states or look at how it would affect Midwest manufacturing employment. To fill this gap, AFPI used data from the Bureau of Labor Statistics' Quarterly Census of Employment and Wages to model the net national auto manufacturing job losses from EV mandates. [EPA-HQ-OAR-2022-0829-0699, pp. 5-7]

Based on the automaker and UAW estimates discussed above, the model assumes EVs require 30% less labor to assemble than conventional vehicles. It also assumes that positions in gas engines and parts manufacturing facilities do not have a role in producing EVs and that four-fifths of positions involved in producing transmission and powertrain parts are similarly unnecessary for EV production. The methodological appendix explains the model in detail. [EPA-HQ-OAR-2022-0829-0699, pp. 5-7]

This model focuses only on auto manufacturing jobs; it does not estimate jobs created or lost in other sectors, such as car dealerships, vehicle maintenance facilities, or battery manufacturing.4 Workers cannot easily transition between these sectors because they generally involve different skill sets (St. John, 2022) (Link: https://www.businessinsider.com/automakers-jobs-desperate-workers-fuel-electric-vehicle-transition-batteries-2022-12). As a European industry association explained, battery manufacturing "typically requires more academically schooled workers and less vocationally trained workers than the production of transmission systems, fuel tanks or other powertrain components" (European Association of Automotive Suppliers, 2022) (Link: https://clepa.eu/mediaroom/5-key-questions-answered/). [EPA-HQ-OAR-2022-0829-0699, pp. 5-7]

4 The North American Industrial Classification System (NAICS) classifies battery manufacturing in a different industrial sector than it does auto manufacturing. NAICS code 336—transportation equipment manufacturing— encompasses motor vehicle and motor vehicle parts manufacturing. Battery manufacturing is covered under NAICS code 335—electrical equipment, appliance, and component manufacturing.

In 2022, electric vehicles accounted for 5.6% of U.S. motor vehicle sales (Mihalascu, 2023) (Link: https://insideevs.com/news/653395/evs-made-up-5point6-percent-of-overall-us-car-market-in-2022-driven-by-tesla/). Table 2 shows estimated net national auto-manufacturing job losses—in both final assembly and parts manufacturing—for different levels of EV growth.5 [See original comment for Table 2: U.S. Auto Manufacturing Job Losses if Electric Vehicle Market Share Rises] [EPA-HQ-OAR-2022-0829-0699, pp. 5-7]

5 The model does not show a strictly linear relationship between job losses and EV market share, i.e. job losses at 20% market share are not two-fifths of the job losses at 50% EV market share. This is because EVs currently account for about 6% of the U.S. market, and the model takes that into account.

These national projections track those of other analysts. If EVs increase to one-fifth of the U.S. market, the model projects, 27,000 net auto-manufacturing jobs will be lost. This closely tracks the UAW's 2018 estimate that EVs would eliminate 35,000 auto manufacturing jobs—at a time when analysts expected EV market share to increase to only 20% over the decade.6 [EPA-HQ-OAR-2022-0829-0699, pp. 5-7]

6 The discrepancy between the AFPI model and the UAW's 2018 estimates is explained by EV market share growth and auto manufacturing job losses between 2018 and 2022. In 2018, EVs accounted for only 2 percent of all vehicle sales (McDonald, 2019) (Link: https://cleantechnica.com/2019/01/12/us-ev-sales-surpass-2-for-2018-8-more-sales-charts/). If the model were specified using employment data from 2018 and estimating job losses from EV market share rising from 2% to 20%, it would project 35,100 jobs lost nationally—almost exactly the UAW estimate.

If EVs rise to half of U.S. vehicle sales—President Biden's original policy—the model estimates almost 85,000 net auto-manufacturing jobs will be lost. This is similar to EPI's estimated 75,000 manufacturing jobs lost at 50% EV market share. [EPA-HQ-OAR-2022-0829-0699, pp. 5-7]

The model also shows that EPA's proposed stricter EV mandate would cost tens of thousands more jobs than its original policy. If EV sales rose to two-thirds of the market—the proposed new requirement—then 117,000 net auto-manufacturing jobs would be eliminated. About two-thirds of those job losses would come from parts manufacturers. The remaining third would be in final assembly positions. Overall, the proposed rule would substantially reduce auto-manufacturing employment. [EPA-HQ-OAR-2022-0829-0699, pp. 5-7]

Job Losses by State

Previous studies do not provide state-specific estimates of EV-induced job losses. EPA also did not consider the regional employment impact of its proposed rule. Table 3 presents "best-case cenario" estimates of auto-manufacturing job losses by state if EVs rise to two-thirds of new vehicle sales. The model assumes that existing auto manufacturers would retain their market share through the EV transition and that they would build these EVs at their existing facilities instead of closing some plants and opening new facilities in different states. Under these optimistic assumptions, total job losses are driven only by the aggregate labor efficiencies in EV assembly and by the elimination of engine and powertrain part manufacturing positions. [EPA-HQ-OAR-2022-0829-0699, pp. 7-8]

Table 3 presents the nine states that, under this best-case scenario, would experience the greatest auto manufacturing job losses under EPA's proposed rule. These states collectively account for almost 84,000 of the 117,000 jobs lost nationally. The model shows that the proposed rule would impose significant economic costs on Michigan, Ohio, and Indiana. These three states bear the brunt of job losses, although several southern states would also see significant losses. [See original comment for Table 3: Auto Manufacturing Job Losses by State under a 67% EV Mandate] [EPA-HQ-OAR-2022-0829-0699, pp. 7-8]

Michigan is projected to experience the worst job losses, with 25,000 jobs lost. About 8,000 of those jobs would occur in final assembly, while about 17,000 would be in parts manufacturing. Indiana (-16,000) and Ohio (-14,000) would suffer the next worst losses. Tennessee (-7,000), South Carolina (-5,600), and Alabama (-5,200) would also experience large job losses. [EPA-HQ-OAR-2022-0829-0699, pp. 7-8]

However, the Midwest is likely to see even greater job losses than these best-case estimates project. EV mandates are likely to push auto manufacturing jobs out of the Midwest. Telsa dominates EV manufacturing, accounting for almost two-thirds of EVs sold in 2022. It is accordingly likely that Tesla will take considerable market share from the other automakers if the government forces them to switch to EVs. This would mean higher employment in Tesla's California, Texas, and forthcoming Nevada manufacturing facilities, but even lower employment in Michigan, Ohio, and Indiana. Similarly, many of the traditional auto manufacturers are building their EVs in new facilities outside the tri-state area. Ford Motor Co., for example, has announced plans to create a large assembly plant for electric trucks in Tennessee (Ford, 2021) (Link: https://media.ford.com/content/fordmedia/fna/us/en/news/2021/09/27/ford-to-lead-americas-shift-to-electric-vehicles.html.) This shift would mitigate job losses in Tennessee but would result in even worse job losses for Michigan. [EPA-HQ-OAR-2022-0829-0699, pp. 7-8]

EPA's proposed rule, which did not analyze or consider potential regional economic effects, would impose heavy economic costs on the Midwest. The rule would directly eliminate tens of thousands of blue-collar jobs in what is currently the epicenter of U.S. automobile manufacturing. Forcing consumers to switch to electric vehicles would eliminate the jobs of many workers who produce those vehicles. To the extent the proposed EV mandate spurs labor reallocation in vehicle manufacturing, Midwest job losses will be even greater. These job losses would devastate many communities in Michigan, Ohio, and Indiana. The EPA should reject this proposed rule for this reason. [EPA-HQ-OAR-2022-0829-0699, pp. 7-8]

Methodological Appendix

The America First Policy Institute (AFPI) used motor vehicle manufacturing employment data from the Bureau of Labor Statistics' Quarterly Census of Employment and Wages (QCEW) to estimate net job losses from EV adoption. The QCEW is based on records derived from unemployment payroll tax payments. It is highly reliable administrative data, but it is produced with a lag. QCEW data from 2021 is the most recent annual data available. AFPI collected both national and statewide QCEW employment data for 2021 from four industry subsectors [EPA-HQ-OAR-2022-0829-0699, pp. 9-11]:

- Automobile and light-duty motor vehicle manufacturing (NAICS code 33611); [EPA-HQ-OAR-2022-0829-0699, pp. 9-11]

- Motor Vehicle Parts Manufacturing (NAICS code 3363); [EPA-HQ-OAR-2022-0829-0699, pp. 9-11]

- Motor Vehicle Gasoline Engine and Engine Parts Manufacturing (NAICS code 336310); and [EPA-HQ-OAR-2022-0829-0699, pp. 9-11]

- Motor Vehicle Transmission and Power Train Parts Manufacturing (NAICS code 33635). [EPA-HQ-OAR-2022-0829-0699, pp. 9-11]

AFPI assumed the annual quantity of vehicles sold would remain constant throughout any transition to EVs. This is a somewhat strong assumption, as—even with substantial tax credits—EVs remain considerably more expensive than gas-powered vehicles. The average cost of vehicles consequently would rise considerably as EV market share increases, and higher prices reduce sales. To the extent that vehicle sales drop instead of remaining constant, the model will tend to underestimate job losses, as fewer workers would be needed to make fewer vehicles. [EPA-HQ-OAR-2022-0829-0699, pp. 9-11]

Assuming constant production and constant market share, the model assumes job losses at the national and state level would be proportional to the reduction in conventional vehicle sales. Automakers report that EVs require 30% to 40% less labor to assemble than conventional vehicles (United Auto Workers, 2020, p.13; Bushey, 2022) (Link: https://region1d.uaw.org/system/files/ev-white-paper-revised-january-2020-final.pdf) (Link: https://www.ft.com/content/8df00b42-4e3f-4a45-b665-2726720105e0). AFPI used the lower end of this range, estimating that the reduction of employment in automobile and light-duty motor vehicle manufacturing ("Motor Vehicle Assembly" in Tables 2 and 3) is proportional to 30% of the reduction in conventional vehicle sales. [EPA-HQ-OAR-2022-0829-0699, pp. 9-11]

This assumption implies that automakers would respond to the mandate by retooling their existing conventional vehicle assembly facilities to produce EVs, keeping the large majority of their current assembly workforces. This is an optimistic assumption. In reality, some facilities that assemble gas-powered vehicles are likely to close entirely, while new EV assembly facilities are likely to open. Those new EV facilities may not be in the same states as the conventional facilities, and they are unlikely to solely reemploy workers laid off from conventional vehicle production. Such shifts in domestic production have no impact on net national job loss estimates. [EPA-HQ-OAR-2022-0829-0699, pp. 9-11]

However, as discussed in the text, they mean the state job loss figures are a "best-case scenario" for the Midwest. In reality, production shifts would mean the Midwest would likely experience even greater job losses. [EPA-HQ-OAR-2022-0829-0699, pp. 9-11]

The model assumes that job losses for workers in motor vehicle gasoline engine and engine parts manufacturing would be fully proportional to decreases in conventional vehicle sales, i.e., none of these jobs would have a role in producing electric vehicles. The model further assumes that job losses in motor vehicle transmission and power train parts manufacturing would be proportional to 80% of the reduction in conventional vehicle sales, e.g., EV manufacturing would require 20% of current transmission and powertrain parts employees. This allows for the possibility that transmission and powertrain parts manufacturers will retool to provide parts for EV power trains, while recognizing that EV power trains are much simpler and require far fewer parts than gas-powered vehicles.7 [EPA-HQ-OAR-2022-0829-0699, pp. 9-11]

7 The UAW reports that an EV Chevy Bolt powertrain has 80% fewer moving parts than the gas-powered version, and predicted that design improvements would enable that figure to rise in the future (United Auto Workers, 2020, pp. 12-13) (Link: https://region1d.uaw.org/system/files/ev-white-paper-revised-january-2020-final.pdf).

The assumption that some current transmission and powertrain parts manufacturing employees will have a role in producing EVs is somewhat optimistic. As discussed above, the UAW's research director has predicted these jobs will be completely eliminated (Beene & Coppola, 2018) (Link: https://www.ttnews.com/articles/electric-vehicles-seen-imperiling-us-jobs-uaw-says?itx%5bidio%5d=5856017&ito=792&itq=7d3aa1df-ab57-4b41-adf2-d079d9c1a42f). If employment losses in transmission and powertrain parts manufacturing are fully proportional to the reduction in conventional vehicle sales, then job losses among powertrain and transmission parts manufacturing employees will be proportionately higher. [EPA-HQ-OAR-2022-0829-0699, pp. 9-11]

Using these assumptions, the model calculated employment losses from increased EV market share at both the state and national levels as follows. [EPA-HQ-OAR-2022-0829-0699, pp. 9-11]

The model first calculates the percentage decrease in conventional gas-powered vehicle sales implied by a given proportion of EV market share. For example, if EV market share rises from 5.6% (2022 levels) to 67% (the Biden Administration's proposed requirement for 2032), then the conventional vehicle market share will drop from 94.4% to 33%. This would be a 61.3 percentage point decrease in conventional vehicle market share, and—assuming vehicles sold remain constant—a 64.9% reduction in conventional vehicles sold (61.3 percentage point reduction in market share / 94.4% initial market share). [EPA-HQ-OAR-2022-0829-0699, pp. 9-11]

The model assumes that all employees in gasoline engine and parts manufacturing work on conventional vehicles. The model estimates job losses in this sector by multiplying the percentage reduction in conventional gas-powered vehicle sales by QCEW employment in that sector. [EPA-HQ-OAR-2022-0829-0699, pp. 9-11]

The number of positions involved in assembling conventional gas-powered vehicles is estimated by multiplying QCEW employment for all automobile and light-duty motor vehicle manufacturing by the 2022 conventional vehicle market share (94.4%), as well as an adjustment factor to account for the fact that EVs require less labor to assemble. The estimated number of positions involved in assembling conventional motor vehicles is then multiplied by the percentage reduction in conventional vehicle sales and the 30% labor efficiency factor to estimate total job losses in motor vehicle assembly. [EPA-HQ-OAR-2022-0829-0699, pp. 9-11]

The number of positions involved in manufacturing transmission and powertrain parts for conventional vehicles is estimated by multiplying QCEW employment for all transmission and powertrain parts by the 2022 conventional vehicle market share (94.6%), plus an adjustment factor to account for the 80% assumed reduced labor requirements for EV powertrains. The estimated number of positions involved in manufacturing conventional vehicle powertrains and transmission parts is then multiplied by the percentage reduction in conventional vehicle sales and the 80% labor efficiency factor to estimate total job losses in transmission and powertrain parts manufacturing. [EPA-HQ-OAR-2022-0829-0699, pp. 9-11]

As discussed in the text, the model assumes that existing automakers maintain their current market share through the transition to EVs. This optimistic assumption seems unlikely to actually materialize. Tesla currently dominates EV production, accounting for almost two-thirds of new EV sales in 2022 (Mihalascu, 2023) (Link: https://insideevs.com/news/653395/evs-made-up-5point6-percent-of-overall-us-car-market-in-2022-driven-by-tesla/). Tesla's U.S. factories are primarily located in California and Texas, with a new facility under construction in Nevada. If Tesla continues to maintain its dominant EV position, the market share of the Detroit-based automakers—General Motors, Ford, and Stellantis/Chrysler—will fall. As long as domestic manufacturers maintain their collective market share, changes in market share will not affect the net national job loss figures. However, such shifts would produce even larger job losses in Michigan and other Midwestern states than the model projects. [EPA-HQ-OAR-2022-0829-0699, pp. 9-11]

Organization: BlueGreen Alliance (BGA)

Climate change, economic injustice, and racial inequity are the most fundamental challenges we face today—and we know they're inextricably intertwined. In the transportation sector, which accounts for nearly 30% of U.S. greenhouse gas emissions, this intersection is visible in the disproportionate impact of transportation emissions on non-white communities.1 It's visible in the disparities in access to cleaner vehicles and other mobility options across income levels. And it's visible in the economic impacts of decades of disinvestment in auto manufacturing communities, which have seen good jobs offshored and anchor facilities shuttered due to ill-conceived policies that gutted the middle class. That's why it is critical that regulators, policymakers, and advocates coordinate standards, policies, investments, and infrastructure projects that engage and benefit all people—from the manufacturing workers who build the vehicles of the future, to the people who drive them, to the communities they drive through. Strong vehicle emissions standards—accompanied by policies to rebuild manufacturing, protect and create good family supporting jobs, and revitalize communities—are critical to achieving these aims. [EPA-HQ-OAR-2022-0829-0667, p. 1]

1 U.S. EPA, "Study finds exposure to air pollution higher for people of color regardless of region or income," September 2021. Available Online: https://www.epa.gov/sciencematters/study-finds-exposure-air-pollution-higher-people-color-regardless-region-or-income

Strong, technology-forcing vehicle standards are essential to meet climate goals, advance environmental justice, and create good jobs in the clean economy. The transportation sector is the single largest contributor to climate-warming greenhouse gas emissions in the U.S., and the local air pollutants emitted by vehicles, including particulate matter (PM), nitrous oxides (NOx), and volatile organic compounds (VOCs) have disproportionate impacts on low-income and non-white communities. Meanwhile, the supply chains for light- and medium-duty vehicles and the manufacturing jobs within them—are critical to the economic health and stability of auto manufacturing communities across the country (See Figure 1). [EPA-HQ-OAR-2022-0829-0667, p. 2]

SEE ORIGINAL COMMENT FOR Figure 1: Light- and Medium-Duty Vehicle Assemblers and Component Manufacturers. Light and Medium Duty Vehicle Manufacturing.

Source: BGA [EPA-HQ-OAR-2022-0829-0667, p. 2]Contrary to the repeated threats of certain industry stakeholders opposing regulation, strong vehicle emissions standards do not have to come at the cost of good auto manufacturing jobs. In fact, they can support U.S. competitiveness in the global auto market, which protects and creates jobs. BGA analysis on the impact of former rounds of light-duty vehicle emissions standards has found that when they are well-designed and supported by worker protections and investments, standards can generate high-quality jobs, and position the domestic auto industry as a leader in a competitive global market.2, 3 [EPA-HQ-OAR-2022-0829-0667, pp. 3-4]

2 BlueGreen Alliance, Supplying Ingenuity II, May 2017: Available Online: https://www.bluegreenalliance.org/resources/supplying-ingenuity-ii-u-s-suppliers-of-key-clean-fuel-efficient-vehicle-technologies/.

3 BlueGreen Alliance, Tech@Risk, August 2019. Available Online: https://www.bluegreenalliance.org/resources/techrisk-the-domestic-innovation-technology-deployment-m anufacturing-and-jobs-at-risk-in-stepping-away-from-global-leadership-on-clean-cars/.

A 2021 Economic Policy Institute (EPI) report conducted in collaboration with BGA, the United Auto Workers, the United Steelworkers, and the AFL-CIO modeled how different timelines and scenarios of light-duty electrification in the U.S. would impact auto manufacturing and supply chain jobs.4 The report found that over 150,000 new auto manufacturing and supply chain jobs could be created under the assumption of 50%new EV sales by 2030—a timeline that closely matches the EPA's preferred proposal (See Scenario 2 in Figure 2). However, such job gains are contingent upon a significant onshoring of the EV supply chain such that 1) the domestic content of EVs at least matches that of ICEs, and 2) there is a 10% increase in the share of U.S.-made vehicles sold in the U.S. auto market. A tech-forcing rule that drives electrification of some share of the vehicle fleet, coupled with investments to ensure that the vehicles and their components are made here, can be a major economic boon to communities across the country. [EPA-HQ-OAR-2022-0829-0667, pp. 3-4]

4 Economic Policy Institute, The stakes for workers in how policymakers manage the coming shift to all-electric vehicles, September 2021. Available Online: https://www.epi.org/publication/ev-policy-workers/.

SEE ORIGINAL COMMENT FOR Figure 2: Potential Auto Manufacturing Job Growth at EV Deployment Scenarios [EPA-HQ-OAR-2022-0829-0667, pp. 3-4]

Onshoring powertrain production and boosting domestic share of vehicles sold would lead to large job gains. [EPA-HQ-OAR-2022-0829-0667, pp. 3-4]

Change in the U.S. auto jobs under various BEV penetration scenarios, if U.S. EV powertrain component production matched ICE average and the share of domestically produced vehicles sold in the U.S. increase by 10 percentage points. [EPA-HQ-OAR-2022-0829-0667, pp. 3-4]

Source: Economic Policy Institute [EPA-HQ-OAR-2022-0829-0667, pp. 3-4]

The fact that EPA's proposed standards address both GHG emissions and local pollutant emissions clearly broadens the scope of auto manufacturing supply chain communities that stand to grow from increased demand for a range of efficiency and pollution reducing technologies. It is essential that automakers achieve gains along both axes. [EPA-HQ-OAR-2022-0829-0667, pp. 5-6]

EPA must consider how the transition to clean vehicles will impact manufacturing workers and the communities they live in. This should be an essential part of the comprehensive analysis that EPA conducts to project its proposals' economic impacts. The map in Figure 1 plots approximately 1,300 facilities manufacturing light- and medium-duty vehicles and their components. Of these facilities, approximately 225 manufacture ICE light- and medium-duty vehicles and their components, like engines and transmissions, fuel efficiency technologies, and tailpipe pollution reducing technologies. These facilities in the ICE supply chain, the nearly 900 facilities making "fuel agnostic" components for light- and medium-duty vehicles, and other as yet unbuilt ZEV manufacturing facilities may experience employment impacts as ZEVs become increasingly cost competitive compared to ICE vehicles. [EPA-HQ-OAR-2022-0829-0667, pp. 5-6]

EPA already develops its proposed standards based on sophisticated economic analyses that model the impact of the proposal on total fuel cost savings, vehicle maintenance savings, and health cost savings from improved health outcomes. EPA's economic analysis should also seek to project the economic and employment impacts of the shift to clean vehicles on auto manufacturing communities. For each of EPA's proposals and alternatives, this analysis should, at minimum, identify light- and medium-duty vehicle manufacturing communities (as in Figure 1), quantify the share of each community's economy that is supported by jobs associated with light- and medium-duty vehicle manufacturing, and quantify the number of jobs associated with that sector. EPA should collaborate with the U.S. Department of Labor and the U.S. Department of Energy (DOE) to conduct this analysis. EPA may consider structuring its analysis to identify communities that are particularly reliant on a domestic vehicle manufacturing supply chain, potentially identified as those with light- and medium-duty vehicle manufacturing "clusters"—or geographic areas where there are at least two manufacturing facilities within a 50-mile radius that are producing light- and medium-duty vehicles, or components for them. BGA collects detailed supply chain data that can support this analysis. [EPA-HQ-OAR-2022-0829-0667, pp. 6-7]

Considering and quantifying the employment opportunities and risks associated with each of EPA's proposals is essential to ensuring that the regulations advance equity along economic axes, as well as climate and public health ones. The domestic auto manufacturing sector has historically been characterized by a higher unionization rate, community-supporting wages and benefits, the provision of pathways to the middle class (particularly for people without a four-year college education), and strong representation of Black workers. Research from EPI finds that "Black workers account for 12.5% of workers economy wide, but 16.6% of workers in the auto sector, while workers without a four-year degree account for 62.2% of workers economy wide, but 74.6% in the auto sector."5 The auto manufacturing sector represents a critical path to the middle class for the very workers and communities that have disproportionately borne the brunt of neoliberal economic and trade policies. It is therefore essential that EPA leverage available data to project how its proposals will shape the domestic auto manufacturing sector, and the workers and communities that comprise it. Such analysis would also help inform stakeholders weighing in on the proposals by projecting tangible, on-the-ground, economic impacts of the transition to cleaner light- and medium-duty vehicles, rather than limiting the scope of the economic analysis to fleet owners and automakers. [EPA-HQ-OAR-2022-0829-0667, pp. 6-7]

5 Economic Policy Institute, The stakes for workers in how policymakers manage the coming shift to all-electric vehicles, September 2021. Available Online: https://www.epi.org/publication/ev-policy-workers/.

[EPA must hold automakers and industry stakeholders accountable to workers and communities in their pursuit of regulatory compliance. In particular, this means collecting data to ensure that standards do not exacerbate the offshoring of the automotive supply chain, or facilitate rent-seeking behavior from automakers seeking to reduce their regulatory burdens and labor costs. BGA research demonstrates the significant economic footprint that the light- and medium-duty auto manufacturing sector has in the United States. This footprint represents both an opportunity and a risk, depending on whether or not the United States emerges as a global leader in the manufacturing of clean vehicles during this critical transitional period. The past two decades have seen significant offshoring of the automotive supply chain to other countries in Asia, Europe, and North America, where automakers have benefitted from lower labor costs, looser environmental regulations, and favorable tax regimes. Between 1998 and 2019, employment in the manufacturing of motor vehicles and motor vehicle components fell by more than 20%.6 A part of a larger globalization trend, this shift not only gutted auto manufacturing communities in the United States, but it also allowed auto suppliers to establish supply chains in other countries, often with minimal labor protections and loose environmental standards.7 [EPA-HQ-OAR-2022-0829-0667, p. 7]

6 Economic Policy Institute, Botched policy responses to globalization have decimated manufacturing employment with often overlooked costs for Black, Brown, and other workers of color, January 2022. Available Online: https://www.epi.org/publication/botched-policy-responses-to-globalization/.

7 Strategic Management Journal, Offshoring pollution while offshoring production, March 2017. Available Online: https://onlinelibrary.wiley.com/doi/10.1002/smj.2656.

EPA recently published a Request for Information (RFI) targeting automakers manufacturing clean school buses receiving funding through the Clean School Bus Program.10 This optional RFI asks bus manufacturers to provide information about worker voice (whether employees are covered by a collective bargaining agreement, whether the company is committed to maintaining union neutrality, etc.), employee benefits, inclusive hiring practices, training and advancement programs, and community partnerships. Such an RFI can be a powerful tool through which EPA can solicit information about how manufacturers interact with their employees and their communities, and facilitate a "race-to-the-top" for the quality of auto manufacturing jobs in the United States. EPA should create a new RFI for automakers regulated by the proposed light- and medium-duty standards that builds upon the data collected by the Clean School Bus RFI to illuminate the quality of jobs currently supported by the light- and medium-duty manufacturing sector. The new RFI should, at minimum, seek detailed information about worker voice, employee wages and benefits, inclusive hiring practices, training and advancement programs, and community partnerships. In order to improve upon the Clean School Bus RFI, automakers should be prompted to provide granular information that not only reveals whether workers receive healthcare benefits, for example, but also the quality of those benefits.11 This RFI could also apply to vehicle battery manufacturers, fuel efficiency technology manufacturers, tailpipe pollution reducing technology manufacturers, and other advanced materials and components manufacturers in the automotive supply chain, which will play a significant role in automakers' ability to meet increasingly stringent emissions standards. [EPA-HQ-OAR-2022-0829-0667, p. 8]

11 EPA. Bus manufacturer job quality and workforce development practices, June 2023. Available Online: https://www.epa.gov/cleanschoolbus/bus-manufacturer-job-quality-and-workforce-development-practices

Ultimately, the transition to cleaner vehicles must function to raise the job quality and safety standards associated with all impacted workforces, including auto assembly workers, and supply chain workers. It is essential, but not enough, to create and protect auto manufacturing jobs in the United States. As increasingly stringent standards drive the transition to cleaner vehicles, we must also work to ensure that all jobs that will facilitate the transition are good, community-supporting jobs in safe and democratic work environments, where workers have the free and fair choice to join a union. The current landscape—wherein some new manufacturing jobs (especially in the battery sector) are low-paid contract roles in hazardous facilities, located in states where employers can evade union organizing—must be corrected.12 [EPA-HQ-OAR-2022-0829-0667, p. 9]

12 The Washington Post. "The unlikely center of America's EV battery revolution," April 2023. Available Online: https://www.washingtonpost.com/climate-environment/2023/04/17/georgia-evs-battery-belt/.

Deregulation, unfavorable trade policy, and the systematic undermining of labor laws have been chipping away at worker power in this country for decades. But as clean vehicle technologies continue to transform the auto industry—regulators, policymakers, advocates, and organizers have an important opportunity to determine what the jobs of tomorrow's auto industry will look like. EPA must leverage its regulatory power to set the industry on the right course, for the climate, for public health, and for workers. [EPA-HQ-OAR-2022-0829-0667, p. 9]

Organization: BorgWarner Inc.

BorgWarner is investing in our workforce and recommends increased public investment to upskill the U.S. talent pool to assist the industry's ZEV transition. [EPA-HQ-OAR-2022-0829-0640, pp. 7-8]

BorgWarner is committed to developing the workforce necessary to support our EV transition and a key facet of that strategy is evolving the skills of our existing talent. Our U.S. production facilities continue to invest in apprenticeships and technical workforce training. In addition, to support our industry-leading automotive engineers' transformation into cutting-edge teams responsible for developing our EV products, we created "Power to Evolve," a training program in partnership with leading universities in the U.S. and Europe. The program is designed to increase our talent's knowledge of, and skills for, electrical engineering by integrating hands-on skills required for productive work and learning modules on inverters, batteries, and motors. [EPA-HQ-OAR-2022-0829-0640, pp. 7-8]

For manufacturers and the broader industry, the need to train and certify workers is paramount. Similarly, for consumers, the lack of qualified BEV technicians is leading to increased costs for repairs, lengthy delays, and higher insurance premiums. These delays could have an impact on the decision-making process of future BEV purchasers who cannot afford to be without a vehicle for an extended period.7 [EPA-HQ-OAR-2022-0829-0640, pp. 7-8]

7 Tesla, insurers take different paths to deal with expensive repairs | Reuters

BorgWarner is also concerned about the shortage of certified automotive technicians trained to analyze and repair BEVs and EV charging stations. The National Institute for Automotive Service Excellence estimates that the U.S. currently has approximately 229,000 certified car technicians. Only about 3,100 (less than 1.4%) of these technicians, however, are certified to work on electric vehicles.8 [EPA-HQ-OAR-2022-0829-0640, pp. 7-8]

8 https://www.bostonglobe.com/2022/08/16/business/ev-sales-soar-its-back-school-car-techs/

We propose that EPA revisit how the lack of qualified technicians could impact the total cost of BEV ownership along with the maintenance and service needed to ensure reliable, consistent charging station operability as both could significantly impact consumer's purchasing decisions. [EPA-HQ-OAR-2022-0829-0640, pp. 7-8]

Organization: California Air Resources Board (CARB) (Part 1 of 5)

Beyond savings to individual consumers, the proposed standards, to the extent manufacturers use ZEVs to comply, present economic growth opportunities for many sectors in the United

States, especially auto manufacturing, electricity generation, and upstream ZEV supply chains as consumers direct more spending to ZEV technology and electricity for transportation fuel. Many manufacturers are already domestically producing ZEVs, providing tangible employment opportunities nationwide. 128 Provisions in the Inflation Reduction Act to support domestic production and materials sourcing will further shore up these benefits. [EPA-HQ-OAR-2022-0829-0780, pp. 65-66]

Even in the short time since U.S. EPA released its proposal, manufacturers have announced new investments in vehicle and battery manufacturing and assembly that will strengthen and expand the ZEV industry across the U.S. For example, Toyota announced that it will assemble its new battery electric sport utility vehicle at its Kentucky facility using batteries from a new battery plant in North Carolina. 129 General Motors and Samsung SDI are investing more than $3 billion to build a battery plan in Indiana, providing local jobs. 130 Hyundai Motor Group and LG Energy Solution announced that they will build a $4.3 billion electric battery plant in Georgia. 131 These are just a few examples of the tremendous economic opportunity this expanding industry can provide to support local jobs and build a resilient supply chain for ZEVs. [EPA-HQ-OAR-2022-0829-0780, pp. 65-66]

Complementary workforce development policies and programs to support job replacement in sectors that may see reduced demand can help ensure equitable participation in the clean technology economy. CARB commends the federal government for taking proactive steps to help support employment opportunities in clean technology sectors, particularly for workers impacted by anticipated reductions in fossil fuel industries associated with increased deployment of ZEV technology. 132 California has likewise recognized the need to support potentially displaced workers and is investing in workforce development strategies as an element of its pathway towards a zero-emission transportation system. For example, the California Workforce Development Board has identified several actions to help further development of robust and equitable ZEV industry in California. 133 CARB also notes an opportunity to support further workforce development and employment through its recommendation on ZEV assurance measures regarding serviceability. Enabling access to vehicle data increases the opportunity for independent repair shops to participate in the servicing and repair of ZEVs, ensuring these businesses benefit from increased ZEV deployment. [EPA-HQ-OAR-2022-0829-0780, pp. 65-66]

Organization: Clean Fuels Development Coalition et al.

- Elimination of American Jobs. EPA’s electrification goal would overhaul the American fuels industry, causing harm to both the petroleum industry and to those who, like commentors, help to supply clean and renewable fuels. Additionally, the proposal would reshape the American automobile industry, which “supports 10 million direct and indirect jobs” and “accounts for more than three percent of GDP.” See Comments of Securing America’s Future Energy (SAFE) on EPA’s Revised 2023 and Later Model Year Light-Duty Vehicle Greenhouse Gas Emissions Standards (Sept. 27, 2021), EPA-HQ-OAR-2021-0208-0527. [EPA-HQ-OAR-2022-0829-0712, p. 6]

Organization: Countymark

CountryMark is a small refiner that operates a small refinery in a rural area in Mt. Vernon, Indiana, with a capacity of 35,000 barrels per day (BPD). CountryMark is wholly owned by Countrymark Cooperative Holding Corp, a regional federated cooperative operating primarily in Indiana. CountryMark and its affiliates operate on a cooperative basis for the benefit of their members and patrons. Unlike most energy companies, CountryMark is completely American owned and controlled by its member local cooperatives. The member cooperatives are, in tum , owned and controlled by individual farmers within their trade territory. Over 100,000 farmers in Indiana, Illinois, Michigan, and Ohio participate in these local cooperatives. CountryMark's Board of Directors is comprised of farmers. Distributions of profit (if any) are distributed back to these farmers via the cooperative system, and these distributions remain in rural communities where the dollars support their local economies. [EPA-HQ-OAR-2022-0829-0665, pp. 1-2]

Although CountryMark is one of the smallest fuel refineries in the country, its local economic impact is significant, directly employing over 470 people whose wages and benefits exceed $40 million per year. Most of the Company's employees do not have college degrees but support their families and communities through well-paying jobs. CountryMark is the second largest employer in Mt. Vernon, a rural community of only about 6,500, and one of the five largest employers in Posey County, Indiana. The Company also partners with the local community onemergency response training, which includes funding fire schools for local firefighters, holding quarterly emergency response meetings, and hosting training exercises. [EPA-HQ-OAR-2022-0829-0665, pp. 1-2]

CountryMark is Indiana's only American-owned oil production, refining, and marketing company. The refinery uses 100% North American crude oil sourced predominantly from the Illinois Basin in southern Illinois, southwest Indiana, and western Kentucky. CountryMark supplies nearly 70% of the agricultural market fuels and 50% of school district fuels in Indiana. The Illinois Basin is a high-cost conventional oil basin abandoned by big oil companies decades ago that, due CountryMark's business, supports 20,000 well-paid industry workers and supplies royalties to over 40,000 landowners. CountryMark will spend over $500 million for crude oil in a typical year, most staying in the three-state area. [EPA-HQ-OAR-2022-0829-0665, pp. 1-2]

Organization: Daniel Hellebuyck

Costs and Job Losses: This "dartboard" approach to setting arbitrary standards like the one in this proposal does not take into account the enormous costs placed on automakers trying to reach the target. Companies- like Ford and General Motors- have tried to fund their EV ventures by laying off employees, sending American jobs to low-wage countries, and dramatically raising prices on ICE vehicles to pay for EVs that the market may not want or be ready for. Quality of ICE vehicles has suffered as car companies have shifted resources from quality control and design to development of EVs. [EPA-HQ-OAR-2022-0829-0526, p. 1]

Organization: Delek US Holdings, Inc.

VI. The Proposed Rule Fails to Holistically Consider Impacts Beyond the Automotive Industry

a. ZEV mandates will negatively affect domestic employment rates.

If EPA's Proposed Rule goes into effect, tens of thousands of high-paying, family- supporting jobs will be lost as refining capacity continues to decline. Indeed, EPA admits that its proposal may affect employment for firms providing fuels: "Reduced consumption of petroleum represents cost savings for purchasers of fuel, as well as a potential loss in value of output for the petroleum refining industry, fuel distributors, and gasoline stations, which could result in reduced employment in these sectors."38 But EPA also presumes that the Proposed Rule will not have a noticeable impact on aggregate net employment as labor will be reallocated from one product use to another and that the reduction in fuel consumption will be met through reduced petroleum imports rather than reductions in domestic production, shielding American jobs in the petroleum refining industry.39,40 Further, EPA's conjectural conclusions are made weaker by the Agency's failure to consider employment impacts in related sectors, including downstream businesses such as automotive dealerships and other small businesses like parts suppliers and auto mechanics.41 [EPA-HQ-OAR-2022-0829-0527, p. 8]

38 Id. at 29,393; DRIA at 4-59.

39 DRIA at 4-46–48 (citing external sources indicating that "although BEVs have fewer parts than their ICE counterparts, there is potential for job growth in electric vehicle component manufacturing, including batteries, electric motors, regenerative braking systems and semiconductors, and manufacturing those components in the US can lead to an increase in jobs… [but] if the US does not become a major producer for these components, there is risk of job loss.").

40 Id. at 4-59.

41 See, e.g., EDMUNDS, "Where Does the Car Dealer Make Money?" (June 13, 2019), available at https://www.edmunds.com/car-buying/where-does-the-car-dealer-make-money.html (automobile dealerships, for example, cannot recoup revenue or maintain employees by merely switching the types of vehicles it sells because parts and service accounts for 44% of revenue).

Organization: Environmental. and Public Health Organizations

H. EPA should expect significant employment opportunities associated with the installation and maintenance of charging infrastructure and related grid infrastructure.

Research conducted on behalf of EV Infrastructure Strike Force suggests that, if the Biden Administration's goal of deploying 500,000 EV charging stations is met with public fast charging stations, it will support about 30,000 job-years.355 [EPA-HQ-OAR-2022-0829-0759, p. 130]

355 Edward W. Carr, James J. Winebrake, and Samuel G. Winebrake, Workforce Projections to Support Battery Electric Vehicle Charging Infrastructure Installation, Energy and Environmental Research Associates, LLC (2021), https://etcommunity.org/assets/files/Workforce-ProjectionstoSupportBatteryElectricVehicleChargingInfrastructureIn stallation-Final202106082.pdf.

XXVIII. U.S. Employment in the Auto Sector is Likely to Increase as Electrification of the Vehicle Fleet Grows.

Finally, we turn to employment considerations. EPA is correct that the employment effects of environmental regulation "are difficult to disentangle from other economic changes (especially the state of the macroeconomy) and business decisions that affect employment, both over time and across regions and industries," 88 Fed. Reg. at 29390, and that there is some uncertainty in the data regarding specific job impacts of increased electrification, id. EPA notes that although BEVs have fewer parts than combustion vehicles, initial results of a vehicle tear-down study commissioned by the Agency and performed by FEV Consulting suggest that the labor hours needed to assemble BEVs and combustion vehicles are "very similar." 88 Fed. Reg. at 29392; DRIA at 2-57 to 2-58. The teardown study performed a side-by-side analysis of significant systems and subsystems to develop a projected cost model comparing a "relatively equivalent" BEV (2021 Volkswagen ID.4) and a combustion vehicle (2021 Volkswagen Tiguan). DRIA at 2-57.664 Although the full final results of EPA's commissioned study are not yet publicly available, the information provided in the docket indicates a well-designed peer-reviewed analysis that considered platform optimization, used an absolute costing approach, considered potential differences in incremental costs, and involved a detailed labor assessment for each component. Id. The docket includes detailed slides from FEV Consulting summarizing the preliminary cost results of the study, and EPA should further incorporate these and other relevant results from the FEV Consulting research into the Agency's support for the final rule.665 [EPA-HQ-OAR-2022-0829-0759, p. 201]

664 See also Michael Safoutin, Cost and Technology Evaluation, Conventional Powertrain Vehicle Compared to an Electrified Powertrain Vehicle, Same Vehicle Class and OEM, Memo to EPA Docket # EPA-HQ-OAR-2022-0829-0422 (Apr. 18, 2023).

665 See FEV Consulting, EPA FEV Cost and Technology Evaluation VW Tiguan and VW ID4, Attachment to Safoutin, Cost and Technology Evaluation, Memo to EPA Docket # EPA-HQ-OAR-2022-0829-0422 (Apr. 18, 2023).

EPA's DRIA notes two additional older teardown studies that the Agency considered in its analysis—a 2017 UBS teardown of the Chevy Bolt EV, and a 2017–2018 teardown study of several EV components performed for CARB—neither of which was as comprehensive or comparative as EPA's project with FEV Consulting, and neither of which specifically looked at total labor hours.666 See DRIA at 2–58. At least one other recent teardown study has considered labor hours and come to a conclusion similar to FEV Consulting's analysis—that "very similar" labor hours are needed between BEVs and combustion vehicles—finding that BEVs require 99% of the total labor hours per vehicle compared to combustion vehicles, primarily due to battery cell manufacturing, and PHEVs require more labor than combustion vehicles.667 As automakers have already begun taking significant steps toward on-shoring battery manufacturing and the rest of the PEV supply chain, supported by the significant funding incentives for domestic manufacturing in the BIL and IRA, the United States is well-positioned to capture battery-related and other PEV manufacturing jobs as the PEV sector grows. The positive impact on employment from this increase in vertical integration is illustrated in preliminary results from the Agency's FEV Consulting study, which finds nearly a 50% increase in labor hours in BEV compared to combustion engine manufacturing for a highly vertically integrated manufacturer.668 [EPA-HQ-OAR-2022-0829-0759, pp. 201-202]

666 The UBS project was an EV teardown only, and UBS did not conduct a side-by-side comparison with a similar combustion vehicle, and the CARB project involved only specific components from strong hybrids and plug-in hybrids, which have cost profiles very different from BEVs.

667 Daniel Kupper et al., Shifting Gears in Auto Manufacturing, Boston Consulting Group (Sept. 28, 2020), https://www.bcg.com/publications/2020/transformative-impact-of-electric-vehicles-on-auto-manufacturing.

668 FEV Consulting, Assembly Times Comparison Draft Report, EPA-HQ-OAR-2022-0829-0460, Slide 28 (May 9, 2023).

EPA cites reports by the Economic Policy Institute, Seattle Jobs Initiative, and Climate Nexus, all of which found that total U.S. employment in the auto sector could increase with electrification, in particular if the share of vehicles sold in the United States that are produced in the United States increases. 88 Fed. Reg. at 29390–92. In fact, Congress has recognized the benefits of ensuring that large shares of vehicles sold in the United States are produced in the United States. Through the on-shoring incentives in recent legislation, particularly the IRA, Congress has encouraged substantial growth in the domestic ZEV manufacturing and supply chain and has indicated congressional support for increasing numbers of ZEVs in the light-duty fleet in order to meet the nation's climate goals. These IRA incentives are having their intended effects of encouraging development of the domestic ZEV supply chain. As EPA notes, reports by the BlueGreen Alliance and the Political Economy Research Institute estimate that the IRA will create over 9 million jobs over the next decade, with about 400,000 attributed directly to the battery and fuel cell provisions. 88 Fed. Reg. at 29390–91. [EPA-HQ-OAR-2022-0829-0759, p. 202]

Other analyses have found similar positive employment impacts. A University of Massachusetts study of job creation resulting from the IRA found that the IRA's programs, including the law's transportation-sector funding programs that encourage ZEV development, could lead to overall job creation.669 The analysis estimated significant job increases in the transportation, electricity, and manufacturing sectors, both annually and in total job-years.670 Analysis of the IRA and BIL by the Boston Consulting Group found that the two laws would increase new U.S. ZEV industry jobs through 2030 from about 455,000 to about 680,000, "primarily due to domestic manufacturing incentives."671 And, supporting this post-IRA upward trend, EDF recently found that "46,400 announced jobs, representing approximately 32% of all EV job announcements, have occurred in the last 6 months since the passage of the IRA."672 [EPA-HQ-OAR-2022-0829-0759, p. 202]

669 Robert Pollin et al., Job Creation Estimates Through Proposed Inflation Reduction Act, University of Massachusetts Amherst Political Economy Research Institute 10-13 (Aug. 4, 2022), https://peri.umass.edu/publication/item/1633-job-creation-estimates-through-proposed-inflation-reduction-act.

670 Id. at 3, 13 (estimating 447,472 additional job-years in relevant transportation jobs due to IRA, along with 31,510 additional job-years due to IRA's EV manufacturing grants under Section 50143 and 114,592 additional job-years due to IRA's clean manufacturing investment tax credit under Section 13501).

Other analyses in addition to those cited by EPA also have concluded that more stringent GHG standards can lead to positive job impacts. For example, several state-level analyses conducted by ERM using the Impact Analysis for Planning (IMPLAN) model found that state adoption of clean car standards would result in net job increases, assuming that incremental spending on PEV batteries and electric drivetrain components would be in the United States.673 Moreover, each of these analyses found that the jobs created would be high-quality, high-paying jobs, with average wages for the new jobs between 33% and 100% higher than average wages for the jobs being replaced.674 Similarly, a state-level analysis conducted by the World Resources Institute (WRI) on increased PEV penetration in Michigan found that the state "stands to gain tens of thousands of high-quality jobs," if it "seize[s] the opportunities" of the PEV sector.675 Because PEVs are cheaper to drive, the analysis found that "[s]witching to EVs will allow drivers to save money on vehicle purchases, maintenance, and gasoline, which will improve household finances and have positive employment impacts" as consumers spend their extra money throughout the rest of the economy.676 Analysis on the nationwide impacts of California's clean car policies also projects significant overall job gains resulting from increased production of ZEVs—with over 7.3 million full-time equivalent job-years of employment created through 2045.677 Another nationwide study found that, compared to a "no new policy" scenario, a scenario with high levels of ZEVs would result in a peak of over 2 million jobs created in 2035, even without accounting for the impact of any additional on-shoring incentives such as those in the IRA.678 [EPA-HQ-OAR-2022-0829-0759, p. 203]

These new clean vehicle jobs are also poised to have positive environmental justice impacts as they bring significant new jobs to communities of color. Research by Climate Power has found that "[a] majority of new clean energy jobs and projects [resulting from IRA investments] are located in communities of color across America," with Arizona, Georgia, South Carolina, Nevada, and Michigan home to the largest number.679 Climate Power's report details numerous gigafactories, cathode manufacturing facilities, and ZEV factories that will bring jobs to communities of color nationwide. For example, Kore Power Gigafactory will bring 6,400 jobs to Arizona, in two counties that are 46.6% and 32% Hispanic/Latino, and Scout Motors will open an EV plant in South Carolina, bringing 4,000 jobs to two counties that are between 40% and 50% Black/African American.680 Climate Power's Clean Energy Jobs Tracker provides detailed data on new clean energy jobs since the passage of the IRA, showing large job growth in numerous states related to battery and ZEV manufacturing.681 [EPA-HQ-OAR-2022-0829-0759, p. 204]

While certain employment sectors may be impacted over time by increased electrification, as EPA notes, 88 Fed. Reg. at 29392, we agree that this will "happen over a longer time span due to the nature of fleet turnover," see Table XVII.G-1 (L/MD PEVs as a Share of Total On-Road L/MD Fleet, 2020–2040), supra, with time to retrain workers for better, higher paying jobs, 88 Fed. Reg. at 29392. A World Resources Institute study considering Michigan's automotive industry noted that many new ZEV-sector jobs will require skill development, with opportunities to "re-skill, upskill, or shift to jobs of equal or greater quality," and that much of this "could be addressed as part of normal rates of retirement, given that 52% of all current auto manufacturing workers in Michigan will reach age 65 by 2040."682 Moreover, programs have already been implemented to train workers with the skills they will need for jobs within ZEV manufacturing. California's Energy Commission, for example, created the state's Clean Transportation Program to "invest[] in manufacturing and workforce training and development, working with a variety of public and private partners."683 Electric bus company Proterra and community colleges in California joined together to provide a nine-week training program to become electric bus manufacturing technicians, which workers have already used to transition from lower-paying restaurant jobs, for example, to higher-paying union jobs at Proterra.684 General Motors launched the Automotive Manufacturing Electrical College (AMEC) "to train current and future employees to work on evolving electrical systems in future GM vehicles."685 States are also funding training for ZEV-related jobs.686 [EPA-HQ-OAR-2022-0829-0759, p. 204]

Organization: Environmental Defense Fund (EDF) (1of 2)

B. Protective standards will help to grow American jobs.

In addition to delivering significant health and environmental benefits, protective standards that help to ensure additional ZEV deployment will also bolster the economy and grow U.S. jobs. The U.S. is currently making historic investments in electric vehicle manufacturing and domestic job creation, both of which have been catalyzed by the IRA and BIL. According to a report by Environmental Defense Fund and WSP USA, more than $120 billion in EV manufacturing investments and 143,000 new U.S. jobs have been announced in the last eight years, with more than 40 percent of those announcements happening in the last six months, since passage of the IRA (Figure 1).5 Over $31 billion of those announced investments has been toward the manufacturing of electric passenger cars and trucks, providing over 55,000 new jobs and $65.3 billion in investment supporting over 60,000 jobs in battery manufacturing. Protective EPA standards that drive additional electrification of the transportation sector can help support and accelerate these important trends, promoting continued investment in zero-emitting vehicles, batteries and components and associated America jobs. [EPA-HQ-OAR-2022-0829-0786, pp. 7-8]

Source: WSP, U.S. Electric Vehicle Manufacturing Investments and Jobs [EPA-HQ-OAR-2022-0829-0786, pp. 7-8]

In addition to these sector-wide trends, EDF also commissioned a study by M.J. Bradley & Associates in 2021 that focused on the broader economic and employment effects associated with the production of electric F-Series light trucks, including the Ford F-150 Lightning, as a case study for the broader electric vehicle manufacturing sector within the U.S.6 The report shows that EV manufacturing in the U.S. has the potential to support significant positive job and GDP impacts. Specifically, the analysis, which was conducted prior to passage of the IRA, finds that a single direct job associated with the production of electric F-Series vehicles could support 13 to 14 jobs in the wider U.S. economy. And every 1,000 such direct electric F-Series production-related jobs would support $1 billion in direct, indirect, and induced labor income benefits and $1.6 billion in U.S. GDP. The results show that a plant supporting 3,300 jobs7 could result in 44,000 jobs in the wider economy, providing $319 million in direct income and over $3.2 billion in direct, indirect, and induced labor income benefits. [EPA-HQ-OAR-2022-0829-0786, pp. 7-8]

7 Ford announcements suggest that its new EV plant in Tennessee would support between 3,200 and 3,300 direct jobs.

Organization: HF Sinclair Corporation

As discussed in further detail below, the Proposed Rule will have significant impacts beyond the traditional automotive market. It will eliminate American jobs in the refining sector, which directly employs more than 100,000 individuals across the United States – it is also widely accepted that every refinery job is a job multiplier of ten. It will significantly strain the electric grid, requiring utilities to rapidly increase generation, transmission, and distribution capacity to a degree not fully contemplated by EPA. [EPA-HQ-OAR-2022-0829-0579, pp. 3-4]

h. The EPA Fails to Properly Consider Employment Impacts

The Proposed Rule fails to appreciate the employment impacts, including those on lower income consumer that will result from rapid electrification. First and foremost, any mandate to replace conventional ICE vehicles with PEVs will have a direct impact on the 890,000 gas station employees around the country.83 A mandate will also have an impact on the 113,000 employees supporting the transportation fuels industry upstream of the pump as well as the many industries tangentially related to the production of ICE vehicles, including motor vehicle parts, automobile dealers, repair and maintenance services, and parts manufacturers.84 [EPA-HQ-OAR-2022-0829-0579, p. 17]

83 CEA Study at 12.

84 Id.

While EPA does mention employment impacts in the Proposed Rule, EPA cannot simply assume that because the U.S. economy is at full employment, the regulation “is unlikely to have a noticeable impact on aggregate net employment" as labor will be reallocated from one productive use to another.85 Even if true on a macro scale, "transitory" impacts of affected industries will be significant as there will not be a one-for-one job replacement – especially if jobs in the domestic transportation fuels industry are replaced with those in battery processing operations, which are largely conducted overseas. It cannot be assumed that trained workers in one field will be able to move to another (both physically and through re-training). Instead, EPA must consider the wholesale changes to the workforce that will come from mass adoption of PEVs. Entire industries may be eliminated, such as emission inspection services, third-party dealer networks, and aftermarket product tuning.86 EPA must fully address how the Proposed Rule will redefine the vast U.S. labor pool supporting the automotive industry. [EPA-HQ-OAR-2022-0829-0579, p. 17]

85 Proposed Rule at 29,390.

86 The Week, "How Tesla's direct sales model is roiling the car dealership industry," (June 21, 223 available at https://theweek.com/us/1024416/tesla-vs-car-dealerships (reporting on PEV manufacturer direct-sales allowances that bypass franchise dealer networks).

Organization: International Council on Clean Transportation (ICCT)

The shift to cleaner cars and trucks can strengthen domestic manufacturing and supply chains, increase industrial competitiveness, and create good-paying jobs.30 Research about the U.S. job potential from electric vehicle manufacturing finds that transitioning 50% of sales to battery electric vehicles (BEVs) can lead to 150,000 net job creation in the auto sector, including auto parts and auto assembly, if coupled with an increase in domestic content for vehicles sold in the U.S., and market share growth for U.S. made vehicles.31 The growth in electric vehicle charging infrastructure can also lead to domestic job creation. Research quantifying the number of jobs associated with EV infrastructure from assembly, deployment, and maintenance appears limited. Draft work by the ICCT is underway that quantifies the number of jobs needed to support this rapidly growing infrastructure network. [EPA-HQ-OAR-2022-0829-0569, pp. 11-12]

30 The White House (2023b). Fact sheet: Biden-Harris Administration announces new private and public sector investments for affordable electric vehicles. https://www.whitehouse.gov/briefing-room/statements-releases/2023/04/17/fact-sheet-biden-harris-administration-announces-new-private-and-public-sector-investments- for-affordable-electric-vehicles/; Naimoli, S., Kodjak, D., German, J., and Schultz, J. (2017, May 23). International competitiveness and the auto industry: what's the role of motor vehicle emission standards? International Council on Clean Transportation. https://theicct.org/publication/international-competitiveness-and-the-auto-industry-whats- the-role-of-motor-vehicle-emission-standards/

31 Barrett, J., and Bivens, J. (2021, September 22). The stakes for workers in how policymakers manage the coming shift to all-electric vehicles. Economic Policy Institute. https://www.epi.org/publication/ev-policy-workers/

Table 1 shows the draft results of the number of infrastructure-related jobs created from the charging infrastructure sector in 2035: more than 183,000. The light-duty vehicle EV infrastructure industry would generate in total close to 160,000 jobs that involve the public, workplace, and home charging infrastructure assembly, deployment, and maintenance, and the MDHV EV infrastructure industry will generate close to 23,700 jobs. Around 36% of these jobs come from electrical work, followed by 29% from assembly, 17% from maintenance, 10% from planning and design, 6% from general labor, and 3% from administration and legal. These jobs would further support supply chain jobs in assembly components and materials for EV charging equipment, which are not included in our estimates but can be significant, especially with increase in domestic production. [EPA-HQ-OAR-2022-0829-0569, pp. 11-12]

SEE ORIGINAL COMMENT FOR Table 1. Estimate of light-duty and medium- and heavy duty vehicle charging infrastructure- related jobs in 2035 [EPA-HQ-OAR-2022-0829-0569, pp. 11-12]

The number of chargers needed for light-duty vehicles and the associated findings for U.S. job growth potential are based on an analysis of charging needs based on achieving Biden administration's goal of 50% EV sales by 2030, which is assumed to increase to 80% sales by 2035. For MHDV, the model a scenario where EV sales achieve 30% for tractor truck, 50% for buses and rigid truck by 2030, and 100% for all segments in 2040, which builds on the manufacturers' ambitions and existing legislation in California and several other states.32 The analysis is being updated based on the projections in EPA's new multi-pollutant standards proposal. Because the EPA proposal estimates that 60% of new light-duty vehicle sales would be battery electric by 2030 and 67% by 2032 – greater than Biden's 50% by 2030 target – updating our analysis for increased BEV penetration would increase the number of chargers needed and thus increase the estimates of the number of jobs in this industry through 2035 compared to what is shown in Table 1. [EPA-HQ-OAR-2022-0829-0569, pp. 11-12]

32 International Council on Clean Transportation. (2022a). ICCT comments on EPA proposed HDV rule. https://theicct.org/comments-epa-proposed-hdv-rule-may22/

Organization: International Union, United Automobile, Aerospace and Agricultural Implement Workers of America (UAW)

Short Summary

The UAW fully supports the transition to a cleaner auto industry, and it must be done in a way that protects both good union jobs and the environment. We urge the EPA to reach a consensus-based standard for light- and medium-duty greenhouse gas emissions that avoids allowing the burden of compliance to fall heaviest on the workers who currently build ICE vehicles and those who will build ZEVs in the future. [EPA-HQ-OAR-2022-0829-0614, p. 1]

Regulations that push the industry to adopt cleaner technologies are important to creating a strong domestic union manufacturing base. We also know that the US auto industry does not have a perfect track record in keeping up with consumer interest. In the 1980s, we saw the decimation of US auto market share and with it of good union auto jobs in this country, in part due to the companies' misjudging the consumer market and failing to adapt. We cannot allow this pattern to repeat in the 21st century in case the existing US automakers fail to keep up with rising EV demand, further sacrificing market share to foreign, non-union, and low-road employers. There is a risk of US automakers focusing on short-term profit while non-union employers capture future generations of market share, with disastrous outcomes for the industry labor standards and union workers. [EPA-HQ-OAR-2022-0829-0614, p. 1]

However, we are also concerned the proposed standards do not adequately address the projected impact on an industry that balances ICE jobs with the quality of new EV jobs. Nor does it properly account for the role that the sale of ICE vehicles will play in the transition or the availability of charging infrastructure. The EPA must involve stakeholders to reach a mutual agreement. [EPA-HQ-OAR-2022-0829-0614, p. 1]

Discussion

I. Direct Impact on UAW Members

The auto industry is reaching a key inflection point with the rise of electrification. Policies and investment decisions made in the next few years will re-shape the industry for decades. There is an opportunity to get this transition right for workers and the environment. That means avoiding the mistakes of the past, adopting a strategy that reverses decades of off-shoring and declining unionization in the industry and ensuring the domestic auto industry keeps pace on the latest clean technologies. The UAW is leading the transition to a cleaner and greener auto industry. UAW members are building light, medium, and heavy- duty electric vehicles (EVs), batteries, and the next generation of efficient and zero-emission vehicles. We are also doing our part to ensure the EV transition is a just transition, organizing the country's first union battery cell manufacturing plant, securing neutrality agreements with firms along the EV supply chain, and negotiating investment commitments for the production of EVs and components in our collective bargaining agreements. Over 1 million people work in motor vehicle parts and manufacturing.2 While auto industry profitability has reached record highs in recent years, autoworker wages have not kept pace. Since 2000, inflation adjusted wages have declined by 25% in motor vehicle manufacturing and by 19% in motor vehicle parts manufacturing.3 [EPA-HQ-OAR-2022-0829-0614, p. 2]

2 See Bureau of Labor Statistics. Automotive Industry: Employment, Earnings, and Hours. Retrieved from: https://www.bls.gov/iag/tgs/iagauto.htm.

3 See Bureau of Labor Statistics. Average hourly earnings of production and nonsupervisory employees, motor vehicle parts manufacturing, not seasonally adjusted and Average hourly earnings of production and nonsupervisory employees, motor vehicle manufacturing, not seasonally adjusted. January 2000 to February 2023 wages adjusted usings Bureau of Labor Statistics CPI Inflation Calculator.

The standards must create economic security for workers in the industry, include safeguards that strengthen the domestic manufacturing supply chain, and require the EV transition to provide the same level of investment and quality jobs as the current ICE footprint, otherwise we will fail to build the popular support necessary to sustain policies for the EV transition and the continued competitive position of the U.S. auto industry. [EPA-HQ-OAR-2022-0829-0614, p. 2]

Despite planning to invest over a trillion dollars globally in electric vehicle production,4 major auto companies seek to use the transition to cleaner vehicles in order to roll back hard-fought gains, including by shuttering and offshoring manufacturing facilities, cutting wages, and fighting attempts to include new facilities under existing collective bargaining agreements. We cannot allow the transition to electric vehicles to continue the erosion of job quality in the auto industry. Yet, initial trends are quite troubling. As the White House notes in its report on domestic supply chains, "the automotive battery plants that are in existence or are advertising for production workers pay much less than existing powertrain plants, in the range of $17-21 per hour [emphasis added]."5 The realized and potential closure of Ford's Romeo Engine Plant, Stellantis's Belvidere Assembly Plant, and General Motors' Lordstown Assembly Plant demonstrate the risk facing autoworkers and our economy if business as usual is allowed to continue. Research indicates that by 2030 the domestic auto industry could add or lose jobs depending on whether EV assembly and parts production is expanded and onshored.6 [EPA-HQ-OAR-2022-0829-0614, pp. 2-3]

4 See Paul Lienert, Reuters, Exclusive: Automakers to Double Spending on EVs, Batteries to $1.2 Trillion by 2030 (Oct. 25, 2022).

5 See The White House. Building Resilient Supply Chains, Revitalizing American Manufacturing, and Fostering Broad-Based Growth (June 2021) at 120.

6 See Jim Barrett and Josh Bivens, Economic Policy Institute, The Stakes for Workers in How Policymakers Manage the Coming Shift to All-Electric Vehicles (Sept. 21, 2022) at 11.

"If policymakers ignore the opportunity to build the [auto] sector back stronger, large job losses and further degradation of job quality is the most likely outcome. If instead policymakers help meet this coming transformation with strong investment targeted at boosting the U.S. position in the electric vehicle market and in advanced vehicle technology manufacturing, and if these investments are accompanied by measures aimed at strengthening bargaining power for workers, then employment will expand in the U.S. auto sector and the number of unionized jobs will grow."7 [EPA-HQ-OAR-2022-0829-0614, pp. 2-3]

7 Id. at 15.

The UAW demands that the electric vehicle transition be a just transition, which prioritizes the creation and preservation of good union jobs, internal combustion engine (ICE)-comparable or better wages, collective bargaining, and the reshoring of vehicle and parts production. [EPA-HQ-OAR-2022-0829-0614, pp. 3-4]

UAW members work at 26 light-duty vehicle final assembly plants in 8 states building vehicles for a wide variety of applications – from sports cars to work pickups. Additionally, the UAW represents auto parts workers throughout the country making engines, transmissions, stampings, axles, drivelines, seats, interiors, and various other components. The shift to EVs presents a challenge to the employment of workers currently making ICE engines, transmissions, exhaust systems, and fuel systems. Tens of thousands of UAW members have high quality union jobs producing such components. If an increasing number of vehicles do not require these components, it could have a negative impact on employment levels at plants making these components. Employers must commit to re-tool plants and re-train workers to maintain employment levels and allow American workers to make advanced technology vehicles. The DOE should support reinvestment in these workforces and plants. Such support should be conditioned on employers maintaining employment levels, job quality standards, and freedom of association. [EPA-HQ-OAR-2022-0829-0614, pp. 3-4]

13. Thomas Built Bus Saf-T-Liner C2 Jouley – BEV School Bus (High Point, NC)

14. IC Bus Electric CE – BEV School Bus (Tulsa, OK)

15. Mack LR – BEV Refuse Truck (Macungie, PA)

16. Volvo Truck VNR – BEV Class 8 Truck (Dublin, VA) [EPA-HQ-OAR-2022-0829-0614, pp. 4-5]

UAW members are also fighting to raise the standards in the emerging domestic EV battery cell industry. Workers at Ultium Cells' battery cell plant in Lordstown, OH, voted overwhelmingly to join the UAW by a vote of 710 to 16.8 The vote by Ultium workers sent a message that is loud and clear – the EV future must be powered by batteries that are union-made and provide wages, benefits, and workplace safety that is comparable or better than ICE powertrain jobs. Just as these workers are fighting for EV jobs that meet union industry standards, federally supported manufacturing projects should also be required to meet these standards. [EPA-HQ-OAR-2022-0829-0614, pp. 4-5]

8 UAW. December 9, 2022, "UAW Statement on Ultium Organizing Victory": https://uaw.org/uaw-statement-ultium- organizing-victory/.

UAW members produce internal combustion vehicles, engines, transmissions, and other ICE-exclusive components. Transmission and engine plants, like final assembly plants, help create economic ecosystems as the success of suppliers and local businesses often depend on the success of the transmission and engine plants. Therefore, the potential for economic displacement can be far greater than meets the eye. [EPA-HQ-OAR-2022-0829-0614, pp. 4-5]

Absent sufficient safeguards incorporated into the rule or revisions to the proposed standards, the burden of compliance is poised to fall heaviest on the workers who currently build ICE vehicles and those who will build ZEVs in the future. The proposed standards' uncertain disruption to ICE jobs and the uncertain quality of new EV jobs must be addressed as the EPA works to finalize the rule. Without this, we fear the proposed standards threaten to facilitate a race to the bottom, allowing manufacturers to pit EV jobs against ICE jobs, and ensuring the standards we fought for are absent for the next generation of vehicles and those who build them. [EPA-HQ-OAR-2022-0829-0614, pp. 4-5]

A. Uncertain Disruption to ICE Jobs

The EPA's proposed standards anticipate a dramatic change in the types of vehicles that will be driven on our roads. But the expedited transition to ZEVs that is required by the standards will not impact vehicles and drivetrains alone. The robust supply chain and domestic manufacturing base that has long supported the production of ICE vehicles will be placed in jeopardy. We are concerned that an impracticable regulatory environment will only encourage original equipment manufacturers (OEMs) to seek cost savings by placing the risk of the electric vehicle (EV) transition solely on autoworkers. The EV transition will not succeed if the workers building ICE vehicles are left behind. Rest assured, it is never a more efficient process, innovative technology, or greater market share that saves the industry. Autoworkers are always expected to sacrifice: [EPA-HQ-OAR-2022-0829-0614, pp. 5-6]

"We absolutely have too many people in certain places, no doubt about it... And we have skills that don't work anymore. We have jobs that need to change." (Ford CEO Jim Farley)9 [EPA-HQ-OAR-2022-0829-0614, pp. 5-6]

9 Neal Boudette, "Ford to Cut 3,000 Jobs to Reduce Costs in Transition to Electric Vehicles", (New York Times, Aug. 22, 2022), https://www.nytimes.com/2022/08/22/business/ford-motor-job-cuts.html.

The scores of workers who power the industry and rely on stable employment to provide for their families deserve a better path forward. Unfortunately, the EPA's projections of the proposed standards' impact on employment will fail to ease concerns about a major disruption to the workforce. The EPA projects that the proposed standards could have a dramatic impact on employment, ranging from a loss of 12,380 – 24,100 jobs per year or an increase in 30,800 – 81,500 job per year.10 We are highly skeptical of claims that the proposed standards will have minimal effect on employment. In the light-duty sector, automakers have used the cost of EVs as an excuse to cut jobs.11 Whether these claims by manufacturers are valid or a pretext to reduce costs should be interrogated, but in either case it is the workers building the vehicles that bear the brunt of these threats. And where EV battery jobs have been established domestically, job quality at these plants threaten to undermine standards in the entire sector. The only way to mitigate these concerns is to build out a completely unionized domestic supply chain for vehicles and batteries. The union workers who build ICE vehicles deserve a comprehensive assessment of the proposed standards' impact on their livelihoods. [EPA-HQ-OAR-2022-0829-0614, pp. 5-6]

10 Supra note 1 at 29392.

11 The Washington Post. April 26, 2023. "Auto giant Stellantis offers buyouts to 33,500 workers": https://www.washingtonpost.com/business/2023/04/26/auto-giant-stellantis-offers-buyouts-33500-workers/; Reuters. May 21, 2021. "Daimler Truck predicts engine job losses in transition to 'green' trucks": https://www.reuters.com/business/autos-transportation/daimler-truck-predicts-engine-job-losses-transition-green-trucks-2021-05-21/.

The EPA should recognize that the domestic vehicle manufacturing footprint relies substantially on the production of profitable ICE vehicles and that those profits will be necessary to fund the transition to cleaner technologies. By requiring increased ZEV adoption, and therefore fewer ICE vehicles, the proposed standards should be expected to disrupt ICE jobs. We urge the EPA to conduct additional analysis of the proposed standards' projected impact on employment, with particular focus on the union workforce that produces ICE vehicles. EPA's analysis should also consider the location, job quality, and unionization rates of workers manufacturing the batteries, fuel cells, and advanced ICE powertrain components that will be necessary to meet the regulations. Viewing employment in the aggregate is not sufficient. Not all jobs should be treated as equal. Vehicle manufacturing relies on a union workforce. Therefore, the preservation of standards, fought for and won by UAW members, in new EV jobs should receive significant attention in the EPA's economic impact analysis. [EPA-HQ-OAR-2022-0829-0614, pp. 5-6]

B. Uncertain EV Job Quality

Federal policy must ensure EV jobs are as good as or better than ICE jobs. Compliance with GHG emissions standards can never justify the offshoring of jobs, the slashing of wages, or the busting of unions. [EPA-HQ-OAR-2022-0829-0614, p. 6]

Unless and until we build a comprehensive domestic EV supply chain, the transition to EVs will risk trading dependency on fossil fuels for dependency on imported EVs, batteries, fuel cells, and materials, all while hollowing out quality union jobs in the process. Uncertainty around the build-out of the domestic EV supply chain is not recognized by the EPA and therefore does not play a significant role in altering the proposed standards' increased adoption of ZEVs.12 The EPA must craft its standards to hold manufacturers accountable to both environmental and labor concerns. [EPA-HQ-OAR-2022-0829-0614, p. 6]

12 For example, the EPA cites to 13 announced domestic battery plants, but does not indicate how many are operational or ready to help achieve compliance with the standards. See supra note 29317.

The EPA must recognize that the current domestic auto assembly footprint is heavily weighted towards the profitable light-duty truck and SUVs that are tasked with funding the EV transition.20 In 2022, nearly 60% of all vehicles produced by the unionized automakers in the U.S. were pickups or SUVs.21 The EPA must also consider the resiliency of the domestic manufacturing footprint that builds both ICEs and EVs. Federal regulation should be geared towards strengthening the domestic auto manufacturing supply chain and requiring that the EV transition provide the same levels of investment and quality jobs as the current ICE footprint. We fear the proposed standards are premature and risk disrupting the market that will make the EV transition possible. [EPA-HQ-OAR-2022-0829-0614, p. 8]

21 S&P Global. 2022. "Light Vehicle Production".

Organization: Job Creators Network Foundation (JCNF)

Finally, there are significant concerns regarding the use of child labor to cultivate these needed minerals. Seventy percent of cobalt needed for lithium-ion batteries comes from the Democratic Republic of the Congo,9 where children hand dig in crowded, primitive mines to try to service the West's insatiable demand.10 [EPA-HQ-OAR-2022-0829-0709, p. 3]

Organization: Matthew DiPaulo

This proposal will disrupt automotive industry supply chains and eliminate large numbers of jobs in vehicle manufacturing, parts production, and repair businesses. While small businesses are the lifeblood of the American economy, they will be hit the hardest by a premature rush to have electric vehicles dominate new vehicle sales. Small, internal-combustion engine-based businesses are not receiving the billions of dollars that large automakers are to make the conversion to electric. Thirty-three percent of automotive aftermarket products purchased by consumers last year were on upgrades and accessories for internal combustion engines and drive trains. That means as much as $17 billion of small business value will be wiped out by this proposal. [EPA-HQ-OAR-2022-0829-1514, p. 1]

Organization: MEMA, The Vehicle Suppliers Associated

The success of our industry is interwoven with the success of this proposal and the ability of the government to work with industry and other stakeholders to meet significant challenges. Therefore, the rule must address: [EPA-HQ-OAR-2022-0829-0644, pp. 2-3]

- The need for regulatory certainty. The final rule must contain an effective mix of feasible, demonstrated technology along with emerging technology, leaving options to improve emissions reductions in today's advanced propulsion designs. This will foster innovation in a coordinated direction, aligned with U.S. policy, but not mandate application of a narrowly defined technology path to make a positive impact on the country's urgent environmental goals. [EPA-HQ-OAR-2022-0829-0644, pp. 2-3]

- The influence of other technologies - including internal combustion engines fueled by hydrogen and other renewable carbon-neutral fuels - which can impact measurable environmental improvements at scale technologies can provide immediate improvement to the environment. This is important not only for environmental improvements but for environmental justice in providing cleaner consumer vehicles immediately to communities living and working close to busy streets, highways, and other transportation networks. Inclusion of all technologies that can decarbonize the transportation sector will foster the necessary growth in manufacturing capacity, vocational performance, infrastructure improvements, and consumer acceptance. [EPA-HQ-OAR-2022-0829-0644, pp. 2-3]

- Technology Neutrality and BEV Emissions. EPA should ensure that battery electric vehicles (BEV) are included in metrics for vehicle-to-vehicle comparison by assigning a metric that captures the pollutant emissions related to BEV operation, aligned with national electricity generation figures. [EPA-HQ-OAR-2022-0829-0644, pp. 2-3]

- Challenges in our nation's infrastructure and power grid. MEMA appreciates the significant public investments being made to support clean transportation infrastructure. As these new investments in highways and main corridors are deployed, federal and state incentives are needed to further expand the EV charging and refueling infrastructure in areas that connect these major thoroughfares. Urban industrial centers will need focused buildout while rural areas will need thoughtful rollouts to achieve an effective EV charging infrastructure. These buildouts must include Direct Current Fast Charge (DCFC) and vehicle-to-grid (V2G) bidirectional charging. [EPA-HQ-OAR-2022-0829-0644, pp. 2-3]

- Supply chain challenges. The proposed rule assumes that all materials advanced vehicles, which are not available today in the quantities needed to support the massive growth in vehicle construction, will become available within sufficient time. This places a significant and unnecessary risk on manufacturers and suppliers. Furthermore, once a company has converted production to new technology lines, that company cannot easily pivot its facilities and workforce back to the previous technology if EPA projections are not realized by the mid-to-late-2020s. [EPA-HQ-OAR-2022-0829-0644, pp. 2-3]

- Workforce challenges. A significant increase in skilled workers will be needed to support the implementation of this rule and long-term success thereof [EPA-HQ-OAR-2022-0829-0644, pp. 2-3]

- Extended warranty. The necessity to clearly define the applicability of the extended warranty and the need to provide repair access to service these new vehicles. [EPA-HQ-OAR-2022-0829-0644, pp. 2-3]

MEMA members are working to accelerate the performance and availability of clean-operating vehicle technologies and are directly contributing to their realization. Besides battery electric options, effective low- and zero-carbon technologies for future and current in-use vehicles also exist and can readily be put to use to reduce nationwide emissions and help EPA meet its climate goals. The success of this rule depends on greater inclusion of all available emissions reduction technologies, significant investment in infrastructure, careful understanding and investment in the domestic and global supply chain and ensured repair access to serve the improved and enhanced domestic vehicle fleet. [EPA-HQ-OAR-2022-0829-0644, pp. 2-3]

Organization: Senator Shelley Moore Capito et al.

Moving to BEVs will also result in a loss of domestic auto manufacturing jobs due to higher levels of automation and a reduction in the number of components that go into these vehicles. For example, Ford has estimated a 30-percent labor reduction in its transition to electric vehicles, with many more jobs to be lost in the specialty automotive aftermarket that has been built on the internal combustion engine. In Europe, more than a half-million jobs are expected to be lost in the auto sector if the European Union relies on an electric vehicle-only approach.13 Similar job losses can be expected in the United States based on these proposals. [EPA-HQ-OAR-2022-0829-5083, p. 4]

13 An Electric Vehicle-only approach would lead to the loss of half a million jobs in the EU, study finds, CLEPA (June 12, 2021)

Organization: Steven G. Bradbury

EPA fails to consider the negative societal consequences and second-order cost effects of its proposals. [EPA-HQ-OAR-2022-0829-0647, pp. 15-16]

In putting forward regulatory proposals designed to force upon the American people a vast and rapid industrial transformation, EPA has an obligation to go further than just considering the direct cost effects of its proposals (which are themselves woefully under- estimated, as highlighted above); it must also consider the broader indirect economic con- sequences and negative societal costs that would follow if these rules are finalized as pro- posed. So far in these rulemakings, the Agency has either ignored or deliberately down- played these second-order effects. [EPA-HQ-OAR-2022-0829-0647, pp. 15-16]

Some of the most consequential burdens and negative ramifications of the proposed rules that EPA hides, disregards, or minimizes include the following: [EPA-HQ-OAR-2022-0829-0647, pp. 15-16]

- Stifling consumer choice at the dealership. Many of the vehicle models most pop- ular with American families will no longer be sustainable under the EPA's proposed rules. Automobiles have long been America's favorite freedom machines. When the models of ICE vehicles Americans love the most disappear from dealerships, that will represent an enormous drop in consumer welfare (in basic happiness and well- being) for the average American family and for the U.S. economy as a whole. For many of these ICE vehicle models, there is no EV option likely to be available that could provide the same performance, utility, or recreational value at a comparable price (or at all). EPA makes no real effort to quantify this generational loss of con- sumer welfare. [EPA-HQ-OAR-2022-0829-0647, pp. 15-16]

- Increasing the purchase price of all new vehicles. Notwithstanding EPA's gaming of the numbers, the true costs of the industrial transformation forced by the EPA's proposed rules will be spread across the automakers' fleets, resulting in a significant increase in the prices of all new vehicles, with greater price increases concentrated on those vehicles for which the demand is highest relative to supply. All Americans will be harmed by these price increases, but the biggest losers will be lower-income Americans who cannot afford to buy an EV or to pay more for a gas-powered vehicle at the dealership, as well as those who live in rural areas and need to drive longer distances and for whom EVs are impractical. [EPA-HQ-OAR-2022-0829-0647, pp. 15-16]

- Destroying jobs in the U.S. auto industry. The loss of popular new vehicle options and the significant price increases at the dealership will mean that fewer new vehicles will be purchased—almost certainly far fewer than EPA is predicting. This drop-off in demand will challenge the profitability of the auto industry and lead to a loss of jobs for tens of thousands of America's autoworkers, as well as a loss of jobs in the many U.S. companies that supply inputs for the production of automobiles and heavy trucks.40 The United Auto Workers union has warned of the potential for job losses from the transition to EVs,41 as automakers announce more plant closures and layoffs due to the costs of electrification.42 [EPA-HQ-OAR-2022-0829-0647, pp. 15-16]

40 See Technality, "Ford Just Proved How Far Ahead Tesla Really Is: Profitability May Continue to Be a Struggle for All Legacy Automakers," May 10, 2023, https://medium.com/tech-topics/ford-just-proved-how-far-ahead-tesla-really-is-6a4d95cff519 ("Despite wanting to be a fully-electric brand by 2035, as of Q4 2022, Ford's average net margin on the Mustang Mach-E was -40.4%. Unfortunately, that's a figure that's only gotten worse since, to the point where Ford is now losing an average of $58,000 for every EV sold.").

41 See Press statement, United Auto Workers, "UAW Statement on Job Cuts at Stellantis," April 26, 2023, https://uaw.org/uaw-statement-job-cuts-stellantis.

42 See Michael Wayland, "Stellantis to indefinitely idle Jeep plant, lay off workers to cut costs for EVs," CNBC.com, December 9, 2022, https://www.cnbc.com/2022/12/09/stellantis-to-idle-jeep-plant-lay-off-workers-to-cut-costs-for-evs.html.

• Causing more deaths and serious injuries on America's highways. As new vehicle models become unaffordable or unappealing, many American families will be left driving older and older used cars, and the age of the nation's auto fleet will rise dramatically. Already, the average age of a car on the road in the United States is approaching 13 years, and many cars are on their fifth or sixth owners. The aging of the American fleet has very negative safety consequences, as NHTSA statistics show that older vehicles are much less safe than newer models in an accident.43 [EPA-HQ-OAR-2022-0829-0647, pp. 15-16]

43 See https://www.nhtsa.gov/sites/nhtsa.gov/files/documents/newer-cars-safer-cars_fact-sheet_010320-tag.pdf.

Organization: United Steelworkers (USW)

As our union represents the majority of unionized workers in the auto supply chain and workers in the oil sector, we have grave concerns regarding this proposed rule's impact on their livelihoods, and the negative impact that the rapid implementation of ZEVs will have on our electric grid and domestic supply chain. [EPA-HQ-OAR-2022-0829-0587, p. 1]

As mentioned prior, USW represents the majority of workers in the auto supply chain and oil refinery workers. The auto supply chain has historically been characterized by high union density, family-supporting wages and benefits, and pathways to the middle class. However, the shift to low-emission vehicle deployment cannot leave these workers behind. Unfortunately, the EPA's proposal for multi- pollutant emissions standards does not address the impact on jobs. EPA must consider how the transition to low-emission vehicles will impact manufacturing workers and the communities they live in. This should be an essential part of the comprehensive analysis that EPA conducts to project its proposals' economic impacts. [EPA-HQ-OAR-2022-0829-0587, p. 2]

Due to the speed of the transition to electric vehicles in EPA's proposal, tens of thousands of America's best manufacturing jobs are at risk, devastating not only oil workers, but those who make catalytic converters, pistons, fuel lines, and numerous other materials, parts, and components for gasoline-powered vehicles. Research finds that there are 1,300 facilities manufacturing light- and medium-duty vehicles and their components. Of these facilities, approximately 225 manufacture ICE light- and medium-duty vehicles and their components, like engines and transmissions, fuel efficiency technologies, and tailpipe pollution reducing technologies. The facilities producing these components and fuel are the most likely to see near-term job loss from the increased deployment of low-emission and ZEVs. Additionally, there are nearly 900 facilities making "fuel agnostic" components for heavy-duty vehicles, such as glass and seat belts, and these components are a large part of the auto supply chain that will be disrupted with the proposed rapid transition to ZEVs.1 [EPA-HQ-OAR-2022-0829-0587, p. 2]

1 BlueGreen Alliance Foundation, (Link: https://www.bgafoundation.org/programs/visualizing-the-clean-economy-autos/) "U.S. Automotive Manufacturing: Motor Vehicles, Parts, and Materials", Accessed July 5, 2023.

The transition to low-emission vehicles must function to raise the job quality and safety standards associated with all impacted workforces, including manufacturing workers, drivers, and mechanics. We remain deeply concerned that workers manufacturing components for and assembling ZEVs earn lower wages and receive less benefits when compared with workers manufacturing components for ICE vehicles.2 The high quality of these jobs is attributable to the

ICE vehicle manufacturing sector's dense unionization. Union membership helps ensure that workers share in the benefits of the economic growth they help generate through collective bargaining, higher wages, increased access to healthcare, and improved retirement security. As a whole, union members earn approximately 20 percent more than their nonunion counterparts, helping to increase social mobility and improving workers' economic outcomes.3 [EPA-HQ-OAR-2022-0829-0587, p. 3]

2 Economic Policy Institute, (Link: https://www.epi.org/publication/ev-policy-workers/) "The stakes for workers in how policymakers manage the coming shift to all-electric vehicles," September 22, 2021.

3 U.S. Department of Labor, (Link: https://www.dol.gov/general/workcenter/union-advantage#%3A%7E%3Atext%3DWorkers%20who%20are%20union%20members%2CPartnership%20for%20Women%20and%20Families) The Union Advantage. Accessed July 5, 2023.

Additionally, it is imperative to highlight that Black workers account for 12.5 percent of workers economy wide, but 16.6 percent of workers in the auto sector, while workers without a four-year degree account for 62.2 percent of workers economy wide, but 74.6 percent in the auto sector.4 The auto manufacturing sector represents a critical path to the middle class for the very workers and communities that have disproportionately borne the brunt of neoliberal economic and trade policies. It is essential that EPA leverage available data to project how its proposals will shape the domestic auto manufacturing sector, and the workers and communities that comprise it. [EPA-HQ-OAR-2022-0829-0587, p. 3]

4 Economic Policy Institute, (Link: https://www.epi.org/publication/ev-policy-workers/) "The stakes for workers in how policymakers manage the coming shift to all-electric vehicles," September 22, 2021.

Fortunately, there is a way to ensure that a transition to low-emission vehicles is equitable for the workers significantly impacted – a gradual transition. An Economic Policy Institute (EPI) report, conducted in collaboration with BGA, the United Auto Workers, the United Steelworkers, and the AFL-CIO, found that a gradual transition to BEVs significantly reduced the amount of jobs lost in the auto sector. For example, one of the best scenarios configured in the report accounted for combustion vehicles taking up 50 percent, hybrid vehicles at 25 percent, and battery electric vehicles at 25 percent of the market share by 2030. This scenario could lead to the creation of over 154,000 new jobs in the auto supply chain and over 36,000 new jobs in auto assembly. However, such job gains are contingent upon a significant onshoring of the BEV supply chain, such that the domestic content of BEVs at least matches that of ICEs, and there being a 10 percent increase in the share of U.S.-made vehicles sold in the U.S. auto market. This report concludes that a more gradual and focused approach in transitioning to ZEVs is key.5 [EPA-HQ-OAR-2022-0829-0587, pp. 3-4]

5 Economic Policy Institute, (Link: https://www.epi.org/publication/ev-policy-workers/) "The stakes for workers in how policymakers manage the coming shift to all-electric vehicles," September 22, 2021.

In order to protect good-paying, union jobs and promote a safer environment, EPA should address the negative impacts on jobs and job quality that the proposed rule creates. Without well-rounded policy, good paying jobs are lost and communities are destroyed. [EPA-HQ-OAR-2022-0829-0587, pp. 3-4]

EPA relies heavily on the potential critical role and incentives from the manufacturing investments from the Inflation Reduction Act (IRA) and the Infrastructure Investment and Jobs Act (IIJA) for its proposed emissions standards. Programs related to the auto manufacturing sector include the Battery Manufacturing and Recycling Grants, the Battery Material Processing Grants, the Domestic Manufacturing Conversion Grants, the 48C Advanced Manufacturing Tax Credit, the Advanced Technology Vehicle Manufacturing Loan Program, the National Electric Vehicle Infrastructure Program, and the Charging and Fueling Infrastructure Grant Program. [EPA-HQ-OAR-2022-0829-0587, p. 4]

While the proposed rule is not wrong that the investments made by IRA and IIJA should spur investments in new technologies to lower emissions of vehicles, it does fail to consider the timeline and effectiveness of program implementation. Undoubtably, these manufacturing investments will take time to achieve their full production capacity. [EPA-HQ-OAR-2022-0829-0587, p. 4]

Organization: Volvo Car Corporation (VCC)

Many uncertainties remain (supply chains, tariffs, infrastructure, incentives) so it is very important that government pursue policies that encourage auto industry investment and jobs, development of the electric vehicle market and advancement of motor vehicle safety. With the right complementary government policies, this rulemaking presents an opportunity for government and industry to pursue these shared goals. [EPA-HQ-OAR-2022-0829-0624, pp. 5-6]

Organization: Zero Emission Transportation Association (ZETA)

Electrification will not only reduce emissions but it will also promote American economic competitiveness, create good-paying jobs, and improve local health outcomes. Private sector investments in the domestic EV supply chain total billions of dollars and support hundreds of thousands of American jobs. Moreover, research has indicated that without adequate regulation of vehicle emissions, U.S. communities would experience avoidable increases in mortality. [EPA-HQ-OAR-2022-0829-0638, p. 2]

4. Transportation Electrification Benefits Consumers and the Economy

Beyond health and environmental improvements, electrification will benefit the country's economic development and Americans' pocketbooks. The transition to EVs is already leading to new manufacturing jobs, improved property values, and new investments in communities.84,85,86 This trend should be expected to continue and accelerate in the coming years. The burgeoning EV industry will create new jobs for the manufacturing of components such as batteries, electric motors, and power electronics, as well as charging infrastructure. In addition, the manufacture of conventional vehicle component parts like brakes and windshields will continue to be a source of employment in the automotive industry. [EPA-HQ-OAR-2022-0829-0638, pp. 18-19]

84 Sklarz and Miller, "The Impact of Noise on Residential Property Value," (September 20, 2018) https://www.collateralanalytics.com/wp-content/uploads/2018/10/CA-RESEARCH-The-Impact-of-Noise-on-Reside ntial-Property-Values.pdf

85 "Electric Vehicle Investments Provide Benefits Across the U.S.," ZETA, accessed June 27, 2023 https://www.zeta2030.org/education-fund/investments

86 "U.S. Energy & Employment Jobs Report," U.S. Department of Energy, (June 2023) https://www.energy.gov/policy/us-energy-employment-jobs-report-useer

Electrification will also help ensure the United States maintains its economic competitiveness with the rest of the world. As discussed further below, governments around the world are establishing more ambitious electrification goals to align with recent announcements from global manufacturers. Ensuring U.S. regulations match or exceed these ambitions is vital to encouraging domestic investments and accelerated job creation in the industry. [EPA-HQ-OAR-2022-0829-0638, pp. 18-19]

a. Electrification Will Continue to Create Good-Paying American Jobs

EVs are the lynchpin to simultaneously tackling the climate crisis and restoring the United States as a global leader in automotive manufacturing. As of March 2023, more than 143,000 jobs in the EV industry had been created since the passage of the Bipartisan Infrastructure Law (BIL) in November 2021.90 Combined with the Inflation Reduction Act (IRA) of 2022 and stringent emissions standards from EPA, manufacturing investments and job creation will continue to grow. The IRA alone is projected to create around 9 million new clean energy jobs over the next decade.91 [EPA-HQ-OAR-2022-0829-0638, pp. 19-20]

90 "Report Finds Investments in U.S. Electric Vehicle Manufacturing Reach $120 Billion, Create 143,000 New Jobs," Environmental Defense Fund, (March 14, 2023) https://www.edf.org/media/report-finds-investments-us-electric-vehicle-manufacturing-reach-120-billion-create-143 000

91 "Job Creation Estimates Through Proposed Inflation Reduction Act," University of Massachusetts, (August 4, 2022) https://peri.umass.edu/publication/item/1633-job-creation-estimates-through-proposed-inflation-reduction-act

Researchers at the Goldman School of Public Policy found that a scenario with 100% electric LDV sales by 2030 and 100% MHDV by 2035 would result in 2 million more jobs than the current trajectory.92 This is a result of the new jobs in the charging infrastructure, electricity, and maintenance sectors. The manufacturing and installation of charging infrastructure alone is projected to create more than 29,000 jobs.93 In general, jobs in the EV industry are high-quality and high-paying and as a result, are attracting a new generation of workers who are eager to work in the sustainable transportation industry. [EPA-HQ-OAR-2022-0829-0638, pp. 19-20]

92 "Switching to Electric Cars and Trucks Would Support 2 Million Green Jobs in 2035," UC Berkeley School of Public Policy, accessed May 15, 2023, https://www.2035report.com/transportation/green-jobs

93 "The Commanding Heights of Global Transportation: Quantifying the Employment Effects," SAFE, (March 9, 2021) https://secureenergy.org/the-commanding-heights-of-global-transportation-quantifying-the-employment-effects/

EV charging infrastructure buildout similarly promises to generate substantial job creation throughout the country. The International Energy Agency (IEA) estimates that 12 new jobs are created for every $1 million invested in charging infrastructure.94 By comparison, ICE vehicle manufacturing creates an average of 7.2 jobs per million dollars invested. At this rate, the BIL's $5 billion allocations through the National Electric Vehicle Infrastructure (NEVI) formula program to build out a national EV charging network could create at least 60,000 direct jobs. [EPA-HQ-OAR-2022-0829-0638, pp. 20-21]

94 "Sustainable Recovery - Transport," IEA, accessed June 23, 2023 https://www.iea.org/reports/sustainable-recovery/transport

Beyond installation, ongoing electric vehicle supply equipment (EVSE) operations and maintenance will create thousands more jobs. This creates an entirely new occupation, that of an

EVSE technician, that goes beyond the role of a traditional electrician. EVSE technicians are responsible for the ongoing maintenance and operations of chargers and are specially trained to handle electrical and parts malfunctions, software upgrades, cell signal issues, damages, and more.95,96 [EPA-HQ-OAR-2022-0829-0638, pp. 20-21]

95 ChargerHelp Guiding Standards 2022, accessed June 23, 2023 https://www.chargerhelp.com/_files/ugd/30e128_0032898550534e609ce4188fa91bc926.pdf

96 “FACT SHEET: Biden-Harris Administration Announces New Standards and Major Progress for a Made-in-America National Network of Electric Vehicle Chargers,” The White House, accessed June 6, 2023 https://www.whitehouse.gov/briefing-room/statements-releases/2023/02/15/fact-sheet-biden-harris-administration-a nnounces-new-standards-and-major-progress-for-a-made-in-america-national-network-of-electric-vehicle-chargers/

As discussed further in section eight of these comments, the U.S. battery manufacturing industry is quickly scaling to meet demand driven by transportation electrification. Since January 2021, the U.S. private sector has announced nearly $82 billion in domestic battery manufacturing investments, translating to 96 new or expanded processing and manufacturing plants creating thousands of new jobs in the process.97 [EPA-HQ-OAR-2022-0829-0638, pp. 20-21]

97 New US Battery Manufacturing and Supply Chain Investments Announced Under President Biden, US Department of Energy, (February 13, 2023) https://www.energy.gov/sites/default/files/2023-02/Battery%20Supply%20Chains%20Investments%20Map.pdf

The average cost of electricity in the U.S. is 16.5 cents per kWh as of May 2023.104 If electricity costs 16.5 cents per kWh, charging an EV with a fully-depleted 100 kWh battery will cost about $16.50 to reach a full charge. While the range of a 100 kWh battery varies depending on a vehicle’s efficiency, a typical Tesla Model S can go up to 400 miles on a single charge.105 Comparatively, the average national gasoline price for regular grade was $3.685 in May 2023.106 Filling up a 12-gallon passenger vehicle with a 30 mpg fuel economy would cost $45.96 to move the vehicle 360 miles. At $16.50 for a full charge, fueling an EV cuts fuel prices by 64%. [EPA-HQ-OAR-2022-0829-0638, p. 22]

According to AAA, over the course of a year the cost of refueling an EV is around $546, compared to $1,255 per year when fueling a gasoline car.107 [EPA-HQ-OAR-2022-0829-0638, p. 22]

c. Electrification Promotes American Economic Competitiveness

Governments around the world are setting more stringent emissions standards to align with recent announcements from global manufacturers. Ensuring U.S. regulations match or exceed these ambitions is vital in allowing certainty and encouraging investment in the industry. If the U.S. does not move more aggressively on LMDEV deployment, it risks ceding market share to other countries and regions who are moving faster, such as China, the European Union, and others. [EPA-HQ-OAR-2022-0829-0638, p. 24]

Complimentary incentives embedded in the IRA will facilitate onshoring of the EV supply chain while robust EPA emission standards will help ensure the United States becomes and remains a leader in EV technology development and manufacturing. While more work remains to craft supportive policies in other areas of the supply chain, EPA emissions standards are crucial drivers of domestic EV supply. [EPA-HQ-OAR-2022-0829-0638, p. 24]

Many countries have made commitments to accelerate EV development and deployment in their borders. An increase in EV sales is taking place across the world, but has been dominated by the Chinese market, which accounts for the majority of all new EV registrations. As of 2022, China had 10.7 million BEVs on the road and the U.S. had 2.1 million.114 Part of this dominance is due to China's purchase incentives, high registration fees for ICEVs, a robust charging network, and national "new energy vehicle" targets.115 [EPA-HQ-OAR-2022-0829-0638, p. 24]

114 Id. at footnote 27

115 "An evaluation of government incentives for new energy vehicles in China focusing on vehicle purchasing restrictions," Energy Policy, (October 2017) https://doi.org/10.1016/j.enpol.2017.07.057

With its own emissions targets, countries in Europe are sending strong signals about the continent's future electric fleet. Europe is the second-largest market for EVs in the world, with 30% of the global share.116 With robust LMDV emissions standards, the U.S. would be encouraging quicker adoption of EV technology to ensure the country remains at the forefront of this global transition. Below is a list of regional and national goals for light-and medium-duty zero-emission vehicle deployment that further underscores the need for the U.S. via EPA to maintain pace with the rest of the world: [EPA-HQ-OAR-2022-0829-0638, p. 24]

116 Id. at footnote 27

EPA Summary and Response

Summary:

Some commenters state that the rule doesn't adequately explain why reports that claim jobs will be lost are wrong, or address the projected impact on jobs, or the role ICE vehicle sales or charging infrastructure will play in the transition. The UAW is skeptical of EPA's projections of small employment impacts, stating that union workers deserve a comprehensive assessment of the impact of the standards on livelihoods. The USW commented that the EPA should leverage data to project how the regulation will shape domestic auto manufacturing, its workers, and their communities. Steven Bradbury commented that EPA has to consider the broader indirect economic consequence of the rule.

Commenters, including the AmFree, AFPI, Dalek, Stephen Bradbury and others, commented that the rule will lead to job losses. AFPI and others mentioned that EVs have fewer parts than their ICE counterparts and will require less labor to assemble. A group of U.S. Senators commented that BEV production will lead to more automating, resulting in job loss. Commenters mentioned the auto industry, as well as jobs both upstream and downstream of the manufacturing sector. Some specific sectors mentioned include the petroleum industry, the refining sector, dealerships, repair and maintenance, oil workers, supply workers, and gas station employees. USW and others stated that the speed of the transition will put workers at risk, and that the standards will lead to a dramatic change in the type of vehicles driven, with some commenters stating that a gradual transition will ensure the transition to low or zero-emission vehicles is equitable. Some commenters stated that jobs will be reallocated overseas, or, similarly, that the success of the rule will depend on the onshoring of electric vehicles and their batteries and parts. The Alliance stated that the EPA analysis assumed that all EVs sold in the U.S. will be made in the U.S. BGA and others are particularly concerned that jobs will be offshored to countries with minimal labor protections and loose environmental standards. Others, including Steven Bradbury, BGA, and USW, commented on possible environmental justice implications of the rule including that the rule is critical to advancing EJ and equity, and that this rule disregards the impact that higher purchase prices will have on lower-income Americans.

Job Creators Network Foundation commented with concerns that battery production will promote child labor in lithium-ion production in foreign countries. MEMA commented that the proposal assumes materials for advanced materials will be available in sufficient time, which places risk on manufacturers and suppliers.

Some commenters stated that there is a lack of qualified technicians for BEVs and EV charging stations, which will lead to higher costs of ownership and impact purchase decisions. AFPI and others also commented on the costs of the rule. AFPI commented that costly minerals will make the cost of the rule higher than estimated. Daniel Hellebuyck commented that the standards don’t account for the costs of companies trying to fund EV ventures. Steven Bradbury commented that the proposal underestimated costs. Some commenters stated that the higher costs will lead to reduced vehicle sales, which will lead to job losses. Steven Bradbury further states that the rule will lead to reduced vehicle choice, with fewer ICE vehicle options and no EV option to replace them.

Some commenters stated that this rule must not mandate the application of specific technology, but contain options including demonstrated and emerging technologies. BGA commented that EPA should include a request for information to seek information on worker voice, employee wages and benefits, hiring practices, training and advancement programs and community partnerships.

UAW commented that the analysis for the rule should consider location, job quality and unionization rates of workers manufacturing batteries, fuel cells and advanced powertrain components that will be needed to meet the regulations. Both the UAW and USW commented that the rule will negatively impact job quality and safety, as well as that there will be localized effects, where some communities may see a decrease in number or quality of jobs even if some communities gain jobs. UAW and USW commented that BEV workers earn lower wages and get less benefits from ICE worker counterparts due to unionization in ICE manufacturing. The UAW also commented that the uncertain quality of new EV jobs must be addressed. BGA commented that the EPA should identify communities associated with manufacturing and quantify the share of the economy supported by auto manufacturing, as well as the number of jobs in the sector.

UAW also commented that not all jobs should be treated as equal, and EPA should pay attention to preserving workforce standards for UAW members in new EV jobs in the analysis for the rule. They commented that setting emissions standards should not justify offshoring, wage cuts or union busting, and that the government should ensure that EV jobs are as good as or better than ICE jobs. BGA and UAW commented that EPA needs to consider how the transition to EVs will affect workers and their communities, that there will be distributional/geographic differences in the effects of the rule on employment where some places will see reduced employment, and others may see increased employment, though the quality or quantity of those jobs may not be equal. AFPI commented that the shift to EVs would cost union jobs. UAW commented that EPA should conduct additional analyses on the impact on employment, focusing on the union workforce, and consider location, quality and unionization rates of workers manufacturing batteries, fuel cells, advances ICE powertrain components; an aggregate view is not sufficient.

Commenters including MEMA, AFPI and HF Sinclair focused comments on the skill sets of workers. AFPI commented that workers can't easily transition due to different skill sets are needed, while MEMA stated that the transitions to EVs will need significantly more skilled workers. HF Sinclair commented that EPA can't assume workers from one field can move to another through retraining, or physically. Commenters stated that there will be geographic impacts, and the rule will spur labor reallocation, with some commenters stating that the midwest will experience the strongest job losses. Commenters also stated that impacts will be felt differently in different industries, with HF Sinclair Corp stating that industries like emissions inspections, third party dealers, aftermarket tuning will disappear, and AFPI commented that production will shift even if there is no national level change in employment.

Some commenters stated that EPA must involve stakeholders, that EPA should collaborate with the Departments and Labor and Energy, and that Federal and State incentives are needed to expand EV charging and refueling infrastructure. Some commenters state that electrification, the IRA and BIL have already led to new jobs, creating incentives and investments in domestic battery manufacturing, Some commenters said that recent investment in EV and battery manufacturing, as well as the installation and maintenance of charging and grid infrastructure provide significant job opportunities. Comments by a collection of Environmental and Public health organizations stated that ZEVs can support good quality jobs and increase employment opportunities. ZETA commented that electrification will create jobs in battery production, electric motor, power electronics and charging infrastructure, as well as continue to employ people in industries like brakes and windshields. They also stated that the rule will help ensure the U.S. remains competitive and can be a crucial driver of domestic EV supply. The USW stated that the IRA and BIL will spur investments, though they stated that the EPA does not account for the time it will take for those investments to come to fruition. Commenters state that increased demand for new technology to meet GHG standards could lead to growth in supply chains, strengthen domestic manufacturing and supply chains, and create jobs in EV charging infrastructure. Commenters state that if EVs are built in the U.S., job gains can happen, and produced labor income effects would ripple through the wider economy, benefit economic development and the consumer pocketbook. BGA commented that strong emissions regulations and economic growth are not mutually exclusive.

Commenters stated that the policy should encourage investment and jobs, the development of the EV market and advancement of safety. Stephen Bradbury commented that the rule will lead to safety issues with older, less safe vehicles remaining on the road longer.

Some commenters stated that EPA should further incorporate the FEV study's labor impacts results into the final rule analysis.

Some commenters, including the USW and HF Sinclair Corp, stated that the rule will have a negative effect on the electric grid. MEMA commented that the rule will need clearly defined applicability of extended warranty and need to provide repair access. Matthew DiPaulo commented that small businesses will be hit hardest because they are not getting the investments that large autos get to convert to electric. They also commented that small businesses in the automotive aftermarket production sector will be negatively affected.

Response:

We acknowledge that the increasing penetration of zero-emission vehicles in the automotive industry will have an effect on employment, including ICE and PEV manufacturing sectors, infrastructure-related employment sectors, and upstream and downstream sectors. While EPA does not mandate a specific compliance pathway for this rule, we recognize that adoption of additional pollution control technologies in response to the rule can also affect employment. This rule provides regulatory certainty to support increased employment in many economic sectors, though we acknowledge that OEM compliance decisions in response to the rule may reduce employment in other sectors. Opposing impacts across many sectors (e.g., increasing employment in PEV and battery manufacturing, decreasing employment in ICE and ICE vehicle manufacturing) are normal, expected changes during periods of technological transition and are not specific to this rule. As is indicated by the partial employment results discussed in Chapter 4.5.4 of the RIA and Section VIII.I.4 of the preamble, we note that there is the potential for net positive employment as an effect of this rule. As also discussed, support from a peer-reviewed tear-down study of a battery electric car and a comparable internal combustion engine vehicle indicates that if production of plug-in vehicles and their power supplies are done in the U.S. at the same rates as ICE vehicles, employment may increase. In addition, as noted by ZETA, research from Goldman School of Public Policy indicates that electrification leads to increased job availability and provides benefits to the economy over other fleet compositions.

According to the U.S. Energy and Employment Report (USEER), jobs related to the energy sector increased from 2020 to 2021, and at a faster rate than the workforce overall.[644] These energy-sector-related jobs include electric power generation; transmission, distribution and storage; fuels; energy efficiency; and motor vehicles and component parts. The report states that employment in motor vehicles and component parts increased about 2.5 percent from 2020 to 2021, and jobs in clean energy vehicles increased by almost 21 percent, with jobs in BEVs increasing by 27 percent, and PHEVs increasing by 10 percent. Employment in producing, building and maintaining charging infrastructure needed to support the ever-increasing number of plug-in vehicles on the road is also expected to significantly increase with the increasing buildout of charging infrastructure and thereby affect the nature of employment in automotive and related sectors. A recent report from the World Resources Institute indicates that if the right investments are made in manufacturing and infrastructure, autoworkers and communities will

[644] https://www.energy.gov/sites/default/files/2022-06/USEER%202022%20Fact%20Sheet_0.pdf. The data in the USEER relies on a comprehensive survey of about 34,000 respondents across the U.S. and because it is a snapshot in time, current events may impact these results. For example, the report notes that COVID-19 and associated effects deeply impacted energy employment, leading the sector to lose jobs at a higher rate in 2020 than the economy as a whole, though the report indicates that the energy sector has recovered about 71% of the jobs lost during 2020. In addition, USEER notes that the conflict in Ukraine has impacted fuels industries leading to increased petroleum and wet gas exports from the U.S.

benefit from job growth, lower auto related costs, and reduced air pollution.[645] The report focused on effects that would be felt in Michigan, which, as of 2023 has the most clean energy jobs in the Midwest, and the ranks 5th nationally.[646] Michigan also ranks second, behind California, for the most hybrid and electric vehicle employment. Taking Michigan as an example, clean energy jobs grew by almost 4.6 percent in 2022, which was twice as fast as the overall economy. Electric vehicle-related jobs, specifically, grew by about 14 percent in the state in 2022. In addition to the 21 percent increase in employment in 2021 that USEER reported in clean energy vehicles, EDF also reports that the job growth and investment in the EV sector that has been seen nationally over the last eight years is expected to continue, with new factories or production lines for EVs, batteries, components and chargers supporting more than 125,000 jobs being announced across 26 states.[647] EDF reports that more than 140,000 new jobs have been announced in the U.S. since 2015, with 60,000 jobs being created in U.S. battery manufacturing.[648] They also point out that 66 percent of those job announcements were made in the time after BIL was passed, and 32 percent of those jobs were announced after the IRA was passed, and 86 percent of those jobs announcements were concentrated in ten states: Michigan, Tennessee, Georgia, Nevada, Kentucky, South Carolina, Ohio, North Carolina, Indiana and Kansas. DOE reports that more than 80,000 potential jobs in U.S. battery manufacturing and supply chain, and more than 50,000 potential jobs in U.S. EV component and assembly have been announced since 2020.[649]

EPA has considered input from labor groups and others in carefully designing the final rule, which includes a slower phase-in of the final standards compared to the proposed standards (as described in Section I.B of the preamble). In addition, EPA has consulted other federal partners, including the Department of Energy (DOE) and the Department of Labor (DOL), and engaged in significant dialogue with EJ and labor groups. Here in this RTC section, as well in the RIA and preamble, we note many of the ongoing efforts that labor-oriented groups, federal agencies and others are engaging in to support workers and their communities in providing opportunities for a just economic transition. The list of programs and other efforts discussed throughout this rulemaking not exhaustive, and there may be more programs available that are not included here. While EPA does not set standards for labor, the agency fully supports a just economic transition for workers in association with the transition to clean vehicle technologies, and we believe that the numerous Federal, State, and private efforts we have identified, as well as other efforts not included here, significantly support quality jobs for workers across the nation.

There is a DOE funding package which makes $2 billion in grants and up to $10 billion in loans available to support projects converting existing automotive manufacturing facilities to

support electric vehicle production.[650] This package is focused on the retention of high-quality, high-paying jobs in communities that currently host manufacturing facilities, and along the full supply chain for the automotive sector from components to assembly, and it gives priority to refurbishing and retooling manufacturing facilities, especially for those likely to retain collective bargaining agreements and/or an existing higher-quality, high-wage hourly production workforce.[651] DOE has also announced funding to support clean energy supply chains, with the funding going toward projects to support domestic clean energy manufacturing (including projects supporting battery production) in, or near, nine communities that were formerly tied to coal mining, and are expected to create almost 1,500 jobs.[652] The Joint Office of Energy and Transportation (JOET), created by the BIL, supports efforts related to deploying infrastructure, chargers and zero emission vehicles.[653] One example of a project from the JOET is the Ride and Drive grant program, which targets investments in EV charging resiliency, community-driven workforce development and EV charging performance and reliability. The ongoing actions discussed throughout this section supporting green jobs, including those by DOE, the Department of Labor (DOL), the Office of Energy Jobs, and others, are particularly focused on jobs with high standards and the right to collective bargaining.

In addition to the many programs at the federal level, states are making efforts to support increasing domestic production of electric vehicles and batteries, including support for the workforce. An Executive Order issued in South Carolina prioritized implementing a strategic initiative to explore opportunities related to ongoing economic development, business support and recruitment efforts with electric vehicle and automotive manufacturers.[654] A study from Ohio estimates that there will be more than 25,000 new jobs in EV manufacturing and maintenance, battery development and charging station installation and operations in the state by 2030.[655] California has a Workforce Development Board that has been focused on furthering the development of an equitable PEV industry, including high quality jobs and access to them, since at least 2021.[656] Illinois has invested in EV training programs, research and development in the EV industry, and in workforce development and community support in the clean energy sector.[657] The Nevada Battery Coalition is tasked with identifying gaps in, and developing

solutions for, workforce and economic development supporting the lithium industry in Nevada.[658] Kentucky has been the location for at least two recent automotive sector development projects, and it is providing resources toward upgrading industrial sites throughout the state, with funding evaluated based on factors including workforce availability.[659] Tennessee is co-locating a new Tennessee College of Applied Technology with a new EV manufacturing facility Ford is building in the state to provide specialized technical training.[660] In Michigan, the Department of Labor and Economic Opportunity created the Electric Vehicle Jobs Academy to assist with tuition and other supportive services for those training to be in the advanced automotive mobility and electrification industry, and the University of Michigan contracted with the state to open the University of Michigan Electric Vehicle Center focusing on research and development and developing a highly skilled workforce.[661,662]

Regarding comments that EVs have fewer parts than ICE counterparts, and that BEV production will lead to automation, resulting in job loss, we first note that even if EVs have fewer parts, these analyses do not include the labor needs of battery manufacturing or infrastructure build out and maintenance. In addition, as discussed throughout this section, as well as in Section VIII.I.3 of the preamble and Chapter 4.5.4 of the RIA, research indicates that if PEV and PEV power supply production is done in the U.S. at the same rates as ICE vehicles, employment may increase, and this is even more likely if job creation related to infrastructure is included in the analysis. We also note that there will likely be a significant increase in demand for labor in sectors that manufacture, build and maintain charging stations associated with the increasing penetration of electric vehicles. To that end, the BIL is investing in the build out of EV chargers along America's major roads, freeways and interstates, focusing on domestically produced iron and steel, and domestically manufactured chargers.[663] The magnitude of all of these impacts depends on a variety of factors including the labor intensities of the related sectors, as well as the nature of the linkages (which can be reflected in measures of elasticity) between them and the regulated firms.

Regarding comments that there will be upstream and downstream job impacts, we refer to our discussions in RIA Chapter 4.5.5 and Section VIII.I.4 of the preamble where we discuss possible impacts in sectors such as petroleum refining, dealerships and more. As stated earlier in this section, according to the U.S. Energy and Employment Report, jobs related to the energy sector (including electric power generation; transmission, distribution and storage; fuels; energy efficiency; and motor vehicles and component parts) have increased at a faster rate than the workforce overall, from 2020 to 2021.[664] ZETA cites a study by the Goldman School of Public

Policy indicating that as EV sales increase, reductions in auto repair and maintenance jobs are more than offset by increases in jobs in construction and maintenance in green sectors like wind, solar, and battery storage, and in electric grid infrastructure.[665] EDF noted that almost 60,000 jobs were added in the battery production and components sector over the last 8 years. The projects, agencies and efforts mentioned above will support the continued investment in domestic, quality jobs in a transition to cleaner transportation, which will happen slowly over time. Traditional gas stations and liquid fuel providers are already incorporating EV charging into their business strategies. Many retail gas stations are being outfitted with EVSE right now.[666,667,668] With respect to the effect a change in petroleum demand may have on employment, the petroleum refining industry is material intensive and not labor intensive, and we estimate that only part of the reduction in liquid fuel consumption will be met by reduced refinery production in the U.S.; therefore, we expect that any employment effect due to reduced petroleum demand will be small. With respect to possible employment effects at dealerships, we note that vehicle sales are affected by more than regulation, including macroeconomic conditions, and that dealers may be affected by more than just changing sales (for example, changing maintenance needs). We discuss this, and more, in RIA Chapter 4.5.5.

In response to comments that the standards will lead to a dramatic change in the type of vehicles driven, we first note that this rule is not a mandate and does not force manufactures to use any specific technology. Manufacturers can determine the best path of compliance for them. Allowing manufacturers to meet the standards in the most effective way for their fleet is expected to lead to the lowest cost path for each manufacturer, yet still achieve the environmental and health benefits associated with the reduced level of emissions set by the rule. In addition, as described in Section IV.F of the preamble, we demonstrate that there are multiple pathways to compliance, and that these pathways include a wide range of mixes of technologies in the fleet, including various mixes of ICE vehicles, strong hybrid vehicles, PHEVs and BEVs. See Sections 13 of the RTC for information on consumer considerations as part of this rule, and 14 of the RTC for more information on vehicle sales.

In response to comments on the speed of the transition to electrification, and that a slower phase in will support workers during the transition, as described in Section III.C of the preamble, EPA is finalizing standards for both light- and medium-duty vehicles that have a slower ramp rate in the early years of the program compared to the proposal. For the light-duty GHG standards, we have reduced the stringency of the standards from MYs 2027 through 2031 compared to the proposed standards and have also extended the phase-down of certain optional

[668] Love's: Electrify America Announces Collaboration with Love's Travel Stops: https://www.loves.com/en/news/2020/august/electrify-america-announces-collaboration-with-loves-travel-stops

credit flexibilities. These changes were made in response to comments from labor groups and the auto industry that the pace of the standards was too fast, and that more lead time was needed to provide a more orderly transition that allowed for the scale up of battery supply chains and vehicle production. In turn, EPA believes that this slower pace of the final standards will further support workers and labor impacts during the transition to manufacturers building a range of vehicle technologies to meet the standards, as well as allow for increased opportunities for training, education and facility upgrades over time. This will also allow for continued investments from IRA, BIL and other programs, as described throughout this section.

Regarding comments that we do not adequately address the impact the rule may have on employment, and other comments that the supply chain supporting auto manufacturing will be affected in addition to domestic auto manufacturing, we first refer to our discussion on employment in RIA Chapter 4.5 where we discuss quantitative partial employment effects of this rule in auto manufacturing sectors, as well as possible qualitative employment impacts in related sectors. The partial employment effects we estimate indicate that the joint cost and demand effect of this rule will lead to an increase in employment for sectors related to the electrified portion of vehicle production that outweighs possible decreases in the ICE portion of vehicle production and possible decreases in sectors that are common to both ICE and electric portions of vehicle production. To estimate further effects of this final rule on employment would necessitate data which is not available to EPA, and quantifying employment effects in sectors upstream or downstream from the directly affected sector is dependent on more than just the effect of this final regulation, for example macroeconomic conditions in each state, as well for the country as whole. We note that in addition to the partial employment analysis described and presented in the RIA, in cooperation with DOE and DOL, we did qualitatively assess a number of employment initiatives currently underway pertaining to EVs and EV-related industries. These are discussed throughout Section VIII.I of the preamble, Chapter 4.5 of the RIA, and this RTC section. These initiatives support continued growth, training, and investment in workers and their communities throughout the automotive manufacturing and supply chain industries, as well as throughout industries related to charging infrastructure.

Regarding claims this rule will affect, and we should account for, job quality and safety as well as quantity, that there may be geographically localized effects even if there are not national net effects, and that jobs may look different in a market where vehicles are electrified, we acknowledge that different markets and different workers may be affected differently by a transition to clean vehicle technologies. If, as some commenters claim, the transition to EVs will require more skilled workers, we note that jobs that require a higher skill level generally provide a higher wage. In addition, we find that there are significant Federal, State, and private efforts to support quality jobs and training opportunities for workers across the nation, including those we summarized earlier in this section and more below. We point to work by the Departments of Energy (DOE) and Labor (DOL), as well as others, who are funding grants and initiating programs to support green jobs, including those related to electric vehicle battery production, training and apprenticeship programs, and more. JOET is responsible for executing funding from the Investing in America Agenda granted to 30 projects across 16 states and Washington D.C. to support EV charging performance, resiliency and reliability, support equitable access to clean transportation solutions, and to help grow the clean energy workforce.[669] DOE has an

669 https://www.energy.gov/articles/biden-harris-administration-announces-over-46-million-enhance-ev-charging-reliability-and

Office of Energy Jobs, focused on supporting the creation of jobs in the energy sector, with particular focus on jobs with high standards and the right to collective bargaining.[670] The office works with other federal agencies to support meaningful jobs in the transition to a zero-emission economy, including through:

- The 21st Century Energy Workforce Advisory Board to support current and future energy-sector labor needs, and to expand energy jobs and training opportunities
- A DOE Labor Working Group, a forum with labor unions and others to engage on key energy topics
- A Community Benefits Plan to account for labor and community engagement, quality jobs, worker investment and more
- The Battery Workforce Initiative established by the Department of Energy (DOE) in coordination with the Department of Labor (DOL), AFL-CIO and other organizations to bring together industry stakeholders, including employers and unions, to develop consensus on skills and training needed to support a growing domestic battery supply chain with the goal of accelerating the development of high-quality training

DOL's Employment and Training Administration oversees the DOL Building Pathways to Infrastructure Jobs Grant Program aimed at investing in the development and implementation of worker-centered strategies and training programs needed to support the transition to a zero-emissions economy.[671] These programs include support aimed at jobs in renewable energy, energy efficiency, broadband expansion, smart city grids, and jobs facilitating the design, construction, modernization and maintenance of infrastructure. DOL also provides grants to help community colleges provide skilled pathways to good jobs in the transportation and clean energy sectors. DOL is providing technical assistance to the Southeast EV Collaborative, which is made up of collection of state workforce agencies in the southeast region of the U.S. focused on identifying opportunities to work together to provide equitable access to good jobs across the region.

Research on domestic employment in the EV transition funded by the Department of Energy (DOE) indicates that a wide range of jobs in the ICE vehicle sector have a relatively high similarity in needed skill sets to jobs in the EV sector, as well as in other sectors, including the heat pump, solar panel manufacturing and transformer industry.[672] The research also indicates that higher-wage jobs with more specialized skills may be better positioned to transition their skill sets from ICE sectors to EV sectors, although they are more geographically concentrated and hence dependent on co-location of EV production capacity with automotive production for transition opportunities. This research is supported by comments provided by ZETA, indicating that the EV industry is attracting workers transitioning from other industries. At the same time, we note the considerable efforts to support workers with lower wages and lower skill levels, including, for instance, the targeting of IRA funds to economically disadvantaged counties

671
https://www.dol.gov/sites/dolgov/files/ETA/skillstraining/Building%20Pathways%20to%20Infrastructure%20Grantee%20Abstracts_12-4-2023.pdf
672 Workforce Analytic Approaches to Find Degrees of Freedom in the EV Transition; https://papers.ssrn.com/sol3/papers.cfm?abstract_id=4699308

discussed below. Also, we point out that even though vehicle manufacturing and battery manufacturing may create more localized employment effects, infrastructure work is, and will continue to be, a nation-wide effort. We note that ICCT estimated that charging infrastructure growth in the U.S. could create about 160,000 jobs by 2032, in sectors ranging from electrical installation, maintenance and repair, charger assembly, general construction, software maintenance and repair, planning and design, and administration and legal.[673] We also note that JOET has funded initiatives related to job training for many sectors related to charging resiliency and performance, including those in the electrical industry.[674]

Regarding community-level effects, we note data at sub-national level is not consistent, nor consistently available, and subnational estimations are too precise compared to the uncertainty in estimating possible future effects for the nation as a whole. Regarding comments that we should quantify effects on job quality at existing ICE plants versus those at new or to-be-built electric vehicle or battery manufacturing plants, we point out that data related to job quality is not widespread or consistent enough and is too uncertain to rely on, in addition to the fact that we do not know where these plants may be in 2030, nor their size or employment capacity. We may be able to obtain data from a select few manufacturers, but this would ignore the possible effects at all vehicle and battery plants, leading to a high level of uncertainty. Also, we would need to determine a consistent measure of job "quality." Commenters who advocated for this kind of quantitative job quality analysis did not provide any such analysis themselves. Notwithstanding the technical difficulties with performing such an analysis, we find there is considerable support for quality jobs in association with the ongoing transition to clean vehicle technologies, as discussed throughout this section, as well as in comments by EDF, ZETA and others. And though crafting standards about labor concerns are not in the purview of EPA, we point out that these efforts, among others, support the workforce in the transition to cleaner vehicles, as well as supporting and encouraging domestic production of electric vehicles and battery manufacturing.

Regarding related comments that the rule will have possible environmental justice implications and the rule is critical to advancing environmental justice and equity, as well as the impact the higher purchase price will have on lower-income Americans, we refer to RTC Sections 9 (environmental justice) and 13 (consumer impacts). It is also important to note that investments from the IRA have, so far, been focused in more economically disadvantaged counties. The U.S. Department of Treasury states that as of November 2023, 70 percent of post-IRA investments in clean energy have happened in counties with a smaller share of the population employed than the U.S. average; almost 80 percent have happened in counties with below-average median household incomes; more than 80 percent of have happened in counties with below-average wages; and more than 85 percent have gone to counties with below-average college graduation rates.[675] We also note that during and after the comment period, several major U.S. automakers were negotiating new labor contracts, with an emphasis on workers in facilities

[673] ICCT: Charging Up America, https://theicct.org/wp-content/uploads/2024/01/ID-28-%E2%80%93-U.S.-infra-jobs-report-letter-70112-ALT-v6.pdf.
[674] JOET: New Funding Enhances EV Charging Resiliency, Reliability, Equity and Workforce Development, https://driveelectric.gov/news/workforce-development-ev-projects.
[675] The Inflation Reduction Act: A Place-Based Analysis: https://home.treasury.gov/news/featured-stories/the-inflation-reduction-act-a-place-based-analysis

that support the production of electrified vehicles.[676] The negotiations resulted in many workers in EV production, including EV battery workers, becoming newly eligible to join the union, as well as in raising wages for those employed by unionized automakers, and those employed by non-unionized automakers.[677]

Regarding comments that there is a lack of qualified technicians for electric vehicle and infrastructure manufacturing, repair and maintenance, As described throughout this section, there are many programs available to support training of electric vehicle repair and maintenance technicians, as well as technicians supporting ZEV infrastructure. We do not agree that there will be a significant lack of technicians in the timeframe of this rule given investments and programs focused on training for EV sector positions, including those discussed throughout this RTC section, as well as other programs, such as those at many community colleges supporting jobs related to EV technology, including technicians.[678] Additionally, the phase-in of this final rule, described in Section I.B of the preamble, will allow time for technicians to be trained. We do find that this rule provides regulatory certainty that supports significant job growth for qualified technicians that service electric vehicles..

Regarding comments that EPA should create a request for information (RFI) like the voluntary one EPA published targeting manufactures receiving funding in the Clean School Bus (CSB) Program to solicit information from affected parties, we disagree, noting that the CSB Program was not a regulation that limits pollution emissions from school buses, but instead is a program meant to help schools replace existing buses with zero- or low-emission models through grants and rebate funding opportunities. The RFI in the CSB was created to support the overall success of the CSB Program, and to help EPA, partners, and stakeholders understand how the CSB Program, with funds provided by the BIL, is contributing to the creation of high-quality jobs across the country. We appreciate the information provided by those OEMs who have already volunteered to participate, and those who might in the future.[679]

We note that comments suggesting EPA track and hold industry accountable for specific business practices such as offshoring or child labor are out of scope for this rulemaking. For comments specific to child labor said to take place in the supply chain for batteries, see the response to comments in RTC Section 15. While we set standards and prescribe test procedures to demonstrate compliance, and consider costs, employment impacts, and potential supply chain concerns in setting the standards, EPA's engine and vehicle regulations do not dictate how

[678] For a list of some of the community college and other programs that support the electric vehicle industry, see the Community College and Other EV Training Programs memo to the docket.

[679] For responses provided to the Clean School Bus RFI, see https://www.epa.gov/cleanschoolbus/bus-manufacturer-job-quality-and-workforce-development-practices. A copy of this webpage as of March 5, 2024 is provided in the docket for this rule.

manufacturers source their materials or staff their production to meet the standards. This approach allows each manufacturer to identify the business approach most appropriate for their company, yet still achieve the environmental and health benefits associated with the reduced level of tailpipe emissions allowed by the rule. Similarly, we do not account for business decisions regarding how to fund research and development, and therefore do not include costs such as the cost of funding EV ventures into the analysis for this rule.

Regarding comments that EPA should further incorporate FEV results into the final rule analysis, we refer to RIA Chapter 4.5, where we discuss the employment focused FEV results.

Regarding comments on a gradual phase-in of the standards, we refer to Section III.C and D of the preamble, where we describe how this final rule phases in over time, which will allow for training, education, and planning for workforces as the market transitions to BEVs. We also point out that there are many alternative pathways to compliance for this rule, and they include continued production of vehicles with IC engines (e.g., ICE, hybrids, PHEVs).

Regarding comments on the costs of the rule, we refer to RTC Section 8. Regarding comments about the impact of the rule on vehicle sales, we refer to RIA Chapter 4 and RTC Section 14. Regarding comments that this rule will result in reduced vehicle choice, we do not agree. See Section 13 of the RTC for more information. In addition, we do not agree that critical minerals will lead to higher costs than estimated. We present our analysis of critical minerals in preamble Section IV.C.7 and respond to comments in Section 15 of this document. Regarding comments that this rule will lead to safety issues, we refer to RTC Section 22, where we respond to comments on safety impacts associated with this rule. Regarding comments that this rule will have a negative effect on the electric grid, we refer to Section 18 of this RTC where we discuss the interaction between the electric grid and our regulation. Regarding comments that this rule will disproportionately affect small businesses, we refer to RTC Section 25.1 and RIA Chapter 11 where we discuss how we account for small businesses in our analysis. Regarding comments that this rule needs clearly defined applicability of extended warranty and need to provide repair access, we refer the reader to RTC Section 16.

21 - Energy security

Comments by Organizations

Organization: American Enterprise Institute

III. The Purported Energy Security Benefits of the Proposed Rule Are Illusory

EPA argues that the proposed rule would provide “energy security” benefits in the form of a reduction in the prospective costs “caused by U.S. petroleum consumption and imports.” EPA views such benefits as a reduction in the adverse effects of future disruptions in the supplies of crude oil, refined products, and other liquid fuels, a reduction in the costs of public preparation as embodied in the Strategic Petroleum Reserve (SPR), and a reduction in the defense costs of defending sea lanes and other dimensions of national security spending. Each of those arguments is incorrect. [EPA-HQ-OAR-2022-0829-0571, pp. 11-12]

Because there can be only one world market price for such fungible commodities as crude oil, abstracting from such second-order differences as transportation costs, exchange rate impacts, and the like, nations that import all of their oil (e.g., Japan) face the same prices and price changes as those importing none of their oil (e.g., the UK).32 Accordingly, the common view of “energy security” as a direct impact of the level or proportion of imports is incorrect. Japan is not less “energy secure” than the UK, and a U.S. that imports more oil is not less “energy secure” than a U.S. that imports less. [EPA-HQ-OAR-2022-0829-0571, pp. 11-12]

32 Natural gas is a somewhat different case, in that delivery through pipelines cannot be shifted quickly. Deliveries of liquified natural gas can be expensive, but analytically are similar to deliveries of crude oil, although the importation facilities are more complex and cannot be created quickly.

Note that the queues and market disruptions experienced in the U.S. in 1973 did not result from the oil “embargo” imposed by Arab OPEC and directed at the U.S., the Netherlands, and a few others. The targeted nations faced the same international prices, and the same changes in prices, as all other economies. Prices increased because of the production cutback in the Middle East in the Wake of the 1973 Middle East war; it was the imposition of price and allocation controls and other regulatory rigidities and constraints that yielded the market disruptions. Note that there was no “embargo” in 1979; but there was a production cutback in the wake of the Iranian revolution, higher international prices, the re-imposition of price and allocation regulations in the U.S. market, and resulting queues and market dislocations.33 “Energy security” — the risk of disruptions from a given source and the cost of obtaining substitute supplies over some (short) time horizon — is an attribute of liquid fuels reflected fully in market prices. “Insecure” — that is, unreliable — suppliers will command market prices lower than those enjoyed by suppliers more reliable. [EPA-HQ-OAR-2022-0829-0571, pp. 11-12]

33 See Benjamin Zycher at https://www.aei.org/wp-content/uploads/2016/06/14jun2016Zycher.pdf, https://www.aei.org/wp-content/uploads/2016/06/World-Oil-Prices.pdf, and https://www.econlib.org/library/Enc/OPEC.html.

The market is fully capable of anticipating supply disruptions, even if not the precise magnitudes and timing, and then stockpiling supplies for periods when supply disruptions yield higher prices.34 Market prices unconstrained by regulatory distortions provide efficient incentives for such preparation; it is the threat of price controls and “windfall profits” taxes and other such policies that are likely to yield investment in private sector preparation smaller than economically efficient in the aggregate.35 This means that the costs of the SPR are the direct result of adverse government policies anticipated with some nontrivial probability. [EPA-HQ-OAR-2022-0829-0571, pp. 11-12]

34 See the Energy Information Administration data on U.S. oil stocks at https://www.eia.gov/petroleum/data.php.

35 It is likely to be the case that the corporation income tax also, by forcing the private sector to use a before-tax discount rate higher than the after-tax return to investment, yields suboptimal investment.

Similarly, the defense cost argument is misguided. In a narrow context, the portion of the costs of the U.S. defense effort that can be attributed to defense of the sea lanes and the like is a hugely complex analytic calculation. More broadly, defense capital assets serve multiple functions; because national security needs and the physical and human force structures evolve only over decades, it is reasonable as a first approximation to assume that defense capital provides those multiple functions in more-or-less fixed proportions. It is axiomatic that the allocation of fixed costs across multiple functions in fixed proportions is arbitrary. Accordingly, the analysis of the purported benefits of a forced reduction in the consumption of transportation fuels in terms of an asserted reduction in (long-run) defense costs is illusory. [EPA-HQ-OAR-2022-0829-0571, pp. 11-12]

2. The Availability of North American Crude, Refining, and Biofuel Capacity Makes the United States Energy Secure

Unlike critical minerals, the U.S. is the largest producer of crude oil and petroleum products in the world. We are also home to the world's largest biofuels industry. Our refineries and petrochemical producers are the most competitive in the world, taking advantage of a sophisticated workforce, low-cost resources, refinery complexity, and scale to compete with even the largest state-owned enterprises in foreign markets. In 2022, the crude oil processed by U.S. refineries was 84 percent sourced from North America. The U.S. produces more crude and refined products than it consumes and became a net exporter of crude and refined petroleum products in late 2019, after being a net exporter of refined products for the past decade.22 EPA's DRIA undervalues the energy security aspects of the domestic petroleum industry, particularly by failing to distinguish between sources of imported crude oil, ignoring that 70 percent and 84 percent of imported and total crude oil, respectively, is sourced from North America. The proposal also ignores the significant pipeline connectivity between the U.S. and our North American trading partners, as well as the unique configurations of each U.S. refinery. For example, many U.S. refiners require heavier crude oils, which are not produced in the U.S. and must be sourced from Canada or other heavy crude producers. U.S. energy leadership means that the energy security impacts of reduced oil imports are not as significant as they historically had been. It also means that reduced U.S. demand for liquid fuels will impact U.S. oil producers as much, if not more so, than existing trading partners. This employment effect is not contemplated in EPA's analysis. [EPA-HQ-OAR-2022-0829-0733, p. 10]

22 EIA, "Oil imports and petroleum product explained" (Jun. 12, 2023) available at https://www.eia.gov/energyexplained/oil-and-petroleum-products/imports-and-exports.php.

U.S. refiners are also critical suppliers of fuel to the U.S. military. In the most recent contract year, U.S. refiners provided 750 million gallons of fuel on the West Coast alone, supporting force readiness for conflict in the Pacific. EPA did not assess the impact of likely refinery closures on military operations and readiness. Instead, the DRIA inexplicably focuses on a narrow aspect of energy security, choosing to describe the cost of protecting trade routes. [EPA-HQ-OAR-2022-0829-0733, p. 10]

Organization: American Petroleum Institute (API)

In ORNL's study, a significant portion of the estimated security premium is the potential reduction of "the transfer of U.S. wealth to foreign producers" which "can lead to macroeconomic contraction, dislocation, and GDP losses" during an oil supply disruption. In 2008, when ORNL calculated energy security premiums, net U.S. crude and product imports were over 50 percent of U.S. liquid petroleum consumption. However, since ONRL's calculations the U.S. has become, and is projected to be, a net oil and product exporter, thus an increase in global oil prices would likely lead to a net transfer of wealth to the U.S. not away from it. Without modifications that account for the transfer of wealth to the U.S. during a supply disruption, EPA's calculated energy security premium estimates are likely overstated and not meaningful. [EPA-HQ-OAR-2022-0829-0641, pp. 21-22]

Organization: California Air Resources Board (CARB)

In addition to individual cost savings and broader economic growth, U.S. EPA's proposal will provide economic benefits for the nation's energy systems. For example, increased ZEV deployment will reduce our reliance on foreign oil, providing economic resilience to global fuel supply chain disruptions and price shocks. With the integration of emerging vehicle-to- grid communication strategies, as CARB recommends, vehicles will be able to promote grid resilience through enabling demand response load management strategies, providing backup power during blackouts, and supporting storage of renewable energy. [EPA-HQ-OAR-2022-0829-0780, pp. 66-67]

Organization: Clean Fuels Development Coalition et al.

Even by its own logic, EPA's rule fails because it fails to account for decreased energy security owing to an increased demand for natural gas, which currently makes up 40 percent of our grid's electricity generation. This share—or at least the volume of energy generated—will need to grow dramatically to make up for the increased electricity demand.19 [EPA-HQ-OAR-2022-0829-0712, p. 36]

19 Of course, "[t]he United States is [also] the leading producer of natural gas," and so increasing reliance on natural gas does little to move the needle on energy security. C. Boyden Gray, American Energy, Chinese Ambition, and Climate Realism, 5 American Affairs Journal (Winter 2021), https://americanaffairsjournal.org/2021/11/3333tellant-energy-chinese-ambition-and-climate-realism/. But if the proposal intends to count decreases in petroleum in its favor it is completely unreasonable to ignore the concomitant increases in natural gas consumption.

Organization: Delek US Holdings, Inc.

II. EPA's Proposed Rule Will Increase Domestic Reliance on Foreign Supply Chains.

Today, the U.S. is virtually independent in terms of transportation fuels (i.e., petroleum- and ethanol-based liquid fuel products) for ICE-powered vehicles.9 Although EPA spends a not insignificant amount of space in its draft Regulatory Impact Analysis ("DRIA") assessing energy security, EPA limits itself to drawing broad conclusions regarding future projections for exports, imports, and consumption of crude oil and refined petroleum products—as well as relying on inflated support from potential funding mechanisms of the Bipartisan Infrastructure Law ("BIL") and the Inflation Reduction Act ("IRA").10,11,12 But this ignores the larger concern regarding energy and national security: an unfavorable transition from reliable, abundant, domestically-sourced fuels to a complex supply chain reliant on foreign-sourced critical minerals. [EPA-HQ-OAR-2022-0829-0527, p. 3]

9 While "energy independence" has varying definitions, we are using the term consistent with EPA's use in the Proposed Rule—"[t]he goal of U.S. energy independence is the elimination of all U.S. imports of petroleum and other foreign sources of energy, but more broadly it is the elimination of U.S. sensitivity to the variations in the price and supply of foreign sources of energy"). Proposed Rule at 26,077.

10 Public Law 117-58, Nov. 15, 2021.

11 Public Law 117-169, Aug. 16, 2022.

12 EPA, Draft Regulatory Impact Analysis for Proposed Rule, 3-19–29 (Apr. 2023) [hereinafter "DRIA"]. Notably, EPA concludes that U.S. oil consumption is projected to be fairly steady for the time period from 2027 to 2050" and will actually increase gradually over that time. Id. At 11-26 (Table 11-1). EPA also concludes that the Proposed Rule will result in a 90.7% reduction in oil imports.

Organization: Electrification Coalition (EC)

The national and economic security concerns that persist from our nation still exposed to a global oil market characterized by volatility and instability are critical to consider when considering a regulation such as the EPA's Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles. The U.S.'s exposure is most recently exemplified by the global ramifications of Russia's invasion of Ukraine in February 2022, and of Russia's willingness to use petroleum resources as a weapon, which sent oil prices to their highest point since 2008. Despite the U.S.'s increased prominence in the world's oil markets – which includes a roughly six-fold increase in oil exports between 2015 and 2019 – the oil market is only as strong as its weakest links, which the U.S. must expend considerable resources to defend to minimize market disruptions. More broadly, the nation's costs to protecting the flow of oil includes the roughly $81 billion spent annually by the U.S. taxpayer – which proportionally represents 16 percent of the current defense budget – but also less quantifiable losses of global strength and leadership, and distorted American diplomacy goals which must prioritize the global flow of oil.3 [EPA-HQ-OAR-2022-0829-0588, p. 2]

In short, the underlying factors that led to record oil prices in 2008 and 2022 have not substantially changed, nor will they in the future as there are additional influencing factors for the global oil market. These influencing factors include a growing demand for oil from emerging markets, geopolitical instability that causes global oil shocks, market manipulation across many oil-producing nations, limited access to reserves owned by national oil companies, and the higher cost of production of fields that are available to international oil companies. While oil has facilitated the rise of the modern era, these persistent national and economic security threats indicate it is past time to shift to a better, more stable fuel source: electricity. [EPA-HQ-OAR-2022-0829-0588, p. 2]

Organization: Environmental and Public Health Organizations

XXVII. Stronger Standards Will Improve U.S. Energy Security.

Energy security considerations also support strong final standards. Reducing U.S. reliance on oil enhances U.S. energy security, and—with energy security in mind—Congress has specifically directed the U.S. to conserve energy. Energy Policy and Conservation Act of 1975, 42 U.S.C. § 32902(f). EPA defines energy security as "the uninterrupted availability of energy sources at affordable prices," 88 Fed. Reg. at 29388; DRIA at 11-1, and states that "[t]he goal of U.S. energy independence is the elimination of all U.S. imports of petroleum and other foreign sources of energy, but more broadly, it is the elimination of U.S. sensitivity to variations in the price and supply of foreign sources of energy." 88 Fed. Reg. at 29388. Despite increases in domestic oil production that have made the United States an energy exporter, EPA should continue to consider the energy security impacts of GHG standards. EPA notes that combustion vehicles continue to present an energy security risk because the United States remains vulnerable to "episodic oil supply shocks and price spikes." Id. U.S. refineries continue to import heavy crude oil from potentially unstable regions of the world, and sudden disruptions in supply pose a threat to U.S. financial and strategic interests. DRIA at 11-1. Moreover, EPA is correct that "oil exporters with a large share of global production have the ability to raise or lower the price of oil by exerting the market power associated with the Organization of Petroleum Exporting Countries (OPEC) to alter oil supply relative to demand," id., which would cause oil price shocks that have greater impacts when nations are heavily reliant on oil. Because the Proposed Standards will significantly reduce U.S. reliance on foreign oil, see 88 Fed. Reg. at 29388, Tbl.198 (showing decrease of 42,000 barrels of imported oil per day in 2027 and decrease of 2.3 million barrels of imported oil per day by 2055, and even greater import reductions under Alternative 1), EPA's Proposal and Alternative 1 both enhance U.S. energy security and make progress toward the goal of energy independence. [EPA-HQ-OAR-2022-0829-0759, p. 197]

For the Proposal, EPA has quantified the energy security risks using a macroeconomic oil security premium. 88 Fed. Reg. at 29389. Oil security premiums measure the extra cost of importing oil beyond the price paid for the oil itself (or, in the case of a reduction in demand, the extra benefit of reducing oil imports beyond the actual expenditures saved). The main input to calculating the oil security premium is the macroeconomic benefit, which measures the potential macroeconomic disruptions and increased oil import costs to the economy resulting from oil price spikes or "shocks," or the value of avoiding these costs due to less domestic reliance on oil. In estimating the macroeconomic benefit used to calculate oil security premiums, EPA has historically relied on research conducted by Oak Ridge National Laboratory (ORNL), and EPA again takes this approach in the Proposal.653 Id. EPA has estimated macroeconomic oil security premiums based on ORNL's methodology developed in 1997 and updated in 2008654 for a series of past rulemakings including the 2010, 2012, and 2021 Final Rules and the heavy-duty vehicle GHG and fuel economy Phase I and Phase II standards and Phase III proposal.655 In this Proposal, EPA reasonably utilizes the long-used ORNL methodology and applies the same values for the price elasticity of demand for oil and elasticity of GDP to oil price shocks as for the 2021 Rule. DRIA at 11-28 to 11-29. Similarly, EPA reasonably calculates the oil import reduction factor by the same method used for the most recent rulemaking. Id. At 11-25. [EPA-HQ-OAR-2022-0829-0759, p. 198]

653 In this Proposal, EPA reasonably calculates the macroeconomic oil security premiums using the same price elasticity of demand for oil and the same elasticity of GDP to an oil price shock as for the 2021 Rule. DRIA at 11-28 to 11-29.

654 Leiby, P.N., Estimating the Energy Security Benefits of Reduced U.S. Oil Imports, Final Report, ORNL/TM-2007/028, Oak Ridge National Laboratory (Rev. Mar. 14, 2008); Leiby, P.N. et al., Oil Imports: An Assessment of Benefits and Costs, ORNL-6851, Oak Ridge National Laboratory (Nov. 1997); see also R. Uria-Martinez, et al., Using Meta-Analysis to Estimate World Oil Demand Elasticity, ORNL Working Paper (2018).

655 The 2020 LDV GHG standards proposal also relied on the ORNL literature and methodologies for estimating oil security premiums, and only the 2020 Final Rule abandoned this research and methodology, instead relying on a single paper (Brown (2018)) to drastically reduce oil security premiums. Stephen A. Brown, New Estimates of the Security Costs of U.S. Oil Consumption, 13 Energy Policy 171-92 (2018). Reliance on Brown was inappropriate for two reasons: (1) EPA failed to provide adequate justification for departing from the established ORNL methodologies and research that had been used for over 20 years to instead rely on a single study; and (2) the 2020 Final Rule did not appear to have used Brown's best or most accurate estimates in setting oil security premiums, but rather used estimates that even Brown (2018) suspected to be inaccurate. Id. At 181 (noting that Brown's estimate of the "combined" value for oil

security premiums “might best reflect the uncertainty in what we know about oil security premiums,” and that the values derived from only the most recent research—which EPA used in the 2020 Final Rule—may not be the most reliable).

In addition to the macroeconomic oil security premium, military and monopsony benefits are considered energy security benefits of reduced U.S. oil demand. DRIA at 11-2, 11-30 to 11-32. While EPA has historically refrained from applying these values in any quantified way, it is important to recognize that energy security benefits that take into account only the macroeconomic oil security premiums could be low estimates. EPA’s Proposal correctly explains that one cost of oil use is “maintaining a military presence to help secure a stable oil supply from potentially vulnerable regions of the world,” id. At 11-30, and therefore, reducing domestic reliance on oil has the potential to result in some form of military benefit. EPA states that the Agency does not include these benefits because they are hard to quantify. Id. At 11-31 to 11-32. EPA is encouraged to consider methodologies for quantifying these benefits in the future, and to acknowledge that their existence makes EPA’s current estimations of energy security benefits conservative. [EPA-HQ-OAR-2022-0829-0759, p. 199]

Finally, EPA is correct that electricity used in PEVs will “improve the U.S.’s overall energy security position,” 88 Fed. Reg. at 29389, because electricity is more affordable and less price volatile than oil, a point that numerous sources support.656 Even more importantly, the electricity will be almost exclusively produced in the United States, “mov[ing] the U.S. towards the goal of energy independence.” Id. Additionally, PEVs offer significant energy security benefits in that “[e]lectric vehicles can be powered by any energy source because all energy sources can be converted to electricity.”657 Unlike combustion vehicles—which can be powered only by oil—PEVs can utilize solar, wind, hydroelectric, geothermal, or any other electricity resources available to the grid.658 [EPA-HQ-OAR-2022-0829-0759, p. 199]

656 See, e.g., Talor Gruenwald, Reality Check: The Myth of Stable and Affordable Natural Gas Prices, Rocky Mountain Institute (Nov. 17, 2021), https://rmi.org/the-myth-of-stable-and-affordable-natural-gas-prices/ (“Electricity prices, which are driven by the costs of a variety of fuels including renewables, are much less susceptible to individual commodity price shocks.”); Jeremy Martin, Why Are Gasoline Prices So Volatile?, Union of Concerned Scientists (Mar. 29, 2022), https://blog.ucsusa.org/3336tella-martin/why-are-gasoline-prices-so-volatile/ (explaining the price volatility of the oil market and noting that its global nature “means that U.S. consumers remain vulnerable to changes in oil prices across the globe” and that “electricity prices are far less volatile than gasoline.”); U.S. Department of Energy, Saving Money with Electric Vehicles (Sept. 28, 2022), https://www.energy.gov/energysaver/articles/saving-money-electric-vehicles (noting that “electricity is less expensive than gasoline,” and that “[p]etroleum prices are historically very volatile and change substantially over time,” while “electricity prices are much more stable.”).

657 Nicholas Brown, Evs Provide Energy Security, Aid Energy Transitions During Conflicts, Clean Technica (July 12, 2022), https://cleantechnica.com/2022/07/12/evs-provide-energy-security-aid-energy-transitions-during-conflicts/.

Gunn, Electric Vehicles Improve Our National Security, Orlando Sentinel (June 9, 2023), https://www.orlandosentinel.com/2023/06/09/electric-vehicles-national-security-opinion/ (“Diversified energy resources and Evs are already beginning to reduce our dependence on unpredictable oil-exporting partners. Accordingly, Evs can reduce our exposure to energy supply shocks and, importantly, limit the risk of supply disruptions for military operations.”).

Organization: Fuel Freedom Foundation

Increase national and energy security. The decades-long strategic imperative to reduce petroleum dependence has not been inhibited by record-breaking U.S. domestic drilling, as succinctly laid out in the U.S. National Blueprint for Transportation Decarbonization (U.S. Blueprint): "More than 95% of transportation energy use comes from petroleum-based fuels, making it the least energy-diverse sector and subjecting the American economy to the volatility of global markets." Oil prices still regularly rise rapidly in response to world events or market manipulation, even after the U.S. surpassed Saudi Arabia as the world's largest producer. Americans remain subject to such price fluctuations, driven by geopolitics and market dynamics that reflect a lack of fuel alternatives. From a policy perspective, our national options remain inhibited by overwhelming petroleum dependence in transportation. We can only gain genuine energy and economic security by weakening petroleum's strategic consequence. The EPA can move us in the right direction by incentivizing the re-adoption of FFVs that can quickly enable displacement of large volumes of gasoline at little to no cost to consumers. [EPA-HQ-OAR-2022-0829-0711, p. 4]

Organization: Institute for Policy Integrity at New York University School of Law

Turning to energy security, EPA reasonably concludes that the Proposed Rule will benefit domestic energy security by shifting consumption from petroleum to electricity, which is cheaper, more price-stable, and more domestically-produced.110 In addition to a thorough qualitative analysis,111 EPA conducts a quantitative analysis of the Proposed Rule's oil security premium using a peer-reviewed methodology.112 In a nutshell, this analysis estimates the economic benefits resulting from reductions in oil imports.113 An important parameter in this analysis is the own-price elasticity of demand for oil. This parameter reflects the sensitivity of oil sales to oil price changes. More specifically, it represents the expected decline in oil demand (on a percentage basis) from a 1% increase in oil price. [EPA-HQ-OAR-2022-0829-0601, pp. 17-18]

110 Proposed Rule, 88 Fed. Reg. at 29,388–89.

111 RIA at 11-1 to 11-26.

112 Id. At 11-26 to 11-30.

113 Id. At 11-26; see also Proposed Rule, 88 Fed. Reg. at 29,389.

EPA should update the own-price elasticity of demand for oil to account for increased electrification over time. Specifically, EPA adopts a low own-price elasticity of demand for oil of -0.07—meaning that oil sales only marginally decline when prices increase, reflecting the fact that oil cannot be easily substituted with other products.114 But in the future, as electric vehicles become more prominent, this is likely to change as electricity becomes more easily substitutable for oil.115 Accordingly, the own-price elasticity of demand for oil is likely to increase in the future. EPA should thus use a higher absolute valuation of this parameter that is not based purely on historical data. One option is to apply a valuation between –0.175 and –0.33 as the research from Resources for the Future shows.116 Alternatively, EPA could recalculate the own-price elasticity of demand for oil within the NEMS model.117 [EPA-HQ-OAR-2022-0829-0601, pp. 17-18]

114 RIA at 11-28.

115 See infra p. 30 figs.1–2.

116 Id.

117 See Bureau of Energy and Ocean Management, Consumer Surplus and Energy Substitutes for OCS Oil and Gas Production: The 2021 Revised Market Simulation Model (MarketSim) Model Description 22 (2021) (describing similar methodology). Using this methodology, the elasticity of demand may still be too low because the latest version of NEMS only considers current policy and fails to consider the likely path of policy—such as the Proposed Rule—that could further increase electricity-to-oil substitution.

Organization: MEMA, The Vehicle Suppliers Association

Vehicles that use alternative, lower-carbon fuels can help advance EPA climate goals while also contributing to improved national security by lowering our dependence on foreign oil. Additionally, encouragement and investment in carbon-neutral fuels will also positively impact existing vehicles already on the road. [EPA-HQ-OAR-2022-0829-0644, p. 6]

Organization: Missouri Corn Growers Association (MCGA)

If the economic damages are not bad enough, the impact of EPA's forced change to BEVs may compromise our national security. Who is in favor of a move that would incentivize batteries and minerals produced and mined in countries that are hostile to the U.S. and have questionable labor standards over relying on homegrown renewable liquid fuels, along with our domestic energy sources found right here in America, much of it in the Midwest? [EPA-HQ-OAR-2022-0829-0578, p. 3]

Organization: Pearson Fuels

g. The use of E85 as a decarbonization strategy is a uniquely cost-efficient GHG strategy that reduces petroleum dependence and enhances energy security

As has been discussed, it is now clear that Californians are embracing E85 fuel with the second largest gasoline market in the country showing 66% year-on-year growth in E85 sales from 2021 to 2022. CARB has confirmed the rigor of its oversight program and the rate of E85 growth in a letter to Pearson Fuels that is attached as Exhibit 4 to this comment.24 The sustained growth in demand for E85 from FFVs in California is remarkable, surging from less than 6.5 MGY in 2006 to over 103 MGY in 2022. [EPA-HQ-OAR-2022-0829-0577, p. 13]

24 Letter from Alexander "Lex" Mitchell, Manager, Emerging Technologies Section, California Air Resources Board regarding E85 use, to Graham Noyes, Noyes Law Corporation. This CARB letter is attached as an exhibit to the comment of Pearson Fuels to this proceeding.

The primary reason E85 use is on the rise in California is a typical and crucial driver in the fuel market, price. At the retail level, California FFV owners can fill up on E85 and routinely save 10 percent or more compared to conventional unleaded on a price per mile basis. It is due to these favorable economics that FFV stations are flourishing in disadvantaged communities where spiking gasoline prices are most damaging to consumer budgets. FFV owners previously unable to fuel with E85 because of limited availability are just now being exposed to a robust network of E85 stations offering steep price discounts to gasoline, and providing a cleaner fuel that simultaneously boosts octane, the farm economy, and U.S. energy security. E85's rapidly growing market appeal is not limited to California and is part of a broader U.S. market transition toward higher ethanol blends. This rapid growth in E85 demand is occurring at the same time that diminished FFV crediting under the GHG program has undercut the incentive for automakers to manufacture FFVs. This deployment of FFVs utilizing E85 by U.S. consumers to save money and reduce GHG emissions would be greatly enhanced to the extent EPA establishes an appropriate GHG emissions factor for FFVs. [EPA-HQ-OAR-2022-0829-0577, p. 13]

Organization: Plains All American Pipeline, L.P.

In general, we have serious concerns about the Proposal. It will render America more dependent on foreign-controlled supply chains and create irreparable harm to our energy security, while missing the mark on well-intentioned emission reductions. By focusing solely on tailpipe emissions, the Proposal would only address certain transportation emissions and fail to quantify the full lifecycle of emissions for all vehicles, including materials resourcing, production, operation, battery replacement, recycling and end-of-life disposal. [EPA-HQ-OAR-2022-0829-0713, p. 1]

By 2032—less than 10 years from now—the EPA's Proposal would require nearly 70% of light-duty cars and trucks sold in the U.S. to be electric or "zero tailpipe emission." We have a number of concerns with this approach, a few include [EPA-HQ-OAR-2022-0829-0713, pp. 1-2]:

- By focusing on tailpipe emissions alone, most internal combustion engine vehicles that run on gasoline, diesel and biofuels would be unable to meet the standards set forth in the Proposal. This overlooks critical efforts of the energy and automotive industries to pursue continued innovation and optimization of fuel/vehicle systems to improve efficiency and reduce emissions.1 [EPA-HQ-OAR-2022-0829-0713, pp. 1-2]

- Effectively outlawing most liquid fuel-powered vehicles would undercut U.S. energy security,2 harm our domestic energy industry and leave the U.S. more dependent on foreign-controlled supply chains.3 [EPA-HQ-OAR-2022-0829-0713, pp. 1-2]

- Transferring a significant amount of energy demand to electricity will strain already challenged electrical generation and transmission infrastructure. Without substantial additional investment and significant streamlining of electric transmission permitting, it's unclear whether the electrical grid could support charging new Evs at the level necessary to support the proposed emissions reductions.4 [EPA-HQ-OAR-2022-0829-0713, pp. 1-2]

- Traditional energy sources are essential for ensuring effective evolution of the energy landscape-including the manufacture and growth of renewable energy sources and Evs. However, the Proposal would reduce energy investments and increase costs to consumers for all forms of energy. Furthermore, this policy risks the continued viability of critical domestic energy manufacturing infrastructure, which, if idled, would be very challenging to restore. [EPA-HQ-OAR-2022-0829-0713, pp. 1-2]

- Eliminating most new gasoline and diesel vehicles from the market limits consumer choice. Significantly fewer new affordable vehicles are available for sale today5 than a few years ago. Used cars are also increasing in price6 as some automakers warn that they will be forced to cut back on supplying popular gasoline models because of government regulations restricting sales of traditional vehicles.7 [EPA-HQ-OAR-2022-0829-0713, pp. 1-2]

Organization: The Heritage Foundation

Security benefits are overstated.

The study purports to find small energy security benefits by having less imported oil. See Table 200. The analysis ignores that United States can well be an oil-exporting, rather than an oil-importing country. For that reason alone, the stated energy security benefits are likely costs rather than benefits. [EPA-HQ-OAR-2022-0829-0674, p. 14]

Organization: Valero Energy Corporation

F. EPA fails to account for potential energy security impacts.

EPA acknowledges a lack of literature on the energy security implication of PEV charging: "Even though there is likely to be a substantial increase in the use of electricity from PEVs in the U.S., the literature on the topic of the energy security implications of wider use of PEVs is somewhat limited. We have not been able to identify any study that systematically quantifies the differential energy security risks of using electricity versus petroleum-based fuels to power vehicles in the U.S."276 While EPA focuses on the energy security benefits of reducing dependence on oil imports, its consideration of the energy security threats associated with PEV adoption is limited to the electricity consumption by PEVs277 – EPA fails to address the energy security threats of increasing dependence on imports for minerals and battery supply chains. [EPA-HQ-OAR-2022-0829-0707, pp. 50-51]

276 DRIA at 11-10.

277 DRIA at 11-1 to 11-40.

EPA refers to the 2021 ransomware attack of Colonial Pipeline278 but fails to consider cybersecurity threats associated with PEV charging.279 As published recently by Sandia National Laboratories in a study of EV charging infrastructure, [EPA-HQ-OAR-2022-0829-0707, pp. 50-51]

278 DRIA at 11-1, footnote 170.

279 See Cloete, Schalk, "Electric Cars and Energy Security: Out of the Frying Pan and Into the Fire", March 14, 2022, https://medium.com/a-balanced-transition/electric-cars-and-energy-security-out-of-the-frying-pan-and-into-the-fire-a3a27bfb54d5.

The breadth and complexity of EVSE connections create a large cybersecurity profile and raise concerns that bad cyber actors could use insecure chargers as an unauthorized access point to abuse charging equipment, vehicles, buildings, or grid resources. Each of these systems represents a set of interconnected attack vectors. Evs, for example, interface with dealerships, mobile phones, navigation, mapping, telemetry, entertainment, vehicle-based web browsers, other vehicles, driver assist systems, over-the-air software updates, and more [], using an array of protocols, including Bluetooth, GSM Mobile, and Wi-Fi. Autonomous-driving electric vehicles add further cybersecurity complexity []. Researchers have highlighted the manipulation of onboard, safety-critical electronic control units (ECUs) to interfere with braking, steering, engine and battery controls []. Vehicle data are also at risk, including telematics, tracking [], customer, dealer and insurance data []. EVSE interfaces with highly connected Evs and vendor systems, charger owners, and grid operator systems.280 [EPA-HQ-OAR-2022-0829-0707, pp. 50-51]

C. EPA's action would undermine the Renewable Fuel Standard and Congress' goals for renewable fuels and energy security.

EPA's proposal and ZEV sales mandate are also inconsistent with the broader statutory scheme and Congress's plan for tackling climate change. When Congress sought to address greenhouse-gas emissions from the transportation sector, it did so by promoting renewable liquid fuels, which are used in conventional vehicles and which—unlike electric-vehicle components—are in abundant domestic supply. See, e.g., Inflation Reduction Act of 2022, Pub. L. No. 117-169. §§ 13202, 13404, 22003, 136 Stat 1818, 1932, 1966-69, 2020 (2022). Indeed, Congress has consistently legislated against the background expectation that conventional vehicles powered by liquid fuels will remain on the market. [EPA-HQ-OAR-2022-0829-0707, pp. 86-]

The Clean Air Act also includes the Renewable Fuel Standard (RFS) program, which "requires that increasing volumes of renewable fuel be introduced into the Nation's supply of transportation fuel each year." Americans for Clean Energy v. EPA (ACE), 864 F.3d 691, 697 (D.C. Cir. 2017). Two goals animate the RFS: (1) to "move the United States toward greater energy independence and security," and (2) to "increase the production of clean renewable fuels." Id. (quoting Pub. L. No. 110-140, 121 Stat. 1492, 1492 (2007)). To these ends, "Congress ordained the inclusion of 4 billion gallons of renewable fuel in the Nation's fuel supply" for calendar year 2006, and required that, "[b]y 2022, the number will climb to 36 billion gallons." HollyFrontier Cheyenne Refining, LLC v. Renewable Fuels Ass'n, 141 S. Ct. 2172, 2175 (2021). [EPA-HQ-OAR-2022-0829-0707, pp. 86-]

In other words, through the RFS, which is also in the Clean Air Act, Congress mandated that "fuel sold or introduced into commerce in the United States" must contain increasing shares of renewable fuels and specifically increasing shares of advanced biofuel, cellulosic biofuel, and biomass-based diesel. 42 U.S.C. § 7545(o)(2)(A)(i). For these fuels, Congress called for not simply a percentage of the fuel market but mandated a minimum volume of biofuel in the market. The proposed standards, on the other hand, would reduce the use of renewable fuels, particularly renewable diesel and other advanced biofuels, cellulosic biofuels, and biomass-based diesel, and make it impossible to meet the mandates of the RFS. EPA is thus working at cross-purposes with Congress, which has required a move toward increases in liquid renewable fuels at the same time that EPA is seeking to eliminate vehicles that use such fuels. Congress has never mandated, nor authorized, that EPA issue regulations to phase out the use of liquid fuels. [EPA-HQ-OAR-2022-0829-0707, pp. 86-]

The congressional intent underlying these mandated obligations under the RFS was to incentivize liquid fuels with lower lifecycle greenhouse gas emissions. For example, renewable diesel generates credits under the RFS, whereas traditional diesel generates an obligation. Here, however, treating renewable diesel and traditional diesel the same—giving no recognition of or benefit to manufacturers based on use of liquid fuels with lower lifecycle greenhouse gas emissions— underscores EPA's failure to read its statutory authority as a whole and emphasizes the conflict between the proposal and the RFS. [EPA-HQ-OAR-2022-0829-0707, pp. 86-]

Congress also cited national energy security as one of the primary reasons for implementing the RFS. In the proposal, EPA deigns to resolve energy security concerns by reducing use of liquid fuels without accounting for the impact on renewable fuels. EPA has also not adequately accounted for increased energy security risks associated with battery production and use in the transportation of the nation's commerce and in all the industries that use and rely on LDVs and MDVs. See supra at XX. [EPA-HQ-OAR-2022-0829-0707, pp. 86-]

With no apparent recognition that its proposed vehicle standards will reduce consumption of both nonrenewable and renewable fuels, EPA continues to mandate increasing volumes of renewable fuels consistent with its mandates under the RFS, proposing a 1.7 billion gallon increase in all renewable fuels by 2025 in its proposed "RFS Set" rule.368 [EPA-HQ-OAR-2022-0829-0707, pp. 86-]

368 Final Rule: Renewable Fuel Standard (RFS) Program: Standards for 2023-2025 and Other Changes, signed June 2023, pre-publication version available at https://www.epa.gov/renewable-fuel- standard-program/final-renewable-fuels-standards-rule-2023-2024-and-2025.

Organization: Western Energy Alliance

Energy Security: EPA makes the specious assertion that the energy security benefits of the rule will include, "…reductions in energy security externalities caused by U.S. petroleum consumption and imports…" p. 29199 Given the huge supply of American oil and the fact that the United States is the number one oil producer in the world, EPA strains its credibility by justifying the proposed rule in such a way. Unlike the ICEV fleet with its majority consumption of American oil, EV batteries are sourced from minerals largely mined unsustainably in China and Africa, as are the minerals required for wind turbines and solar panels. Further, the U.S. lacks copper and aluminum smelting capacity required to expand the grid and it takes years to develop new mines. Without expansion, the grid is susceptible to reliability issues. [EPA-HQ-OAR-2022-0829-0679, p. 4]

EPA's cost-benefit analysis regarding energy security is troublesome, finding that the proposed rule delivers $21 billion to $42 billion in energy security benefits from reduced oil imports, but ignoring the security implications of the huge foreign mineral needs arising from the proposed rule. With huge domestic reserves of oil and the fact that Canada is the primary exporter to the United States, our country enjoys an energy security benefit in terms of oil. [EPA-HQ-OAR-2022-0829-0679, p. 4]

Organization: Zero Emission Transportation Association (ZETA)

As EPA notes in the proposed rule, the light- and medium-duty GHG standards would reduce U.S. oil imports by 2.3 million barrels per day in 2055, meaning American consumers would be more insulated from foreign geopolitical turmoil and associated oil price volatility.87 Finalizing more stringent standards than Alternative One would reduce U.S. oil imports by more than 2.5 million barrels per day in 2055. Mark Zandi, chief economist at Moody's has noted that fossil fuels were a major cause of every period of inflation since World War II. "Every recession since World War II has been preceded by a jump in oil prices."88 As discussed further below, reducing exposure to such volatility that affects the transportation of goods, people and services, electrification can stabilize costs as these are often heavily affected by transportation fuel costs.89 [EPA-HQ-OAR-2022-0829-0638, p. 19]

87 See 88 FR 29388 (May 5, 2023)

88 "Fight climate change. End fossilflation. Here's how," Vox, (August 12, 2022) https://www.vox.com/science-and-health/2022/8/12/23290488/fight-climate-change-end-fossil-fuel-inflation

89 'Energy Price Stability: The Peril of Fossil Fuels and the Promise of Renewables,' Roosevelt Institute, (2022) https://rooseveltinstitute.org/wp-content/uploads/2022/05/RI_EnergyPriceStability_IssueBrief_202205.pdf

With the price of oil subject to a wide range of economic, geopolitical, and operational factors, Evs help protect consumers from rapid fuel price spikes. As shown in Figure 4 below, Evs are not only cheaper to drive per mile but their fuel costs are more consistent and predictable compared to similar ICEVs. Electricity prices tend to be less volatile and subject to fewer supply shocks than oil prices.108 Even when sourcing petroleum domestically, disturbances can have dramatic price consequences. For example, on December 24, 2022, Suncor shut down its 103,000-barrel per day (bpd) oil refinery in Commerce City, Colorado, just outside of Denver. [EPA-HQ-OAR-2022-0829-0638, pp. 22-23]

Suncor announced that extreme cold weather earlier in the month had damaged equipment and that the repairs would require a full shutdown of the facility and delay operations until the end of the first quarter of 2023. By February 2023 gasoline prices in the Rocky Mountain region had increased by 51%, considerably higher than the 9% national average.109 [EPA-HQ-OAR-2022-0829-0638, pp. 22-23]

108 Id. At footnote 89

[See original comment for Figure 4: A comparison of operating costs for electric and gas-powered vehicles from March 2022 to March 2023.]110 [EPA-HQ-OAR-2022-0829-0638, pp. 22-23]

110 "Electric vehicles are far cheaper to drive than gas-powered cars," ZETA, (March 2023) https://8829857.fs1.hubspotusercontent-na1.net/hubfs/8829857/ZETA-EV%20vs.%20Gas%20Report_V4.pdf

Reliance on petroleum for light- and medium-duty vehicles also exposes American consumers' wallets to geopolitical instability. The February 2022 Russian invasion of Ukraine resulted in rapid, significant spikes in the price of crude oil, which contributes about half the cost of finished gasoline.111 In June 2023, Saudi Arabia announced it would cut oil production by 1 million bpd, pushing up oil prices in the short term and causing them to be projected to remain high through at least summer 2023.112 This will ultimately result in higher prices for gasoline in the US per oil analysts at Rystad Energy who believe gas will become marginally more expensive for consumers. In addition to Saudi Arabia, other members of OPEC agreed on recent surprise cuts in oil production, adding to the ultimate uncertainty for consumers that relying on oil provides.113 [EPA-HQ-OAR-2022-0829-0638, pp. 23-24]

111 "Yes, Russia's War on Ukraine Did Raise the Price of Gasoline," Cato Institute, (April 6, 2022) https://www.cato.org/blog/yes-russias-war-ukraine-did-raise-price-gasoline-0

112 "Saudi Arabia is slashing oil supply. It could mean higher gas prices for US drivers," Associated Press, (June 4, 2023) https://apnews.com/article/opec-oil-prices-saudi-arabia-russia-8d70999cb8258aebc3edbfdfcae278b7

113 Id. At footnote 112

Americans are at the mercy of these decisions with the reliance of ICEVs. The shift to Evs is a hedge against this price volatility and will bring stability to the cost of transportation in the U.S. [EPA-HQ-OAR-2022-0829-0638, pp. 23-24]

As EPA accurately notes in the proposed rule, there is an important distinction between energy security and mineral security. Utilization of critical minerals is inherently different from the utilization of petroleum, in that petroleum is consumed as a fuel while minerals become a component of manufactured vehicles. Supply disruptions and fluctuating prices for critical minerals are felt differently and by different parties as opposed to petroleum which has an immediate impact on consumers through higher fuel prices, as discussed in section 3(b) of these comments. In contrast, supply disruptions or price fluctuations of minerals affect only the production and price of new vehicles. [EPA-HQ-OAR-2022-0829-0638, p. 33]

Moreover, critical minerals are not a single commodity but a number of distinct commodities, each having its own supply and demand dynamics, and some being capable of substitution by other minerals. Further, while petroleum is consumed as a fuel and thus requires continuous supply, minerals become part of the vehicle and have the potential to be recovered and recycled, as discussed further in section 8(b)(ii) of these comments. [EPA-HQ-OAR-2022-0829-0638, p. 33]

EPA Summary and Response

Summary:

Some commenters (Electrification Coalition, Zero Emission Transportation Association, Institute for Policy Integrity, Environmental and Public Health Organizations, California Air Resources Board) claimed that the proposed rule will improve the U.S.'s energy security and independence position by resulting in an increase in the use of plug-in electric vehicles (PEVs). According to two commenters (Institute for Policy Integrity, Environmental and Public Health Organizations), PEVs are cheaper to drive per mile than light- and medium-duty vehicles (LMDVs) that use petroleum-derived fuels such as gasoline. Also, according to the same commenters, electricity prices are more stable and are not subject to as much price volatility as oil-derived petroleum products such as gasoline. Finally, the same two commenters suggested that the electricity to power PEVs will likely be domestically produced. Since electricity used to power the PEVs will be produced in the U.S., the wider use of PEVs would move the U.S. to the goal of energy independence, the commenters claimed. In contrast, according to these commenters, the global oil market is subject to price volatility and price instability, which reduces the U.S.'s energy security.

Response:

EPA believes that the wider use of electricity in light- and medium-duty vehicles will increase the U.S.'s energy security and independence by reducing the U.S.'s petroleum consumption and imports. A reduction of U.S. petroleum consumption and imports reduces both financial and strategic risks caused by potential sudden disruptions in the supply of imported petroleum to the U.S., thus increasing the U.S.'s energy security. We agree with the commenters that electricity is generally a more affordable fuel for powering light- and medium-duty vehicles compared to petroleum-derived fuels. See Chapter 10, Section 10.3.1, of the RIA for more discussion on this topic. Also, electricity prices have been less volatile than petroleum-derived fuels used to power light- and medium-duty vehicles. See Chapter 10, Section 10.3.2, of the RIA for more discussion on this topic. Since it is anticipated that the electricity to power LMDVs will be produced in the U.S., the wider use of PEVs will likely increase the U.S.'s energy independence. See Chapter 10, Section 10.3.3, of the RIA for more discussion on this topic.

Summary:

Some commenters (Valero, Motor and Equipment Manufacturers Association, Fuel Freedom Foundation, Pearson Fuels, Missouri Corn Growers Association, Plains All American Pipeline, L.P.) suggested that since this proposed rule focuses on the promotion the wider use of PEVs, that the demand for renewable fuels will be reduced. These commenters suggested that EPA should instead focus upon achieving U.S. energy security and independence objectives with increasing use of renewable fuels and, more specifically, flexible-fueled vehicles/higher ethanol blends and the greater use of renewable diesel fuel. One result of this proposed rule, according to one commenter (Valero), is that it would be more difficult to meet the renewable fuel mandates of the Renewable Fuel Standards (RFS). When the U.S. Congress passed the RFS, one goal of the RFS was to promote U.S. energy security and energy independence. Thus, according to this commenter, the proposed rule is at odds with the Congressional intent of the RFS requiring renewable fuels to achieve energy security and independence objectives.

Response:

As explained in preamble Section V, EPA is setting the final LMDV GHG standards under our CAA section 202(a)(1)-(2) authority. EPA also evaluated the impacts of the final LDMV GHG standards on energy, in terms of oil conservation and energy security through reductions in fuel consumption. EPA considers this final rule to be beneficial from an energy security perspective and thus this factor was considered to be a supportive and not constraining consideration.

EPA agrees with the commenters that use of renewable fuels can further the U.S.'s energy security and energy independence since use of those fuels results in reduced consumption and reduced U.S. net imports of petroleum, but the use of renewable fuels are not the only available or appropriate strategies for reducing demand for petroleum-based fuels. A reduction of U.S. petroleum consumption and imports reduces both financial and strategic risks caused by potential sudden disruptions in the supply of imported petroleum to the U.S., thus increasing the U.S.'s energy security. EPA responds to issues about flexible-fueled vehicles in RTC Section 26. In addition, the wider use of renewable fuels increases the U.S.'s energy independence, since the renewable fuels used to meet the RFS requirements are expected to be almost exclusively produced in the U.S. We also note that renewable fuels also may have some energy security risks, for example, as a result of weather-related events (e.g., droughts that limit crop production used to make biofuels). As discussed further below, we view this rule and the recently finalized RFS rule as complementary strategies in promoting the U.S.'s energy security.

All energy sources, including petroleum-based fuels and renewable biomass-based fuels, have associated potential energy security risks that depend on their domestic availability, price volatility, and the regionality and global integration of their markets and associated vulnerabilities to market disruption events. However, EPA is aware of robust quantitative methods for estimating the energy security benefits of reductions in petroleum use only; we are not aware of any published estimates of the energy security risks associated with increased use of either electricity or renewable fuels. Thus, in this final rule we are not able to quantify any potential energy security risks associated with use of non-petroleum-based fuels in our method of estimating energy security impacts. In general, however, we consider the energy security risks of these fuels to be lower because they are less likely to have supply disruptions and include a diversity of energy sources.[680]

Additionally, EPA disagrees with the commenter regarding their claims on the interaction of this final rule with the RFS program. First, as we explain further in RTC Section 2, Congress specifically determined that the RFS provisions do not limit EPA's authority to regulate GHGs under any other provision of the Clean Air Act, including section 202(a)(1).[681] Second, the recently finalized RFS Set Rule, which established the highest RFS volumes in the history of the program, and the final LMDV GHG rule are complementary in achieving GHG reductions in the U.S. transportation sector. The RFS Set rule is relevant to renewable fuel volumes in the 2023–2025 timeframe, and this final rule sets GHG emissions standards for LMDV vehicles in the 2027–2032 timeframe. As a result, the RFS Set rule and the LMDV GHG rule's GHG emissions standards do not have overlapping timeframes. Finally, any impacts of the increasing use of advanced vehicle technologies, including EV technologies, in U.S. vehicle fleets on renewable fuel volumes can be taken into consideration in future RFS rules under the RFS program. Both

[680] Renewable Fuel Standard (RFS) Program: Standards for 2023–2025 and Other Changes. Federal Register / Volume 88, No. 132 / Wednesday, July 12, 2023.

[681] Notwithstanding the savings clause noted above, to the extent the RFS statute is of any relevance, we think it clearly is consistent with this rulemaking. For years after 2022, Congress authorized the Administrator to establish the standards based on his analysis of various factors. Congress mandated only a single numeric floor for renewable fuel use: the requirement that the minimum volume of biomass-based diesel (BBD) be not less than one billion gallons, CAA section 211(o)(2)(B)(v). This requirement can be met by BBD used in any kind of transportation fuel, including fuel used in motor vehicles, nonroad vehicles, jet fuel, and home heating oil. The commenters did not explain with any specificity how the proposed standards would be an impediment to meeting the one-billion-gallon statutory floor for BBD.

programs, vehicle standards and renewable fuel standards, support meeting our nation's GHG goals.

Summary:

One commenter (American Enterprise Institute) suggested that EPA's energy security analysis in this rule was inaccurate because it focuses on the level or proportion of U.S. oil imports, not changes in U.S. consumption. According to the commenter, there is only "one world price" for oil that influences every country in the world, so it is U.S consumption levels, and not U.S. imports, that influences the U.S.'s energy security. Since oil price shocks are transmitted globally, according to the commenter, countries that consume oil cannot be shielded from the change in world oil prices when world oil supply disruptions occur. Also, private markets are capable of anticipating oil supply disruptions and minimizing the disruption impacts. Thus, the energy security benefits estimated in this proposed rule are "illusory".

Response:

This final rule is anticipated to simultaneously reduce both U.S. oil consumption and U.S. net oil imports. Using the AEO 2023 with updated refinery throughput assumptions for this final rule, EPA estimates that approximately 94.8 percent of the change in fuel consumption resulting from these final standards will be reflected in reduced U.S. net oil imports. Reductions in U.S. product demand (i.e., gasoline and diesel fuels) and, in turn, reductions in U.S. net oil imports stemming from this final rule rebalance the pattern of oil supplies being produced worldwide, reducing the quantity of oil produced in countries that are likely to experience oil supply disruptions over the analytical timeframe of this final rule, 2027-2055. From this perspective, the impacts of any future world oil supply disruptions are lessened.

The ORNL oil security premium methodology acknowledges the availability of private market mechanisms that allow the U.S. economy to anticipate and prepare for oil supply disruptions. However, those private market mechanisms lead to less investment in insurance protection (through private stockholding, hedging in oil futures markets, investment in energy conservation etc) than would be socially optimal because private individuals generally only protect themselves from the economic costs they expect to bear directly. Private individuals do not necessarily take into account the external and non-market consequences of their oil production or consumption activities. As a result, market mechanisms mitigate, but do not eliminate, oil supply disruption costs to the U.S. economy. Thus, reductions in both U.S. oil consumption and net oil imports improve the U.S.'s energy security position.

Summary:

Two commenters (Electrification Coalition, Environmental and Public Health Organizations) asserted that the U.S. spends a considerable amount of its national defense budget to protect access to oil in regions of the world (i.e., the Middle East) which have significant oil supply disruption risks. If the U.S. could shift to the wider use of electricity to power light- and medium-duty vehicles and away from oil, these defense costs would be lower, which would be a benefit to the U.S. Another commenter (American Enterprise Institute) suggested that changes in military costs to secure oil from unstable parts of the world should not be counted as a benefit for this rule. According to this commenter, estimating the U.S. effort of providing defense for overseas sea lanes for oil shipments is a hugely complex analytical calculation, which cannot be reasonably calculated. Thus, according to this commenter, military cost savings from reduced U.S. oil use as a result of this proposed rule should be left unquantified.

Response:

We agree that the U.S. likely incurs defense costs in maintaining access to oil from regions of the world that have significant oil supply risks such as the Middle East. For this final rule, we are not quantifying avoided defense costs from decreased consumption of oil used in the U.S. transportation sector, which would be a benefit to the U.S. There is an ongoing literature on the measurement of this component of energy security, but methodological and measurement issues – attribution and incremental analysis – pose two significant challenges to providing a robust estimate of this component of energy security. The attribution challenge is to determine which military programs and expenditures can properly be attributed to oil supply protection, rather than some other objective (i.e., other strategic/geopolitical concerns). The incremental challenge is to estimate how much the petroleum supply protection costs might vary if U.S. oil use were to be reduced, but not eliminated. EPA has not been able to identify a robust methodology to quantify the U.S. military costs of securing overseas oil. Thus, our analysis for this final rule leaves this benefit, avoided military costs with reductions in U.S. oil imports, unquantified. From this perspective, the monetized energy security benefits presented in the RIA are conservative.

Summary:

One commenter (Environmental and Public Health Organizations) supported the use of the Oak Ridge National Laboratory (ORNL) energy security methodology being used by EPA to estimate the oil security premiums in the proposed LMDV rule. Another commenter (American Petroleum Institute) raised concerns that the ORNL oil security premium estimates that EPA is using in this proposed LMDV GHG rule are too high. According to this commenter, the estimated energy security benefits of the proposed rule are overstated and not meaningful. This commenter suggested that the energy security methodology developed by ORNL and entitled, *Estimating the Energy Security Benefits of Reduced U.S. Oil Imports* (2008), is outdated and no longer applicable to the current structure of global oil markets.[682] When the oil security model methodology was developed, net U.S. crude oil and product imports were roughly 50 percent of U.S. petroleum consumption, according to the commenter. Currently, the U.S. is, and projected to continue to be, a net crude oil and product exporter. Another commenter (Heritage Foundation) suggested that EPA's energy security methodology ignores that the U.S. is an oil-exporting country, rather than an oil-importing country. For this reason, according to this commenter, the stated energy security benefits are likely costs, rather than benefits. Another commenter (Western Energy Alliance) suggested that since the U.S. is a large supplier of oil, that the final rule would not result in energy security benefits.

Response:

Several of the commenters (American Petroleum Institute, Heritage Foundation, Western Energy Alliance) fundamentally misunderstand the ORNL model as well as how EPA is applying it in this final rule. The ORNL model is a flexible economic model that allows for changes in input parameters to account for the kinds of changes the commenters are describing. Specifically, the ORNL model accounts for the fact that the U.S. is a net crude oil and refined

[682] Leiby, P., Estimating the Energy Security Benefits of Reduced U.S. Oil Imports: Final Report. March 2008. Oak Ridge National Laboratory. ORNL/TM-2007/028.

product exporter, which reduces the oil security premium estimates used in both the proposal and final rule. The ORNL model also accounts for other key changes, such as oil price responsiveness and U.S. GDP sensitivity, to accurately model oil security premiums and energy security benefits. We further explain each of these points below.

The ORNL energy security model used to estimate oil security premiums in this final rule is structurally the same as the version of the model described in the 2008 documentation cited by one commenter. The ORNL energy security methodology calculates oil security premiums based upon the macroeconomic disruption/adjustment import costs, which are numerically estimated with a compact model of the oil market by performing simulations of market outcomes using probabilistic distributions for the occurrence of oil supply shocks, calculating marginal changes in economic welfare with respect to changes in U.S. oil import levels in each of the simulations, and summarizing the results from the individual simulations into a mean and 90 percent confidence intervals for the oil security premium estimates. The macroeconomic disruption/adjustment import cost component is the sum of two parts: the marginal change in expected import costs during disruption events and the marginal change in gross domestic product due to the macroeconomic disruption of an oil supply shock. While the U.S. is a net exporter of crude oil and refined products and a large producer of oil, the U.S. economy is also a large consumer of oil. When there is an oil supply disruption in the world, the supply disruption results in a loss of economic output in the U.S., measured in terms of a loss in U.S. gross domestic product (GDP). From this perspective, since this rule reduces U.S. oil consumption and U.S. oil imports, EPA believes that there are energy security benefits associated with the rule.

The ORNL energy security model was peer reviewed in March 2008 before it was utilized in EPA rules.[683] EPA's use of the ORNL energy security model underwent public comment and review in the in the LDV GHG rule (2012-2016) in 2010.[684] While the ORNL model structure is unchanged since 2010, ORNL has regularly updated data and other quantitative inputs to the model to account for new and emerging oil market trends. ORNL estimates revised oil security premiums based upon the most recent Annual Energy Outlooks (AEOs) used in support of each of the LDV rulemakings undertaken by EPA. As the U.S. has gone from a net importer to a net crude oil and refined product exporter, the oil security premiums have steadily declined over the timeframe of the different EPA LDV rules, in part, due to evolving oil market trends. The value of the oil security premium remains positive because of its GDP disruption cost premium component. It continues to hold that a reduction in U.S. imports results in a lower amount of "at risk" oil supply susceptible to disruption and mitigates the price increase during a supply shock and the resulting GDP losses. Moreover, a decrease in oil imports partly results in a decrease in consumption, and the GDP losses with respect to the disrupted oil price decrease with reductions in the level of oil consumption.

In addition, two key parameters that influence the size of the impacts of oil supply disruptions on U.S. GDP have been updated since the ORNL model was used in the EPA's LDV GHG rule

[683] Transmittal of the Peer Review Document and Peer Review Comments Document, both in support of the Oak Ridge National Laboratory Report, "*Estimating the Benefits of Reduced U.S. Oil Imports*", March 2008. ORNL/TM-2007/2008.

[684] Joint Technical Support Document, Final Rulemaking to Establish Light-Duty Vehicle Greenhouse Gas Emission Standards and Corporate Average Fuel Economy Standards. EPA-420-R-10-901. April 2010.

(2012-2016) in 2010.[685] The first parameter updated is the oil price responsiveness (i.e., the short-run price elasticity of demand for oil). In the LDV GHG rule (2012-2016), EPA used a short-run price elasticity of demand for oil of -0.045. In this current proposed and final LMDV GHG rule (2027-2032), we are using a short-run elasticity of demand for oil of -0.07, a 56 percent increase (in absolute value). The effect of the increase in the short-run price elasticity of demand is to lower the impacts of an oil price shock on U.S. GDP. It is thought that consumers of oil in the U.S. are likely to be more responsive and consume less oil when the price of oil rises than previously estimated in the older version of the ORNL model.

The second parameter that has been updated is the U.S. GDP sensitivity (i.e., the elasticity of GDP to an oil price shock). This parameter has been updated to be more inelastic, i.e., there is less sensitivity of U.S. GDP to an oil price shock. In other words, for a given oil price shock, there will be a smaller loss of U.S. GDP. In the LDV GHG rule (2012-2016), EPA used an elasticity of U.S. GDP to an oil shock of –0.032.[686] For the current proposed and final light- and medium-duty GHG rule (2027-2032), we are using an elasticity of U.S. GDP with respect to an oil price shock of –0.021, a 34 percent reduction (in absolute value). The paper by Oladosu et al., *Impacts of oil price shocks on the U.S. economy: a meta-analysis of oil price elasticity of GDP for net oil-importing economies*, provides the basis for the updated GDP elasticity.[687] Thus, for an equivalent oil price shock, there will be less adverse impacts on the U.S. economy than with the older version of the ORNL model.

A variety of factors that have occurred over the last decade are thought to have reduced the impacts of oil shocks on the U.S. economy. First, the U.S. is less dependent on imported oil than in the early 2000s due in part to the “fracking revolution” (i.e., increased U.S. production of tight/shale oil), and to a lesser extent, increased U.S. production of renewable fuels such as ethanol and biodiesel. As one commenter notes, the increase in U.S. tight oil production and the resulting expansion of the U.S.’s net oil export position over roughly the last decade, has resulted in less of a wealth transfer from the U.S. to foreigners during an oil price shock, lowering the oil security premium. In addition, it is thought that the U.S. economy is more resilient to oil shocks than in the earlier 2000s timeframe because of increased global financial integration and greater flexibility of the U.S. economy (especially labor and financial markets).

In summary, EPA believes that the ORNL model has been updated for this proposed and final rule to account for concerns raised by several of the commenters (American Petroleum Institute, Heritage Foundation, Western Energy Alliance). Even though the U.S. is a net oil exporter, EPA believes that there are energy security benefits, not costs, associated with the rule. EPA agrees with one of the commenters (Environmental and Public Health Organizations) that the ORNL model provides reasonable energy security benefits estimates of this final rule.

Summary:

One commenter (Institute for Policy Integrity) suggested that EPA should update the own-price elasticity of demand for oil in its energy security analysis to account for increased electrification over time. According to the commenter, EPA used an own-price elasticity of

[685] Ibid.

[686] Ibid.

[687] Oladosu et al., *Impacts of oil price shocks on the U.S. economy: a meta-analysis of oil price elasticity of GDP for net oil-importing economies*, Energy Policy, 2018.

demand for oil of -0.07 – meaning that oil sales only marginally decline when oil prices increase, reflecting the fact that oil cannot be easily substituted with other fuels. But in the future, as electric vehicles become more widely adopted, this is likely to change as electricity becomes more easily substitutable for oil.

Response:

We agree with the commenter that the own-price elasticity of demand for oil could change with increasing penetration of electric vehicles over the timeframe of this final rule, 2027-2055. Increased substitution between oil and electricity would likely first occur in multi-vehicle households that have both an electric and a gasoline-powered vehicle. But there could also be substitution of electricity for oil in the household purchase decision when choosing between buying an electric or a gasoline-powered vehicle. A higher own-price elasticity of demand for oil would lower the oil security premiums and the energy security benefits of this final rule. We are unaware of any study to date that has addressed this issue, how the own-price elasticity of demand for oil could change with the wider use of electric vehicles. It is a topic for further, future research in our view. Thus, EPA does not consider it appropriate to adjust its quantitative estimates of the energy security benefits of this final rule based upon changes in the own price elasticity of demand for oil with greater electric vehicle usage in the timeframe of this final rule.

Summary:

One commenter (Valero) suggested that EPA should consider cybersecurity threats associated with PEV charging infrastructure as part of its energy security analysis of this rule.

Response:

Cybersecurity threats are an increasing concern for all types of energy infrastructure in the U.S including oil and natural gas pipelines, electric transmission lines, electric vehicle supply equipment and PEV charging infrastructure. Currently, the magnitude and frequency of the disruption risks associated with cybersecurity threats to the U.S.'s PEV charging infrastructure is not well characterized. Until a better characterization of PEV charging infrastructure cybersecurity risks is developed, it is not possible to quantify the energy security impacts of this type of risk. The same is true for cybersecurity risks associated with petroleum production and distribution infrastructure, which EPA is also not quantifying in this rule. Further study is needed on this topic before it can be systematically included in EPA's energy security analysis of its GHG vehicle rules.

Summary:

One commenter (Clean Fuels Development Coalition et al.) suggested that the proposed rule does not address the U.S. energy security impacts of the greater use of natural gas in the U.S. electricity sector stemming from the wider use of PEVs from this proposed rule.

Response:

As discussed in Chapter 5.2 of the RIA, EPA used the IPM model to assess the impacts of this rule on U.S. electricity generation. In the IPM modeling, natural gas use for electricity generation declines by roughly 52 percent between 2028 and 2050 in the reference (no action) case, and 48 percent in the central case representing the standards in the final rule.[688] In other words, over the timeframe assessed in this rule and in either scenario, use of natural gas for electricity generation is projected to decline substantially in both absolute and relative terms.

The United States has been the world's largest producer of natural gas since 2011 and is a substantial net exporter of natural gas.[689,690] Proven U.S. reserves of natural gas substantially exceed projected U.S. demand in the coming decades, and are not expected to be a constraint on the ability of U.S. production to meet the marginally larger natural gas demand for electricity generation estimated to result from these standards in the IPM analysis.[691]

The IPM analysis does not provide estimated impacts of the rule on U.S. trade of natural gas, and specific quantitative estimates of this potential effect were not readily available for our analysis of this rule. While the magnitude of the effect of the final rule on natural gas trade remains uncertain without additional energy sector modeling specific to the reference case (no action) and central case, some insight can be drawn from considering differences in natural gas use and trade in different Annual Energy Outlook scenarios. When we consider the difference in consumption and net imports of natural gas between the AEO 2023 Reference and Low Economic Growth cases – the two cases compared in EPA's methodology for estimating its oil import reduction factor (see RIA section 10.4.1) – we calculate that cumulative differences in net imports (i.e., reduced net exports) account for only 18 percent of the cumulative difference in U.S. consumption of natural gas over the time period covered by the AEO (2022-2050).[692] In other words, a significant portion – more than 80 percent – of marginal increases in U.S. demand for natural gas demand may be expected to be met by increased domestic production.

While the effect of this rule on trade of natural gas is uncertain, based on the current domestic production, exports, proven reserves, the projected decline in natural gas as a proportion of overall U.S. electricity generation, and trends seen in AEO cases discussed above, we expect that any increase in net imports of natural gas (i.e., decrease in net exports) will be relatively small, on an energy equivalent basis, compared to the size of reduced U.S. net oil imports expected to result from this final rule. Additionally, we are not aware of, nor has the commenter provided, a methodology sufficient to quantify the energy security risks associated with trade of natural gas. We note that natural gas markets are more regionally distinct than oil markets, meaning prices and potential disruptions of natural gas markets outside of North America, are less correlated

---

688 Because of the lead times necessary to complete our IPM modeling for the final rulemaking analysis, it was necessary to run IPM on interim versions of the reference and policy cases which we expect overestimate the impact of the final standards on energy demand. Therefore, these estimates of increased use of natural gas should be considered conservative; an updated IPM analysis aligned with the final standards would be expected to show a decline in natural gas use for electricity generation from 2028 to 2050 somewhere between 48 percent and 52 percent. The IPM modelling done for this final rule is described in RIA section 5.2.

689 U.S. Energy Information Administration (EIA). "Dry Natural Gas Production: International." Accessed January 23, 2024. Available online: https://www.eia.gov/international/data/world/natural-gas/dry-natural-gas-production.

690 U.S. Energy Information Administration (EIA). "Natural gas explained: Natural gas imports and exports." Last updated June 30, 2023. Available online: https://www.eia.gov/energyexplained/natural-gas/imports-and-exports.php

691 U.S. Energy Information Administration (EIA). "U.S. Crude Oil and Natural Gas Proved Reserves, Year-end 2021." December 30, 2022. Available online: https://www.eia.gov/naturalgas/crudeoilreserves/

692 U.S. Energy Information Administration (EIA). "Annual Energy Outlook 2023". March 16, 2023. Available online: https://www.eia.gov/outlooks/aeo/

with price impacts on U.S. consumers.[693] Thus, while we are not aware of existing estimates of probabilities of disruptions of North American natural gas supply – a necessary component of any extension of EPA's oil security premium methodology to natural gas – one might expect the probabilities of significant global events impacting U.S. natural gas supply to be smaller than the existing estimates for globally integrated oil markets. Lower disruption probabilities, all else equal, would result in lower potential energy security premia. In summary, while we are not able to quantify the potential energy security risks associated with an increased use of natural gas for electricity generation, for the reasons above, we believe these impacts would be relatively modest when compared with the energy security impacts of decreased use and net U.S. imports of petroleum.

Summary:

One commenter (American Fuel & Petrochemical Manufacturers) suggested that EPA's energy security analysis of the proposed rule does not account for the fact that there will likely be petroleum refinery closures in the U.S. According to the commenter, petroleum refinery closures in the U.S., in turn, will likely have an adverse impact on the supply of petroleum-derived fuels that are necessary for U.S. military operations and readiness. The availability of refined oil products for U.S. military use is an energy security issue.

Response:

EPA has updated its estimates of the impacts of this final rule on U.S. refinery output. Based upon comments EPA received on the proposed rule and in consultation with DOE and NHTSA, EPA is estimating that U.S. refineries will operate at higher production levels in this final rule. Given a reduction in U.S. refined fuel demand as a result of this final rule, U.S. refinery output will account for half (50 percent) of that reduced demand, while reduced U.S. net imports (i.e., increases in refined product exports) will account for the other half (50 percent) of that reduced demand. Using the AEO 2023 with updated refinery throughput assumptions for this final rule, EPA estimates that approximately 94.8 percent of the change in fuel consumption resulting from these final standards will be reflected in reduced U.S. net oil imports. See Chapter 8 of the RIA for more discussion on this topic.

Under the central case, manufacturers choose to comply with the final rule principally by producing more PEVs, and their operation is associated with a gradual, but steady reduction in the demand for petroleum-derived fuels from light- and medium-duty vehicles in the U.S. through the timeframe of analysis for this final rule, 2027-2055. Yet there is still anticipated to be significant, ongoing need for petroleum-derived fuels in the U.S. through 2055. Sources of petroleum-derived fuel demand in the U.S. include: new and existing gasoline and diesel powered light- and medium-duty vehicles, heavy-duty vehicles, nonroad equipment, and fuels for use in the aviation sector of the U.S. economy. Given the significant, future demand for petroleum-derived fuels in the U.S., it is not likely that there will be closures of U.S. refineries due to this final rule. In any case, it is widely expected that there will be sufficient U.S. refinery capacity to supply fully anticipated petroleum-derived fuels for U.S. military purposes through 2055. Also, EPA has not seen any economic study that suggests that its GHG vehicle rules will result in refinery shutdowns in the U.S.

[693] U.S. Energy Information Administration (EIA). "Natural gas markets remain regionalized compared with oil markets." April 29, 2020. Available online: https://www.eia.gov/todayinenergy/detail.php?id=43535

Summary:

According to this commenter (American Fuel and Petrochemical Manufacturers), EPA's energy security analysis of the proposed rule inaccurately characterized the U.S. oil industry's energy security situation. EPA's energy security analysis ignored that a significant percentage of total crude oil consumed in the U.S. is produced in the U.S. and a significant percentage of U.S. oil imports are from Canada. Also, the EPA analysis ignored the significant pipeline connectivity between the U.S. and Canada. Further, many U.S. oil refineries require heavy crude oils, which are likely to be imported from Canada. According to the commenter, reduced demand for petroleum-derived fuels will impact U.S. oil producers as much, if not more, than the U.S.'s existing oil trading partners.

Response:

EPA is in general agreement with the commenter's characterization of the U.S. oil industry and the links between the U.S. and Canadian oil supply industries. EPA's energy security analysis stems from the characteristics of the global oil market. Oil is bought and sold in a world market and there are periodic oil supply disruptions typically from foreign (i.e., non-North American) oil producers. Also, oil exporters with a large share of global production have the ability to raise or lower the price of oil by exerting the market power associated with the Organization of Petroleum Exporting Countries (OPEC) to alter oil supply relative to demand. World oil price instability and volatility are a result of these features of the global oil market.

EPA estimates that this final rule will reduce both U.S. oil consumption and U.S. net oil imports. For the final rule, using the AEO 2023 and updated refinery throughput assumptions, EPA estimates that approximately 94.8 percent of the change in fuel consumption resulting from these final standards is likely to be reflected in reduced U.S. net imports of crude oil and refined products over the timeframe of the analysis of this final rule, 2027-2055. See Chapter 8 of the RIA for more discussion on this topic. Reductions in U.S. oil demand and U.S. oil imports as a result of the final rule rebalance the pattern of oil supplies being produced worldwide, reducing the quantity of oil produced in countries that are likely to experience oil supply disruptions. This in turn mitigates oil supply disruptions and associated price shocks that affect the world market, including U.S. oil consumption, resulting in energy security benefits for the U.S. From this perspective, the impacts on the U.S. economy of any future world oil supply disruptions are lessened. Thus, the final rule provides energy security benefits to the U.S., even when the U.S. and North American oil supplies are relatively integrated and secure.

Summary:

Many commenters (Valero, Delk U.S. Holdings, Missouri Corn Growers Association, Western Energy Alliance, Plains All American Pipeline, L.P.) suggested that while EPA focuses on the energy security benefits of reduced dependence on U.S. oil imports, EPA failed to address the energy security threats of the U.S.'s increasing dependence on imports of critical minerals and PEV battery supply chains. One commenter (Zero Emission Transportation Association) agreed with EPA that the issues of energy security and mineral security are distinct and should be addressed separately.

Response:

For this final rule, EPA distinguishes between energy security and critical minerals, mineral security and security issues associated with the importation of PEV batteries and component parts. Energy security focuses on the impacts of the use of different fuels by light- and medium-duty vehicles, such as electricity and gasoline, on the U.S.'s energy security position. Critical minerals/mineral security, on the other hand, involves the risks associated with the reliance on different minerals used in the manufacturing and ultimate sale of the batteries in electric vehicles. Importation of PEV batteries and their component parts is an additional security issue that is associated with this final light- and medium-duty vehicle GHG rule. EPA addresses comments on the energy security impacts of this rule in this Section, Section 21, of this Response to Comment document. Critical minerals/mineral security/PEV supply chain issues are addressed in Section 15 of the Response to Comment document. We agree with Zero Emission Transportation Association that energy security and mineral security are two distinct issues that should be addressed separately.

22 - Vehicle safety

Comments by Organizations

Organization: Alliance for Automotive Innovation

In the past, customers who sought greater vehicle utility or higher performance did so through selection of optional engines with greater displacement. However, industry, driven in part by GHG and fuel economy regulations, has developed entire families of downsized engines that have proven capable of meeting customer demands for power while simultaneously increasing efficiency and lowering GHG emissions. This is exactly the strategy that EPA previously identified as the technological pathway to meeting increasingly stringent GHG emissions regulations while maintaining existing performance levels. [EPA-HQ-OAR-2022-0829-0701, p. 183]

Enrichment is a critical strategy that has enabled this technological shift to lower displacement engines, ensuring their safe and durable operation in transient high-power demand situations. Manufacturers use enrichment to ensure that when customers demand high power, they can do so without the risk of costly damage or interrupted performance. [EPA-HQ-OAR-2022-0829-0701, p. 183]

Customer needs for power include, but are not limited to, the ability to tow a large trailer up an occasional steep grade, to operate the vehicle with a full load of passengers and cargo, and to rapidly accelerate on a short freeway entrance ramp to safely merge into traffic. Other customers, for example those purchasing supercars, expect superior performance and racetrack i. In each case, the power requirement from the engine depends on the customer's usage, and if its "sufficient power" is inadequate to accomplish their task, then the customer may be exposed to potentially unsafe and inadequate operation and will be dissatisfied with their vehicle's utility. A sudden reduction or interruption of power in the midst of a driving maneuver (e.g., passing on a grade) could be disruptive to the driver and confusing to other drivers. In some cases, this may create an unsafe traffic condition if the vehicle suddenly loses power, forcing other drivers to take evasive actions. [EPA-HQ-OAR-2022-0829-0701, p. 183]

Customers who seek specific power levels and are dissatisfied with the reduced power of downsized engines due to prohibitions on enrichment would likely revert to seeking out higher displacement engines or shift into larger vehicle segments. Worse yet, customers may simply reject new offerings and remain in older vehicles longer, further increasing the rising average age of vehicles on the road and delaying rollouts of other technologies. Any of these outcomes would detract from achieving the agency's overall goals of reduced emissions and improved fuel economy. [EPA-HQ-OAR-2022-0829-0701, p. 183]

Organization: American Free Enterprise Chamber of Commerce (AmFree) et al.

Beyond critical minerals, the United States lacks adequate infrastructure for electric vehicle charging and hydrogen refueling. Developing the necessary infrastructure would cost billions of dollars in funding and require immediate planning and coordination. Even if enough new charging stations could be built, the Nation's electricity grids could not currently supply them with sufficient power. And batteries and fuel cells present an array of documented safety risks, including spontaneous fires and explosions that have resulted in death, injuries, and extensive property damage. All of these considerations would further stifle electric-vehicle adoption. [EPA-HQ-OAR-2022-0829-0683, pp. 4-5]

Finally, battery-electric vehicles implicate significant, well-documented safety concerns that could materially impede deployment of electric vehicles. [EPA-HQ-OAR-2022-0829-0683, p. 51]

Spontaneous fires involving battery-electric vehicles have been reported across the country, and major manufacturers have reported battery defects and issued recalls due to fire-related risks. See Joce Sterman et al., Ignition: Sponta- neous Electric Vehicle Fires Prompt Recalls, But Some Owners Stalled Waiting on Re- pairs, WBTV (Sept. 26, 2022), https://tinyurl.com/bddjbbw6. In addition, the National Transportation Safety Board conducted an investigation of electric-vehicle crashes and found that, "[i]n each case, emergency responders faced safety risks related to electric shock, thermal runaway, battery ignition and re- ignition, and stranded energy." Safety Risks to Emergency Responders from Lith- ium-Ion Battery Fires in Electric Vehicles, Nat'l Transp. Safety Bd. (Nov. 13, 2020), https://tinyurl.com/4b9bw869. Electric vehicles also are frequently heavier than conventional vehicles, and their greater weight could exacerbate injuries in the case of an accident. See Raul Arbelaez, As Heavy Evs Proliferate, Their Weight May Be a Drag on Safety, Ins. Inst. For Highway Safety (Mar. 9, 2023), https://tinyurl.com/txwb5wtn. [EPA-HQ-OAR-2022-0829-0683, p. 51]

EPA must consider these safety concerns as part of its feasibility analysis. See Sierra Club v. EPA, 325 F.3d 374, 378 (D.C. Cir. 2003) ("The statute also intends the agency to consider many factors other than pure technological ca- pability, such as costs, lead time, safety, noise and energy."). But there is no mention of them in the proposed rule. Cf. 88 Fed. Reg. at 29,387 ("[T]here is strong reason to believe that BEVs are at least as safe as conventional vehicles, if not more so." (footnote omitted)). The only material safety risk EPA even acknowledges is the possibility that declining fuel costs will cause drivers to drive more often, resulting "in an increase in accidents, injuries, and fatalities." Id. At 29,345. It offers no discussion of the unique safety risks posed by electric vehicles. That omission is striking because the agency does speculate on the unique safety benefits of such vehicles. See id. At 29,387 ("[T]he BEV architecture often lends itself to the addition of a 'frunk' or front truck. The frunk can pro- vide additional crush space and occupant protection in frontal or front offset impacts."); id. (claiming that electric-vehicles have a lower center of mass, which "provides additional vehicle stability and could reduce the propensity for vehicle rollover”). That cursory, cherry-picked analysis is insufficient given the safety problems that have arisen already, and the likely increase in similar incidents if use of electric vehicles substantially increases, as the proposed rule not only anticipates but affirmatively intends. [EPA-HQ-OAR-2022-0829-0683, pp. 51-52]

The safety concerns accompanying fuel-cell vehicles are at least as serious. Hydrogen leaks are reportedly common in fuel-cell vehicles and can lead to spontaneous combustion and explosions. See Hao Li et al., Safety of Hydrogen Storage and Transportation, 8 Energy Reps. 6258, 6259 (May 2022). Already, catastrophic accidents have occurred in the United States and abroad resulting in death, injury, and major property damage. See id. At 6259; see also Agnete Klevstrand, “Explosion After Explosion,” Hydrogen Insight (Feb. 7, 2023), https://tinyurl.com/ypea2at8; Report on the June 2019 Hydrogen Explosion and Fire Incident in Santa Clara, California, H2 Hydrogen Safety Panel, at 7 (June 2021), https://tinyurl.com/yeyu28bj; Norway Fines Nel Units $3 Million over 2019 Blast at Hydrogen Fuel Station, Reuters (Feb. 16, 2021), https://ti- nyurl.com/3twp99k4; CSB Releases AB Specialty Silicones Factual Update, U.S. Chem. Safety Bd. (Dec. 18, 2019), https://tinyurl.com/yc4pyz4c; Hyunjoo Jin & Jane Chung, Hydrogen Hurdles: A Deadly Blast Hampers South Korea’s Big Fuel Cell Car Bet, Reuters (Sept. 24, 2019), https://tinyurl.com/yx93d5c9; Luz Pena, Hydrogen Explosion Shakes Santa Clara Neighborhood, ABC7 NEWS (June 2, 2019), https://tinyurl.com/mr3r3yxe. Manufacturers are unlikely to pro- duce, and consumers are unlikely to buy, a vehicle technology that poses such substantial risk. [EPA-HQ-OAR-2022-0829-0683, pp. 52-53]

Organization: American Fuel & Petrochemical Manufacturers

2. EPA Fails to Adequately Evaluate ZEV Safety Risks as Required by Clean Air Act Section 202(a)(4)(B).

In setting new emissions standards, EPA must consider whether any technology used to comply with the requirements “will cause or contribute to an unreasonable risk to public health, welfare, or safety in its operation or function.”102 The Proposed Rule’s health and safety assessment, however, is myopically limited to the health effects of tailpipe emissions and fails to fully account for all of the risks posed by ZEV mandates. Increased prices to the consumer resulting from EPA’s proposed rule (when purchasing a new vehicle) likely will delay the purchase of all vehicles subject to the rule and slow fleet turnover. For example, nowhere in the Proposal does EPA assess how slower fleet turnover impacts safety and the environment. Older vehicles have fewer safety features and higher emissions profiles than new vehicles. Other interested parties have raised safety issues that EPA has a duty to analyze.103 EPA must analyze and take comment on the safety issues associated with ZEV mandates prior to finalizing the Proposed Rule. [EPA-HQ-OAR-2022-0829-0733, pp. 24-25]

We show that, controlling for own-vehicle weight, being hit by a vehicle that is 1,000 pounds heavier results in a 47% increase in the baseline fatality probability. [EPA-HQ-OAR-2022-0829-0562, p. 3]

https://www.cnn.com/2021/06/07/business/electric-vehicles-weight/index.html [EPA-HQ-OAR-2022-0829-0562, p. 3]

The Ford F-150 Lightning will weigh about 1,600 pounds more than a similar gas-powered F-150 truck. Similarly, the electric Volvo XC40 Recharge weighs about 1,000 pounds more than a gas-powered Volvo XC40. [EPA-HQ-OAR-2022-0829-0562, p. 3]

Organization: Arconic Corporation (ARCO)

In the automotive industry, material engineers are increasingly turning to aluminum to improve vehicle performance, fuel efficiency and to enhance battery life and driving range in electric vehicles. Arconic's lightweight aluminum sheet and extruded solutions are found bumper to bumper in a variety of vehicles from doors and hoods to heat exchangers and structural parts. Aluminum sheet products are used in auto closures and body-in-white (BIW) components. Arconic also produces proprietary heat exchanger products like multilayer brazing sheet used in battery pack cooling systems and aluminum sheet used in truck cab structures and fuel tanks and plate products used in trailer applications. Additionally, the company produces a range of extruded products, including driveshafts, anti-lock brake housings, and components of turbo chargers. [EPA-HQ-OAR-2022-0829-0741, pp. 1-2]

Mass reduction utilizing advanced materials like aluminum is recognized as one of the technology options to achieve safe, fuel-efficient and cost-effective vehicles that meet or exceed consumer demands. As future standards are more and more reliant on Battery Electric Vehicle (BEV) implementation, lightweighting can provide improved vehicle range or reduced battery size for a given range and improve vehicle safety. [EPA-HQ-OAR-2022-0829-0741, pp. 1-2]

In general, Arconic urges EPA to consider a few key points as it moves to finalize this proposed rulemaking. [EPA-HQ-OAR-2022-0829-0741, p. 2]

- EPA should include a fixed electric generation emission value per kWh in the standard for calculation of vehicle emissions for battery electric vehicles (BEVs) based upon their energy efficiency. This would provide an incentive for improved vehicle efficiency, and it would also allow the EPA rules to easily equate to the DOT I standards. [EPA-HQ-OAR-2022-0829-0741, p. 2]

- Emissions standards should correlate with passenger and pedestrian safety imperatives. If all BEVs are counted as zero emission, irrespective of their size and weight, there is no incentive for vehicle manufacturers to continue seeking weight reductions that clearly improve safety. [EPA-HQ-OAR-2022-0829-0741, p. 2]

- Similarly, adding incentives for weight reduction for BEVs will correlate to reductions in electricity use, reduced embedded emissions and reduced use of critical minerals that can be difficult to produce in an environmentally friendly manner or recycle. [EPA-HQ-OAR-2022-0829-0741, p. 2]

2. Currently, a BEV version of a vehicle is 500 to 2000 pounds heavier than a comparable ICE model depending on the battery pack size. It is reasonable to assume that the adoption of BEVs will result in higher vehicle weights across the fleet compared to ICE vehicles. [EPA-HQ-OAR-2022-0829-0741, p. 3]

Over the past 17 years (2004-2021), the average weight increase was 178 pounds for the U.S. new vehicle fleet. In the current fleet comprised of mainly ICE vehicles, lightweighting has been applied predominantly in larger vehicles, which results in improved fleet crash compatibility. [EPA-HQ-OAR-2022-0829-0741, p. 3]

If the BEV share reaches 50% by 2032, the new vehicle fleet will be 500 to 800 pounds heavier on average than the current new vehicle fleet. This is an unprecedented weight increase, along with slightly smaller footprints. This results in reduced crash compatibility as many heavier vehicles will be introduced into the fleet over a very short time period resulting in higher percentages of accidents where heavier vehicles strike lighter vehicles. [EPA-HQ-OAR-2022-0829-0741, p. 3]

Moving the fleet to BEVs without lightweighting incentives will result in the largest weight increases occurring in the heaviest vehicles (due to the need for larger battery packs). If all BEVs are counted as zero emission, there is no incentive for weight reduction which will be detrimental to safety of the fleet. [EPA-HQ-OAR-2022-0829-0741, p. 3]

Organization: Arizona State Legislature

7. The proposed rule fails to consider safety issues. EPA does not sufficiently address the greater fire and explosion risk from electric and hydrogen vehicles or appreciate the increased fatality risk on impact from heavier electric vehicles. [EPA-HQ-OAR-2022-0829-0537, p. 3]VII. The proposed rule is arbitrary and capricious because it fails to consider safety issues.

EPA understands that when acting under Section 202(a) it should consider relevant factors such as impacts on safety. 88 Fed. Reg. 29,186. In fact, EPA interprets Section 202(a)(4) to "specifically prohibit[] the use of an emission control device, system or element of design that will cause or contribute to an unreasonable risk to public health, welfare, or safety." Id. at 29,387. [EPA-HQ-OAR-2022-0829-0537, pp. 24-25]

Stunningly, EPA accepts that the proposed rule will increase the number of traffic deaths. Id. at 29,345. Because EPA estimates that the proposed rule will cause people to drive more since driving will be less expensive, "EPA projects this will result in an increase in accidents, injuries, and fatalities." Id. Specifically, EPA estimates a proposed 0.2% increase in annual fatalities per billion miles driven, which results in an increase of 1,595 total fatalities from 2027 through 2055. Id. at 29,387. [EPA-HQ-OAR-2022-0829-0537, pp. 24-25]

EPA downplays the increased number of deaths in three ways. First, EPA claims the increase in fatalities per distance traveled is not "statistically significant." Id. at 29,345, 29,387. Tell that to the approximately 1,600 families who EPA projects will lose family members. Every life has significant value. [EPA-HQ-OAR-2022-0829-0537, pp. 24-25]

Second, EPA claims that the "only statistically significant increase in fatalities is due to consumers' voluntary choices to drive more." Id. But while EPA is blaming Americans for causing increased fatalities by driving more, EPA is separately calculating the benefits associated with "social and economic opportunities that become accessible with additional travel." Id. at 29,383. EPA estimates this "drive value" generates more than $300 million in benefits. Id. at 29,362. [EPA-HQ-OAR-2022-0829-0537, pp. 24-25]

Third and finally, EPA argues that more premature deaths will be avoided by the proposed rule reducing exposure to PM2.5 (between 730 and 1,400) and ozone (between 15 and 330). Id. at 29,345, 29,387. But that is only true if EPA's upper-end estimate is correct. Under EPA's lower- end estimates, the 1,595 increased traffic fatalities from the proposed rule would more than double the 745 deaths EPA projects will be avoided from exposure to PM2.5 and ozone. [EPA-HQ-OAR-2022-0829-0537, pp. 24-25]

EPA likely underestimates the serious safety issues presented by electric vehicles. Increased weight also may lead to increased fatalities. The head of the National Transportation Safety Board has expressed concern about the increased weight of electric vehicles: "I'm concerned about the increased risk of severe injury and death for all road users from heavier curb weights and increasing size, power, and performance of vehicles on our roads, including electric vehicles."30 The executive director of the Center for Auto Safety warned, "These bigger, heavier batteries are going to cause more damage. It's a simple matter of mass and speed."31 [EPA-HQ-OAR-2022-0829-0537, p. 25]

30 NTSB head warns of risks posed by heavy electric vehicles colliding with lighter cars, THE ASSOCIATED PRESS, Jan. 11, 2023, available at https://www.npr.org/2023/01/11/1148483758/ntsb-heavy-electric-vehicles-safety-risks.

31 Id.

Heavier electric vehicles increase the risk of fatal crashes. A 2011 study by the National Bureau of Economic Research found that "a 1,000-pound increase in striking vehicle weight raises the probability of a fatality in the struck vehicle by 47%."32 Converting this increased fatality risks into external costs, "total external costs of vehicle weight from fatalities alone are estimated at $93 billion per year."33 Electric vehicles can weigh more than 1,000 pounds more than their gas- powered counterparts.34 EPA does not estimate the cost from the increased fatalities or more severe injuries from crashes caused by electric vehicles. [EPA-HQ-OAR-2022-0829-0537, p. 25]

32 Michael Anderson and Maximilian Auffhammer, Pounds That Kill: The External Costs of Vehicle Weight, National Bureau of Economic Research Working Paper 17170, June 2011, 3, available at https://www.nber.org/system/files/working_papers/w17170/w17170.pdf.

33 Id.

34 Peter Valdes-Dapena, Why electric cars are so much heavier than regular cars, CNN, June 7, 2021, available at https://www.cnn.com/2021/06/07/business/electric-vehicles-weight/index.html.

Electric vehicles also increase safety risks from fires. The National Transportation Safety Board has warned that “[f]ires in electric vehicles powered by high-voltage lithium-ion batteries pose the risk of electric shock to emergency responders from exposure to the high-voltage components of a damaged lithium-ion battery.”35 The National Transportation Safety Board also found that “[t]hermal runaway and multiple battery reignitions after initial fire suppression are safety risks in high-voltage lithium-ion battery fires.”36 [EPA-HQ-OAR-2022-0829-0537, p. 25]

35 National Transportation Safety Board, Safety Risks to Emergency Responders from Lithium-Ion Battery Fires in Electric Vehicles, NTSB/SR-20/01, Nov. 13, 2020, viii, available at https://www.ntsb.gov/safety/safety- studies/Documents/SR2001.pdf.

36 Id at 63.

Neither the proposed rule nor EPA’s draft regulatory impact analysis discuss fire risk. EPA recognizes this risk elsewhere, hinting at it in its draft regulatory impact analysis for the companion emissions rule for heavy-duty vehicles. In that analysis, EPA notes that first responders need “large amounts of water”—2,600 gallons for a 600-pound lithium-ion battery—“to cool the batteries and eliminate the risk of fire.” Greenhouse Gas Emissions Standards for Heavy-Duty Vehicles: Phase 3, Draft Regulatory Impact Analysis, 38. EPA also suggests that fire remains a risk days after a crash: “Safe storage of crashed vehicles is critical as internal battery failure reactions may occur days after the crash and reignite.” Id. EPA recommends standard maintenance and safety training to mitigate these risks. Id. EPA does not estimate the cost or timetable for the safety training or the potential cost from fires and other damage. [EPA-HQ-OAR-2022-0829-0537, pp. 25-26]

The risk is greater for hydrogen-powered vehicles. EPA recommends flame detectors since hydrogen flames are “almost invisible”; ventilation for vehicles stored indoors or under a roof to avoid hydrogen accumulation; safety training for first responders to turning the vehicle off or physically interrupting the power supply; and storage in “an isolated area” after a crash. Id. at 74-75. One study simulating a vehicle’s hydrogen tank explosion in an underground parking garage and road tunnel found fatality distances from 1-3.2 meters and 3-9.5 meters, respectively, depending on the size of the tank.37 Again, EPA does not estimate the cost or timetable for the safety training or the potential cost from fires, explosions, and other damage. [EPA-HQ-OAR-2022-0829-0537, pp. 25-26]

EPA’s failure to adequately consider safety issues is arbitrary and capricious. [EPA-HQ-OAR-2022-0829-0537, pp. 25-26]

Organization: Daniel Hellebuyck

Weight: An EV can weigh up to 1 ½ times a comparable internal combustion engine (ICE) vehicle. This creates more safety issues in a collision and more weight that our crumbling infrastructure has to absorb. Furthermore, insurance companies may be charging higher premiums to all customers to pay for the increased risk of injury and the larger costs involved in repairing EVs versus and ICE vehicle. [EPA-HQ-OAR-2022-0829-0526, p. 1]

Organization: Donn Viviani

Also not addressed is evidence that the increased weight of BEVs com- pared to comparable ICE vehicles, because of battery weight, will result in nonexhaust emissions (NEE) of particulate matter (PM) that will significant- ly lessen or even may exceed the proposal's anticipated reductions. While there is controversy as to whether NEE PM is as large as exhaust PM, with evidence on both sides. What is known for certain however, is that heavier vehicles produce more NEE PM and BEVs are significantly heavier than in-ternal combustion vehicles17. While it is true BEVs regenerative braking removes most brake-NEE, the greater torque of BEVs will cause some ag- gressive drivers to produce increased NEE PM18. This needs to be ac- knowledged and to the extent practicable included in the benefit assess- ment. In my view, the potential climate benefits of the necessary transi- tion to EVs is too important to risk with an inadequate analysis as to other effects. [EPA-HQ-OAR-2022-0829-0546, pp. 5-6]

17 Liu, Ye, et "l. "Comparative analysis of non-exhaust airborne particles from electric and in- ternal combustion engine vehic"es." Journal of Hazardous Materials 420 (2021): 126626.

18 Liu, Ye, et "l. "Impact of vehicle type, tyre feature and driving behaviour on tyre wear under real-world driving conditi"ns." Science of the Total Environment 842 (2022): 156950.

3) Recommendations for changes in the rule to decrease emissions further

What can be done under this rule to extract additional reductions in GHGs? Reducing the average weight of the fleet can address both the NEE issue and reduce carbon emissions further. Lighter EVs extend mileage and re- duce EGU emissions. Lighter IC vehicles will reduce fuel combustion. [EPA-HQ-OAR-2022-0829-0546, pp. 6-7]

Lighter vehicles result in less NWW PM.. Perhaps more importantly, lighter vehicles can reduce emissions in the manufacturing sector, especial- ly important in light of the quantity new BEVs EPA projects will penetrate the market. EPA should investigate regulatory options for reducing fleet gross vehicle weights (GVW). One way to require lower fleet average weight and decrease the emissions from manufacture of vehicles is to limit the embedded carbon allowed per ton of vehicle. [EPA-HQ-OAR-2022-0829-0546, pp. 6-7]

Savings promoted by weight reduction are immediate and do not depend on the pace of decarbonization of the electricity grid. The sooner the emis- sion reductions occur the better the chance of avoiding catastrophic non- linear feedback warming effects. [EPA-HQ-OAR-2022-0829-0546, pp. 6-7]

GHG emissions embedded in the production of vehicles is responsible for ~10% of vehicle carbon footprints. Slowly reducing down the allowable embedded carbon by class will have several outcomes. [EPA-HQ-OAR-2022-0829-0546, pp. 6-7]

Limiting the embedded carbon per ton would result in, e.g., more steel made with green hydrogen, less metal and more plastic parts (already these are replacing metal) which can require less energy to produce, and even parts made with bio-based plastics which count as negative carbon. [EPA-HQ-OAR-2022-0829-0546, pp. 6-7]

Lighter vehicles burn less fuel or draw less electrical power from EGUs, all these reduce carbon emissions. The lighter weight will produce less NEE PM as well. Weight is one driver of road friction and resuspension of PM. [EPA-HQ-OAR-2022-0829-0546, pp. 6-7]

Lastly, here, it is important to ensure that imports would be subject to any such embedded carbon restrictions, as that would serve to increase pres- sure on overseas EGUs to transition away from coal. [EPA-HQ-OAR-2022-0829-0546, pp. 6-7]

Organization: Dylan Ondek

Everyone thinks Tesla is the greatest electric vehicle but it is not. I have seen videos of these cars in wrecks and they just go up in flames. It can take four to five hours to extinguish the fire of a tesla that is not safe. If two cars have a head on collision and one is a tesla it could easily ignite the other vehicle on fire. There would be no possible quick way to get out of the vehicle already on fire after the head on collision. [EPA-HQ-OAR-2022-0829-5089]

Organization: Energy Innovation

ther research from the University of California, Berkeley, Grid Lab, and Energy Innovation, 2035 2.0: Plummeting Costs and Dramatic Improvements in Batteries Can Accelerate Our Clean Transportation Future (April 2021), evaluated the technical and economic feasibility (and associated impacts and benefits) of achieving a future scenario where electric vehicles make up 100 percent of new sales of all vehicles by 2035, combined with a 90 percent clean grid (called the DRIVE Clean Scenario).[iv] Compared with the No New Policy scenario (which was pre-IRA and BIL), the total transportation sector pollutant[v] and carbon dioxide emissions reductions in the DRIVE Clean Scenario would reduce ground transportation sector CO2 emissions by 60 percent in 2035 and by 93 percent in 2050, relative to 2020 levels.9 See Figure 3. The DRIVE Clean Scenario would also avoid approximately 150,000 premature deaths and generate nearly $1.3 trillion in health and environmental savings through 2050.10 Compared to the No New Policy, the DRIVE Clean Scenario would also resIlt in approximately $2.7 trillion in consumer savings through 2050 compared—a household savings of about $1000 per year on average over 30 years.11 [EPA-HQ-OAR-2022-0829-0561, pp. 5-6]

XXVI. BEV Safety Should Not Be a Constraining Factor in This Rulemaking.

We agree with EPA’s conclusion that, taking safety into consideration, the standards are appropriate under Section 202(a). 88 Fed. Reg. at 29347. While some have put forward misguided arguments about the safety of BEVs as a reason for EPA to set weak standards in this rulemaking, those claims miss the mark for many reasons. BEVs have been on the road in appreciable numbers for more than a decade already, and BEV sales will continue to grow due to market forces alone. OEMs, trade and professional associations, and safety authorities at all levels have long been studying, planning for, and responding to BEV safety matters.637 With or without this rulemaking, the number of BEVs will continue to grow, and safety research, planning, and design efforts will continue apace. Thus, safety should not act as a constraining factor in this rulemaking. [EPA-HQ-OAR-2022-0829-0759, p. 195]

637 Indeed, these efforts began more than a decade ago. For example, in 2010, the National Fire Protection Association and SAE International hosted a summit on EV safety standards. Am. Nat’l Standards Inst. (ANSI), U.S. National Electric Vehicle Safety Standards Summit Report Released (Jan. 5, 2011), https://www.ansi.org/news/standards-news/all-news/2011/01/us-national-electric-vehicle-safety-standards-summit-re port-released-05. And in 2011, ANSI convened a workshop on behalf of the U.S. DOE “to consider current and future U.S. domestic, regional, and international standards, codes, and conformity assessment activities needed to facilitate the introduction and widespread deployment of grid-connected electric vehicles.” ANSI, ANSI Workshop: Standards and Codes for Electric Drive Vehicles (Apr. 5-6, 2011), https://share.ansi.org/Shared%20Documents/Meetings%20and%20Events/EDV%20Workshop/EDVSponsorship.pdf

In the Proposal, EPA considered the impact of projected changes in vehicle weight on safety, including heavier BEV vehicles. See 88 Fed. Reg. at 29387-88; DRIA Ch. 9.4. EPA relied on analysis developed by the National Highway Traffic Safety Administration (NHTSA), which found no statistically significant impact on safety due to vehicle weight changes, holding vehicle footprint constant. 88 Fed. Reg. at 29387 n.796.638 EPA also considered the possible safety effects of changes in fleet composition due to changes in new vehicle sales and fleet turnover, also relying on underlying analysis by NHTSA. See DRIA Ch. 9.4. Based on these analyses, EPA concluded that “there are no changes to the vehicles themselves, nor the combined effects of fleet composition and vehicle design, that will have a statistically significant impact on safety.” 88 Fed. Reg. at 29387. [EPA-HQ-OAR-2022-0829-0759, p. 195]

638 In addition, the weight of future BEVs will be influenced by a variety of factors, including developments in battery chemistries and other technologies that could reduce weight. See generally Sebastian Blanco, The Future of Solid-State Batteries, J.D. Power (Apr. 3, 2023),

https://www.jdpower.com/cars/shopping-guides/the-future-of-solid-state-batteries; Chris Teague, What You Need To Know About Solid-State Batteries, Autoweek, https://www.autoweek.com/news/technology/a36189339/solid-state-batteries/ (last visited June 15, 2023); Michael Bull, Mass Reduction and Performance of PEV and PHEV Vehicles (undated), https://www-esv.nhtsa.dot.gov/Proceedings/22/files/22ESV-000346.pdf; Stanley, How Electric Vehicle Light-weighting is Changing the Automotive Industry, https://www.stanleyengineeredfastening.com/en/News%20and%20Stories/How%20Electric%20Vehicle%20Light-weighting%20is%20Changing%20the%20Automotive%20Industry (last visited June 15, 2023).

While EPA did not find any statistically significant impacts on safety from changes in vehicle weight and fleet turnover, EPA nonetheless quantified those impacts, based on NHTSA's underlying analysis, as well as the impacts of rebound driving (i.e., increased driving due to lower fueling costs). Id. at 29387. EPA's modeling projected that over the full period of 2027-2055, the Proposal would lead to an increase of 1,595 vehicle fatalities from all three sources (weight changes, fleet turnover changes, and rebound driving). Id. As EPA notes, this is of a similar scale to the expected reductions in premature deaths from air pollution in just a single year (2055) that would result from the Proposed Standards. Id. at 29388. [EPA-HQ-OAR-2022-0829-0759, pp. 195-196]

As EPA explained in its proposal for the Phase 3 Heavy-Duty GHG standards, numerous standards and codes govern BEV safety. 88 Fed. Reg. at 25962; Phase 3 DRIA Ch. 1.5.2. BEVs must meet the same federal safety requirements and undergo the same safety testing as combustion vehicles.639 Evidence shows that BEVs "are at least as safe" as combustion vehicles in terms of crashworthiness test performance, while "injury claims are substantially less frequent" for BEVs than for combustion vehicles.640 And on some safety metrics, BEVs perform substantially better than combustion vehicles. Due to their battery architecture, for example, BEVs typically have a lower center of gravity than combustion vehicles, which increases stability and reduces the risk of rollovers641 (the cause of up to 35% of accident deaths642). Fire risk and emergency response can also be managed effectively. BEVs are significantly less likely to catch fire than combustion vehicles in the first place.643 While BEVs can behave differently in fires than combustion vehicles, emergency responders have been gaining experience in BEV fire response as the number of BEVs on the road has grown. Numerous agencies and associations, including the National Transportation Safety Board,644 National Highway Traffic Safety Administration,645 and National Fire Protection Association,646 have established fire safety and emergency response recommendations for BEVs. The National Fire Protection Association and other organizations offer BEV fire response trainings,647 as do OEMs, which also produce emergency response guides for their vehicles.648 The National Institute for Automotive Service has also developed safety-related standards and a testing and certification program for automotive technicians who service BEVs.649 Expected future use of solid state batteries will further reduce BEV fire risk.650 Other research efforts have identified battery designs that can improve thermal management,651 as well as improved methods of extinguishing battery fires.652 [EPA-HQ-OAR-2022-0829-0759, pp. 196-197]

In sum, EPA properly considered the impact of the Proposal on safety, including by placing vehicle safety impacts "in the context of all projected health impacts from the rule including public health benefits from the projected reductions in air pollution." 88 Fed. Reg. at 29345. In addition, the public and private sectors have been working diligently to address BEV safety considerations; those efforts will continue as the number of BEVs on the road grows, regardless of EPA's regulatory actions. EPA is correct in not treating safety as a constraining factor in this rulemaking. [EPA-HQ-OAR-2022-0829-0759, p. 197]

Organization: HF Sinclair Corporation

g. EPA Failed to Evaluate PEV Safety Risks

In setting new emissions standards, EPA must consider whether any technology used to comply with the requirements "will cause or contribute to an unreasonable risk to public health, welfare, or safety in its operation or function."79 The Proposed Rule's health and safety assessment, however, is limited to the health benefits of reduced tailpipe emissions and fails to fully account for all of the risks posed by more PEVs on the road. While EPA presumes that the heaver PEVs will not have a statistically-significant effect on safety, and particularly, fatalities, the data relied upon from EPA was based on crash studies for MY 2007-2011 vehicles, well before PEVs were on the road.80 As recognized by NHTSA Administrator Ann Carlson, "[b]igger is safer if you don't look at the communities surrounding you and you don't look at the other vehicles on the road . . . [i]t actually turns out to be a very complex interaction."81 [EPA-HQ-OAR-2022-0829-0579, pp. 16-17]

79 42 U.S.C. § 7521(a)(4)(A).

80 88 Fed. Reg. at 29,387.

81 Reuters, "U.S. NTSB chair raises safety concerns about heavy electric vehicles," David Shepardson (January 11, 2023) available at https://www.reuters.com/business/autos-transportation/us-ntsb-chair-raises-safety-concerns- about-heavy-electric-vehicles-2023-01-11/. EPA also fails to recognize that PEVs are heavier than equivalent ICE vehicles and, therefore, may present result in more severe accidents given the additional mass of the battery. PEVs, as compared to ICE vehicles, are quieter and prone to rapid acceleration, making them 37% more likely to cause accidents involving pedestrians and 57% more likely to cause accidence involving cyclist.82 Yet EPA has not considered this interaction, on safety directly or the associated increase in insurance costs.

82 NHTSA report DOT HS 811 526, "Incidence Rates of Pedestrian And Bicyclist Crashes by Hybrid Electric Passenger Vehicles: An Update," (October 2011), available at https://crashstats.nhtsa.dot.gov/Api/Public/ViewPublication/811526.

F. EPA Should Work With NHTSA to Incorporate Electric Vehicles Into the Safety Analysis

To measure the Proposed Rule's safety impacts, EPA relies on two safety models developed by the National Highway Traffic Safety Administration (NHTSA).130 First, the safety-trend model uses regression analysis to determine the impact of the model year on safety (fatalities and injuries) and property damage, and then estimate an underlying trend in baseline safety. Second, the safety-weight model identifies the impact of weight on crash fatalities by each vehicle type. EPA then combines the results of the two models and considers the effect of total vehicle miles traveled (including the Proposed Rule's rebound effect) to measure the rule's total safety impacts. Through this safety analysis, EPA concludes that the Proposed Rule could increase traffic fatalities by 1,595 compared to the No Action case.131 This total increase in traffic fatalities is comparable to one year of avoided premature deaths from the Proposed Rule due to reductions in particulate matter.132 [EPA-HQ-OAR-2022-0829-0601, pp. 20-21]

130 RIA at 9-7; see also National Highway Traffic Safety Administration, Technical Support Document: Final Rulemaking for Model Years 2024-2026 Light-Duty Vehicle Corporate Average Fuel Economy Standards 646–83 (2022) ("NHTSA 2022 TSD") (describing impact of weight reduction, vehicle scrappage and sales response, and rebound effect on fatalities).

131 Proposed Rule, 88 Fed. Reg. at 29,387.

132 See, e.g., id. at 29,345.

EPA does not monetize these traffic fatalities as part of its benefit-cost analysis for two distinct reasons. First, because some of the projected fatality increase (approximately 19%133) is due to "consumers' voluntary choices to drive more when operating costs are reduced" (i.e. the rebound effect), EPA concludes that the cost of these fatalities are offset by the benefit of additional driving.134 Second, because the majority (approximately 81%135) of the projected fatality increase is due to a statistically insignificant change in the estimated risk of fatalities per distance traveled due to the change in the vehicle mix,136 EPA reasonably chooses not to incorporate that risk into its benefit-cost analysis because it cannot be distinguished from zero.137 [EPA-HQ-OAR-2022-0829-0601, pp. 20-21]

133 See id. at 29,387 (projecting increase of 300 fatalities attributable to increased driving).

134 Proposed Rule, 88 Fed. Reg. at 29,345.

135 Id. at 29,387 (projecting increase of 1,265 fatalities due to non-statistically significant increase in fatality risk from driving on a per-mile basis).

136 EPA projects that of the 1,595 increased fatalities from the Proposed Rule, 300 are attributable to increased driving and 1,265 are attributable to the non-statistically significant increase in fatality risk. Id. at 29,387.

137 Id. at 29,345.

In either this rule or future standards, EPA should work with NHTSA to incorporate electric vehicles into both safety models. While NHTSA's safety modeling accounts for various changes in the vehicle mix such as model year and age,138 it does not account for electrification as part of the vehicle mix and instead appears to assume constant safety trends regardless of whether a vehicle is electric or gas-powered. But due to their distinct engineering, electric vehicles present unique safety implications that EPA and NHTSA should explore further. Some of these safety implications are positive. For instance, electric vehicles have additional crumple space due to a lack of a combustion engine, which improves crash safety.139 Additionally, the typical placement of the heavy electric powertrain under the vehicle lowers the car's center of gravity and thus improves handling and reduces the risk of dangerous rollover accidents. In fact, current electric- vehicle models are associated with some of the lowest rates of rollover accidents.140 But some of these safety implications are negative. For instance, the additional acceleration of electric vehicles could increase safety risks to electric-vehicle passengers, passengers in ICE vehicles, and pedestrians.141 Because electric vehicles present both safety benefits and risks, it is not clear how accounting for electric vehicles in the safety modeling would affect EPA's results. [EPA-HQ-OAR-2022-0829-0601, pp. 20-21]

141 Chao Gong et al., Safety of Electric Vehicles in Crash Conditions: A Review of Hazards to Occupants, Regulatory Activities, and Technical Support, 8 IEEE Transactions on Trasp. Electrification 3870, 3872 (2022).

Including electrification in the safety analysis can admittedly be challenging given the limited information available about the relative safety of electric versus ICE vehicles.142 Nonetheless, a few principles are helpful. First, because NHTSA's safety-weight model already accounts for the impact of vehicle weight on safety, weight (and any features of electric vehicles associated with it) should be run through regression to avoid double-counting. Specifically, weight may be correlated with other safety features, such that the regression suffers from omitted variable bias. Second, the safety-trend model should control for horsepower, which may have a negative safety externality in both electric and ICE vehicles.143 And third, the safety-trend model should control for vehicle type more generally such as cars, crossovers, and minivans (which the weight model already does). [EPA-HQ-OAR-2022-0829-0601, pp. 20-21]

143 See Insurance Institute for Highway Safety & Highway Loss Data Institute, Flexing Muscle: Sports Car Ratings Show Range of Performance, 51 Status Report, no. 5 (2016), at 4–5, https://www.iihs.org/iihs/sr/statusreport/article/51/5/2 (explaining how “high-horsepower vehicles are more likely to exceed the speed limit, particularly by 10 mph or more, and have higher mean speeds than vehicles with less powerful engines”).

Organization: Kentucky Office of the Attorney General et al.

The Proposed Rule also fails to consider the adverse safety impacts of its mandate. EPA represents that fatality risk will increase “0.2% per distance travelled” under the Proposed Rule, a value it deems is “non-statistically significant.” 88 Fed. Reg. at 29,345. EPA also argues that while there will be a projected “increase in accidents, injuries, and fatalities,” this increase will stem from “personal decisions[s] by consumers to drive more due to the reduced cost of driving.” Id. [EPA-HQ-OAR-2022-0829-0649, p. 16]

The National Transportation Safety Board (“NTSB”)—one of the federal agencies actually charged with regulating vehicle safety—disagrees with EPA’s assertions. The Chair of NTSB recently stated “I’m concerned about the increased risk of severe injury and death for all road users from heavier curb weights and increasing size, power, and performance of vehicles on our roads, including electric vehicles.” NTSB Head Calls Out Heavy EVs As A Safety Risk, Autoweek (Jan. 13, 2023), https://bit.ly/464YR0j. She noted that a “GMC Hummer EV weighs over 9000 pounds,” with a “gross vehicle weight rating [of] a staggering 10,550 pounds” and a battery pack that “weighs over 2900 pounds—about the weight of a Honda Civic.” Id. Likewise, a Ford F-150 Lightning weighs between 2000 and 3000 pounds more than non-electric versions, while battery- powered SUVs are roughly 33% heavier than non-battery options. Id. According to the Chair of NTSB, these factors have “a significant impact on safety for all road users.” Id. So while EPA may be sanguine about added safety risks, consumers may have good reason not to be. The Proposed Rule does not adequately account for these concerns, either. [EPA-HQ-OAR-2022-0829-0649, p. 16]

Organization: National Farmers Union (NFU)

Another concern with BEVs is increased vehicle weight. Chair of the National Transportation Safety Board has expressed concerns “about the increased risk of severe injury and death for all road users from heavier curb weights and increasing size, power, and performance of vehicles on our roads, including electric vehicles.”20 [EPA-HQ-OAR-2022-0829-0581, pp. 10-11]

20 The Honorable Jennifer Homendy, Chair, National Transportation Safety Board, Remarks as Prepared for Delivery Before the Transportation Research Board, January 11, 2023, 102nd Annual Meeting, https://www.ntsb.gov/Advocacy/Activities/Pages/Homendy-20230111.aspx.

A GMC Hummer EV weighs over 9,000 pounds, up from about 6,000 pounds. Its gross vehicle weight rating is a staggering 10,550 pounds. The battery pack alone weighs over 2,900 pounds—about the weight of a Honda Civic. [EPA-HQ-OAR-2022-0829-0581, pp. 10-11]

The Ford F-150 Lightning is between 2,000 and 3,000 pounds heavier than the non-electric version. The Mustang Mach-E, Volvo XC40 EV, and RAV4 EV are all roughly 33% heavier. That has a significant impact on safety for all road users.21 [EPA-HQ-OAR-2022-0829-0581, pp. 10-11]

21 Id.

Organization: Renewable Fuels Association (RFA)

d. Vehicle weight: Safety concerns and increased PM emissions

Another concern with BEVs is increased vehicle weight. The chair of the National Transportation Safety Board testified that "the Ford F-150 Lightning is between 2,000 and 3,000 pounds heavier than the non-electric version. The Mustang Mach-E, Volvo XC40 EV, and RAV4 EV are all roughly 33% heavier. That has a significant impact on safety for all road users."38 EPA should not artificially incentivize heavy BEVs by counting them as "zero emissions," when lighter weight solutions can provide similar GHG emissions benefits and better safety. [EPA-HQ-OAR-2022-0829-0602, pp. 18-19]

38 https://www.ntsb.gov/Advocacy/Activities/Pages/Homendy-20230111.aspx

Organization: Senator Shelley Moore Capito et al.

Further, the proposals lack coordination with the US Department of Transportation (DOT) to address safety issues that increased vehicle weight will introduce on our roadways. Safety should always come first. The National Transportation Safety Board recently warned that the heavier weight of electric vehicles pose increase risks of severe injury or death to passengers in lighter vehicles. The increased weight of BEV s not only calls into question safety impacts during vehicle-to-vehicle collisions and vehicle-to-pedestrian or bicyclist collisions, but also the overall design and safety standards of our roads, bridges, and roadside safety hardware such as guardrails. [EPA-HQ-OAR-2022-0829-5083, p. 3]

The DOt has a responsibility to research and ensure vehicle and roadway design and safety standards meet the challenges and demands of our future transportation system. This Administration continues to push policies that will result in more BEV s on our roadways, but has failed to plan from a safety and infrastructure perspective. The sequence of proposals is misguided; vehicle and roadway design and safety standards should have been under development and deployed well before the EPA proposed a rule to force consumer adoption of heavier EV s. This type of research and development, including vehicle, roadway lifespan, and guardrail and work zone safety equipment testing all will require years to undertake. If these proposals move forward without the appropriate safeguards in place, backed by sound science, the vehicle and infrastructure investments being made today may miss the mark on safety and longevity in the years to come. [EPA-HQ-OAR-2022-0829-5083, p. 3]

Organization: Steven G. Bradbury

In the current rulemaking, EPA is downplaying and minimizing the loss of lives on U.S. highways that its proposals will cause by estimating them on a per-distance- traveled basis, and is ignoring altogether the many more serious injuries that will be attributable to these regulations.44 In contrast, NHTSA was more candid in acknowledging these negative safety effects just last year when it promulgated stringent fuel economy standards through model year 2026 in lockstep with EPA's 2021 emissions rule.45 Meanwhile, EPA is playing up and magnifying the economic value of the lives it claims will be saved in the long run from the reduction of toxic pollutants.46 EPA's starkly different accounting treatment for the lives lost from less safe vehicles versus those saved by improved air quality is telling. [EPA-HQ-OAR-2022-0829-0647, pp. 16-17]

Organization: The Aluminum Association

Efficiency is not the only consideration that supports assigning a carbon emission value to BEVs. Safety is also an important factor supporting this conclusion. In the proposed rule, EPA states that it placed emphasis on the level of risk of injury per mile traveled, considered the projected change in injuries in that context, and concluded that, with the proposed rule, the increase in fatalities per distance traveled is not statistically significant11. However, with the expected acceleration of the transition to BEV's an additional factor arises that has not been adequately addressed. This is the net increase in weight projected for BEV's versus equivalent internal combustion engine vehicles.12 This increased weight increases the differential weights in both vehicle-to-vehicle impact collisions as well as in vehicle to pedestrian impact collisions. Because lightweighting is of most value as applied to larger/heavier ICE vehicles and BEV's, it plays an important role in these areas in terms of reducing the weight differential between vehicles and in vehicle to pedestrian impacts. EPA devotes considerable attention to safety factors in this rulemaking (88 FR 29344) and should not lose sight of the significant safety benefits that will come from lightweighting when BEVs are assigned an accurate emission level above zero g/mile. [EPA-HQ-OAR-2022-0829-0704, pp. 8-10]

11 88 FR 29345

12 This can be 500-2000 lbs. depending on the vehicle size and battery configuration.

In a broad context, the Association has long focused on the relationship between vehicle size, mass, and societal safety,13 and aluminum-intensive vehicles have a long history of achieving 5-star ratings, either from NHTSA or the EU's analogous new car assessment program (NCAP). Notably, the economic value of mass reduction is most recognized in larger, heavier vehicles such as pickup trucks and SUV's, and lightweighting these vehicle classes also helps improve the differential weight safety concerns referenced above. Moving the fleet to BEVs without lightweighting incentives will result in the largest weight increases occurring in the heaviest vehicles due to the need for larger battery packs. If all BEVs are assigned zero g/mile GHG emissions, there is no incentive for vehicle weight reduction with this ultimately being detrimental to overall societal safety. [EPA-HQ-OAR-2022-0829-0704, pp. 8-10]

Organization: The Heritage Foundation (Kevin Dayaratna and Diana Furchtgott-Roth)

Almost 43,000 people died on the roads in 2022,21 the equivalent of 215 plane crashes a year killing 200 people each time. EPA's tailpipe emissions proposal would, if implemented, make Americans even less safe on the road. EPA does not sufficiently analyze these effects. The prior 2022 fuel economy proposal22 from the National Highway Transportation and Safety Administration (NHTSA) raises the 2026 Corporate Average Fuel Economy standard to 49 miles per gallon (MPG) from the current standard of 40 MPG. The rule sets a new minimum standard of 59.4 MPG for passenger cars and 42.4 MPG for light trucks made in the United States by model year 2026, with fines for non-compliant carmakers. NHTSA concludes that the higher price of cars would increase fatalities because fewer people would be able to afford the safer, newer, cars, "The slowing of fleet turnover due to higher vehicle prices has the largest impact of the three factors on fatalities."23 [EPA-HQ-OAR-2022-0829-0674, p. 5]

21 National Highway Transportation Safety Administration. "Early Estimate of Motor Vehicle Traffic Fatalities in 2022", Apr. 2023, Crash Stats: Early Estimate of Motor Vehicle Traffic Fatalities in 2022 (dot.gov) (accessed 22 June 20.

1 22 Federal Register, Vol. 87, No. 84, (May 2, 2022), pp. 25710-26092, https://www.govinfo.gov/content/pkg/FR-2022-05-02/pdf/2022-07200.pdf (accessed May 1, 20.

1 23 Ibid., p. 25896.

NHTSA estimates that the decline in new vehicle sales would result in up to 812 additional deaths on the road each year, 16,206 more injuries, and almost 50,000 more crashes involving property damage.24 This is because fewer people would be able to afford new and later-model used cars, which are safer than old cars. EPA's proposed regulations would make the situation worse. EPA does not account for this in the rule. [EPA-HQ-OAR-2022-0829-0674, pp. 5-6]

This increase in prices caused by successive reductions in emissions contradicts NHTSA's core values,25 namely leading "the Nation by setting the motor vehicle and highway safety agenda," and serving "as the catalyst for addressing critical safety issues that affect the motor vehicle and highway safety communities." Deaths and injuries from the new rules would be concentrated among low-income Americans, disproportionately minorities, who would pay the price of the new rule: due to the price increases, they would buy fewer new cars and fewer later-model used cars. [EPA-HQ-OAR-2022-0829-0674, pp.]

1 24 Ibid., pp. 25894-5.

25 U.S. Department of Transportation, National Highway Traffic Safety Administration, "'HTSA's Core Values," https://www.nhtsa.gov/about-nhtsa/nhtsas-core-values (accessed May 1, 2023).

There is no mention of additional equipment, training, or hazards mentioned regarding the increased number of EVs on the road. The risk of toxic exposure in the event of an EV on a public roadway should be a profoundly serious consideration and yet is not mentioned.36 [EPA-HQ-OAR-2022-0829-0674, p. 10]

Organization: Transfer Flow, Inc

The National Transportation Safety Board has raised concerns about the safety of electric vehicles in automobile accidents due to the increased weight associated with carrying a heavy electric vehicle battery,18 and the British Parking Association published a report outlining the dangers associated with the increased weight of electric vehicles causing older parking structures to collapse,19'20 which we recently saw in New York City where one person died.21 [EPA-HQ-OAR-2022-0829-0496, pp. 3-5]

20 https://www.curbed.com/2023/04/parking-garage-collapse-heavier-electric-vehicles-suvs.html

21 https://nypost.com/2023/04/19/electric-vehicles-could-put-pressure-on-parking-garages/

1. Organization: Valero Energy Corpora EPA has failed to address the on-road safety implications of its proposed rule which would require 67% of all LDV and MDVs to be zero emission by 2032.

EPA has placed the cart before the horse by promulgating a rule that fails to address the on-road implications of its proposed rule; including the impact of the increased risk of crash related fatalities to the motoring public and the disproportionate impact of the fatality risk born by low-income and other environmental justice commuters. [EPA-HQ-OAR-2022-0829-0707, p. 29]

In promulgating the LDV and MDV rule EPA has failed to address the safety issues surrounding the real-world implications of requiring 67% of the LDV and MDV to be significantly heavier battery electric vehicles (BEV). In fact, Jennifer Homendy, the head of the National Transportation Safety Board recently warned that the heavier weight of electric vehicles pose increased risk of severe injury or death to passengers in lighter vehicles.143 Her comments center around the multi-thousand-pound weight differential between BEV's and their much lighter conventional internal combustion engine (ICE) LDV counterparts. In work performed by the National Bureau of Economic Research, Pounds that Kill: The External Cost of Vehicle Weight, showed that "controlling for own-vehicle weight, being hit by a vehicle that is 1,000 pounds heavier results in a 47% increase in the baseline fatality probability".144 Unfortunately, the weight of the BEV battery packs alone can weigh as much as an entire ICE vehicle, putting the overall weight difference between BEV's and their ICE counterparts at double, or even triple that of an ICE vehicle. Take for example GM's new 9,000-pound Hummer EV, which touts a massive 3,000- pound battery.145 In fact the weight of the Hummer battery pack alone is approximately equal to the total curb weight of a new 2023 Honda Civic Sedan.146 [EPA-HQ-OAR-2022-0829-0707, p. 29]

143 NTSB head warns of risks posed by heavy electric vehicles colliding with lighters cars, NPR, January 11, 2023

144 National Bureau of Economic Research, Pounds That Kill: The external costs of Vehicle Weight, June 2011

145 The 2022 GMC Hummer EV's Battery Alone Weighs 2,923 Pounds, That's roughly a third of its 9,63-pound curb weight, The Drive, Feb 15, 2022

146 https://automobiles.honda.com/civic-sedan#trims-specs

Finally, EPA's proposal disproportionately exposes middle-and lower-income commuters to increased on-road dangers as they are left behind in lighter weight ICE LDV's as more affluent consumers purchase significantly heavier BEV's. Further, EPA's proposal lacks coordination with the National Transportation Safety Board and the U.S. Department of Transportation (DOT) to address safety issues created directly from EPA's proposed LDV and MDV rule. "The DOT has a responsibility to research and ensure vehicle and roadway design and safety standards meet the challenges and demands of our future transportation system. This Administration continues to push policies that will result in more BEVs on our roadways, but has failed to plan from a safety and infrastructure perspective. The sequence of proposals is misguided; vehicle and roadway design and safety standards should have been under development and deployed well before the EPA proposed a rule to force consumer adoption of heavier EVs. This type of research and development, including vehicle, roadway lifespan, and guardrail and work zone safety equipment testing all will require years to undertake. If these proposals move forward without the appropriate safeguards in place, backed by sound science, the vehicle and infrastructure investments being made today may miss the mark on safety and longevity in the years to come."320 [EPA-HQ-OAR-2022-0829-0707, p. 58]

320 Letter from the United States Senate to EPA Administrator, May 25, 2023

Organization: Western Energy Alliance

Safety: It does not appear that EPA is taking into consideration the added weight of EVs. With their large batteries, they are generally one third heavier than a similarly sized vehicle of a similar body style. Section 9.4.2 of the DRIA dealing with vehicle weight does not take the increased battery weight into account, and therefore, needs to be updated before it can make the conclusion that "there is no statistically significant change in the estimated risk of fatalities per distance traIed..." and "…virtually no change in fatality risk as a result of the proposed standards…" (p. 29345) [EPA-HQ-OAR-2022-0829-0679, p. 5]

Likewise, it does not appear that EPA has considered the risk of EV battery fires. It is well known that EVs carry an increased risk of fire because of the nature of their batteries and that these chemical fires are extremely hot and hard to put out.7 Firefighters have reported the difficulty of extinguishing EV fires, which burn much more intensely than ICEV fires because of the batteries and require 40 times the amount of water needed to contain an ICEV.8 Firefighters report that that there is no obtainable extinguishing agent available to them. EPA's analysis on safety is deficient in failing to consider the impact of battery fires on safety. [EPA-HQ-OAR-2022-0829-0679, p' 5]

7 "' We're not putting t'is out:' F-150 Lightning fire melts EV trucks," Detroit Free Press, April 21, 2023.

8 "F irefighters have to blast 40 times more water at burning Tesla than other cars," The Hill, August 17, 2021.

EPA Summary and Response

EPA appreciates the range of comments that were submitted related to safety. The majority of these comments can be categorized into one of two different topics related a future shift in the vehicle stock towards more PEVs. The first comment topic of mass-safety is one that EPA has analyzed quantitatively in this and previous light- and medium-duty GHG rulemakings (and in consultation with NHTSA as it has also analyzed safety effectsIits CAFE rulemakings). This rulemaking's analysis of the impacts on societal crash safety due to mass changes (including mass changes associated different powertrains and PEV batteries) was conducted using the same methodology as previous rulemakings, which is based on a statistical analysis of empirical crash data. The second group of comments was on the topic of fire safety, for which detailed responses are provided below. Additional comments related to coordination with other relevant agencies, fleet turnover, and the proposed elimination of enrichment for ICE vehicles are also summarized and discussed below.

Valero commented that EPA did not coordinate with the National Transportation Safety Board and the U.S. Department of Transportation (DOT) on the topic of safety when developing these standards. EPA disagrees with this comment. EPA has engaged in a long-standing process spanning multiple rulemakings of continuous coordination with DOT, specifically the National Highway Traffic Safety Administration (NHTSA), on safety issues relevant to vehicle emissions standards. EPA has continued this coordination during the development of this rulemaking, with technical meetings and exchanges of data and information continuously throughout the rulemaking process. See, for example, Memorandum from Michael Landgraf "Response from Shashi Kuppa, Director, Office of Crashworthiness Standards Rulemaking Office, Department of Transportation, National Highway Safety Administration" (Dec. 8, 2022). Specifically, throughout this rulemaking process, EPA and NHTSA have exchanged information on the best available data and information to inform our assessment of the safety impacts of this rule. In fact, as describe further below, in both the proposed rule and this final rule, EPA has used NHTSA's recommended mass-safety coefficients in our statistical analysis of historical crash data, and our methodology is consistent with that used by NHTSA in its most recent proposal for CAFE standards.Amfree, Arizona State Legislature and Valero commented that the additional weight of batteries for PEVs may negatively impact crash safety due to an increased risk to drivers of lighter vehicles and other road users. In response, EPA cannot conclude based on the available evidence that the final standards will have any impact on societal fatality rates. More detailed information on EPA's crash safety analysis is provided in RIA Chapter 8.4 and Preamble VIII.K. Summarizing briefly here: EPA has conducted an analysis of crash safety for these final standards, using the same methodology as the NPRM analysis, and similar to prior light-duty GHG rulemakings. The projected mass of each vehicle is estimated by EPA's OMEGA compliance modeling (including the mass of PEV batteries), and any associated changes in societal fatality rates are then calculated based on mass-safety coefficients that were developed by NHTSA's statistical analysis of historical crash data. Consistent with the NPRM, the results of this societal safety analysis show that the final GHG standards are projected to result in a small increase in the societal fatality rate. From a statistical standpoint, EPA cannot conclude that the effect is different from zero (i.e., the effect is not statistically significant).

Several commenters cited statements by Jennifer Homendy, the head of NTSB, as evidence that BEVs create increased safety risks, particularly due to the increased vehicle weight of BEVs. EPA carefully reviewed the statement,[694] which the NTSB website identifies as advocacy activity by Chair Homendy. The statement lacks any technical findings regarding BEV safety. In addition, commenters selectively omit to cite the remainder of the statement, which says "We do have a climate crisis that needs to be addressed. The U.S. transportation sector accounts for the largest portion of U.S. greenhouse gas emissions, and I firmly believe it is a human right to breathe clean air. But we have to be careful that we aren't also creating unintended consequences: more death on our roads. Safety, especially when it comes to new transportation

[694] https://www.ntsb.gov/Advocacy/Activities/Pages/Homendy-20230111.aspx

policies and new technologies, cannot be overlooked. Ever." We agree with Chair Homendy that safety risks should not be overlooked. As discussed above and in the preamble and RIA, EPA has conducted a thorough analysis of safety associated with the standards, including specifically with increased vehicle weight of PEVs. We find that PEVs are as safe as ICE vehicles and that the final standards actually result in a slight (statistically insignificant) decrease in fatalities per mile driven.

ARCO commented that the additional weight of PEV batteries can be offset to some extent with the expanded use of lightweight materials, and that will help address concerns about crash compatibility between heavier PEVs and lighter ICE vehicles. EPA appreciates these comments, and notes that in our compliance modeling, we account for the compounding effect where lightweighting technologies will enable smaller (and lighter) batteries for a given electric range. As a result, many of the future PEV models projected for this rulemaking's compliance and safety analyses include lightweighting strategies as part of manufacturers' cost effective compliance plans. Beyond our modeling results, EPA believes that manufacturers have an incentive to pursue strategies to reduce the weight of PEVs to improve efficiency, which could allow for smaller batteries or to meet customer demands for longer range.

Arizona State Legislature, Amfree commented that there is an increased safety risk from PEV battery fires, and that EPA did not fully account for that safety impact in the NPRM. EPA agrees that different kinds of fires have different properties. Vehicle fires involving large capacity batteries have different properties than the types of vehicle fires that have been more common to-date, which involve low-voltage electrical systems and liquid fuels. However, EPA does not agree that the safety risk, in terms of the rate at which harm occurs, is necessarily higher than for other non-PEV vehicles. Data available today from NTSB indicate that BEV fire rates after a crash may be lower than from HEV and ICE vehicles. While the number of occurrences may be too low to draw a definitive conclusion, there is also no statistically significant finding that shows the safety risk of PEV fires is higher than non-PEVs. See AutoinsuranceEZ: Gas vs. Electric Car Fires [2023 Findings], Nov. 11, 2022 (rate of fires from BEV light duty vehicles is nearly two orders of magnitude less than rate for gasoline or hybrid vehicles). EPA recognizes that battery fires are of a different character, and can pose different and more difficult challenges to extinguish, and the vehicles may have stranded electrical power, such that first responder training is desirable. The standard practice for putting out fires involving large batteries today involves the use of large amounts of water, and first responders can and should be trained to deal with fires of electrical origin (as they are trained to deal with fires from other chemical, ignitable, or flammable origins).

Several commenters expressed concern that the high-voltage PEV batteries will pose a shock hazard, especially for mechanics and first responders. In response, EPA concludes that appropriate repair and emergency response procedures have been and will continue to be developed, refined, and applied to manage shock risk effectively. There has been extensive activity to date by governmental and non-governmental organizations to update the protocols and guidance for first responders. And EPA expects that information will be frequently reviewed and updated as the best practices from field experience are communicated and refined.

The Alliance asserted that EPA's proposal to eliminate enrichment operation for ICE vehicles would potentially expose consumers to a sudden reduction or interruption of power during a driving maneuver, and result in an unsafe condition. EPA is not finalizing the proposed elimination of enrichment for this final rulemaking. At the same time, EPA does not agree that elimination of enrichment will impact the manufacturer's ability to continue to produce ICE vehicles that can be safely operated over the full range of conditions. EPA does not agree that enrichment is a necessary prerequisite for safe vehicle operation. Specifically, EPA disagrees with the commenters assertion that vehicles without enrichment will inherently exhibit unpredictable interruptions in power. Through proper design and calibration, EPA is confident that it's possible to deploy stoichiometric powertrains which operate predictably, even during aggressive driving maneuvers. Indeed, there are many vehicles in the fleet today that operate at stoichiometric with no evidence of safety issues.

In response to comments on safety and reliability of EVs, and electrical safety and fire risk, EPA finds no evidence that the nature of an electric vehicle necessarily leads to lower reliability, greater safety risk to service or emergency personnel, or a greater probability of a fire. The smaller number of moving parts in an EV is consistent with a potential for greater reliability and lower maintenance costs. Regarding electrical safety, all vehicles sold in the U.S. are required to pass Federal Motor Vehicle Safety Standard (FMVSS) standards. For example, this includes FMVSS No. 305, "Electric-powered vehicles: Electrolyte spillage and electrical shock protection." In addition, for all commercially produced vehicles, manufacturers routinely publish guides to emergency responders to show where mechanical means may be used to access the interior of the vehicle after a crash without disturbing airbags or other hazardous components, including high voltage pathways. In regard to fire safety, EPA sees no evidence that EV fires are more frequent on a per-vehicle or per-mile basis than for gasoline powered vehicles. While some manufacturers have recalled electric vehicles due to specific fire risks, there is also evidence that these were caused by specific defects in manufacturing, that are being recognized and addressed by the manufacturers. EPA also disagrees with comments that batteries are inherently unsafe, that they contain all of the reactants necessary to combust, or that they generate large amounts of heat during operation sufficient to jeopardize the safety of the vehicle. Electric vehicles and their battery systems are designed to maintain appropriate temperature operation and are safeguarded against usage that would cause excessive heat generation. Battery chemistries being used in electrified vehicles lack the necessary oxygen to combust without exposure to air.

23 - Economic concerns from industries that are not directly regulated under this rule

Note that Section 25.2 contains comments regarding industries that are directly regulated under this final rule.

<u>Comments by Organizations</u>

Organization: Darius

The large-scale shift to electric vehicles, which would comprise two-thirds of all new-car sales in the U.S. by 2032 under this proposal, will hurt workers, small businesses, and consumers while doing little to help the environment. The proposed rule would lead to fewer vehicle choices for individuals and families, reducing the selection of vehicles that fit their household budgets and unique needs. [EPA-HQ-OAR-2022-0829-0519, p. 1]

This proposed rulemaking will disrupt automotive industry supply chains and eliminate large numbers of jobs in vehicle manufacturing, parts production, and repair businesses. While small businesses are the lifeblood of the American economy, they will be hit the hardest by a premature rush to have electric vehicles dominate new vehicle sales. Small, internal-combustion engine-based businesses are not receiving the billions of dollars that large automakers are to make the conversion to electric. Thirty-three percent of automotive aftermarket products purchased by consumers last year were on upgrades and accessories for internal combustion engines and drive trains. That means as much as $17 billion of small business value will be wiped out by this proposal. [EPA-HQ-OAR-2022-0829-0519, p. 1]

Organization: Energy Marketers of America (EMA)

EMA is conce’ned over EPA's tailpipe emission standards for light-duty and medium-duty vehicles for model year 2027 and later which will effectively discourage investment in lower carbon liquid fuels. EPA projects that a potential outcome of the rule would require nearly 70 percent of all new light duty vehicle sales to be battery electric vehicles (EVs) by 2032. Unfortunately, the focus on EV production will fundamentally eliminate an opportunity to provide clean green liquid fuels such as renewable diesel, biodiesel, renewable gasoline, clean hydrogen and ethanol that immediately lower emissions not only for new vehicles, but for the vehicles currently on the road. In addition, the rule will limit consumer choice on cleaner internal combustion engines and threaten the viability and jobs of small business energy marketers around the country. [EPA-HQ-OAR-2022-0829-0616, pp. 1-2]

Organization: Kentucky Office of the Attorney General et al.

Furthermore, the Proposed Rule implicates “question[s] of deep economic and political significance,” King v. Burwell, 576 U.S. 473, 486 (2015), due to the huge “number of people affected,” United States Telecom Ass’n v. Fed. Commc’ns Comm’n, 855 F.3d 381, 423 (D.C. Cir. 2017) (Kavanaugh, J., dissenting from the denial of rehearing en banc). Because “Americans place a high value on car ownership,” almost 92% of households have at least one vehicle, and over 22% have access to at least three. Car Ownership Statistics 2023, Forbes (May 8, 2023), https://bit.ly/3NnPXnn. A regulation affecting so many people is bound to collide with “a significant portion of the American economy,” West Virginia, 142 S. Ct. at 2608 (cleaned up), and require “billions of dollars in spending by private persons or entities,” id. at 2621 (Gorsuch, J., concurring) (quoting King, 576 U.S. at 485). By EPA’s own estimate, technology increases “through 2055 are estimated at $260 billion to $380 billion.” 88 Fed. Reg. at 29,344. [EPA-HQ-OAR-2022-0829-0649, pp. 6-7]

Organization: Matthew DiPaulo

This proposal will disrupt automotive industry supply chains and eliminate large numbers of jobs in vehicle manufacturing, parts production, and repair businesses. While small businesses are the lifeblood of the American economy, they will be hit the hardest by a premature rush to have electric vehicles dominate new vehicle sales. Small, internal-combustion engine-based businesses are not receiving the billions of dollars that large automakers are to make the conversion to electric. Thirty-three percent of automotive aftermarket products purchased by consumers last year were on upgrades and accessories for internal combustion engines and drive trains. That means as much as $17 billion of small business value will be wiped out by this proposal. [EPA-HQ-OAR-2022-0829-1514, p. 1]

Organization: Missouri Corn Growers Association (MCGA)

The impact on small businesses will be far-reaching as well. According to Mike Spagnola, president and CEO of Specialty Equipment Markets Association (SEMA), “this large-scale shift would significantly disrupt automotive industry supply chains and potentially eliminate large numbers of jobs in vehicle manufacturing, parts production, and repair shops. Ford alone estimates a 30% labor reduction in its transition to electric vehicles. Small businesses would be the most vulnerable to the disruptions caused by a seismic shift to battery-electric vehicles. According to the most recent Census Bureau tally of the almost 1,200 auto engine and transmission parts suppliers in the U.S., more than 60% had 20 or fewer employees. These companies often make specialized components, operate on tight margins, and rely on long-term contracts. They employ American workers with technical skills and create the often politically celebrated blue-collar jobs.”1 [EPA-HQ-OAR-2022-0829-0578, pp. 2-3]

1 SEMA President and CEO Mike Spagnola, “New EPA Emissions Proposal Puts Automotive Supply Chains, Small Businesses at Risk”, https://www.sema.org/EPA-Proposed-Greenhouse-Gas-Rules

Organization: Specialty Equipment Market Association (SEMA)

On behalf of our more than 7,000 member companies, SEMA has significant concerns regarding the impact of the EPA’s proposed regulations on automotive small businesses. The specialty automotive aftermarket industry supports more than one million U.S. automotive jobs. Thousands of small businesses and their employees will be adversely impacted by this proposal’s overly aggressive push to electrify America’s automotive sector. SEMA supports the EPA’s intent to reduce greenhouse gas emissions, but the American people must have the ability to choose the vehicle technology that works best for their families. It is crucial for government policy to remain technology neutral in pursuit of decarbonizing motor vehicles. There are many options on the road to zero emissions. American-grown biofuels, carbon capture, and innovations in engine production are all aimed at this shared goal. The specialty automotive aftermarket has also led the way in fuel innovations and conversions of old vehicles into new and cleaner technologies and is committed to playing a central role in the evolution of automotive technology, including the parts and products that power our vehicles. However, this proposal embraces electrification as the technology of choice to the detriment of many of our members and their innovations. [EPA-HQ-OAR-2022-0829-0596, p. 1]

This proposal’s large-scale transition to Battery Electric Vehicles (BEV) over a truncated timeline will significantly disrupt automotive supply chains and potentially eliminate many jobs in vehicle manufacturing, parts production, and repair shops. As drafted, it would adversely impact small business innovators and the hundreds of thousands of men and women their companies employ. SEMA members want to continue to be part of the solution to making vehicles more efficient and reducing emissions. The best way to accomplish this goal is to let the market and innovation drive solutions to the environmental challenges we all seek to solve. [EPA-HQ-OAR-2022-0829-0596, pp. 1-2]

Impact on Small Business

This proposal is effectively a far too fast mandate for automakers to transition their production to BEVs in order to avoid being fined. It will produce a seismic shift for automotive aftermarket businesses who don't have the capacity to make the transition to zero-emissions vehicle technology this quickly, especially when they're not receiving billions in federal and state grants and incentives to support those transitions. [EPA-HQ-OAR-2022-0829-0596, p. 3]

The specialty automotive aftermarket has leI technology innovation, making vehicles more fuel efficient, safer, and more appealing to consumers. According to SEMA's data, 55% of our manufacturing businesses produce internal combustion engine (ICE) components, including parts for air and fuel, ignition, emissions controls, engine parts, and exhaust systems. To put this in perspective, 33% of consumer spending on performance and accessory products goes toward upgrading ICE engines and dri'etrains. That's nearly $17 billion dollars of the $51 billion specialty aftermarket industry and disproportionately impacts small businesses. [EPA-HQ-OAR-2022-0829-0596, p. 3]

Government policies should support the work of small business innovators that employ nearly a million American workers by letting the market and innovation drive solutions to the environmental challenges that we all seek to solve. [EPA-HQ-OAR-2022-0829-0596, p. 3]

It is no secret that large automakers' BEV programs are losing billions each year despite the massive financial infusion of taxpayer dollars they receive from the government and subsidies to purchase EVs. If the largest automakers are struggling right now, how are small automotive businesses, including specialty aftermarket, repair and replacement parts businesses, and local garages, expected to survive? [EPA-HQ-OAR-2022-0829-0596, p. 3]

Organization: United Steelworkers (USW)

Also, small and medium manufacturers in the auto supply chain must be informed, encouraged, and assisted in utilizing these investment opportunities in order to prevent job loss. At this time, outreach to these companies is limited. [EPA-HQ-OAR-2022-0829-0587, p. 4]

EPA Summary and Response

Summary:

Commenters including Darius, Matthew DiPaulo, MCGA, SEMA and EMA commented that the proposal would lead to loss in small business value and eliminate jobs. Some commenters noted that small businesses are not receiving the investments to support the transition to zero-emission vehicles that the large auto manufacturers are. Some commenters specifically pointed out these effects for the specialty automotive and automotive aftermarket industries. Darius also commented that the rule will reduce vehicle choice. SEMA and EMA commented that this rule will lead to reduced vehicle choice. Kentucky Office of the Attorney General noted that this rule will affect many people.

EMA noted that the proposed rule will discourage investment in lower carbon fuels and eliminate opportunities to provide clean green liquid fuels. SEMA commented that there are other options to zero emission vehicles, and that this rule is a "far too fast mandate." They also stated that the market and innovations should be allowed to drive solutions to environmental challenges. USW commented that more outreach is needed to small and medium manufacturers in the auto supply chain to prevent job loss.

Response:

Regarding comments that this rule will lead to loss in small business value, including in aftermarket and specialty automotive markets, we first note we address small business impacts related to the Regulatory Flexibility Act in RTC Section 25.1. In addition, commenters asserting that this rule will lead to a loss of small business value generally do not make specific assertions beyond claims that PEVs will be disruptive. This rule is not a mandate and does not force manufactures to use any specific technology. Manufacturers can determine the best path of compliance for them. In addition, as described in Section IV.F and G of the preamble, we demonstrate that there are multiple pathways to compliance, and that these pathways include a wide range of mixes of technologies in the fleet, including various mixes of ICE vehicles, strong hybrid vehicles, PHEVs and BEVs. In the central modeling case for the final rule, results show that over 80% of the onroad fleet will still be ICE vehicles, and over 50% will still be ICE vehicles in 2050. As the vast majority of the onroad fleet will continue to be ICE vehicle in 2032, they will continue to provide business opportunities for small businesses that service ICE vehicles. In addition, there are considerable opportunities for small businesses to play a role in the EV supply chain. RTC Section 20 discusses many training and investment opportunities for jobs along the EV supply chain, including for jobs in high demand like BEV technicians.

Regarding comments that this rule is a “far too fast mandate” we disagree. First, we note that, as described in Section III.C of the preamble, EPA is finalizing standards for both light- and medium-duty vehicles that have a slower ramp rate in the early years of the program compared to the proposal. For the light-duty GHG standards, we have reduced the stringency of the standards from MYs 2027 through 2031 compared to the proposed standards and have also extended the phase-down of certain optional credit flexibilities. These changes are responsive to comments from labor groups and the auto industry that the pace of the standards was too fast, and that more lead time was needed to provide a more orderly transition that allowed for the scale up of battery supply chains and vehicle production. In turn, EPA believes that this slower pace of the final standards will further support workers and labor impacts during the transition to manufacturers building a range of vehicle technologies to meet the standards, as well as allow for increased opportunities for training, education and facility upgrades over time.

Regarding comments that more outreach is needed to small and medium manufacturers to prevent job loss, we note that EPA engaged stakeholders, including labor groups, small volume manufactures, and others, throughout the proposal and final rule making processes. After the publication of the proposed rule, EPA held three days of public hearings to provide oral presentation of data, views and arguments, and held an open comment period during which all members of the public were encouraged to submit comments on the proposed rule. In addition, RTC Section 20 discusses some of the programs and investments that may be available to small and medium manufacturers to support a transition to green sector jobs.

Regarding comments that this rule will discourage investment in lower carbon fuels, refer to RTC Section 19.1, where other fuels related comments are discussed.

Regarding comments that the rule will hurt workers or eliminate jobs, we refer to our discussion in RTC Section 20.

Regarding comments that this rule will reduce vehicle choice, we refer to our discussion in RTC Sections 13 and 14.1.

25 - Statutory provisions and Executive Orders

Comments by Organizations

Organization: American Fuel & Petrochemical Manufacturers

Ignoring actual ZEV production costs, including credit trading costs, is arbitrary and capricious. [EPA-HQ-OAR-2022-0829-0733, p. 54]

The Administrative Procedure Act requires opportunity for meaningful public input, and Executive Order 12866 states that, in most cases, agencies should provide a comment period "of not less than 60 days." Even counting the handful of additional days afforded by EPA's pre-publication release of the preambles, this period is not sufficient to adequately address the sweeping scope of EPA's proposals to force electrification of the nation's transportation fleet. Considerable time is required simply to read and respond to the sheer volume of material covered in each rulemaking docket, particularly given EPA's evident lack of rigor and discipline in its citation and characterization of underlying sources. As illustrated in these comments, our review identified numerous instances in which examination of sources cited by EPA as support for its conclusions indicated that characterization of these sources is inaccurate, incomplete, or misleading. Thus, to meaningfully respond to EPA's proposal, the public must fact-check EPA's work. There are 1,040 footnotes in the text of the HDV rule preamble and 908 in the LD/MDV rule. Assuming it takes an average of one hour to identify, locate or acquire and read the underlying reference work cited, and draft a meaningful comment in response, that equates to 130 eight- hour workdays that would be required just to fact-check the HD rule (65 days if one assumes this work takes only half an hour per cite on average). For the LD/MDV rule, which would equate to 113.5 eight-hour workdays (or 57 based on assuming 30 minutes per citation). This analysis does not include the time required to verify sources cited in the DRIAs, much less the 1,420 supporting and related materials posted to the HDV docket and the 429 posted to the LD/MDV docket. [EPA-HQ-OAR-2022-0829-0733, pp. 62-63]

Further, the short and concurrently running comment periods on these closely related rules are exacerbated by EPA's unduly narrow identification of industries affected by this rule. Under the heading "Does this action apply to me," EPA limits its identification of affected industries to entities with direct compliance obligations: motor vehicle manufacturers, commercial importers of vehicles and vehicle components, alternative fuel vehicle convertors, and medium duty engine & vehicle manufacturers.283 Although EPA notes that "this table is not intended to be exhaustive…other types of entities could also be affected," EPA understands many entities necessarily rely on regulatory screening tools based on search terms tied to their own NAICS codes to alert them to new proposed rules that may impact them. [EPA-HQ-OAR-2022-0829-0733, p. 63]

283 Proposed Rule at 29,184.

By narrowly limiting the identification of industries affected based on this extremely short and incomplete list of NAICS codes and by its arbitrary refusal to extend the comment periods, EPA has unreasonably constrained the number and types of entities that will find out about these proposed actions in time to comment. EPA appears to be counting on closing the comment period before consumers, retailers, farmers, fleet operators, bio and renewable fuel producers, small businesses, emergency response providers, local governments, or any of the host of other interests who will be affected by the profound changes in how light and medium duty vehicles are sold or even realize what is at stake. This sort of gamesmanship is at odds with EPA's responsibility under the Administrative Procedures Act and the Due Process clause of the U.S. Constitution. [EPA-HQ-OAR-2022-0829-0733, p. 63]

Organization: Arizona State Legislature

VIII. The proposed rule is arbitrary and capricious because it relies on non-final reports.

On at least two occasions, EPA identifies reports that are not yet final because they are undergoing peer review. [EPA-HQ-OAR-2022-0829-0537, p. 26]

First, EPA reports that it "commissioned a new full-vehicle teardown study" to compare manufacturing cost and assembly requirements between gas-powered and electric-powered vehicles. 88 Fed. Reg. 29,303. "The report was delivered to EPA in February 2023 and will undergo a contractor-managed peer review process to be completed by mid-2023." Id. EPA even plans to rely on the report for the final rule: "The results of this study will be used to inform the analysis for the final rulemaking where appropriate." Id. EPA later admits, "We hope to use this information in additional analytical discussions in the final rule." Id. at 29,391. [EPA-HQ-OAR-2022-0829-0537, p. 26]

Second, as discussed in Section IV, significant issues exist with EPA's current social cost of greenhouse gas methodology. However, EPA apparently is working on an update: "Most recently, EPA has developed a draft updated SC-GHG methodology within a sensitivity analysis in the regulatory impact analysis of EPA's November 2022 supplemental proposal for oil and gas standards that is currently undergoing external peer review and a public comment process." After it published the proposed rule, on May 11, 2023, EPA announced that it had received the peer review and was "taking the peer reviewers' recommendations under advisement."38 [EPA-HQ-OAR-2022-0829-0537, p. 26]

38 U.S. EPA, Peer Review of EPA's Draft 'Report on the Social Cost of Greenhouse Gases: Estimates Incorporating Recent Scientific Advances' Concludes, May 11, 2023, available at https://www.epa.gov/environmental- economics/scghg-tsd-peer-review.

Commenters do not know the conclusions and analysis contained in the final versions of these reports. Presumably, EPA will make changes after receiving the peer-review comments. Commenters cannot provide fully informed comments on the proposed rule without having the opportunity to review the final versions of these reports. [EPA-HQ-OAR-2022-0829-0537, p. 27]

EPA should reopen the public comment process for the proposed rule after it has received the final versions of these reports. This should occur whether or not EPA intends to make revisions to the final rule based on the reports or to rely on the reports to support the final rule. If EPA intends to make revisions of the final rule based on the final versions of these reports, commenters should have the opportunity to comment on all revisions. The same is true with any other reports or data that EPA does not cite in the proposed rule. [EPA-HQ-OAR-2022-0829-0537, p. 27]

Failure by EPA to reopen the public comment process would be arbitrary and capricious. See, e.g., Texas v. United States Env't Prot. Agency, 389 F. Supp. 3d 497, 506 (S.D. Tex. 2019) ("However, the Agencies' decision not to reopen the Proposed Rule for comment after the publication of the Final Connectivity Report prejudiced the ability of interested parties to (1) provide meaningful comments regarding the Final Rule's continuum-based approach to connectivity and (2) 'mount a credible challenge' to the Final Rule."); Ctr. for Biological Diversity, Defs. of Wildlife v. Kelly, 93 F. Supp. 3d 1193, 1207 (D. Idaho 2015) (granting partial summary judgment and ordering an additional public comment period after federal agency relied on peer review comments not discussed or cited in the proposed rule). [EPA-HQ-OAR-2022-0829-0537, p. 27]

Organization: Environmental. and Public Health Organizations

EPA should set strong emissions standards to meet its obligations under presidential directives on environmental justice. Under Executive Order 12,898, EPA "shall make achieving environmental justice part of its mission by identifying and addressing, as appropriate, disproportionately high and adverse human health or environmental effects of its programs, policies, and activities on minority populations and low-income populations." 59 Fed. Reg. 7629 (Feb. 11, 1994). And Executive Order 14,008 directs EPA to develop "programs, policies, and activities to address the disproportionately high and adverse human health, environmental, climate-related and other cumulative impacts on disadvantaged communities, as well as the accompanying economic challenges of such impacts.'' 86 Fed. Reg. 7619, 7629 (Jan. 27, 2021). It also establishes the Administration's policy ''to secure environmental justice and spur economic opportunity for disadvantaged communities that have been historically marginalized and overburdened by pollution.'' Id. [EPA-HQ-OAR-2022-0829-0759, p. 18]

Organization: Environmental Defense Fund (EDF) (1of 2)

The IRA and BIL both include myriad provisions that seek to support a transition to ZEV technology through funding of credits for vehicles, components, and critical infrastructure. These laws were passed with the knowledge that EPA was already setting standards under Section 202(a) that would increase ZEV proliferation and an intent to support those regulations.15 Congress' aim with the funding was to "combine[] new economic incentives to reduce climate pollution with bolstered regulatory drivers that will allow EPA to drive further reduction under its CAA authorities,"16 with the expectation that "future EPA regulations will increasingly rely on and incentivize zero-emission vehicles as appropriate."17 [EPA-HQ-OAR-2022-0829-0786, pp. 10-11]

15 The BIL was passed after EPA's 2023-2026 light-duty GHG standards, which rely on ZEV technology, had been proposed and the IRA was passed 9 months after they were finalized. Brief of Senator Thomas R. Carper and Representative Frank Pallone, Jr. as Amici Curiae in Support of Respondents, Texas v. EPA, No. 22-1031, 29 (D.C. Cir, Mar. 2, 2023), https://www.edf.org/sites/default/files/2023-03/Texas%20-%20Members%20of%20Congress%20%28Sen.%20Carper%20and%20Rep.%20Pallone%29.pdf (Attachment J).

16 168 Cong. Rec. E868-02 (daily ed. Aug. 12, 2022) (statement of Rep. Pallone discussing the IRA).

17 168 Cong. Rec. at 880-02 (daily ed. Aug. 12, 2022) (statement of Rep. Pallone); see also Greg Dotson and Dustin J. Maghamfar, The Clean Air Act Amendments of 2022: Clean Air, Climate Change, and the Inflation Reduction Act, 53 ENV'T L. REP. 10017, 10030 (2023) ("The IRA directs EPA to support zero

emission technologies for heavy-duty vehicles and port equipment, to reduce emissions in low-income and disadvantaged communities, as well as to support state ZEV requirements. This is a recognition of the evolving importance and availability of zero emission technologies."), https://www.eli.org/sites/default/files/files-pdf/53.10017.pdf (Attachment K).

The BIL is another source of considerable federal investment in infrastructure development. Through its National Electric Vehicle Infrastructure (NEVI) and Charging and Fueling Infrastructure (CFI) discretionary grant programs, the law allocates $7.5 billion in funding explicitly towards building out ZEV charging and refueling infrastructure.130 The NEVI program directs the Federal Highway Administration (FHWA) to provide funding to states to deploy EV charging stations to build an interconnected and reliable charging network. The FHWA has already announced its first set of plans under the program, which includes investment in all 50 states plus the District of Columbia and Puerto Rico.131 This first round of NEVI investment is set to bring EV charging to 75,000 miles of highway across the country.132 The CFI program provides additional funding for FHWA administered grants to state and local authorities for development of publicly accessible charging infrastructure.133 [EPA-HQ-OAR-2022-0829-0786, pp. 52-53]

On top of these programs, the BIL authorized more than $40 billion combined for the Congestion Mitigation & Air Quality Improvement Program, National Highway Performance Program, and Surface Transportation Grant Block Program.134 These programs are not dedicated exclusively to charging, but constructing and installing charging infrastructure is an eligible activity under each of them. Additional funding from the BIL provides grants to states and local governments for reducing transportation carbon pollution, which will fund additional infrastructure investments.135 [EPA-HQ-OAR-2022-0829-0786, pp. 52-53]

Organization: HF Sinclair Corporation

III. The Proposed Rule is Arbitrary and Capricious

[EPA-HQ-OAR-2022-0829-0579, pp. 16-17]

Organization: Travis Fisher

2. Does not comply with Executive Order 12866; and [EPA-HQ-OAR-2022-0829-0655, p. 1]

3. Violates the Unfunded Mandates Reform Act. [EPA-HQ-OAR-2022-0829-0655, p. 1]

2. THE PROPOSED RULE DOES NOT COMPLY WITH EXECUTIVE ORDER 12866

EPA states that it sought review by the Office of Management and Budget and that “[a]ny changes made in response to Executive Order 12866 review have been documented in the docket.”19 Notwithstanding whatever review EPA sought, there remain numerous omissions regarding the Proposed Rule’s compliance with Executive Order 12866. Specifically, section 1 of Executive Order 12866 offers a list of “Principles of Regulation.” EPA violates several of the principles listed. Specifically, the Proposed Rule does not conform with principles 6, 7, 8, nor 10, and thus fails to comply with Executive Order 12866. Before moving forward with a final rule (or a new proposed rule), EPA should address these areas of non-compliance. [EPA-HQ-OAR-2022-0829-0655, p. 7]

19 Proposed Rule, 88 FR 29184 at 29404.

Principle 6 states:

“Each agency shall assess both the costs and the benefits of the intended regulation and, recognizing that some costs and benefits are difficult to quantify, propose or adopt a regulation only upon a reasoned determination that the benefits of the intended regulation justify its costs.” [EPA-HQ-OAR-2022-0829-0655, pp. 7-8]

EPA fails to comply with Principle 6 because it has not undertaken a reasonable assessment of the cost of the Proposed Rule. As discussed above, EPA does not fully account for the Proposed Rule’s impacts on the electricity system, which include increasing the cost of electricity and harming electric grid reliability. [EPA-HQ-OAR-2022-0829-0655, pp. 7-8]

EPA also overstates the benefits of the Proposed Rule by claiming unreasonably high benefits from reductions in emissions of fine particulate matter (PM2.5).20 A more accurate estimate of “co-benefits” from PM2.5 reduction would improve cost-benefit assessments for EPA rules across the board, including in this Proposed Rule.21 Given the requirement in principle 6 of Executive Order 12866 for an agency to “adopt a regulation only upon a reasoned determination that the benefits of the intended regulation justify its costs,” EPA should revisit its cost-benefit analysis using more accurate estimates of PM2.5 impacts before it can determine that the benefits of the Proposed Rule in fact outweigh the costs.22 [EPA-HQ-OAR-2022-0829-0655, p. 8]

20 Comments to EPA Re: Reconsideration of the National Ambient Air Quality Standards for Particulate Matter. Travis Fisher. 2023. Available at: https://thf_media.s3.amazonaws.com/2023/PM25comments.pdf (accessed July 2, 2023).

21 Will EPA Stop Its Abuse of Costly Pollution-Control ‘Co-Benefits’ Assessments? Daren Bakst. October 4, 2018. Available at: https://www.heritage.org/agriculture/commentary/will-epa-stop-its-abuse-costly-pollution-control-co- benefits-assessments (accessed July 2, 2023).

22 EPA unreasonably treats all species of PM2.5 as equally toxic. This is an incorrect assumption and should be remedied if EPA moves forward with a final rule. A recent study in the journal Nature (available at: https://www.nature.com/articles/s41598-018-35398-0) explains the variability in toxicity among different chemical species of PM2.5 (and even among combustion temperatures and engine sizes for the same fuel). Noting the wide range of toxicity of the various chemical components and sources of PM2.5 pollution, EPA should tailor its estimates of PM2.5 co-benefits to match the toxicity of the various forms of PM2.5. Not all PM2.5 is equally toxic, and therefore not all exposure to PM2.5 is equally costly.

Principle 7 states:

"Each agency shall base its decisions on the best reasonably obtainable scientific, technical, economic, and other information concerning the need for, and consequences of, the intended regulation." [EPA-HQ-OAR-2022-0829-0655, p. 8]

EPA fails to comply with Principle 7 because, as detailed above, it has not availed itself of the ample scientific and technical information—well known and published by leading sources such as NERC, FERC, and PJM—regarding the consequences of EPA regulations on the cost and reliability of the electricity system. [EPA-HQ-OAR-2022-0829-0655, p. 8]

Principle 8 states:

"Each agency shall identify and assess alternative forms of regulation and shall, to the extent feasible, specify performance objectives, rather than specifying the behavior or manner of compliance that regulated entities must adopt." [EPA-HQ-OAR-2022-0829-0655, p. 8]

EPA fails to comply with Principle 8 because the Proposed Rule is a de facto mandate for PEVs. Much like the unlawful Clean Power Plan,23 the thrust of the Proposed Rule is to force a shift away from internal combustion engine vehicles and toward PEVs. Indeed, the performance objectives outlined in the Proposed Rule are only viable if the regulated entities—drivers in the U.S.—behave as specified by EPA. [EPA-HQ-OAR-2022-0829-0655, p. 8]

23 See https://archive.epa.gov/epa/cleanpowerplan/clean-power-plan-existing-power-plants-regulatory-actions.html (accessed July 2, 2023).

Principle 10 states:

"Each agency shall avoid regulations that are inconsistent, incompatible, or duplicative with its other regulations or those of other Federal agencies." [EPA-HQ-OAR-2022-0829-0655, p. 9]

EPA fails to comply with principle 10 because, as outlined in the section on electric grid reliability above, the Proposed Rule is incompatible with the suite of existing and new EPA regulations that are forcing a large reduction in electricity supply. Although a minor conflict with an obscure rule from a different agency might be forgivable, EPA's Proposed Rule unreasonably conflicts with a concurrent proposed rule issued by EPA—the Greenhouse Gas Standards and Guidelines for Fossil Fuel-Fired Power Plants, issued in May of 2023.24 In fact, it appears that the DRIA fails to reference or otherwise acknowledge the power plant rule. [EPA-HQ-OAR-2022-0829-0655, p. 9]

24 New Source Performance Standards for Greenhouse Gas Emissions From New, Modified, and Reconstructed Fossil Fuel-Fired Electric Generating Units; Emission Guidelines for Greenhouse Gas Emissions From Existing Fossil Fuel-Fired Electric Generating Units; and Repeal of the Affordable Clean Energy Rule, 88 FR 33240; May 23, 2023. Available at: https://www.federalregister.gov/documents/2023/05/23/2023-10141/new-source- performance-standards-for-greenhouse-gas-emissions-from-new-modified-and-reconstructed (accessed July 2, 2023).

3. THE PROPOSED RULE VIOLATES THE UNFUNDED MANDATES REFORM ACT

The Proposed Rule must satisfy section (a)(3)(B) of the Unfunded Mandates Reform Act (UMRA).25 The UMRA establishes that "before promulgating any general notice of proposed rulemaking that is likely to result in promulgation of any rule that includes any Federal mandate that may result in the expenditure by State, local, and tribal governments, in the aggregate, or by the private sector, of $100,000,000 or more (adjusted annually for inflation) in any 1 year … the agency shall prepare a written statement" containing five categories of analysis, including "any disproportionate budgetary effects of the Federal mandate upon any particular regions of the nation or particular State, local, or tribal governments, urban or rural or other types of communities, or particular segments of the private sector," and "a description of the extent of the agency's prior consultation with elected representatives … of the affected State, local, and tribal governments." [EPA-HQ-OAR-2022-0829-0655, p. 9]

25 2 U.S.C. 1532. Available at: https://www.law.cornell.edu/uscode/text/2/1532 (accessed July 2, 2023).

The Proposed Rule acknowledges that it would have major financial impacts but claims the provisions of the UMRA regarding State, local, or Tribal governments do not apply. EPA states: [EPA-HQ-OAR-2022-0829-0655, p. 9]

This action contains no unfunded Federal mandate for State, local, or Tribal governments as described in UMRA, 2 U.S.C. 1531–1538, and does not significantly or uniquely affect small governments. This action imposes no enforceable duty on any State, local or Tribal government.26 [EPA-HQ-OAR-2022-0829-0655, p. 9]

26 Proposed Rule, 88 FR 29184 at 29405.

If the EPA moves forward with a final rule, it should explain why it finds that the federal mandates included in the Proposed Rule would not significantly affect State, local, or Tribal governments. As drafted, the Proposed Rule does not detail how it has satisfied the above procedural requirements of the UMRA and does not indicate that the EPA has undertaken the required analysis of the impacts on states and local governments and tribes of compliance with the Proposed Rule. For example, some electric utilities are owned and operated by State, local or Tribal governments.27 The Proposed Rule will significantly impact the cost of the distribution systems of those publicly owned utilities, and the DRIA should be amended to evaluate the extent of the cost increases and the impact of the Proposed Rule on the budgets of State, local or Tribal governments. [EPA-HQ-OAR-2022-0829-0655, pp. 9-10]

27 Navigating the EV Market: Trends and Changes for Public Power to Know. American Public Power Association. Available at: https://www.publicpower.org/system/files/documents/Navigating-the-Electric-Vehicle-Market.pdf (accessed July 2, 2023).

CONCLUSION

Thank you for the opportunity to comment on the Proposed Rule. For the foregoing reasons, the EPA should not move forward with this rule without first correcting the many dire flaws in the Proposed Rule: its violation of section 202 of the Clean Air Act and Executive Order 12866, its faulty cost-benefit analysis, and its woeful misunderstanding of the U.S. electricity sector as reflected in the DRIA. [EPA-HQ-OAR-2022-0829-0655, p. 10]

EPA Summary and Response

Summary:

The American Fuel & Petrochemical Manufacturers, as well as the Alliance for Consumers, expressed that the comment period for this rule was not sufficiently long to adequately read and respond to the material covered in EPA's rulemaking docket. American Fuel & Petrochemical Manufacturers also expressed that EPA's proposal listed an incomplete list of NAICS codes of the number and types of entities that will find out about these proposed actions in time to comment.

Response:

EPA believes that the time for public comment allowed a meaningful opportunity for comment, as illustrated by the detailed comments submitted by the American Fuel & Petrochemical Manufacturers and hundreds of thousands of members of the public. The proposal was announced on April 12, 2023, and the pre-publication version of the notice of proposed rulemaking was posted to the EPA's website on that same day. The notice was published in the Federal Register on May 5, 2023, and the public comment period was open until July 5, 2023. In addition to the written public comment period, the EPA offered a multi-day virtual public hearing for the public to provide oral comments to the Agency on the proposed rule in May 2023. The EPA considers this a fully adequate amount of time for commenters to provide comments to the Agency regarding the proposed standards for MY 2027 through MY2032 light and medium duty vehicles, and we note that EPA received more than 250,000 public comments on the proposed rulemaking. EPA also considered comments received after the close of the comment period to the extent practicable.

With respect to identifying the industries that EPA anticipates will be affected by this rule, EPA identified entities with direct compliance obligations: motor vehicle manufacturers, commercial importers of vehicles and vehicle components, alternative fuel vehicle convertors, and medium duty engine & vehicle manufacturers. The corresponding table of NAICS codes is not intended to be exhaustive, and other types of entities could also be affected, as stated in the rule text.

Summary:

The Alliance for Consumers commented that the rationale for the proposal and its justification in the context of the tailpipe emissions program is "pretextual," for replacing nearly all gas-powered cars with EVs.

Response:

EPA neither proposed nor is adopting any mandates for EVs. EPA's standards are performance-based, meaning that manufacturers choose the mix of technologies they believe best suited for their fleet to meet the standards, and EPA has demonstrated in this final rule a wide range of example pathways that manufacturers might choose which include various mixes of ICE vehicles, hybrids, PHEVs and BEVs.

Summary:

The Alliance for Consumers comments that this rule is arbitrary and capricious under the APA because it has failed to properly consider the rising price of electric vehicles in the wake of the Inflation Reduction Act, the limits on credits and subsidies that have resulted from this surge in electric vehicle pricing, and the true cost of repairing electric vehicles over a relevant time horizon. The HF Sinclair Corporation also commented that the proposed rule is arbitrary and capricious. The American Fuel and Petrochemical Manufacturers commented that this rule is arbitrary and capricious because it ignores actual ZEV production costs, including credit trading costs.

Response:

EPA considers in its analysis of the proposed rule in Sections IV.D.4 and VIII of the Preamble the vehicle technology costs for manufacturers to meet the final standards with a range of technologies including electric vehicles; we also include estimates for maintenance/repair in Section VIII. As well, EPA considers a sensitivity case with no credit trading in Section IV.F.5 of the Preamble.

Summary:

The Arizona State Legislature commented that the proposed rule is arbitrary and capricious because it relies on non-final reports through its commissioned, new full-vehicle teardown study and social cost of greenhouse gas methodology. Commenters cannot provide fully informed comments on the proposed rule without having the opportunity to review the final versions of these reports. EPA should reopen the public comment process for the proposed rule after it has received the final versions of these reports. Failure by EPA to reopen the public comment process would be arbitrary and capricious.

Response:

Regarding the full-vehicle teardown study, in the proposal, we described a new full-vehicle teardown study comparing a gasoline-fueled vehicle and a comparable BEV conducted for EPA by FEV of America.[695] We also indicated in the proposal that we may rely on the information from this work for the final rule. For example, we indicated that component costs for the BEV and ICE vehicle might be used to support or update our battery or non-battery costs for electrified vehicles, or our costs for ICE vehicles; assembly labor data might be used to further inform the employment analysis; and any other qualitative or quantitative information that could be drawn from the report might be used in the analysis. Therefore, EPA believes we provided the public with ample notice about the types of information we were considering for, and in fact now have applied in, the final rule analysis. The project report was delivered to EPA in February 2023 and underwent a contractor-managed peer review process that has now been completed.[696]

Regarding social cost of greenhouse gas benefits, EPA noted in the light/medium-duty vehicle proposal that in the December 2022 Oil and Gas NSPS/EG Supplemental Proposal the Agency included a sensitivity analysis of the climate benefits of the Supplemental Proposal using a new set of SC-GHG estimates that incorporates recent research addressing recommendations of the National Academies in addition to using the interim SC-GHG estimates presented in the Technical Support Document: Social Cost of Carbon, Methane, and Nitrous Oxide Interim

[695] FEV Consulting Inc., "Cost and Technology Evaluation, Conventional Powertrain Vehicle Compared to an Electrified Powertrain Vehicle, Same Vehicle Class and OEM," prepared for Environmental Protection Agency, EPA Contract No. 68HERC19D00008, February 2023.

[696] Memo to Docket ID No. EPA-HQ-OAR-2022-0829, titled "External Peer Review of Cost and Technology Evaluation, Conventional Powertrain Vehicle Compared to an Electrified Powertrain Vehicle, Same Vehicle Class and OEM."

Estimates under Executive Order 13990[697] that the IWG recommended for use until updated estimates that address the National Academies' recommendations are available. EPA believes this provided sufficient notice for commenters about the updated SC-GHG values that EPA was considering for, and in fact has decided to apply in, this final rule. A full discussion of the SC–GHG estimates and the important considerations and limitations associated with its use are provided in the RIA in Chapter 10. In addition, EPA presents the IWG SC-GHG values as a comparison in the Appendix to RIA Chapter 9.

Summary:

Environmental and Public Health Organizations commented that EPA should set strong emissions standards to meet its obligations under Executive Order 12898, which says that EPA "shall make achieving environmental justice part of its mission by identifying and addressing, as appropriate, disproportionately high and adverse human health or environmental effects of its programs, policies, and activities on minority populations and low-income populations." Additionally, Executive Order 14008 directs EPA to develop "programs, policies, and activities to address the disproportionately high and adverse human health, environmental, climate-related and other cumulative impacts on disadvantaged communities, as well as the accompanying economic challenges of such impacts."

Response:

As noted in Section IX.J of the preamble that accompanies this final rule, EPA believes that this action is likely to reduce existing disproportionate and adverse effects on many communities with EJ concerns. The air pollutant emission reductions that will be achieved by this rule will improve air quality for the people who reside in close proximity to major roadways and who are disproportionately represented by people of color and people with low income. We expect that localized increases in criteria and toxic pollutant emissions from EGUs and reductions in petroleum-sector emissions could lead to changes in exposure to these pollutants for people living in the communities near these facilities. Analyses of communities in close proximity to these sources (such as EGUs and refineries) have found that a higher percentage of communities of color and low-income communities live near these sources when compared to national averages. We also note that people of color, low-income populations and/or indigenous peoples may be especially vulnerable to the impacts of climate change. The GHG emission reductions from this action will contribute to efforts to reduce the probability of severe impacts related to climate change.

Summary:

The Environmental Defense Fund commented that the IRA and BIL were passed with the knowledge that EPA was already setting standards under Section 202(a) that would increase ZEV proliferation and an intent to support those regulations. Congress' aim with the funding was to "combine[] new economic incentives to reduce climate pollution with bolstered regulatory drivers that will allow EPA to drive further reduction under its CAA authorities," with the expectation that "future EPA regulations will increasingly rely on and incentivize zero-emission vehicles as appropriate."

[697] Interagency Working Group on Social Cost of Carbon (IWG). 2021 (February). Technical Support Document: Social Cost of Carbon, Methane, and Nitrous Oxide: Interim Estimates under Executive Order 13990. United States Government.

Response:

EPA acknowledges that Congressional passage of the BIL and IRA represent pivotal milestones in the creation of a broad-based infrastructure instrumental to the expansion of clean transportation, including light- and medium-duty zero-emission vehicles, and we have taken these developments into account in our assessment of the feasibility of the standards (see e.g., preamble section I.A.3).

Summary:

Travis Fisher commented that EPA's proposal does not comply with Executive Order 12866, because it has not undertaken a reasonable assessment of the cost of the Proposed Rule, overstates the benefits of the Proposed Rule by claiming unreasonably high benefits from reductions in emissions of fine particulate matter (PM2.5), has not availed itself of the consequences of EPA regulations on the cost and reliability of the electricity system, is a de facto mandate for PEVs, and is incompatible with the suite of existing and new EPA regulations that are forcing a large reduction in electricity supply. Travis Fisher further comments that EPA's proposal does not detail how it has satisfied the requirements of the UMRA and does not indicate that the EPA has undertaken the required analysis of the impacts on states and local governments and tribes of compliance with the Proposed Rule.

Response:

Regarding the comment claiming that EPA did not comply with EO 12866, EPA disagrees. EPA notes that, consistent with CAA section 202, in evaluating potential standards we carefully weigh the statutory factors, including the emissions impacts of the standards, and the feasibility of the standards (including cost of compliance in light of available lead time). We monetize benefits of the standards and evaluate other costs in part to enable a comparison of costs and benefits pursuant to E.O. 12866, but we recognize there are benefits that we are currently unable to fully quantify. EPA's practice has been to set standards to achieve improved air quality consistent with CAA section 202, and not to rely on cost-benefit calculations, with their uncertainties and limitations, as identifying the appropriate standards. Nonetheless, our conclusion that the estimated benefits exceed the estimated costs of the program reinforces our view that the standards are appropriate under section 202(a).

Comments regarding PM health benefits are addressed in RTC section 8.5. Comments regarding potential impacts on the electric grid are addressed in RTC section 18. Comments that this rule is a de facto BEV mandate are addressed in the first response in this section and elsewhere (e.g., RTC section 3.3.1).

In response to the comment that EPA's proposal did not satisfy the requirements of UMRA, this action contains no unfunded Federal mandate for State, local, or Tribal governments as described in UMRA, 2 U.S.C. 1531–1538, and does not significantly or uniquely affect small governments. This action imposes no enforceable duty on any State, local or Tribal government. This action contains Federal mandates under UMRA that may result in expenditures of $100 million or more for state, local, and Tribal governments, in the aggregate, or the private sector in any one year. Accordingly, the EPA has prepared a written statement of the costs and benefits associated with action as required under section 202 of UMRA. This action is not subject to the requirement of section 203 of UMRA because it contains no regulatory requirements that might significantly or uniquely affect small governments. This issue is further discussed Section IX.D of the Preamble.

25.1 - Regulatory Flexibility Act

Comments by Organizations

Organization: Ad Hoc Tier 4 Light-Duty Small Manufacturer Group

B. Overview

US vehicle sales by Small OEMs have no meaningful environmental impact:

-The above companies as a group represent a tiny fraction of the US automobile market. The fraction is so small that the companies have a minuscule impact on US air pollution. Together the companies accounted for about 4000 car sales in the US in CY 2022, which represents 0.15% of the total 2.9 million US passenger car sales for that year. If we just look at the Small Businesses in the Ad Hoc Group, they collectively sold about 100 cars in the US in 2022 -- a mere 0.003% of the 2.9 million volume. [EPA-HQ-OAR-2022-0829-0509, pp. 1-2]

-The vehicles of the Ad Hoc Group's members are not "daily drivers" but rather "occasional use" cars. As a result, the average annual mileage driven by these vehicles is drastically less than-- perhaps 25% of -- the average annual mileage of a typical passenger car. Fewer miles driven is one way to reduce vehicular pollution. [EPA-HQ-OAR-2022-0829-0509, pp. 1-2]

- EPA's apparent misunderstanding of what Small OEMs are selling in the US [EPA-HQ-OAR-2022-0829-0509, p. 3]

Neither with regard to criteria emissions nor GHG does EPA explain its thinking behind the elimination of Small OEM flexibility. But a misstatement in the NPRM preamble may shed light on the absence of necessary and proper Small OEM additional leadtime / flexibility in the NPRM: on page 596 of the preamble of the NPRM document, EPA incorrectly states (as it does the Draft Regulatory Impact Analysis) that the "proposed NMOG+NOx standards should have no impact on the existing Small Business manufacturers, which currently produce only electric vehicles." This is simply not so. There most certainly are Small Businesses that produce internal combustion engine (ICE) vehicles for the US market. Four of the seven members of the AD Hoc Group preparing this report are Small Businesses who are, or soon will be, selling ICE vehicles in the US market.[2] [EPA-HQ-OAR-2022-0829-0509, p. 3]

2 At least one of these Small Businesses tried in 2022 to participate in EPA's Regulatory Flexibility Act SBREFA process, but for some unexplained reason was not included by EPA.

3 EPA has mistakenly indicated that the SBREFA process is only open to US small businesses. This is not correct. In a 2021 US District Court (DC) case, plaintiffs challenged the Internal Revenue Service's alleged failure to conduct a small business impact analysis under the Regulatory Flexibility Act ("RFA") when it promulgated a set of rules. The court stated as follows: Defendants [government] argued that because [plaintiffs] did not have a place of business in the United States and did not make any showing as to the economic effects of the business in the United States, it had failed to establish itself as a "small business concern" under the Small Business Act and thus was not a "small entity" under the RFA. ... To complete the record, the court now rejects that argument. The court is unconvinced that the supplemental definition contained in 13 C.F.R. § 121.105 applies to the definition of "small entities" for purposes of the RFA. The Small Business Act allows the SBA Administrator to supplement the Act's statutory definition with criteria "by which a business concern may be determined to be a small business concern for purposes of this chapter or any other Act. " 15 U.S.C. § 632(a)(2)(A) (emphasis added). The regulation on which Defendants rely, 13 C.F.R. § 121.105, on its face only provides a further definition of "small business

> concern" for purposes of "eligib[ility] for assistance from SBA"—which is not at issue here. Section 121.105 does not purport to supply additional definitional terms for "any other Act," including the RFA. So, the court cannot conclude that because [plaintiffs do] not meet the supplemental defining terms contained in section 121.105 it does not qualify as a "small entity" for purposes of filing suit under the

-EPA is requesting comment on the idea of imposing on Small Business manufacturers an annual production cap (e.g., 200-500 vehicles per year) on vehicles eligible for the Small Business GHG exemption. The Small Business members of the AD Hoc Group oppose any such cap on the grounds that setting a cap at a given level is totally arbitrary, and the environmental benefits of any such cap are virtually nonexistent and are vastly outweighed by the potential burden. [EPA-HQ-OAR-2022-0829-0509, pp. 7-8]

Organization: Job Creators Network Foundation (JCNF)

In addition to being unconstitutional, EPA also improperly certifies the proposed rule as not having a significant economic impact on a substantial number of small entities under the Regulatory Flexibility Act. That is false. Millions of small businesses use a car or light-duty truck for their work. Cars are an integral part of certain industries, like limousine or other car service providers. But the local landscaper, caterer, interior designer, or even the hairdresser who sees clients at their homes, will use a car for all or a significant part of their business. [EPA-HQ-OAR-2022-0829-0709, p. 2]

Electric cars are at least $10,000 more than the equivalent gas-powered car. For the small business owner operating on razor-thin margins, $10,000 is a significant increased expense. And that is just the cost represented to purchase the vehicle. It does not include the cost of lost time waiting forty-five minutes for an electric car to charge. Or the fact that if the battery pack of an electric vehicle is damaged in an automobile accident, it likely means the car is totaled and would have to be replaced. [EPA-HQ-OAR-2022-0829-0709, p. 2]

EPA should certify that its proposed rule has a significant impact on a substantial number of small entities under the RFA, prepare the required Initial Regulatory Flexibility Analysis, and conduct the required Small Business Advocacy Review Panel. [EPA-HQ-OAR-2022-0829-0709, p. 2]

Organization: National Association of Convenience Stores (NACS) et al.

VI. The Proposed Rule Is Contrary To The Small Business Regulatory Enforcement Fairness Act of 1996.

Finally, EPA's certification that the Proposed Rule will not have a significant economic impact on a substantial number of small entities is unsupported by the record.72 Our industry is one of small businesses. More than 60 percent of convenience stores are single-store operators. Less than 0.2 percent of convenience stores that sell gas are owned by a major oil company and about 4 percent are owned by a refining company, meaning that independent businesses comprise more than 95 percent of the industry. Though small, our members in the industry process more than 165 million transactions every day. While EPA considered effects to manufacturers it considered small businesses, EPA did not fairly assess the potential impacts of the Proposed Rule to non-manufacturer small businesses like our members—contrary to Congress's intent. [EPA-HQ-OAR-2022-0829-0648, p. 18]

72 Proposed Rule at 29,404.

The Regulatory Flexibility Act, as amended by the Small Business Regulatory Enforcement Fairness Act ("SBREFA"), requires agencies like EPA to determine, to the extent feasible, the rule's economic impact on small entities, explore regulatory options for reducing any significant economic impacts on a substantial number of such entities, and explain their ultimate choice of regulatory approach. But the Proposed Rule is accompanied by little to no information on potential impacts on these small businesses. There is no formal or informal analysis of the adverse economic impacts to small businesses, no SBREFA screening analysis, no analysis, advice, and no recommendation from a Small Business Advocacy Review ("SBAR") Panel. As reiterated throughout these comments, the impacts on our members are far from inconsequential. Thus, we urge EPA in any future rulemaking to further engage in a thorough review of adverse effects to small businesses like our members consistent with their charge under the SBREFA. [EPA-HQ-OAR-2022-0829-0648, p. 18]

EPA Summary and Response

Summary for JCNF and NACS:

EPA received two comments on the draft Regulatory Flexibility Act analysis performed for this rule, one on behalf of small businesses and one on behalf of fuel providers. JCNF, an organization founded by entrepreneurs, commented that the proposed rule would affect small businesses that use cars or light-duty trucks, such as limousine or other car service providers, landscapers, caterers, interior designers, and hairdressers. This commenter believed that these small companies should have been included in EPA's RFA analysis because the cost of purchasing and using EVs would be a significant increase in costs for them. NACS, NATSO, and SIGMA, which represent the convenience store industry (NACS), travel centers and truck stops (NATSO), and independent chain retailers and marketers of motor fuel (SIGMA) commented that many of their members are single-store operators. They stated that these non-manufacturer small businesses, which together represent 9 percent of the motor fuel sold in the United States, should be included in EPA's Regulatory Flexibility Act analysis for this rule. The commenters stated that the proposed rule had little to no information on potential impacts on these small businesses, and there is no formal or informal analysis of the adverse economic impacts to small businesses, no SBREFA screening analysis, and no recommendation from a Small Business Advocacy Review ("SBAR") panel.

Summary for Ad Hoc Tier 4 Light-Duty Small Manufacturer Group:

The Ad Hoc Tier 4 Light-Duty Small Manufacturer Group stated the EPA wrongly excluded small gasoline vehicle producing OEMs that they believed should have been included in EPA's consideration of the NMOG+NOx standards. They also responded to EPA's request for comment on limiting the number of vehicles exempted from the GHG standards stating that they thought this limitation was arbitrary and provided no environmental protection.

Response for JCNF and NACS:

Our assessment of small business impacts prepared to support EPA's certification that the rule will not have a significant economic impact on a substantial number of small entities was appropriately, as required under the Regulatory Flexibility Act, limited to small entities that would be regulated under the proposed rulemaking (i.e., vehicle manufacturers, alternative fuel converters and independent commercial importers). Other than those entities, this rule does not impose any requirements on small businesses. Other small entities, such as small convenience store operators, are not regulated entities under the final rule. The impacts on small businesses to which the commenters refer would not be effects of the rule on regulated entities, and thus are not impacts that EPA is required to analyze per the RFA. See *Cement Kiln Recycling Coal. v. EPA*, 255 F.3d 855, 869 (D.C. Cir. 2001) (noting that "this court has consistently rejected the contention that the RFA applies to small businesses indirectly affected by the regulation of other entities"), *Mid-Tex Elec. Coop. v. FERC*, 773 F.2d 327, 342-43 (D.C. Cir. 1985) ("An agency may properly certify that no regulatory flexibility analysis is necessary when it determines that the rule will not have a significant economic impact on a substantial number of small entities that are subject to the requirements of the rule. . . . Congress did not intend to require that every agency consider every indirect effect that any regulation might have on small businesses in any stratum of the national economy."); see also *Coalition for Responsible Regulation v. EPA*, 684 F. 3d 102, 129 (D.C. Cir. 2012).

Even though EPA is not required in our Regulatory Flexibility Act analysis to include effects on non-regulated small businesses since they are not regulated entities under the rule, the Agency nonetheless considered issues such as vehicle affordability, charging time, and effects on employment. These are discussed in the RIA for this rule in chapters 4, 5 and 10 as well as in Sections 8, 13, 14, 17, and 21 of this RTC document.

Response to the Ad Hoc Tier 4 Light-Duty Small Manufacturer Group:

EPA recognizes that small entity manufacturers make up a small portion of total vehicle fleet sales. As for the commenter's concern that EPA did not consider small gasoline vehicle manufacturers, EPA did assess these potential manufacturers and determined that none of them qualified under the RFA for various reasons. One of the potential manufacturers has never certified a vehicle or initiated the vehicle certification process. EPA believes it is not appropriate to consider companies that may hypothetically at some future date apply to certify a vehicle. EPA also cannot consider foreign companies that do not meet all of the requirements for the RFA. There are specific requirements for a foreign company to qualify under the RFA and none of the potential gasoline vehicle manufacturers we evaluated met those qualifications. The RFA defines "small business" as having the same meaning as "small business concern" under section 3 of the Small Business Act. Section 3 of the Small Business Act, in turn, provides that "the Administrator may specify detailed definitions or standards by which a business concern may be determined to be a small business concern for the purposes of this Act..." 15 U.S.C. § 632(a)(2)(A). The Small Business Administration has issued regulations with a detailed definition of a "business concern" as a "a business entity organized for profit, with a place of business located in the United States, and which operates primarily within the United States or which makes a significant contribution to the U.S. economy through payment of taxes or use of American products, materials or labor." 13 C.F.R. § 121.105.[698] This is a longstanding definition which applies broadly to SBA programs under the Small Business Act.[699] Indeed one

[698] See also, US Small Business Administration, Small Business Compliance Guide, (March 2023), at 7 (same requirements). A small agricultural cooperative has distinct requirements but those are not relevant here.
[699] This provision has been recodified several times. See e.g., 54 FR 52634 (Dec. 21, 1989) (promulgating a prior recodification to "define 'business concern or concern' for the purpose of Small Business Administration (SBA) programs"), id. at 52636 ("This section restates SBA's definition of 'concern' previously found at 13 CFR 121.3(b) and applies to all small business programs, except SBA's Small Business Innovation Research (SBIR) Program") (rejecting proposal to add a requirement of US ownership as well).

of the central purposes of the Small Business Act is to "to maintain and strengthen the overall economy of the Nation" and to achieve that purpose Congress directed the SBA to assist small business by "enhancing their ability to compete effectively and efficiently against imports." Public Law 85–536, section 2. It would be directly contrary to Congressional purpose to ignore the SBA's regulatory definition pursuant to the Small Business Act, which is incorporated by reference in the RFA, and instead interpret the statutory definition of "business concern" in the Small Business Act to require agencies to make it easier for businesses with no presence in the United States and which make no contribution to the United States economy to compete with businesses, including small businesses, that do contribute to the US economy.

Under this final rule, EPA exempted small entity manufacturers from complying with the GHG standards, subject to a limitation as described in the next paragraph. As for the NMOG+NOx standards, EPA is finalizing an alternate phase-in which delays compliance for small entities. Details are available in section III.C.10 of the preamble.

EPA disagrees with the comments claiming there is no environmental protection from limiting the number of vehicles exempted from the GHG standards. The comments didn't provide any data or analysis or offer a specific basis for these claims. Limiting the number of exempt vehicles will create a cap on the number of vehicles that can be sold with potentially extremely high GHG emissions compared to other vehicles in the fleet subject to our final fleet-average standards, which EPA believes is necessary to provide an important safeguard for both environmental protection and a level playing field for manufacturers. Moreover, EPA's evaluation shows that existing small entities sell volumes of vehicles well below this limit, and thus the cap is expected to have no material adverse impact on small entities.

26 - Coordination/harmonization between EPA's GHG standards, NHTSA's CAFE standards, and state regulations

Comments by Organizations

Organization: Alliance for Automotive Innovation

4. NHTSA Car and Truck Definitions

EPA intends to continue to use the NHTSA car and truck definitions for its light-duty GHG program. We generally support this approach. However, because NHTSA has yet to propose its CAFE rules for MY 2027 and beyond, we do not know for certain whether NHTSA will maintain the existing definitions that EPA has based its proposal upon. Additionally, our understanding is that NHTSA is developing test procedures that may have the effect of changing the classification of some vehicles regardless of the present definitions. [EPA-HQ-OAR-2022-0829-0701, pp. 110-111]

There is also the potential for misalignment between EPA and NHTSA in the definition of medium-duty passenger vehicles. EPA is proposing to modify the definitions of medium-duty vehicles / medium-duty passenger vehicles. It is unclear what NHTSA may or may not do to align with EPA's proposal. [EPA-HQ-OAR-2022-0829-0701, pp. 110-111]

We urge EPA to coordinate with NHTSA in developing its final rule to ensure that the proposed greenhouse gas standards in the NPRM are not in conflict with changes NHTSA may propose in its CAFE rulemaking, or through later test procedure changes. [EPA-HQ-OAR-2022-0829-0701, pp. 110-111]

Organization: Alliance for Vehicle Efficiency (AVE)

AVE requests that EPA provide the automotive industry with greater certainty.

AVE is concerned that EPA and National Highway Traffic Safety Administration's (NHTSA) decision to proceed independently of the other with new LD and MD vehicle standards will create additional regulatory uncertainty for the automotive industry. [EPA-HQ-OAR-2022-0829-0631, pp. 2-4]

One National Program

In 2010, EPA and NHTSA touted the benefits of joint rulemaking under the umbrella of a National Program. [EPA-HQ-OAR-2022-0829-0631, pp. 2-4]

The National Program will deliver additional environmental and energy benefits, cost savings, and administrative efficiencies on a nationwide basis that would likely not be available under a less coordinated approach. The National Program also represents regulatory convergence by making it possible for the standards of two different Federal agencies and the standards of California and other states to act in a unified fashion in providing these benefits. The National Program will allow automakers to produce and sell a single fleet nationally, mitigating the additional costs that manufacturers would otherwise face in having to comply with multiple sets of Federal and State standards.1 [EPA-HQ-OAR-2022-0829-0631, pp. 2-4]

1 Federal Register / Vol. 75, No. 88 / Friday, May 7, 2010, at 25326

This approach was not an isolated occurrence. EPA and NHTSA proceeded in 2012 to finalize joint standards for LD vehicles starting in 2017 and beyond.2 The agencies then worked jointly again in 2017 and issued a Final Determination on the Appropriateness of the Model Year 2022-2025 Light- Duty Vehicle Greenhouse Gas Emissions Standards under the Midterm Evaluation.3 [EPA-HQ-OAR-2022-0829-0631, pp. 2-4]

2 Federal Register / Vol. 77, No. 199 / Monday, October 15, 2012, at 62624

3 https://nepis.epa.gov/Exe/ZyPDF.cgi?Dockey=P100QQ91.pdf

Although EPA states that the Agency has consulted with NHTSA on the Proposal, no explanation is given as to why the two agencies have changed course after more than a decade of working jointly. The reasoning stated in earlier rulemakings for one National Program remains relevant. Without full coordination, the U.S. will emerge with vastly different standards for greenhouse gas (GHG) emissions and fuel economy that will vary from state to state. More importantly, automakers may be forced to choose between compliance with one agency's program and non-compliance with another. [EPA-HQ-OAR-2022-0829-0631, pp. 2-4]

Organization: American Fuel & Petrochemical Manufacturers

Relatedly, Congress established the need to consider technology feasibility in establishing fuel economy regulations under the Energy Policy and Conservation Act ("EPCA"). Here, the National Highway Traffic Safety Administration ("NHTSA") "may not consider" the fuel economy of EVs in setting Corporate Average Fuel Economy (CAFE) standards.107 Conducting joint EPA- NHTSA rulemakings for complementary GHG and CAFE requirements helps OEMs comply with both agencies' standards. But in forgoing joint rulemaking, EPA ignores Congress' determination that EVs cannot be considered when determining what is the maximum feasible fuel economy level from which to develop regulations. Allowing EPA to consider EVs and, in turn, establish de facto ZEV mandates (and de facto average fuel economy standards) ultimately skews the new vehicle market and impede NHTSA's ability to establish its own CAFE standards that comport with EPCA. Most importantly, such an approach directly contravenes the underlying premise of the Supreme Court's holding in Massachusetts v. EPA that "[EPA and NHTSA] obligations may overlap, but there is no reason to think the two agencies cannot both administer their obligations and yet avoid inconsistency."108 After implementing GHG standards jointly with NHTSA's fuel economy standards since 2012, and despite Government Accountability Office recommendations to the contrary,109 EPA separated the rulemaking to undo previously established MY 2023-2026 standards and, in this case, to avoid the direct statutory prohibition on consideration of EVs when establishing fuel economy standards. [EPA-HQ-OAR-2022-0829-0733, pp. 25-26]

107 49 U.S.C. § 32902(h). Here, NHTSA may not consider the fuel economy of "dedicated automobiles," which are defined as those that operate only on "alternative fuel." Alternative fuel, in turn, includes electricity. 49 U.S.C. § 32901(j).

108 549 U.S. 497, 532 (2007).

109 GOVERNMENT ACCOUNTABILITY OFFICE, "NHTSA and EPA's Partnership for Setting Fuel Economy and Greenhouse Gas Emissions Standards Improved Analysis and Should be Maintained" (February 2010) available at https://www.gao.gov/assets/gao-10-336.pdf

Organization: Arconic Corporation (ARCO)

In general, Arconic urges EPA to consider a few key points as it moves to finalize this proposed rulemaking. [EPA-HQ-OAR-2022-0829-0741, p. 2]

Organization: BMW of North America, LLC (BMW NA)

With regard to the Agency's Proposed Rule, we respectfully submit that coordination between NHTSA and EPA during the rulemaking process is critical toward establishing harmonized standards. In light of differing statutes and regulations between NHTSA's CAFE program and EPA's GHG program, the Agencies have historically recognized and accounted for these differences in the standard setting process. However, as of this date, NHTSA has not publicized an NPRM for CAFE MY27+, and we therefore share the concern of the Alliance of Automotive Innovators, that the decoupling of the rulemaking timeline of both regulations may lead to material inconsistencies. [EPA-HQ-OAR-2022-0829-0677, p. 1]

BMW NA therefore would like to encourage the agencies to continue to work closely together, to enable manufacturers to abide by both sets of regulations with one single fleet. [EPA-HQ-OAR-2022-0829-0677, p. 1]

Organization: Competitive Enterprise Institute

Second, the Supreme Court in Massachusetts v. EPA (2007) directed the EPA and the National Highway Traffic Safety Administration (NHTSA) to “avoid inconsistency” between future corporate average fuel economy (CAFE) standards and GHG motor vehicle standards.51 Accordingly, in 2010, 2012, 2016, and 2020, the EPA and NHTSA engaged in joint rulemakings, simultaneously promulgating coordinated fleet-average GHG and fuel economy standards. Coordination is readily achieved because fleet-average tailpipe CO2 emissions and fuel economy standards are mathematically convertible. For example, NHTSA’s CAFE standards are calibrated in both miles per gallon and grams of CO2 per mile:52 [EPA-HQ-OAR-2022-0829-0611, pp. 13-14]

51 Massachusetts v. E.P.A., 549 U.S. 497, 532 (2007).

52 NHTSA, Corporate Average Fuel Economy Standards for Model Years 2024-2026 Passenger Cars and Light Trucks, 87 FR 25710, 25735-25736, May 2, 2022, https://www.govinfo.gov/content/pkg/FR-2022-05-02/pdf/2022- 07200.pdf.

Table II-4 – Estimated Average of CAFÉ Levels *MPG Required under Final Rule [EPA-HQ-OAR-2022-0829-0611, pp. 13-14]

Fleet	2024	2025	2026	2027	2028	2029
Passenger Cars	49.2	53.4	59.4	59.4	59.3	59.3
Light Trucks	35.1	38.2	42.4	42.4	42.4	42.4
Overall Fleet	40.6	44.2	49.1	49.1	49.2	49.3

[EPA-HQ-OAR-2022-0829-0611, pp. 13-14]

Table II-6 – Estimated CO2 Levels Equivalent to Average of CAFÉ Levels Required Under Final Rule (Gram per Mile CO2 Levels) [EPA-HQ-OAR-2022-0829-0611, pp. 13-14]

Fleet	2024	2025	2026	2027	2028	2029
Passenger Cars	181	166	150	150	150	150
Light Trucks	253	253	210	210	210	210
Overall Fleet	219	201	181	181	181	180

[EPA-HQ-OAR-2022-0829-0611, pp. 13-14]

As the EPA and NHTSA’s proposed 2018 joint rulemaking put it, “Basic chemistry makes fuel economy and tailpipe CO2 emissions two sides of the same coin.”53 [EPA-HQ-OAR-2022-0829-0611, pp. 13-14]

53 NHTSA and EPA, The Safer Affordable Fuel-Efficient (SAFE) Vehicles Rule for 2021-2026 Passenger Cars and Light Trucks, 83 FR 42937, 43209, 43327, August 24, 2018, https://www.govinfo.gov/content/pkg/FR-2018-08- 24/pdf/2018-16820.pdf.

Although the agencies no longer conduct joint rulemakings, they profess a continuing “commitment” to coordinate their respective standards.54 The seriousness of that commitment may well be questioned. NHTSA’s passenger car target in 2029 is 150 grams CO2 per mile. The EPA’s target for 2029 is 99 grams CO2 per mile55—51 percent more stringent. [EPA-HQ-OAR-2022-0829-0611, pp. 13-14]

54 86 FR 74434, 74457; 87 FR 25710, 25730.

55 88 FR 29201.

2029	99	89	108	112

[EPA-HQ-OAR-2022-0829-0611, pp. 13-14]

Congress Prohibits NHTSA, the Only Agency Authorized to Establish Fleetwide-Average Standards, from Regulating Gasoline-Powered Vehicles Out of the Market.

In 1992, Congress prohibited NHTSA from considering the fuel economy of EVs and other alternative vehicles when promulgating CAFE standards. The clear intent was to ensure that NHTSA does not set fleet-average standards that no gasoline-powered vehicle can meet. Petitioners explain: [EPA-HQ-OAR-2022-0829-0611, p. 18]

In the Energy Policy Act of 1992, Congress directed NHTSA to set fuel-economy standards based on averages, but prohibited NHTSA from setting fuel-economy standards that average in the fuel economy of electric vehicles. See Pub. L. No. 102-486 §§ 302,403, 106 Stat. 2776, 2870-2871, 2876 (later codified at 49 U.S.C. § 32902(h)). [EPA-HQ-OAR-2022-0829-0611, p. 18]

Petitioners spotlight the key point:

This prohibition bars NHTSA from doing exactly what EPA is doing here: misusing its regulatory authority to force a transition from conventional vehicles to electric vehicles by artificially tightening the “average” standard a fleet must meet. Of course, when Congress finalized the language of Section 202(a)(l) in 1977, it had no need to explicitly block EPA from considering electric vehicles, because it did not contemplate that EPA would set emission standards using averaging in the first place (or that EPA would be setting standards for greenhouse gases). The prohibition on NHTSA nevertheless underscores just how far EPA is reaching here: it is straining statutory language to seize a power that Congress expressly denied to a sister agency that actually has authority to promulgate fleetwide-average standards.71[EPA-HQ-OAR-2022-0829-0611, p. 18]

71 Petitioners' Initial Brief, pp. 61-62.

Organization: Cummins

- A harmonized national program for criteria pollutant, GHG, and fuel efficiency standards by EPA, the California Air Resources Board (CARB), and the National Highway Traffic Safety Administration (NHTSA) is essential to assure the greatest improvements are achieved in the most cost-efficient manner and to provide vehicle and engine manufacturers, suppliers, and end-users with the certainty necessary for investment in technologies to improve emissions. We urge the agencies to work together towards a single, nationwide program. [EPA-HQ-OAR-2022-0829-0645, pp. 2-3]

Organization: Ford Motor Company

Finally, beyond the regulation proposed here, we encourage EPA, National Highway Traffic Safety Administration, and California to harmonize their GHG standards, fuel economy standards, criteria emissions, testing protocols and ZEV requirements. Each of these requirements is ultimately regulating the same aspects of the same vehicles and fleets, at the same time. During this extraordinary period of transition, automakers need harmonization between these programs. We are concerned that well-intentioned but technically contradictory rules from different agencies—especially those designed to continue to eke out marginal improvements on internal combustion vehicles—will divert resources from electrification. [EPA-HQ-OAR-2022-0829-0605, p. 4]

Organization: Fuel Freedom Foundation

Harmonize NHTSA and EPA policies. FFVs are credited under the CAFE program, but not in EPA's own GHG Standards. From the beginning of the unified National Program, the agencies have committed to harmonizing the requirements to minimize the regulatory burden on OEMs. The current disharmony between the programs can be easily addressed by incorporating equivalent credit for the manufacture of FFVs within the GHG Standards program, to not only enable more widespread use of lower-carbon E85, but to spur vehicle technology innovation for high-performance spark ignition engines that can be coupled with electrification in plug-in hybrid vehicles. Toyota is already leading the way on developing flex-fuel hybrids with its Hybrid Flex Corolla that is being pioneered by Toyota of Brazil and exported to India.13 [EPA-HQ-OAR-2022-0829-0711, pp. 3-4]

13 ET Auto, "Toyota launches pilot project on flex-fuel strong hybrid EVs in India," at https://auto.economictimes.indiatimes.com/news/toyota-launches-pilot-project-on-flexi-fuel-strong-hybrid-electric-vehicles- ffv-shev-in-india-signs-mou-with-iisc-bengaluru/94786626, and Nikkei Asia, "Toyota to invest $334m to make compact biofuel hybrids in Brazil, Carmaker seeks to provide consumers with

cheaper, eco-friendly vehicles," at https://asia.nikkei.com/Business/Automobiles/Toyota-to-invest-334m-to-make-compact-biofuel-hybrids-in-Brazil

There are significant public policy reasons to justify further harmonizing the GHG Standards and CAFE Standards with a commensurate FFV credit: 1.) maximize the cost effectiveness of GHG reductions in light-duty transportation, 2.) realize GHG emissions reductions sooner rather than later, 3.) increase national and energy security by reducing petroleum dependence, and 4.) achieve GHG Standards program goals while minimizing consumer disruption and cost. [EPA-HQ-OAR-2022-0829-0711, pp. 5-6]

In light of these rationales, to both fully realize the ambitious GHG reductions in the GHG Standards Proposed Rule and ensure the program's long-term success in progressing to Net-Zero GHG emissions in transportation, Fuel Freedom strongly encourages the EPA to re-adopt credit for the production of FFVs within the GHG Standards program. [EPA-HQ-OAR-2022-0829-0711, pp. 5-6]

[See original attachment for Appendix A: Photo of prices at a fueling station in Costa Mesa, California in April 2022] [EPA-HQ-OAR-2022-0829-0711, pp. 5-6]

Organization: General Motors, LLC (GM)

GM supports and encourages whole-of-government coordination between the applicable federal and
state agencies to achieve them. In particular, we encourage the Environmental Protection Agency (EPA), the Department of Transportation's National Highway Traffic Safety Administration (NHTSA), Department of Energy (DOE), and California Air Resource Board (CARB) to work together to ensure a fleet that complies with the finalized EPA greenhouse gas (GHG) programs (light-duty, medium-duty) also complies with EPA's criteria pollutant (light-duty, medium-duty), NHTSA's light-duty Corporate Average Fuel Economy (CAFE), NHTSA's medium-duty Corporate Average Fuel Consumption (CAFC), CARB's criteria pollutant Low Emission Vehicle IV (LEV IV), and CARB's GHG regulations. Coordination across the US federal government and with CARB will best ensure that communities, workers, consumers, and industry can successfully achieve this decarbonization transition [EPA-HQ-OAR-2022-0829-0700, p. 4]

Including the proposed EPA standards, that makes six regulations with varying sub-level averaging sets for classes within each (e.g., for cars, trucks, and within given weight thresholds). These regulations could require each automaker to exceed 50% EVs in at least a dozen vehicle averaging sets in the approximate 2030 timeframe. GM is confident in its approach to transition to 50% EVs by 2030, and towards 100% in 2035, but our ability to meet such precise EV shares in every applicable averaging set in each model year is less clear. As a result, we are concerned that either a potential lack of clarity or a lack of coordination across the agencies may hinder an automaker's ability to remain in compliance, year-after-year, across each of these regulatory programs even while meeting EPA's overall EV targets. Worse, regulatory misalignment can lead to unanticipated consequences that can include higher emissions through OEM- specific settlement agreements and added costs for OEMs that will impact jobs, capital investments, and ultimately the success of the transition. [EPA-HQ-OAR-2022-0829-0700, p. 4]

GM fully supports GHG regulations in line with the Executive Order goals (i.e., 50% EV share 2030, 60% GHG reduction from model year 2021 to 2030) and believes it's critical that all the other associated regulations also allow that same federal GHG-compliant fleet to comply without paying penalties, restricting product, or purchasing credits. We urge EPA, NHTSA, and CARB to base their regulations, and their analyses of industry compliance, on the same level of EV deployment and internal combustion engine (ICE) criteria pollutant and efficiency improvement. Any mismatch in these assumptions could lead to de facto stringency that supersedes the technology deployment projected by any of the agencies individually. Any such mismatches, as mentioned above, have the potential to slow progress on the industry's EV transition and the nation's decarbonization journey. Finalizing aligned regulations ensures industry's ability to meet our collective EV transition and climate goals. [EPA-HQ-OAR-2022-0829-0700, p. 4]

For the agencies to navigate this coordination across regulations, we have four primary recommendations: First, we recommend the federal agencies develop a "Leadership Pathway" (described below) which reduces duplicative requirements across the regulations for any automaker that exceeds national-level EV goals (e.g., 50% EVs by 2030, 67% by 2032). Second, we recommend that regulators continue their due diligence to ensure that one fleet of vehicles simultaneously complies across the six regulations with the deployment of the same set of vehicles. Such an analysis for each automaker would be applicable to each one of the agencies' final rule regulatory analyses, including how the modeled EPA-, NHTSA-, and CARB-regulated fleets each maintain a consistent level of EVs and ICE improvement compliant with each of the regulated classes in the six separate regulations. Third, we recommend that the agencies fully and completely align their vehicle class definitions. Fourth, we recommend that each agency allow full fungibility of credits across regulated vehicle classes or otherwise adjust standard stringency, if vehicle classes have constraints that prevent alignment. [EPA-HQ-OAR-2022-0829-0700, pp. 4-5]

Considering that the transition to EVs can successfully achieve the objectives of each regulation, we see great potential for EPA, in collaboration with the other agencies, to steer the regulations to be fully aligned. As vehicle manufacturers move toward all EVs, and the regulations are each dependent on this same underlying EV trend, the above recommendations are all warranted and fitting to ease the duplicative burdens in this transformative and unprecedented industry-wide EV transition to which we are committed. [EPA-HQ-OAR-2022-0829-0700, pp. 4-5]

We urge EPA to coordinate with NHTSA and DOE to ensure the agencies have a common set of assumptions for how companies can comply with the various rules, and also that the relative compliance value for EVs be aligned across the regulations. If DOE's Petroleum- Equivalent Fuel Economy Calculation is adopted as published, there is the potential for the NHTSA CAFE regulation to effectively require much greater EV shares and/or greater internal combustion improvements than the EPA GHG rule. Such unaligned EV compliance ratings could create mixed market signals, with some automakers complying with the GHG rule and not CAFE, and vice versa for other companies, with no deliberate environmental benefit in either case. [EPA-HQ-OAR-2022-0829-0700, p. 5]

Organization: Governing for Impact and Evergreen Action (GFI)

Finally, suggestions by some opponents that the EPA must promulgate its emissions standards in coordination with the National Highway Traffic Safety Administration ("NHTSA"),75 which sets fuel- economy standards but is prohibited from taking EVs' fuel economy into account in setting those standards, are wrong. While it is true that the two agencies have jointly promulgated GHG and fuel economy regulations in the past, there is no statutory requirement that they do so—and the agencies did not do so in 2021 when the EPA promulgated 202(a) GHG regulations for MYs 2023-2026.76 In fact, the Supreme Court has described the EPA's authority to regulate carbon emissions from motor vehicles as "a statutory obligation wholly independent" from NHTSA's energy efficiency mandate regarding mileage requirements.77 [EPA-HQ-OAR-2022-0829-0621, pp. 9-10]

Cir. 2012) (explaining why NHTSA's regulatory obligations do not affect the EPA's obligations under the CAA); Proposed Rule at fn. 388; Dan Farber, "The Car Rule and the Major Questions Doctrine," Legal Planet (April 24, 2023), https://legal-planet.org/2023/04/24/the-car-rule-and-the-major-questions-doctrine/; Proof Brief of the Institute for Policy Integrity at 10–11.

Organization: HF Sinclair Corporation

c. The Proposed Rule Runs Afoul of the Energy Policy and Conservation Act

Under the Energy Policy and Conservation Act ("EPCA"), Congress provided that NHTSA "may not consider" the fuel economy of EVs in setting Corporate Average Fuel Economy (CAFE) standards.25 Doing so puts an important restriction on how NHTSA evaluates the technological feasibility of fuel economy standards. Conducting joint EPA-NHTSA rulemakings for complimentary GHG and CAFE requirements ensures that OEMs can comply with both agencies' standards with the same fleet. But in forgoing a joint rulemaking, EPA seeks to ignore Congress' determination that EVs cannot be taken into account when considering what is the maximum feasible fuel economy level from which to develop regulations. Allowing EPA to consider EVs and, in turn, establish de-facto EV mandates will ultimately skew the market of new vehicles and impede NHTSA's ability to establish its own CAFE standards that comport with EPCA. Most importantly, such an approach directly contravenes the underlying premise of the Supreme Court's holding in Massachusetts v. EPA—"[EPA and NHTSA] obligations may overlap, but there is no reason to think the two agencies cannot both administer their obligations and yet avoid inconsistency."26 [EPA-HQ-OAR-2022-0829-0579, p. 7]

25 49 U.S.C. § 32902(h). Here, NHTSA may not consider the fuel economy of "dedicated automobiles," which are defined as those that operate only on "alternative fuel." Alternative fuel, in turn, includes electricity. 49 U.S.C. § 32901(j).

26 549 U.S. 497, 532 (2007).

Organization: Kentucky Office of the Attorney General et al.

EPA first regulated GHG emissions from motor vehicles following the Supreme Court's decision in Massachusetts v. EPA, which held that EPA had certain authority under the CAA to regulate greenhouse gas emissions from new motor vehicles. 549 U.S. 497 (2007). Following the Massachusetts decision, EPA issued an endangerment finding for "six well-mixed greenhouse gases," including carbon dioxide ("CO2"). 74 Fed. Reg. 66,496 (Dec. 15, 2009). EPA then promulgated its initial standards for these gases through joint rulemaking with the National Highway Traffic Safety Administration ("NHTSA"). NHTSA is authorized to set corporate average fuel economy standards under the Energy Policy and Conservation Act, Pub. L. No. 94-163, 89 Stat. 871 (1975). [EPA-HQ-OAR-2022-0829-0649, pp. 2-3]

The first of these joint EPA-NHTSA rulemakings occurred in 2010. At that time, EPA and NHTSA set initial CO2 emissions standards for model years 2012–2016 and later. 75 Fed. Reg. 25,234 (May 7, 2010). In 2012, EPA and NHTSA set new, more stringent CO2 emissions standards for model years 2017–2025 and later. 77 Fed. Reg. 62,624 (Oct. 15, 2012). In 2020, EPA and NHTSA issued a rule ("the 2020 Rule") that revised the standards for model years 2022– 2025, making those standards less stringent and setting a new standard for model years 2026 and later. 85 Fed. Reg. 24,174 (Apr. 30, 2020). [EPA-HQ-OAR-2022-0829-0649, pp. 2-3]

Then President Biden took office and began instituting his climate agenda. By executive order, he required the whole of the federal government to commit the full extent of its authority to reducing GHG emissions. Executive Order on Tackling the Climate Crisis at Home and Abroad, Exec. Order No. 14008 of January 27, 2021 ("[W]e must combat the climate crisis with bold, progressive action that combines the full capacity of the Federal Government with efforts from every corner of our Nation, every level of government, and every sector of our economy."). In response, EPA revised the CO2 emissions standard for model years 2023 and later (the "2021 Rule"). 86 Fed. Reg. 74,434 (Dec. 30, 2021). [EPA-HQ-OAR-2022-0829-0649, pp. 2-3]

The 2021 Rule fundamentally changed EPA's approach to the regulation of motor vehicle emissions. Previously, emissions standards occurred via joint rulemaking with NHTSA and were set in concert with its promulgation of fuel economy standards. This approach made sense because emissions and fuel economy standards are inextricably linked. But the President's climate agenda made joint rulemaking with NHTSA problematic. NHTSA is statutorily prohibited from considering the fuel economy of EVs when setting fuel economy standards. 49 U.S.C. § 32902(h)(1). Consequently, to avoid legal impediments to the President's climate agenda, the 2021 Rule decoupled EPA emissions standards from NHTSA fuel economy standards. The State of Texas, the Commonwealth of Kentucky, and other state and private petitioners challenged the 2021 Rule in the United States Court of Appeals for the D.C Circuit. Texas, et al. v. EPA, et al., Case No. 22-1031. Those challenges remain pending. [EPA-HQ-OAR-2022-0829-0649, pp. 2-3]

In December 2021, President Biden issued yet another executive order, stating that "America must lead the world on clean and efficient cars and trucks" by "bolstering our domestic market by setting a goal that 50 percent of all new passenger cars and light trucks sold in 2030 be zero-emission vehicles, including battery electric, plug-in hybrid electric, or fuel cell electric vehicles." Strengthening American Leadership in Clean Cars and Trucks, Exec. Order 14037 of August 5, 2021. In support of this policy, the President specifically dictated that "[t]he

Administrator of the Environmental Protection Agency (EPA) shall, as appropriate and consistent with applicable law, consider beginning work on a rulemaking under the [CAA] to establish new multi-pollutant emissions standards, including for greenhouse gas emissions, for light- and medium-duty vehicles beginning with model year 2027 and extending through and including at least model year 2030." Id. [EPA-HQ-OAR-2022-0829-0649, pp. 2-3]

The Proposed Rule is the result of the President's mandate. The Proposed Rule sets "increasingly stringent" standards for CO2. 88 Fed. Reg. at 29,240. For light-duty passenger cars, the proposal would require a reduction in emissions from 152 grams of CO2 emitted per mile traveled ("g/mile") for model year 2026 to 73 g/mile for model years 2032 and later—a reduction of 52%. 88 Fed. Reg. at 29,239. For light-duty trucks, the Proposed Rule would require a reduction from 207 g/mile for model year 2026 to 89 g/mile for model years 2032 and later—a reduction of 57%. Id. Fleet-wide for all light-duty vehicles, the Proposed Rule would require a reduction in emissions from 186 g/mile for model year 2026 to 82 g/mile for model years 2032 and later—a reduction of 56%. Id. at 29,239-29,240. For medium-duty vehicles, the Proposed Rule would require a reduction in CO2 emissions from 438 g/mile for model year 2027 to 275 g/mile for model years 2032 and later—a reduction of 37%. Id. at 29,243. In addition to the revised CO2 standards, EPA's proposal establishes more stringent emissions standards for non-methane organic gases plus nitrogen oxides, particulate matter, carbon monoxide, and formaldehyde. [EPA-HQ-OAR-2022-0829-0649, pp. 2-3]

The Proposed Rule also generates tension with the regulatory efforts of agencies in other areas. As described above, the Department of Transportation, through NHTSA, has the authority to set average fuel economy standards for automobiles. 49 U.S.C. § 32902(a). EPA and NHTSA have previously acted in concert. Now that those efforts have been bifurcated, EPA's proposals could limit dramatically not just the effect of NHTSA's regulatory scheme, but also automakers' ability to comply with the suite of regulations. It seems this may have been the plan all along. See Private Pet'r Opening Br., Texas v. EPA, No. 22-1031 (D.C. Cir. Apr. 27, 2023), ECF No. 1996915, at 9-10 ("Before joining the administration, the heads of the Council on Environmental Quality and EPA's Office of Air and Radiation (which wrote this rule) advocated this 'decoupling' precisely so that EPA could take 'a bolder approach on light duty vehicle electrification.'" (quoting Climate 21 Proj., Transition Memo: Environmental Protection Agency 11 (2021))). But EPA has no authority to wield this kind of power and reduce NHTSA's role in this way, especially considering that Congress has spoken clearly that NHTSA "may not consider" EV fuel economy in setting its own standards. 49 U.S.C. § 32902(h)(1). EPA's apparent attempt to expand its own authority under the CAA ignores the broader statutory context. [EPA-HQ-OAR-2022-0829-0649, p. 5]

Organization: Kia Corporation

Kia continues to support the long-standing goal where EPA, National Highway Traffic Safety Administration (NHTSA), and the California Air Resources Board (CARB) work together to coordinate emissions regulations, strive to align stringency, and reduce unnecessary testing burdens. [EPA-HQ-OAR-2022-0829-0555, p. 3]

Kia Supports Coordinated Programs

Kia continues to support the long-standing goal where EPA, NHTSA, and the California Air Resources (CARB) work together to coordinate emissions regulations, strive to align stringency, and reduce unnecessary testing burden. Harmonization and consistency are even more critical as technology investments need to be focused on shifting to electrification. Closely coordinated programs will provide the stability and predictability that automakers need during this important transition toward vehicle electrification. [EPA-HQ-OAR-2022-0829-0555, p. 4]

Unfortunately, NHTSA’s proposal on Corporate Average Fuel Efficiency (CAFE) for MYs 2027 - 2032 has not yet been released and there is no overlap between the EPA and NHTSA comment periods. It is critical that the industry understands how these programs interact and align. Kia is concerned that these two programs could require conflicting fleet compositions, include unnecessary testing burden, and affect compliance planning. [EPA-HQ-OAR-2022-0829-0555, p. 4]

Coordination and alignment between all three programs are of the utmost importance as the industry pursues a rapid transition to electrification while working towards one of the most aggressive regulations in history. [EPA-HQ-OAR-2022-0829-0555, p. 4]

Organization: Mazda North American Operations

As a member of the Alliance for Automotive Innovation we strongly support the comments that they have submitted; we have also highlighted some specific areas of the proposed regulation that will be particularly problematic below. [EPA-HQ-OAR-2022-0829-0595, p. 2]

While noting the massive shift that this proposal would require, we also recognize that other US federal laws and regulations are also in play. More and better coordination between federal agencies is desired as various requirements impact the overall market. [EPA-HQ-OAR-2022-0829-0595, p. 2]

First, while these comments are on the EPA proposal, a CAFE proposal from NHTSA is also coming soon. It's imperative that the CAFE proposal align as much as possible to the final EPA rule. It's untenable to consider different requirements in similar areas, or the possibility that Mazda could comply with EPA's requirements, but not with NHTSA's (or vice-versa). [EPA-HQ-OAR-2022-0829-0595, p. 2]

Organization: MEMA, The Vehicle Suppliers Associated

EPA must also closely align the final rule for LD/MD Multi-Pollutant Emissions with the emerging National Highway Traffic Safety Administration (NHTSA) Corporate Average Fuel Economy (CAFE) standards so neither creates confusion or unnecessary burdens. [EPA-HQ-OAR-2022-0829-0644, p. 4]

The aggressive pace and scope of the proposed rule obliges EPA to work to ensure success throughout the course of this rule's implementation. EPA must follow through on all assumptions in the regulatory impact analysis (RIA), and act accordingly to help make them a reality and reassure manufacturers and consumers along the way. [EPA-HQ-OAR-2022-0829-0644, p. 4]

MEMA urges:

- the Biden Administration to align regulations and priorities in concert with the Joint Office of Energy and Transportation throughout the implementation period of this rule to identify shared concerns and solutions for the many moving parts of the rule. EPA needs this broad support to follow through on all assumptions regarding critical materials, infrastructure, and timing of milestones identified in the rule's analyses. [EPA-HQ-OAR-2022-0829-0644, p. 4]

- EPA work closely with NHTSA to align the CAFE standards rule with the LD/MD Multi-Pollutants rule. [EPA-HQ-OAR-2022-0829-0644, p. 4]

Organization: Mercedes-Benz AG

The EPA should also strive for regulatory consistency with the National Highway Traffic Safety Administration ("NHTSA") and California to minimize redundancies and look for opportunities to extend program credits, like air conditioner and off-cycle. [EPA-HQ-OAR-2022-0829-0623, p. 2]

Organization: Mitsubishi Motors North America, Inc. (MMNA)

C. Potential Effect of UF and PEF on CAFE Standard

The development of the proposed utility factor by EPA considers the impact of changes within the context of the light-duty GHG standard. However, the utility factor is also used in developing fuel economy compliance values for the NHTSA CAFE standard. There is little mention of the utility factor's influence on CAFE compliance, despite the direct effect it has on PHEV CAFE compliance values. Unlike the GHG standard, which correctly treats electric operation as zero emissions, the CAFE regulation assigns PHEVs and BEVs a petroleum-equivalent fuel economy. The disconnect between the GHG and CAFE programs results in different weighting of compliance benefits for PHEVs and BEVs relative to conventional ICE vehicles. [EPA-HQ-OAR-2022-0829-0682, pp. 5-6]

Expanding on this issue, the Department of Energy (DOE) is proposing changes to the Petroleum Equivalency Factor (PEF) starting with MY27. The PEF is used to estimate the mile per gallon equivalent (MPGe) of BEV and PHEV electric mode operation. The DOE is proposing a 72% reduction of the PEF resulting in a significant reduction of the BEV and PHEV CAFE compliance value. [EPA-HQ-OAR-2022-0829-0682, pp. 5-6]

The combined effect of the changes to the UF and PEF on the CAFE standard are difficult to assess considering the proposed CAFE standard for MY27 through MY32 has not been published. For now, we can only assume that the structure of the current CAFE standard will remain unchanged. Based on this assumption, the combined effect of the UF and PEF will result in certain PHEVs having less compliance benefit than comparable Strong Hybrid-Electric Vehicles (SHEVs). Figure 1 is an example of the effects the proposed UF and PEF would have on the CAFE compliance of small SUV PHEVs relative to comparable SHEVs. In Figure 1 (left), the current Utility Factor and PEF means most PHEVs correctly have fuel economy greater than all comparable SHEVs. For Figure 1 (center), the proposed PEF with current UF results in a CAFE compliance value reduction of all PHEVs, in addition, several PHEVs would have a CAFE compliance value less than many SHEVs. For Figure 1 (right), the proposed changes to the UF are added resulting in further reductions in PHEVs compliance values and additional reductions in performance relative to SHEVs. Despite the real-world petroleum reduction advantage of PHEVs, the reduced UF and PEF will result lower CAFE compliance values for several PHEVs relative to comparable SHEVs. [EPA-HQ-OAR-2022-0829-0682, pp. 5-6]

[See original for graph titled "Figure 1. Comparison of PHEV and SHEV CAFE Compliance Value with Current and Proposed PEF and UF"] [EPA-HQ-OAR-2022-0829-0682, pp. 5-6]

In addition, Mitsubishi recommends EPA coordinate with DOE and NHTSA to ensure the combined effects of the proposed UF, PEF and structure of the NHTSA CAFE standard ensure CAFE compliance reflects the real-world petroleum reduction benefit of PHEVs. [EPA-HQ-OAR-2022-0829-0682, pp. 5-6]

It is important to note that NHTSA's CAFE program in the past has mirrored EPA's GHG approach to these flexibilities. Since it is not possible to comment on a proposed CAFE regulation that has not yet been published, it is only reasonable to assume that NHTSA will follow previous precedent regarding flexibilities and adopt the same structure as EPA. However, there is a significant deviation with regard to the treatment of EV compliance under the CAFE and GHG programs. Where EVs are rightly considered zero g/mi under the GHG program, the CAFE program requires EVs to be assign a mile per gallon equivalent compliance value based on the PEF. Increasing this discrepancy in the GHG and CAFE programs, DOE has proposed reducing the PEF by 72% compared to the current value. The PEF reduction will lead to a substantial decrease in the CAFE compliance value of BEVs and PHEVs. The elimination of air conditioning and off- cycle credits for EVs combined with changes to the PEF, and UF within the CAFE program could put BEVs and PHEVs at a distinctive compliance disadvantage relative to some Strong Hybrid-Electric Vehicles (SHEVs). Keeping these flexibilities in the GHG program for electric vehicles should reduce potential harmonization issues between the GHG and CAFE regulations. For this reason and the reasons stated by Auto Innovators, Mitsubishi supports Auto Innovators proposed approach to apply all available credits at the vehicle level regardless of propulsion, but ensure fleet-wide average emissions are not allowed to go below a value equivalent to zero g/mi. [EPA-HQ-OAR-2022-0829-0682, pp. 8-9]

Organization: National Automobile Dealers Association (NADA)

IV. A Single Set of National Fuel Economy/GHG Emissions Standards Are Needed.

EPA asserts that it coordinated with NHTSA in developing its proposed standards and concluded that, despite EPA and NHTSA jointly adopting fuel economy and emissions standards on several prior occasions, it is not necessary to do so in this instance.73 NADA disputes EPA's assertion with respect to GHGs and contends, as it has in prior comments, that a single national fuel- economy/GHG emissions program, administered principally by NHTSA, is not only needed, but consistent with the structure designed by Congress in the Energy Policy and Conservation Act.74 [EPA-HQ-OAR-2022-0829-0656, pp. 16-17]

73 88 Fed. Reg. at 29293.

74 Pub. L. 94–163, 89 Stat. 871 (Dec. 22, 1975).

The regulation of motor vehicle fuel economy and tailpipe GHG emissions is largely duplicative. The physics and chemistry involved establish a direct relationship; controlling fuel economy controls GHG emissions and vice versa. Two federal agencies independently regulating essentially the same thing raises government inefficiency and waste concerns, results in unnecessary regulatory burdens and complexities, inevitably leads to higher vehicle costs for households and businesses. [EPA-HQ-OAR-2022-0829-0656, pp. 16-17]

By acting on its own and in advance of NHTSA, EPA may be rendering irrelevant any forthcoming NHTSA fuel economy proposal for the same timeframe, and arguably usurps NHTSA's authority to set fuel economy standards. NADA supports harmonized federal fuel economy/GHG emissions standards that are technologically feasible and economically practicable and that will result in cars and trucks that are attractive and affordable to prospective new motor vehicle consumers. NADA urges EPA to reconsider the unilateral issuance of GHG emissions standards and to issue standards that are harmonized with the fuel economy standards expected to be issued by NHTSA. [EPA-HQ-OAR-2022-0829-0656, pp. 16-17]

Organization: Nissan North America, Inc.

Moreover, Nissan encourages EPA to continue its efforts to coordinate the Federal greenhouse gas ("GHG") emission standards and Criteria Emission standards ("Tier 4") with the National Highway Traffic Safety Administration's ("NHTSA's") corporate average fuel economy ("CAFE") program and California Air Resources Board's ("CARB's") emission programs (GHG standards and LEV III/IV criteria emission standards). Manufacturers should be able to design one cohesive fleet that meets all Federal and state standards. Close coordination between these three regulatory entities would ensure that manufacturers can focus on developing the cleanest, most fuel efficient, and most affordable vehicles rather than expend excessive resources on compliance with uncertain and unnecessarily fragmented regulatory programs. [EPA-HQ-OAR-2022-0829-0594, p. 1]

VI. Continued Support for a Coordinated National Approach

Nissan strongly encourages EPA, NHTSA, and CARB to develop a coordinated national approach to automotive regulation. A patchwork of different federal and state GHG, CAFE, and criteria pollutant programs is neither effective nor efficient. In contrast, a harmonized national program maximizes both GHG, CAFE, and criteria pollutant benefits on a nationwide basis while also providing regulatory certainty and minimizing unnecessary compliance burdens for the industry. Such an approach would allow automakers to develop a single, unified fleet that meets all federal and state requirements while maintaining a full range of vehicle options for consumers. More importantly, a harmonized approach also would allow manufacturers to focus their planning and investments on achieving fuel economy improvements and emissions reductions rather than on tracking compliance with unnecessarily fragmented regulatory standards and programs. Under a harmonized approach, environmental benefits can be achieved at a lower cost to manufacturers and consequently a lower cost to consumers. Lower costs will help address social equity concerns related to EV accessibility and also encourage faster fleet turnover, replacing older vehicles with more efficient, cleaner, and safer vehicles. [EPA-HQ-OAR-2022-0829-0594, pp. 8-9]

As EPA and NHTSA consider potential changes to the federal GHG, and criteria pollutant programs, Nissan believes it is essential that the agencies work together to maximize compatibility and coordination of the programs. Nissan understands that, due to statutory limitations, certain programmatic elements of the GHG and CAFE programs may not be identical. Nissan encourages EPA and NHTSA to make the standards as equivalent and complementary as possible, however, by adopting appropriate regulatory adjustments where available. Nissan also encourages EPA to coordinate with NHTSA and the Department of Energy ("DOE") regarding DOE's proposal for a permanent petroleum equivalency factor ("PEF") for use in calculating petroleum-equivalent fuel economy values of EVs in the CAFE program. [EPA-HQ-OAR-2022-0829-0594, pp. 8-9]

Nissan also urges the Administration to work with California regulators to harmonize the federal and CARB programs to the fullest extent possible. This could be accomplished by reinstating California's "deemed-to-comply" measures, under which vehicles that meet federal standards are "deemed-to-comply" with CARB standards. Nissan is also open to new alternative approaches for harmonizing federal and California standards, as well. Nissan encourages EPA to work proactively with CARB to clarify the relationship between federal and California standards and harmonize them to the extent possible. [EPA-HQ-OAR-2022-0829-0594, pp. 8-9]

- Support coordination and harmonization between EPA, NHTSA, and CARB. One fleet should meet all programs with a common goal. [EPA-HQ-OAR-2022-0829-0594, p. 9]

Organization: Pearson Fuels

On behalf of Pearson Fuels, thank you for the opportunity to submit comments on the Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles (the "Proposed Standards"). These comments are focused on the light-duty greenhouse gas emissions standards (the "GHG Standards"). As the leading supplier of E85 fuel in California, Pearson Fuels' primary interests in this proceeding are to ensure that: 1) the tremendous policy value of flex fuel vehicles (FFVs) that utilize E85 fuel is recognized as an important GHG mitigation strategy, and 2) this policy value is reflected programmatically by EPA re-integrating a commensurate level of FFV crediting into the EPA's GHG Standards. Through precisely calibrated FFV crediting, EPA will revitalize FFV manufacturing by some automakers and facilitate the development of hybrid FFVs like the Toyota Hybrid Flex Corolla that is being pioneered by Toyota of Brazil.1 This revitalization will not impede EPA's aggressive goal of rapid light-duty electrification but will diversify EPA's portfolio of decarbonization strategies for internal combustion engines thereby catalyzing more rapid and comprehensive decarbonization of the light-duty sector. [EPA-HQ-OAR-2022-0829-0577, pp. 1-2]

1 See ET Auto, "Toyota launches pilot project on flex-fuel strong hybrid EVs in India," at https://auto.economictimes.indiatimes.com/news/toyota-launches-pilot-project-on-flexi-fuel-strong-hybrid-electric- vehicles-ffv-shev-in-india-signs-mou-with-iisc-bengaluru/94786626, and Nikkei Asia, "Toyota to invest $334m to make compact biofuel hybrids in Brazil, Carmaker seeks to provide consumers with cheaper, eco-friendly vehicles," at https://asia.nikkei.com/Business/Automobiles/Toyota-to-invest-334m-to-make-compact-biofuel-hybrids-in-Brazil.

FFVs are a proven, robust, cost-saving and energy security enhancing GHG reduction tool that the U.S. Environmental Protection Agency ("EPA") integrated into the 2012-2016 light-duty GHG standards in a manner that aligned with the methodology of the Corporate Average Fuel Economy ("CAFE") program and facilitated extensive FFV manufacturing. Beginning in 2016, EPA eliminated its use of the 0.15 multiplier in the EPA's GHG Standards which triggered the rapid decline of FFV manufacturing. EPA explained its elimination of the multiplier based on the distinct goals of the CAFE program wherein the use of E85 achieves an 85% reduction in petroleum use thereby justifying the multiplier as compared to the EPA's GHG program which is focused on GHG reduction with no comparable justification for a multiplier.2 [EPA-HQ-OAR-2022-0829-0577, pp. 1-2]

2 77 FR 62816.

I. EPA SHOULD ESTABLISH AN APPROPRIATE GHG EMISSIONS FACTOR FOR FFV CREDITING THAT RECOGNIZES THE GHG BENEFITS OF E85 USAGE

a. EPA harmonized the GHG program with the CAFE program on FFV crediting during MY 2012-2015 then eliminated the 0.15 multiplier in the GHG program.

The CAFE and GHG programs are distinct programs in terms of history, objectives and underlying legal authority. The 2021 GHG Rulemaking characterizes the key distinctions between the programs on the multiplier (termed a "divisor" in the rulemaking) issue as follows: [EPA-HQ-OAR-2022-0829-0577, p. 4]

"Congress provided the 0.15 divisor for CAFE compliance because a vehicle that operates on a nonpetroleum fuel (like CNG) consumes zero or near-zero petroleum, and petroleum conservation is a primary objective of the CAFE program."6 [EPA-HQ-OAR-2022-0829-0577, p. 4]

6 77 FR 62816.

(…)

"The primary focus of the GHG standards is GHG emissions."7 [EPA-HQ-OAR-2022-0829-0577, p. 4]

7 Id.

(…)

"We also disagree with those commenters who argued that EPA must adopt the 0.15 divisor in order to not ''negate the Congressional mandate'' for CAFE credits. (…)"8 [EPA-HQ-OAR-2022-0829-0577, p. 4]

8 Id.

b. During the period of harmonized CAFE and GHG crediting, the U.S. FFV fleet grew rapidly. Now, at a critical time for climate change mitigation, the U.S. FFV fleet is in dramatic decline.

On April 22, 2021, President Biden announced a "nationally determined contribution" pledge under the 2015 Paris climate agreement to cut U.S. GHG emissions in half by 2030 at a virtual climate summit attended by dozens of world leaders. In his remarks about the pledge from the White House, the President stated, "These steps will set America on a path of net zero emissions economy by no later than 2050."10 Thus the President has re-established aggressive GHG reduction as a priority policy of the federal government and set a goal of carbon neutrality by 2050. While there has been a significant expansion of BEVs, internal combustion engines continue to dominate the market and roads of America and are anticipated to maintain this dominant role for the next decade and potentially longer. The following illustrative graphics were developed by the Alliance for Automotive Innovation. [EPA-HQ-OAR-2022-0829-0577, pp. 5-6]

10 Josh Lederman and Denise Chow, "Biden Commits to cutting U.S. emissions in half by 2030 as part of Paris climate pact," (April 22, 2021), available at https://www.nbcnews.com/politics/white-house/biden-will-commit- halving-u-s-emissions-2030-part-paris-n1264892.

SEE ORIGINAL COMMENT FOR PIE CHART for the Role of Liquid Fuels and BAR GRAPH of EPA-Projected Cumulative U.S. Sales 2023-2032 [EPA-HQ-OAR-2022-0829-0577, pp. 5-6]

During the period of harmonized GHG crediting, when both the GHG and CAFE programs utilized the 0.15 divisor, there was a substantial expansion of the FFV fleet peaking with the manufacture of 2.8 million total light-duty vehicles in MY 2014. The total registered fleet of FFVs in the U.S. continued to grow incrementally until 2020, but from 2015-2020 automakers sharply reduced the number of vehicle offerings. The attached Exhibit 1 developed by the Renewable Fuels Association details vehicle offerings by model and engine type and shows the massive reduction of models that occurred due to the near total elimination of light-duty GHG program crediting. During the peak period of manufacturing, Chrysler, Ford and General Motors manufactured 76 different models of FFVs. This scale of manufacturing has since been decimated with only 8 FFV models offered in 2023 with 5 of these being limited to fleet models. [EPA-HQ-OAR-2022-0829-0577, pp. 5-6]

Restoring more harmonized FFV crediting between the CAFE and GHG programs would benefit automakers, consumers, and marketers by affording all a choice in the market and by establishing a diversified technology portfolio approach to decarbonization. FFVs deliver a wide array of real-world benefits when fueled with E85 or other gasoline-ethanol blends, including improved U.S. energy security, support for the U.S. farm economy, as well as significant reductions in GHG emissions. FFV consumers can respond to fuel market signals by utilizing high blend E85 ethanol when the fuel is at the greatest discount to petroleum and conventional gasoline when ethanol prices are relatively high as compared to gasoline (which has rarely been the case in the past five years). [EPA-HQ-OAR-2022-0829-0577, p. 6]

These are all vital flexibilities to a successful evolution of the vehicle market and to achieving the goals of the GHG rulemaking – increased efficiency, improved energy security, reduced costs to consumers, and reduced GHG emissions from the transportation sector. [EPA-HQ-OAR-2022-0829-0577, p. 6]

i. EPA established a new methodology for calculating FFV crediting for MY 2016 and later in its joint rule with NHTSA for MY 2012-2016.

In the joint NHTSA Final Rule for MY 2012-2016 ("Joint 2012 Final Rule"), EPA established first the approach for FFV crediting for 2012-2016: [EPA-HQ-OAR-2022-0829-0577, pp. 14-15]

(1) The assumption that the vehicle is operated 50% of the time on the conventional fuel and 50% of the time on the alternative fuel, (2) that 1 gallon of alternative fuel is treated as 0.15 gallon of fuel, essentially increasing the fuel economy of a vehicle on alternative fuel by a factor of 6.67, and (3) a ''cap'' provision that limits the maximum fuel economy increase that can be applied to a manufacturer's overall CAFE compliance value for all CAFE compliance categories

(i.e., domestic passenger cars, import passenger cars, and light trucks) to 1.2 mpg through 2014 and 1.0 mpg in 2015.28 [EPA-HQ-OAR-2022-0829-0577, pp. 14-15]

28 75 FR 25432.

The Joint 2012 Final Rule also established the methodology for FFV crediting for MY 2016 and subsequent years as being distinct from the 2012-2016 methodology as follows: [EPA-HQ-OAR-2022-0829-0577, pp. 14-15]

Starting with model year 2016, as proposed, EPA will no longer allow manufacturers to base FFV emissions on the use of the 0.15 factor credit described above, and on the use of an assumed 50% usage of alternative fuel. Instead, EPA believes the appropriate approach is to ensure that FFV emissions are based on demonstrated emissions performance.29 [EPA-HQ-OAR-2022-0829-0577, pp. 14-15]

29 Id. at 25433.

II. EPA SHOULD TAKE THE OPPORTUNITY IN THIS RULEMAKING TO RECOGNIZE THE TRUE GHG POLICY VALUE OF FFVS BY RESTORING MEANINGFUL GHG CREDITING FOR FFVs

We encourage the Agency to re-affirm the policy value of FFVs and American ethanol production and use by restoring meaningful GHG crediting for the manufacture of FFVs by modifying the methodology for determining GHG crediting for FFVs beginning MY 2027. EPA has authority to better harmonize crediting between the GHG and CAFE standards and thereby expand FFV manufacturing through two alternative means both of which are supported by Pearson Fuels. [EPA-HQ-OAR-2022-0829-0577, p. 16]

a. EPA should re-integrate the methodology that continues to exist in the CAFE program by re-establishing its use of the 0.15 multiplier in the EPA's GHG Standards, or, [EPA-HQ-OAR-2022-0829-0577, p. 16]

b. EPA should establish a new GHG Emissions Factor for the GHG Standards that recognizes the lifecycle emissions reductions of E85 as compared with conventional gasoline. [EPA-HQ-OAR-2022-0829-0577, p. 16]

Crediting based on lifecycle GHG emissions reductions can be accomplished simply by establishing a GHG Emissions Factor that is based on the average GHG emissions reduction provided by ethanol as compared to petroleum gasoline on a lifecycle basis. This GHG Emissions Factor would be subject to adjustment based on a determination by Argonne National Laboratory regarding the average lifecycle emissions of U.S. used as a transportation fuel as compared to the average lifecycle emissions of the U.S. gasoline used as a transportation fuel. [EPA-HQ-OAR-2022-0829-0577, p. 16]

Organization: POET, LLC

3. Renewable fuels crediting would give vehicle manufacturers more options to comply and make for a more durable emissions reduction program.

Adding a renewable fuel crediting mechanism would make it more feasible for automakers to meet EPA's stringent standards. Renewable fuels would further diversify the pathways for manufacturers to comply with the proposed standards. This would be especially important in places, particularly rural areas with lower population densities, where BEV infrastructure will be difficult to develop at scale and may not be cost-effective. Renewable fuels would serve as a viable alternative to attain significant light-duty vehicle emissions reductions. [EPA-HQ-OAR-2022-0829-0609, p. 10]

EPA and the National Highway Traffic Safety Administration ("NHTSA") have experience with exactly this type of bioethanol crediting that POET proposes. In prior iterations of EPA's § 202 standard through model year 2015, and in the existing NHTSA fuel economy standards, FFVs receive compliance benefits because they can run on alternative fuels such as E85.23 This ability to utilize lower GHG fuels is adjusted by an "F Factor" that represents how much renewable fuel is used in the real world.24 EPA should re-introduce crediting for vehicles that can utilize higher blends of renewable fuels, and should expand the program to include technologies other than just FFVs. [EPA-HQ-OAR-2022-0829-0609, p. 10]

23 See EPA regulations at 40 CFR 600.510-12(j)(2)(iv)(B) providing FFV crediting through Model Year 2015. Regarding currently applicable NHTSA regulations at 49 CFR 523.2 (definition of dual-fuel vehicle includes flexible fuel vehicles); 49 CFR 536.10 (indicating that dual-fuel vehicles can earn credits under the standards); 2017 and Later Model Year Light-Duty Vehicle Greenhouse Gas Emissions and Corporate Average Fuel Economy Standards, 77 Fed. Reg. 62624, 62829-30 (Oct. 15, 2012) (providing that FFVs could generate credits under the standards). See the discussion in section III.d below for additional details.

24 40 CFR 600.510-12(k).

Organization: Porsche Cars North America (PCNA)

Porsche notes that EPA's proposed update to the PHEV utility factor will also influence CAFE compliance calculations due to the allowance within statute and regulation for manufacturers to optionally select weighted operation. EPA did not provide analysis as to how this change would affect CAFE compliance especially considering Department of Energy (DOE) recent NPRM to reduce the Petroleum Equivalence Factor (PEF) by 72% for electric vehicles. This dramatic proposal from DOE to undercut the incentive for electric vehicles within CAFE is premature given that proposed CAFE standards for model years 2027 and later have not yet been released by NHTSA. Porsche recommended in comments to DOE for their NPRM that DOE include the assessment of EPA's proposed change in the utility factor to better understand the combined effect of lower PEF and lower utility factor. DOE did not acknowledge, or was unaware of, the proposed reduction in utility factor from EPA. The PEF statutory basis requires DOE, as it has done for over 40 years, to incentivize electrified vehicles in CAFE. This statute also requires DOE, NHTSA and EPA to consult on changes related to PEF and CAFE. Neither the EPA MPR NPRM nor the DOE PEF NPRM appear to discuss the mutual impacts that each other's proposed updates could have on future CAFE compliance. As NHTSA has yet to release their CAFE proposal, it is unclear if NHTSA will address both the EPA and DOE proposals and how both could impact CAFE compliance. To Porsche, it is unclear as to why these NPRMs appear disjointed and so far, have failed to discuss the impacts of each other's proposals on the other regulations. Porsche recommends EPA provide analysis of the impact of the reduced utility factor on the PEF and CAFE compliance in coordination with DOE and NHTSA. Ideally, all the proposals would have been released together to provide manufacturers with the ability to understand how each of the agency's actions would interact with each other and continue to support and incentivize technologies such as PHEV. This is especially relevant considering the overarching goal to achieve a dramatic increase in light-duty electrification. [EPA-HQ-OAR-2022-0829-0637, pp. 21-23]

Organization: Stellantis

EPA must take a more realistic outlook on the policy enablers initiated that are only partially scoped to grow the EV market EPA predicts and set standards that promote a feasible transition to electrification without distracting with unnecessary ICE development. The proposed rule and draft Regulatory Impact Analysis (RIA) include projections of numerous variables (such as benefits and costs) out to 2055 (i.e., well beyond the time period of this rulemaking), which exacerbates the uncertainties that underlie multiple assumptions contained in the NPRM. Stellantis agrees with Auto Innovators' concern raised that the NPRM fails to adequately coordinate and harmonize the stringency between EPA's, NHTSA's, and CARB's standards. Given the significance of electrification, it is more important than ever that there is consistency between agencies to ensure multiple sets of standards do not work at cross-purposes with each other but instead are harmonized allowing automakers to build one fleet that efficiently and effectively meets all requirements. [EPA-HQ-OAR-2022-0829-0678, p. 24]

Stellantis recommends that EPA should:

- Include a provision that compliance with EPA's GHG standards would constitute compliance with CAFE standards [EPA-HQ-OAR-2022-0829-0678, p. 24]

Organization: Steven G. Bradbury

EPA may not use carbon dioxide regulation to displace DOT's exclusive authority over fuel economy standards.

Setting limits on carbon dioxide emissions for gas-powered vehicles and prescribing fuel economy standards for those vehicles are two sides of the same regulatory coin. They cannot be separated, because there is a direct and consistent relationship between the amount of carbon dioxide a vehicle's internal-combustion engine will generate per mile traveled and the number of miles the vehicle will go on a gallon of gas. [EPA-HQ-OAR-2022-0829-0647, pp. 4-5]

The problem for the EPA is that ever since enactment of the Energy Policy and Con- servation Act (EPCA) in 1975, which created the fuel economy program, Congress has given the Secretary of Transportation, not the EPA, the sole authority to establish fuel economy standards for new motor vehicles offered for sale to private buyers in the United States8—authority delegated by the Secretary to the National Highway Traffic Safety Administration (NHTSA), a component of DOT. NHTSA consults with EPA and the Energy Department in setting the standards, and EPA is tasked with measuring the auto- makers' compliance with the standards NHTSA sets, but neither EPA nor any other agency has authority to supersede or interfere with NHTSA's mandate under EPCA. [EPA-HQ-OAR-2022-0829-0647, pp. 4-5]

8 See 49 U.S.C. § 32902, https://www.law.cornell.edu/uscode/text/49/32902.

Congress assigned to DOT the exclusive authority to set fuel economy standards, rather than EPA under the Clean Air Act, because the fuel economy program is not about environmental regulation. Congress wanted to prod the automakers toward the production of more fuel-efficient vehicle models to help lessen America’s strategic dependence on foreign oil in the wake of the Arab oil embargoes of the 1970s. [EPA-HQ-OAR-2022-0829-0647, pp. 4-5]

Congress’s delegation of authority over the fuel economy program has always been carefully limited.

Initially, Congress specified mileage targets by statute and put a tight collar on DOT’s regulatory authority: Any proposed fuel economy standard that fell outside the collar was subject to veto by either House of Congress—a restraint that was nullified when the Supreme Court held legislative vetoes unconstitutional in INS v. Chadha (1983). And from time to time, Congress has put statutory caps on the mileage standards through appropriations riders. [EPA-HQ-OAR-2022-0829-0647, pp. 4-5]

Ultimately, when it allowed broader standard-setting discretion to DOT under EPCA, Congress still did so in a manner designed to ensure that NHTSA’s regulatory power would never be used to frustrate Americans’ love affair with the automobile or impose disruptions in the traditional automotive industry. [EPA-HQ-OAR-2022-0829-0647, pp. 4-5]

In administering the fuel economy program, NHTSA must (i) respect the practical needs and desires of American car buyers; (ii) take into account the economic realities of supply and demand in the auto markets; (iii) protect the affordability of vehicle options for American families; (iv) preserve the vitality of the domestic auto industry, which sustains millions of good-paying American jobs; (v) maintain highway traffic safety for the country; (vi) consider the nation’s need to conserve energy; and (vii) advance the goal of reducing America’s strategic dependence on foreign supplies of critical inputs. [EPA-HQ-OAR-2022-0829-0647, pp. 4-5]

And, significantly, EPCA expressly prohibits NHTSA from considering the fuel economy of electric vehicles in setting or amending its standards.9 [EPA-HQ-OAR-2022-0829-0647, pp. 4-5]

9 See id. § 32902(h); see also 49 U.S.C. § 32901(a)(1), (8), (9) & (10), https://www.law.cornell.edu/uscode/text/49/32901.In sum, NHTSA has no authority to compel the phaseout of internal-combustion engines or to require automakers to use new technologies that are not responsive to con- sumer demand or that fail to align with the industry’s existing production realities.

In Massachusetts v. EPA,10 the Supreme Court concluded that, in theory, there is no necessary conflict between the control of carbon dioxide emissions under section 202 of the Clean Air Act and NHTSA’s authority to prescribe fuel economy standards under EPCA.11 But, in practice, whenever EPA actually proposes to impose such emissions controls, it must do so in a manner that avoids displacing NHTSA’s authority over fuel economy. [EPA-HQ-OAR-2022-0829-0647, pp. 4-5]

10 549 U.S. 497 (2007), https://www.oyez.org/cases/2006/05-1120.

11 See id. at 532 (“The two obligations may overlap, but there is no reason to think the two agencies cannot both administer their obligations and yet avoid inconsistency.”).

EPA may not use carbon dioxide regulation to displace DOT’s exclusive auth- ority over fuel economy standards. [EPA-HQ-OAR-2022-0829-0647, pp. 4-5]

Setting limits on carbon dioxide emissions for gas-powered vehicles and prescribing fuel economy standards for those vehicles are two sides of the same regulatory coin. 11 See id. at 532 ("The two obligations may overlap, but there is no reason to think the two agencies cannot both administer their obligations and yet avoid inconsistency.").

It is a basic principle of law that when there is a potential for inconsistent application of two federal statutes, the statutes must be interpreted and applied in harmony, if reason- ably possible. The agencies charged with faithfully carrying out those statutory mandates are required to respect and preserve the roles and priorities assigned by Congress. [EPA-HQ-OAR-2022-0829-0647, pp. 5-6]

The Obama administration was the first to confront this issue when it launched the EPA into the business of regulating carbon dioxide emissions from new motor vehicles in 2012. Both the Obama administration and later the Trump administration addressed the requirement for harmonization by having NHTSA and EPA conduct joint rulemakings in the setting of common fuel economy standards and carbon dioxide emissions limits. [EPA-HQ-OAR-2022-0829-0647, pp. 5-6]

But the present administration has broken that mold, and the current proposed tailpipe rules are an egregious example. By acting on its own, in advance of NHTSA, to dictate draconian new reductions in carbon dioxide emissions limits for future model years of vehicles, EPA would render entirely irrelevant NHTSA's judgment about the appropriate fuel economy standards for those same vehicle fleets. If finalized in their current form, the proposed limits on carbon dioxide emissions from new motor vehicles (both for light- and medium-duty vehicles and for heavy-duty trucks) would be an unlawful usurpation by EPA of NHTSA's exclusive statutory role. Any determination by NHTSA to establish fuel eco- nomy standards for gas-powered vehicles that would allow for greater carbon dioxide emis- sions than EPA's proposed rules would have no regulatory effect—it would be a nullity. [EPA-HQ-OAR-2022-0829-0647, pp. 5-6]

[EPA-HQ-OAR-2022-0829-0647, pp. 5-6]

But the present administration has broken that mold, and the current proposed tailpipe rules are an egregious example. By acting on its own, in advance of NHTSA, to dictate draconian new reductions in carbon dioxide emissions limits for future model years of vehicles, EPA would render entirely irrelevant NHTSA's judgment about the appropriate fuel economy standards for those same vehicle fleets. If finalized in their current form, the proposed limits on carbon dioxide emissions from new motor vehicles (both for light- and medium-duty vehicles and for heavy-duty trucks) would be an unlawful usurpation by EPA of NHTSA's exclusive statutory role. Any determination by NHTSA to establish fuel economy standards for gas-powered vehicles that would allow for greater carbon dioxide emissions than EPA's proposed rules would have no regulatory effect—it would be a nullity. [EPA-HQ-OAR-2022-0829-0647, pp. 5-6]

Organization: The Aluminum Association

This disregard for vehicle efficiency distinction across BEV's in the proposed rule conflicts with the existing and historic approaches of the Corporate Average Fuel Economy (CAFE) program and is a potential disruption to harmonization. [EPA-HQ-OAR-2022-0829-0704, pp. 7-8]

Organization: U.S. Chamber of Commerce

Moreover, we note that a forthcoming rulemaking by the National Highway Traffic Safety Administration (NHTSA) addressing fuel economy standards has potential to conflict with EPA's proposal, adding costly and unnecessary compliance burdens on the auto industry. Accordingly, the Chamber reiterates its longstanding recommendation that EPA and NHTSA cooperate to ensure a unified set of federal standards that minimize conflicting regulatory requirements between the overlapping rulemakings. [EPA-HQ-OAR-2022-0829-0604, p. 3]

Organization: Valero Energy Corporation

D. EPA should neither align the proposed rule with the Advanced Clean Cars programs (ACC), nor rely on ACC or any other state standards.

To the extent EPA is considering extending the model years at issue and increasing the stringency of the proposed standards in the final rule to align with and/or reflect California's Advanced Clean Cars programs or any other state greenhouse gas emission standards or ZEV sales mandates, or is otherwise relying on any such state standards or mandates, such changes would be unlawful. State greenhouse gas emission standards and ZEV sales mandates are preempted by both EPCA and the RFS, making any reliance on such standards by EPA equally unlawful. Moreover, such a radical departure from the proposed rule would require EPA to reopen the comment period to allow for meaningful public comment on these issues and their related impacts. [EPA-HQ-OAR-2022-0829-0707, pp. 89-91]

EPCA prohibits States from adopting or enforcing "a law or regulation related to fuel economy standards or average fuel economy standards for automobiles." 49 U.S.C. § 32919(a) (emphasis added). The Supreme Court has described "related to" preemption provisions like this one as "deliberately expansive," Pilot Life Ins. Co. v. Dedeaux, 481 U.S. 41, 46 (1987), and "conspicuous" in their breadth, FMC Corp. v. Holliday, 498 U.S. 52, 58 (1990). As the Court has explained, a state requirement "relate[s] to" a federal law or regulation as long as it has a “connection with,” or contains a “reference to,” the regulated topic. Rowe v. New Hampshire Motor Transport Ass’n, 552 U.S. 364, 370 (2008) (quoting Morales v. Trans World Airlines, Inc., 504 U.S. 374, 384 (1992)). [EPA-HQ-OAR-2022-0829-0707, pp. 89-91]

State electric-vehicle mandates have a clear “connection with” fuel economy. Electric-vehicle mandates like California’s require manufacturers to make a certain number of “vehicles that produce zero exhaust emissions of any criteria pollutant (or precursor pollutant) or greenhouse gas, excluding emissions from air conditioning systems.” Cal. Code Regs. tit. 13, § 1962.2(a). Because emissions of the greenhouse gas carbon dioxide are “essentially constant per gallon combusted of a given type of fuel,” the fuel economy of a vehicle and its carbon-dioxide emissions are two sides of the same coin. 75 Fed. Reg. at 25,324, 25,327 (May 7, 2010). Accordingly, “any rule that limits tailpipe [greenhouse gas] emissions is effectively identical to a rule that limits fuel consumption.” Delta Constr. Co., 783 F.3d at 1294 (citation omitted). EPA has previously found California’s ZEV mandates are expressly and impliedly preempted by EPCA. 83 Fed.Reg. 42,986, 43,238-39 (Aug. 24, 2018). That is consistent with the court’s finding in Central Valley Chrysler-Plymouth v. California Air Resources Board, No. CV-F-02-5017 REC/SMS, 2002 WL 34499459 (E.D. Cal. June 11, 2002), that “Plaintiffs have shown that the 2001 ZEV amendments “relate to” fuel economy standards because they “clearly have the purpose of regulating the fuel economy performance of ... the advanced technology hybrids that the Executive Officer predicts the industry will sell in California....” Id. at *3. As a result of that litigation, CARB has “removed all references to fuel economy or efficiency,” Fact Sheet: 2003 Zero Emission Vehicle Program Changes, California Air Resources Board (Mar. 18, 2004),370 in its ZEV mandates, but removal of the reference does not equate to removal of the fact that these regulations relate to fuel economy standards. [EPA-HQ-OAR-2022-0829-0707, pp. 89-91]

> 370 The Fact Sheet clarifies that the changes made were a direct result of the EPCA preemption finding: “In June 2002, due to a lawsuit against the ARB, a federal district judge issued a preliminary injunction that prohibited the ARB from enforcing the 2001 ZEV amendments with respect to the sale of new motor vehicles in model years 2003 or 2004. The lawsuit was focused on the assertion that AT PREV provisions pertaining to the fuel economy of hybrid electric vehicles were preempted by the Energy Policy and Conservation Act of 1975 – the law directing the National Highway Traffic Safety Administration to establish corporate average fuel economy (CAFE) standards. Since adopting the 2003 Amendments to the ZEV regulation, the parties to the lawsuit have agreed to end the litigation…. ¶ In order to address the preliminary injunction … staff proposed additional modifications to the ZEV regulation in March 2003.”. Id. at 1.

Separately, electric-vehicle mandates also relate to “average fuel economy” because they restrict manufacturers’ choices as to how to meet those standards. EPCA allows manufacturers to meet NHTSA’s fuel-economy standards by producing any combination of vehicles that the national market will bear, using whatever technological approach to fuel economy they think best. State electric-car mandates, by contrast, require automakers to comply in a specific way: either by selling a certain percentage of zero-emission vehicles or purchasing credits from competitors. The state mandates thus relate to federal fuel-economy standards because they “force [a manufacturer] to adopt a certain scheme” and “restrict its choice” of compliance, and are thus preempted. New York State Conf. of Blue Cross & Blue Shield Plans v. Travelers Ins. Co., 514 U.S. 645, 668 (1995); accord Ophir v. City of Boston, 647 F. Supp. 2d 86, 93 (D. Mass. 2009). [EPA-HQ-OAR-2022-0829-0707, pp. 89-91]

State electric-vehicle mandates are also impliedly preempted by a separate statutory provision, the RFS. State laws are impliedly preempted when they “stand[] as an obstacle to the accomplishment and execution of the full purposes and objectives of Congress." Arizona v. United States, 567 U.S. 387, 406 (2012) (citation omitted). A "conflict in technique can be fully as disruptive to the system Congress erected as conflict in overt policy." Id. (citation omitted); see Geier v. American Honda Motor Co., 529 U.S. 861, 881 (2000). [EPA-HQ-OAR-2022-0829-0707, pp. 89-91]

Here, state electric-vehicle mandates conflict with Congress's objectives in enacting the RFS. The RFS reflects Congress's policy decision to "move the United States toward greater energy independence and security" in a specific way: by "increas[ing] the production of clean renewable fuels" to be blended with fossil fuels. ACE, 864 F.3d at 697 (citations omitted). Mandating electrification—in other words, eliminating vehicles that use liquid renewable fuels—puts severe pressure on regulated entities' ability to comply with the RFS by reducing the percentage of vehicles that use those renewable fuels. [EPA-HQ-OAR-2022-0829-0707, pp. 89-91]

By contrast, Congress has never included electric-vehicle mandates in its energy-security plans and in fact has rejected several bills that would have imposed such mandates. See, e.g., Zero-Emission Vehicles Act of 2019, H.R. 2764, 116th Cong. (2019); Zero-Emission Vehicles Act of 2018, S. 3664, 115th Cong. (2018). State electric-vehicle mandates wreak havoc on Congress's carefully crafted scheme in favor of an option that Congress has consistently rejected. Cf. West Virginia v. EPA, 142 S. Ct. 2587, 2614 (2022). [EPA-HQ-OAR-2022-0829-0707, pp. 89-91]

Because these state standards and mandates are themselves preempted and unlawful, any reliance on, or consideration of, such standards by EPA would be equally unlawful. Any such change(s) at this juncture without reopening the public comment period would also deny stakeholders an opportunity for meaningful comment, particularly because EPA has not made available for review the factual or legal basis for any such proposed changes or its analysis of their economic impact and related policy considerations. Moreover, the final rule would constitute a radical departure from the proposal without fairly apprising stakeholders of the standards or their underlying bases. [EPA-HQ-OAR-2022-0829-0707, pp. 89-91]

Organization: Volkswagen Group of America, Inc.

Harmonization with CAFE program – "Deemed to Comply"

Volkswagen supports EPA's goal of transitioning to zero emission mobility. The NPRM includes ambitious GHG reductions. In recognition of this, Volkswagen asks that GHG regulations be harmonized with the future NHTSA CAFE targets, or that a "Deemed to Comply" mechanism be made available, where compliance to the EPA GHG regulations also satisfies compliance to the CAFE program. [EPA-HQ-OAR-2022-0829-0669, p. 3]

Organization: Volvo Car Corporation (VCC)

Harmonization

Unfortunately, US has multiple federal and state agencies regulating auto emissions and this has created various competing and overlapping rules. The EPA differs significantly from the CARB ACCII and we are awaiting an NPRM from NHTSA on fuel economy. The Department of Energy also has a pending proposal that will determine the energy efficiency of EVs. VCC encourages EPA to harmonize with the other programs as much as possible. [EPA-HQ-OAR-2022-0829-0624, p. 5]

VCC has consistently stated that the goal of achieving one single national harmonized program (California, EPA and NHTSA) is the preferred path forward to increase fuel economy and lower emissions year over year. However, VCC believes regulatory consistency, and a clear federal framework are necessary to effectively and efficiently enable the auto industry to develop more efficient vehicles and to advance the market for advanced technology vehicles. Multiple vehicle regulatory programs at the Federal and State level that require separate and duplicative reporting, accounting, and testing are inefficient and increase uncertainty in the market. [EPA-HQ-OAR-2022-0829-0624, p. 5]

The US should work to minimize disparities between EPA (GHG) and NHTSA (CAFE) regulations and California regulations. The program should reduce reporting requirements by allowing manufacturers to demonstrate compliance at the end of the year for all programs. [EPA-HQ-OAR-2022-0829-0624, p. 5]

Compliance reporting should be consolidated so that it is one report for one agency and that agency determines compliance (so reciprocal recognition). Currently, there are separate assessments for each program, and this is unnecessary and especially burdensome for smaller manufacturers like VCC. [EPA-HQ-OAR-2022-0829-0624, p. 5]

EPA Summary and Response

Many commenters urged EPA to coordinate with NHTSA to ensure the GHG program is not in conflict with changes NHTSA may propose in its CAFE rulemaking.[700] Other commenters questioned why EPA and NHTSA were issuing separate and not joint rules for their respective GHG and fuel economy standards as had been done for certain past rules. We discuss in Section III.I of the preamble issues of consultation and coordination between the EPA and NHTSA programs and the decision to issue separate and not joint rulemakings. Executive Order 14037 directs EPA and DOT to coordinate, as appropriate and consistent with applicable law, during consideration of this rulemaking. EPA has coordinated and consulted with DOT/NHTSA, both on a bilateral level during the development of this rule as well as through the interagency review of the EPA rule led by the Office of Management and Budget. EPA has set some previous light-duty vehicle GHG emission standards in joint rulemakings where NHTSA also established CAFE standards. Most recently, in establishing standards for model year 2023-2026, EPA and NHTSA concluded that it was appropriate to coordinate and consult but not to engage in joint rulemaking. EPA has similarly concluded that it is not necessary for this EPA rule to be issued in a joint action with NHTSA. In reaching this conclusion, EPA notes there is no statutory requirement for joint rulemaking and that the agencies have different statutory mandates and their respective programs have always reflected those differences. As the Supreme Court has noted "EPA has been charged with protecting the public's 'health' and 'welfare,' a statutory obligation wholly independent of DOT's mandate to promote energy efficiency."[701] Although there is no statutory requirement for EPA to consult with NHTSA, EPA has consulted

[700] Note that since EPA received these public comments, NHTSA has since issued a proposed rulemaking, "Corporate Average Fuel Economy Standards for Passenger Cars and Light Trucks for Model Years 2027–2032 and Fuel Efficiency Standards for Heavy-Duty Pickup Trucks and Vans for Model Years 2030–2035." 88 FR 56128, August 17, 2023.
[701] *Massachusetts* v. *EPA*, 549 U.S. at 532.

significantly with NHTSA throughout the development of this rule and closely coordinated with NHTSA on a full range of issues related to feasibility, modeling and stringency

The Alliance for Automotive Innovation and many auto manufacturers and suppliers (e.g., BMW, Mazda, MEMA) encouraged the agencies to continue to work closely together, to enable manufacturers to abide by both sets of regulations with one single fleet. Some commenters (e.g., Ford, GM, Kia, Mercedes Benz, Nissan, Volvo) raised this issue of harmonization across programs to include the California program as well, noting their goal of a coordinated national approach to automotive regulations, and further noting that to the extent there are contradictions among rules from different agencies this could divert resources away from electrification. Another automaker (Volvo) urged the agencies to consolidate reporting requirements, which they believe can be burdensome for smaller manufacturers.

In response, EPA notes that since the beginning of the light- and medium-duty GHG programs we have worked together with NHTSA to harmonize program elements, testing and reporting requirements where appropriate (e.g., emissions and fuel economy testing). We also note there have been differences between certain features of the two programs, stemming from different statutory authorities for the two agencies. For example, EPA's program allows credits for air conditioning leakage which impacts GHGs but not fuel economy. To the extent that there remain programmatic differences across the GHG and CAFE programs, due to differences in statutes, we do not believe that such differences will cause difficulties with or be disruptive to manufacturers' strategies to comply with both the GHG standards and the CAFE standards. As we have done for almost 14 years since the EPA GHG program first became effective, we will continue to coordinate with NHTSA during the implementation phase of the final standards. With regard to comments regarding harmonization with California, EPA notes that EO 14037 also directs EPA to coordinate with California and other states that are leading the way in reducing vehicle emissions. EPA has engaged with the California Air Resources Board on technical issues in developing this rule. EPA has considered certain aspects of the CARB Advanced Clean Cars II program, adopted in August 2022, and in some cases, where appropriate, our program is consistent with aspects of the ACC II program, as discussed in the preamble (e.g., see light-duty vehicle criteria pollutant provisions section III.D. 7; on-board diagnostics section III.H; battery durability section III.G.2.). As is our long-standing practice, EPA will continue to coordinate with NHTSA and CARB as we implement the GHG final standards.

Volkswagen similarly urged harmonization including that CAFE compliance be allowed to be determined based on an automaker being "deemed to comply" with the EPA GHG standards. EPA notes that this issue is out of scope for the EPA rulemaking, as such a determination of CAFE compliance would need to be made by NHTSA under its own authority.

GM and a few other commenters recommended the federal agencies develop a "Leadership Pathway" which would reduce duplicative requirements across the regulations for any automaker that exceeds national-level EV goals. EPA responds to this comment in section 3.4 of this RTC.

Auto industry commenters noted EPA's proposed revised definition of "medium-duty passenger vehicle" and questioned how such a change in regulatory classes might be coordinated with the NHTSA CAFÉ program. EPA responds to this comment in section 3.1.1 of this RTC.

A few commenters (e.g., Fuel Freedom Foundation, Pearson Fuels) urged EPA to adopt provisions for flex fueled vehicles (FFVs), which can be fueled on gasoline or E85, in a way that is harmonized with FFV treatment under CAFE. Poet suggested that EPA establish a renewable fuels credit mechanism as part of the GHG standards. EPA did not reopen provisions for the treatment of FFVs in this rulemaking, and did not propose or seek comment on a renewable fuels credit mechanism, and thus considers these comments out of scope. EPA notes that nothing in our performance-based standards precludes automakers from choosing FFVs, or producing renewable fueled vehicles, as part of its mix of technologies for compliance with the final standards. EPA has existing provisions to calculate the emissions weighting of FFVs, based on our projection of actual usage of gasoline vs. E85, referred to as the F-factor (see 40 CFR 600.510–12(k); 40 CFR 86.1819–14 (d)(10)(i)).

Some commenters (e.g., Mitsubishi) noted that, unlike the GHG standard, which treats electric operation as zero emissions, and weights PHEV emissions through use of the utility factor, the CAFE regulation assigns PHEVs and BEVs a petroleum-equivalent fuel economy, or Petroleum Equivalency Factor (PEF). These commenters further note that this will lead to different weightings between the two programs of compliance benefits for PHEVs and BEVs. Several commenters noted NHTSA's restriction for considering BEVs in their standard setting process and seem to conclude that that one limitation in NHTSA's statutory authority would automatically result in a single fleet not being able to comply with both EPA and NHTSA's standards. Another commenter (Aluminum Association) believes that the CAFE program's treatment of BEVs (through the use of the PEF) accounts for improved efficiency whereas EPA's program does not explicitly. In response, EPA recognizes that this final rule's compliance treatment of BEVs (0 grams CO2/mile) and PHEVs (utility factor weighting of electric operation at 0 g/mi vs. gasoline emissions value) is different than that proposed by NHTSA for the CAFE program which relies on the DOE PEF, pursuant to the CAFE statute. Importantly, this difference across the program is not new -- it has existed in the programs since the beginning of EPA's GHG program first established in 2010 for the 2012 MY. EPA and NHTSA have had, and will continue, extensive technical coordination on these issues. Our goal continues to be that each agency can implement its respective statutory authority while avoiding inconsistency, and that auto manufacturers will be able to comply with both sets of standards with a single fleet, as has been the case since the GHG and CAFE programs have existed alongside each other since MY 2012.

Comments about EPA's statutory authority to issue greenhouse gas standards are addressed in section 2 of this RTC. Comments about NHTSA's statutory authority are beyond the scope of this action.

27 - Other comments related to the proposed rule

Comments by Organizations

Organization: Ad Hoc Tier 4 Light-Duty Small Manufacturer Group

The Ad Hoc Group intends to file a Supplemental Comment before the July 5, 2023 comment due date providing additional details [EPA-HQ-OAR-2022-0829-0509, p. 1]

Organization: Alliance for Automotive Innovation

6. CO2 Credits for Advanced Technology Vehicles

EPA proposes changes to the method for calculating MY 2022-2024 caps on multiplier-based advanced technology vehicle credits in the proposed 40 C.F.R. § 86.1866-12.195 Given the limited comment period and the denial of our request to extend it, Auto Innovators did not have sufficient time to evaluate the proposed change. Additionally, we were unable to locate a description of the proposed change in the preamble of the NPRM, so it is difficult to know what the intent of the proposed change is. Following the formal comment period, we may revisit this issue and request a meeting with EPA staff if there is a concern. [EPA-HQ-OAR-2022-0829-0701, pp. 108-109]

195 NPRM at 29438.

To reduce costs while still providing similar (and substantial) environmental benefits, the EPA regulations should seek to align with criteria emissions regulations already adopted by California in ACC II. We worked closely with the California Air Resources Board (CARB) and with EPA staff in attendance and participating,255 for the past several years to develop standards that substantially reduce real-world criteria emissions (including NMOG+NOx and PM), as rapidly as possible without stranding technology or diverting resources from electrification. [EPA-HQ-OAR-2022-0829-0701, pp. 141-142]

255 At no time did EPA staff indicate a different or more stringent pathway was under development federally, while the auto industry provided input, feedback, and technical data to CARB. The California process provided an ideal forum for alignment, even if EPA could not commit to alignment at that stage.

Organization: Alliance for Consumers (AFC)

Failure To Provide Meaningful Opportunity For Public Comment]

Because of substantive oversights in the proposal, including the failure to adequately address EV maintenance and repair costs, the future of cross-subsidization between ICE and EV models at traditional automakers, and the potential for producers to limit sales of ICE vehicles despite limited consumer appetite for EVs (resulting in a vehicle shortage for many everyday consumers), and because of EPA's intended reliance on studies that have yet to published/finalized and the short time provided for public comment overall, the Agency has failed to provide a meaningful opportunity for the public to comment. See S.C. Coastal Conservation League v. Pruitt, 318 F. Supp. 3d 959, 967 (D.S.C. 2018). [EPA-HQ-OAR-2022-0829-0534, p. 5]

Organization: Alliance for Vehicle Efficiency (AVE) Should any of these assumptions be inaccurate, automotive manufacturers will likely assume significant financial risks as they modify their operations and production. The Proposal also assumes that consumers will purchase enough of these new vehicles for manufacturers to meet sales volumes for compliance levels. To reduce these risks, EPA should re-evaluate the ZEV marketplace to determine the new standards' feasibility prior to the effective date. [EPA-HQ-OAR-2022-0829-0631, pp. 2-4]

Political uncertainty

AVE supports a technology-neutral approach to decarbonizing the LD and MD fleets to avoid looming political and litigation challenges. Suppliers do not need to look too far back to recall that federal support for a stringent standard may not always continue as planned. Any future reductions of the subsidies now being promised under the Inflation Reduction Act (IRA) will impact future feasibility. [EPA-HQ-OAR-2022-0829-0631, pp. 2-4]

As recent events have shown, the threat of regulatory ping-pong resulting in changing GHG regulations is real and costly. In under four years, the automotive industry was required to respond to the EPA and NHTSA's midterm evaluation, the freezing of those standards in early 2017, the re- issuing of new standards under the Safer Affordable Fuel-Efficient Vehicles Rule (SAFE), the repeal of SAFE a mere 12-months later, and new standards issued at the end of 2021. [EPA-HQ-OAR-2022-0829-0631, pp. 2-4]

With sizable opposition to EPA's recent rulemakings in Congress,4 suppliers cannot have reasonable assurance of the future standards that will be applicable, and this uncertainty can impact investment in new advanced technologies. [EPA-HQ-OAR-2022-0829-0631, pp. 2-4]

4 See H.R.2811 - Limit, Save, Grow Act of 2023 and S.J.Res.11 - A joint resolution providing for congressional disapproval of EPAs "Control of Air Pollution From New Motor Vehicles: Heavy-Duty Engine and Vehicle Standards".

This very real "political" uncertainty will bring significant risk to the investments made by manufacturers and suppliers. We realize that EPA cannot, and should not, account for political reasoning when planning future standards. EPA can, however, aim to repeat the success of previous rulemakings that brought together numerous industry and regulatory stakeholders. Doing so will produce standards that are supported by those that need to make the investments for future standards to be successful. Without broad support from manufacturers and fleet owners, technology providers could face stranded investments. [EPA-HQ-OAR-2022-0829-0631, pp. 2-4]

Review of the ZEV marketplace

For the reasons stated above, we urge EPA to commit to an assessment of the Proposal's feasibility in a manner similar to the Agency's midterm evaluation in 2017. The Agency should re-evaluate the ZEV marketplace, including the cost of manufacturing, the pervasiveness of charging infrastructure, and consumer acceptance. The basis for doing so is as relevant as it was when EPA committed to the process in 2012.8 [EPA-HQ-OAR-2022-0829-0631, pp. 2-4]

8 Federal Register / Vol. 77, No. 199 / October 15, 2012 / at 62628

Organization: American Chemistry Council Product Approval Protocol Task Group (PAPTG)

The American Chemistry Council's Petroleum Additives Product Approval Task Group (PAPTG) is pleased to provide this comment on the Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles. The PAPTG, a task group of the Petroleum Additives Panel, is comprised of lubricant additive manufacturers. [EPA-HQ-OAR-2022-0829-0666, p. 1]

Engine and driveline lubricants are an important component of light duty and medium duty vehicle design and have been demonstrated to impact fuel economy and durability performance. Lubricants are important in both improving fuel efficiency and enabling fuel efficient engine technology including hybrids. To help ensure that vehicle performance remains as close to the design and certification level as possible, ACC suggests that EPA include language in the proposed standard which recognizes and highlights the importance of using the appropriate OEM or industry certified lubricants in factory fill and service fill (aftermarket) applications. [EPA-HQ-OAR-2022-0829-0666, p. 1]

Organization: American Council for an Energy-Efficient Economy (ACEEE)

Complementary elements of EPA's LDV program should be extended to MDVs

Two other areas in which MDVs could benefit from being folded into the LDV program are compliance reporting requirements and consumer labeling. EPA's compliance report for heavy-duty vehicles24 does not include heavy-duty pickups and vans, and we are not aware of any other source for this data. This situation has hampered our ability to make informed judgments on the current proposal for MDV standards, as data on matters such as compliance credit balances and rates of ICEV technology adoption are not currently available for these vehicles. These vehicles should be incorporated into EPA's Trends report no later than MY 2027. [EPA-HQ-OAR-2022-0829-0642, p. 11]

24 https://www.epa.gov/system/files/documents/2023-05/420r22028A.pdf

MDVs also should have a consumer label, and the label should provide a basis for comparison with LDVs. This could be an important element, along with the reclassification of vehicles for purposes of the standards, of EPA's effort to discourage the upward creep in size and performance attributes of light-duty trucks. California began labeling MDVs on January 1, 2021.25 While the MDV scores are not directly comparable to California's LDV scores, CARB provides a comparison table with LDV GHG scores. We urge EPA to create a meaningful consumer label for MDVs in time for MY 2027. [EPA-HQ-OAR-2022-0829-0642, p. 11]

25 https://ww2.arb.ca.gov/our-work/programs/greenhouse-gas-standards-medium-and-heavy-duty-engines-and-vehicles/ep-label

Organization: American Fuel & Petrochemical Manufacturers

For starters, we are disappointed with the 60-day comment period you allocated for this major rulemaking. Given the enormous stakes of this proposal, which effectively bans new internal combustion engine vehicles, the length of the proposal (262 Federal Register pages), the size of the docket (10,000 plus pages of supporting documents), and the other, related rulemakings with concurrent comment deadlines, there is no reasonable justification for such an abbreviated comment period. No doubt this proposal took EPA many months, if not years, to prepare. Yet, you're asking the public to make the herculean effort to read, analyze, and provide constructive, detailed comments in just a matter of eight weeks (and on July 5th no less). The question this begs is, why? Why would you stifle public feedback on such an important rule? [EPA-HQ-OAR-2022-0829-0733, p. 1]

EPA also failed to provide a meaningful opportunity for public comment by limiting the comment period to 60 days, denying requests form AFPM and other stakeholders to extend the comment period, and concurrently proposing heavy-duty standards and other significant rulemakings related to vehicle electrification, fuels, and electricity generation. Significant time is required to read and respond to the voluminous material in each rulemaking docket, particularly given EPA's evident lack of rigor in its analysis, and lack of discipline in citing and characterizing underlying sources. [EPA-HQ-OAR-2022-0829-0733, p. 3]

A. Advanced Clean Cars II ("ACC II") Cannot be a Basis for this Rulemaking

EPA points to California's ACC II program and adoption by Section 177 states to support its projections of increased PEV penetration,122 but the ACC II has not received a waiver, and EPA did not even have the waiver application when the Proposed Rule was published.123 The CAA requires EPA to evaluate California's waiver request to ensure that California did not arbitrarily determine that it needs "ZEV mandates" to address compelling and extraordinary circumstances. As Principal Deputy Administrator for the Office of Air and Radiation Joe Goffman testified on June 21, 2023, EPA just received the waiver request. Given that the EPA official responsible for overseeing the California waiver request publicly acknowledged that EPA has not determined whether it will grant a waiver for ACC II, the Agency cannot rely on ACC II as a basis for this Proposal. Moreover, because California concedes that ACC II will not meaningfully address the impacts of climate change in California and ACC II will slow fleet turnover and retard California's progress toward meeting the NAAQS, California is NOT eligible for a waiver and ACC II is preempted. EPA's reliance on ACC II as support for this rule is pre-decisional and another example of arbitrary and capricious decision-making. [EPA-HQ-OAR-2022-0829-0733, p. 28]

122 Proposed Rule at 29,118.

123 88 Fed. Reg. 29,189; See, e.g., Initial Br. For Private Petitioners, State of Ohio, et al. v. Envt'l Prot. Agency, et al., No. 22-1081 (D.C. Cir. Oct. 24, 2022). V. The Proposal Fails to Provide Meaningful Opportunity for Public Comment

AFPM welcomes the opportunity to meaningfully engage with regulators to discuss cost-effective, efficient, and feasible measures to reduce the carbon intensity of, and criteria emissions from, the transportation sector. Unfortunately, the concurrent comment periods for this rule and EPA's proposed heavy-duty vehicle GHG emissions standards are insufficient to provide fully informed comments on either proposal. [EPA-HQ-OAR-2022-0829-0733, pp. 61-62]

Although AFPM was one of several entities requesting that EPA extend the comment period for both rules, the agency declined, claiming that its pre-publication release of material meant that the public in fact had 83 days to comment on the Proposed Rule and 66 days to comment on the heavy-duty GHG rule.280 Contemporaneously with these proposals were two related rules addressing electric vehicles: (1) DOE published a proposal to revise its regulations regarding calculating a value for the petroleum-equivalent fuel economy of EVs for use in determining compliance with the CAFE program;281 and (2) the IRS proposed regulations regarding the IRA's New Clean Vehicle Credit. The table below illustrates that in the span of 88 days (April 11 – July 5), interested parties were required to analyze 531 pages of proposed rules in the Federal Register and more than 30,000 pages of supporting material to understand the basis for each proposed rule. The page estimate excludes the voluminous amount of data supporting EPA's two proposed vehicle rules. [EPA-HQ-OAR-2022-0829-0733, pp. 61-62]

280 June 2, 2023, letter from Joseph Goffman, EPA Principal Deputy Assistant Administrator, responding to Patrick Kelly, AFPM; see also letters from Alliance for Automotive Innovation, National Automobile Dealers Association, Hyundai-Kia America Technical Center, Inc., Hyundai Motor America, and National

Center for Public Policy Research, available at https://www.epa.gov/regulations-emissions-vehicles-and-engines/proposed-rule-multi-pollutant-emissions-standards-model.

281 88 Fed Reg. 21,525, 21,526 (Apr. 11, 2023).

Proposed Rule: Petroleum-Equivalent Fuel Economy Calculation [EPA-HQ-OAR-2022-0829-0733, pp. 61-62]

No. of Federal Register Pages: 15

Publication Date: April 11, 2023

Comments Due: June 12, 2023

Comment Period (including pre- publication days): 61 days

Estimated Pages of Supporting Documents: More than 500

Proposed Rule: Greenhouse Gas Emissions Standards for Heavy-Duty Vehicles—Phase 3 (“HDV Rule”)

No. of Federal Register Pages: 236

Publication Date: April 27, 2023

Comments Due: June 16, 2023

Comment Period (including pre- publication days): 66 days

Estimated Pages of Supporting Documents: More than 20,000

Proposed Rule: Proposed Rule (Light- Duty Vehicles—Multi- Pollutant) (“LD/MD Rule”)

No. of Federal Register Pages: 263

Publication Date: May 5, 2023

Comments Due: July 5, 2023

Comment Period (including pre- publication days): 83 days

Estimated Pages of Supporting Documents: More than 10,000

Proposed Rule: 30D New Clean Vehicle Credit

No. of Federal Register Pages: 17

Publication Date: April 17, 2023

Comments Due: June 16, 2023

Comment Period (including pre- publication days): 60 days

Estimated Pages of Supporting Documents: ~30 [EPA-HQ-OAR-2022-0829-0733, pp. 61-62]

EPA’s refusal to grant additional time to respond to the Proposal and the heavy-duty GHG rule denied the public ample time to formulate meaningful comments responsive to the underlying information in support of the Agency’s proposal. The Agency’s action is an arbitrary departure from its typical practice of granting reasonable extensions of time—often thirty days, but frequently sixty or even ninety—to provide meaningful input from the public on proposed rules.282 [EPA-HQ-OAR-2022-0829-0733, pp. 61-62]

282 Around the same time AFPM's extension request was denied, EPA saw fit to grant an extension of time to submit comments on the "Commercial Sterilization Facilities NESHAP." See EPA Docket EPA-HQ-OAR-2019-0178-0154.

Further, the short and concurrently running comment periods on these closely related rules are exacerbated by EPA's unduly narrow identification of industries affected by this rule. Under the heading "Does this action apply to me," EPA limits its identification of affected industries to entities with direct compliance obligations: motor vehicle manufacturers, commercial importers of vehicles and vehicle components, alternative fuel vehicle convertors, and medium duty engine & vehicle manufacturers.283 Although EPA notes that "this table is not intended to be exhaustive…other types of entities could also be affected," EPA understands many entities necessarily rely on regulatory screening tools based on search terms tied to their own NAICS codes to alert them to new proposed rules that may impact them. [EPA-HQ-OAR-2022-0829-0733, p. 63]

283 Proposed Rule at 29,184.

By narrowly limiting the identification of industries affected based on this extremely short and incomplete list of NAICS codes and by its arbitrary refusal to extend the comment periods, EPA has unreasonably constrained the number and types of entities that will find out about these proposed actions in time to comment. EPA appears to be counting on closing the comment period before consumers, retailers, farmers, fleet operators, bio and renewable fuel producers, small businesses, emergency response providers, local governments, or any of the host of other interests who will be affected by the profound changes in how light and medium duty vehicles are sold or even realize what is at stake. This sort of gamesmanship is at odds with EPA's responsibility under the Administrative Procedures Act and the Due Process clause of the U.S. Constitution. [EPA-HQ-OAR-2022-0829-0733, p. 63]

Organization: American Highway Users Alliance

Feasibility of the proposal is highly questionable and benefits are likely overestimated

Further, the two lengthy NPRMs and the lengthy draft Regulatory Impact Analysis (RIA) for each of them do not appear to include any consideration of the adverse impacts of the proposal on revenues flowing to the Highway Trust Fund (HTF) and resulting Federal highway infrastructure investment. The proposed rules in the two dockets seek to accelerate a shift from the public's use of ICE vehicles to EVs. A substantial erosion of revenue into the HTF would result,3 placing major downward pressure on needed highway and bridge investment, which already faces an investment backlog of $786 billion per USDOT's latest "Conditions and Performance Report." Moreover, that $786 billion estimate was developed before recent significant inflation. [EPA-HQ-OAR-2022-0829-0696, pp. 3-4]

3 The draft RIA for the heavy-duty vehicle NPRM includes a brief reference (page 429) that, under the proposed rule, fuel consumption would be "reduced." Fuel sales, which are subject to a Federal excise tax, generate the largest share of HTF revenue.

Organization: American Petroleum Institute (API)

g. Program Review.

i. Assessment of both vehicle and infrastructure development/deployment progress.

The design of a program with heavy reliance on infrastructure that may not be widely available on the timeline proposed is optimistic at best. The proposal appears premature on the stated timeline, and essentially in conjunction with the HD GHG Phase 3 program, which would be competing for the same resources. If EPA is not willing to adjust the timeline and/or standards of the proposed programs, API requests that the agency consider incorporating a pre- program assessment as well as a program progress assessment. It is imperative that EPA provide a real-world evaluation, with an honest assessment provided to the public, regarding progress on infrastructure readiness and ZEV technology deployment. The opportunity for stranded investments by all stakeholders impacted by this program is just too great not to incorporate pre- and mid-program reviews. [EPA-HQ-OAR-2022-0829-0641, p. 23]

For a mid-program assessment, EPA could consider something akin to the Midterm Evaluation that was finalized in the 2012 joint agency rulemaking establishing the MY 2017-2025 LD GHG standards.77 Further, we recommend that EPA engage a broad stakeholder community to identify necessary elements to incorporate into such an assessment. [EPA-HQ-OAR-2022-0829-0641, p. 23]

77 "Midterm Evaluation of Light-Duty Vehicle Greenhouse Gas Emissions Standards for Model Years 2022-2025." https://www.epa.gov/regulations-emissions-vehicles-and-engines/midterm-evaluation-light-duty-vehicle- greenhouse-gas.

ii. Future program incentives and program adjustment of standards.

In the development of the program, EPA needs to consider future program incentives such as adoption of a lifecycle approach, combined with fuel carbon intensity reductions. Such an approach would provide a broad spectrum of industries that power the transportation system (e.g., OEMs, petroleum refiners, power generators, and renewable fuel manufacturers) with incentives to reduce emissions. [EPA-HQ-OAR-2022-0829-0641, p. 23]

In addition, we also request that the agency report on the findings following review with enough time to adjust the standards if needed. Adequate lead time must be provided to the regulated community to allow for necessary adjustments to regulatory compliance strategies, and to avoid stranded investments as much as possible. A proposal based on stretch goals must incorporate an "offramp" or some opportunity to pivot if the essential elements of the program, such as charging/fueling infrastructure, do not materialize. [EPA-HQ-OAR-2022-0829-0641, p. 23]

Organization: Arconic Corporation (ARCO)

Arconic appreciates the opportunity to provide input to EPA as it considers revisions to vehicle emissions standards for MY 2027 and beyond. Arconic also generally supports the technical comments submitted by the Aluminum Association. [EPA-HQ-OAR-2022-0829-0741, p. 4]

Organization: Arizona State Legislature

8. The proposed rule does not allow comment on key final documents. EPA discusses at least two documents that have not been finalized after a peer review, and EPA should reopen the public comment process once the final versions of these documents are available. [EPA-HQ-OAR-2022-0829-0537, p. 3]

Commenters do not know the conclusions and analysis contained in the final versions of these reports. Presumably, EPA will make changes after receiving the peer-review comments. Commenters cannot provide fully informed comments on the proposed rule without having the opportunity to review the final versions of these reports. [EPA-HQ-OAR-2022-0829-0537, p. 27]

EPA should reopen the public comment process for the proposed rule after it has received the final versions of these reports. This should occur whether or not EPA intends to make revisions to the final rule based on the reports or to rely on the reports to support the final rule. If EPA intends to make revisions of the final rule based on the final versions of these reports, commenters should have the opportunity to comment on all revisions. The same is true with any other reports or data that EPA does not cite in the proposed rule. [EPA-HQ-OAR-2022-0829-0537, p. 27]

Failure by EPA to reopen the public comment process would be arbitrary and capricious. See, e.g., Texas v. United States Env't Prot. Agency, 389 F. Supp. 3d 497, 506 (S.D. Tex. 2019) ("However, the Agencies' decision not to reopen the Proposed Rule for comment after the publication of the Final Connectivity Report prejudiced the ability of interested parties to (1) provide meaningful comments regarding the Final Rule's continuum-based approach to connectivity and (2) 'mount a credible challenge' to the Final Rule."); Ctr. for Biological Diversity, Defs. of Wildlife v. Kelly, 93 F. Supp. 3d 1193, 1207 (D. Idaho 2015) (granting partial summary judgment and ordering an additional public comment period after federal agency relied on peer review comments not discussed or cited in the proposed rule). [EPA-HQ-OAR-2022-0829-0537, p. 27]

Organization: California Air Resources Board (CARB) (Part 1 of 5)

Lastly, as part of the California Phase 2 GHG program, CARB requires manufacturers to display environmental performance labels to provide buyers with important vehicle information when they are considering purchasing a new medium-duty vehicle. CARB recommends that U.S. EPA establish a similar labeling requirement for medium-duty vehicles as it does for light-duty vehicles. [EPA-HQ-OAR-2022-0829-0780, p. 17]

Serviceability

Vehicle serviceability is the ability for a driver to be able to repair their vehicle at any repair shop of their choosing and is key to sustaining driver use and maintaining emission benefits from ZEVs. If consumers cannot find suitable repair shops for their ZEVs, there is a risk that they will revert to conventional vehicles, limiting the emission benefits. To service vehicles, repair shops need access to on-board vehicle data and service information defining how to diagnose, repair, and maintain the vehicle, which not only requires some data standardization but also a way to access the data on the vehicle through a standardized means, such as the SAE J1962 compliant diagnostic connector. With the ACC II regulations, CARB added ZEVs to its service information regulation 56 to require the same access and disclosure of repair information and tooling, as well as the requirement that each vehicle be equipped with a standardized data set and equipped with a SAE J1962 diagnostic connector. 57 This regulation requires manufacturers to provide the same information to independent repair shops as they provide to their dealerships as is done for internal combustion engine vehicles today. 58 CARB strongly recommends that U.S. EPA include serviceability requirements for ZEVs in its proposal and, at minimum, a way to access that data through a standardized SAE J1962 compliant diagnostic connector. [EPA-HQ-OAR-2022-0829-0780, p. 42]

56 Cal. Code Regs., title 13, section 1969.

57 Cal. Code Regs., title 13, section 1962.5.

58 For additional background on CARB's inclusion of ZEVs in the service information regulation as part of ACC II, see ACC II Final Statement of Reasons for Rulemaking (FSOR), Including Summary of Comments and Agency Response Appendix D Summary of Comments to ZEV Assurance Measures and Agency Response, pp. 59 – 65 https://ww2.arb.ca.gov/sites/default/files/barcu/regact/2022/accii/fsorappd.pdf and ACC II ISOR, Appendix F-7, pp. 1, 10-13, 16.

Direct Current Fast Charging Standardization

CARB agrees with U.S. EPA's findings that the increased deployment of ZEVs will require more charging infrastructure to be installed. For this infrastructure to be most effective, CARB recommends that U.S. EPA require manufacturers to standardize vehicle charging inlets. In particular, direct current fast charging (DCFC) will play a key role in charging away from home both for longer travel trips and for those without convenient access to home or workplace charging. Making sure that consumers can easily access charging and that all BEVs are DCFC capable can help increase uptake of ZEVs, better ensure they can be effectively used by second and third owners, and help fully realize emission benefits from U.S. EPA's proposed standards. Currently, three distinct DCFC inlets exist on BEVs deployed in the U.S.: CHAdeMO, SAE Combined Charging System (CCS1) Type 1 (SAE J1772), and Tesla's North America Charging Standard connector. Having three different DCFC inlets, standards, and communication protocols can lead to inconsistent and unnecessarily complex charging experiences for consumers, including interoperability and charging reliability concerns. [EPA-HQ-OAR-2022-0829-0780, pp. 45-46]

Most manufacturers are already utilizing the SAE J1772 CCS1 standard in current vehicle production. In 2020, the CCS1 inlet was on 13 available BEV models and only 2 BEV models came with the CHAdeMO inlet. For the 2022 MY, 45 BEV models have the CCS1 inlet, with only 2 vehicle models remaining with the CHAdeMO inlet. 71 The federal government is also already investing in CCS1 infrastructure through the NEVI program, which requires that each funded DCFC port have at least one CCS1 connector. 72 However, in Spring 2023, Ford and General Motors both announced partnership with and future implementation of Tesla's North America Charging Standard on their vehicles. 73, 74 These moves by industry electric vehicle leaders are significant and continued lack of standardization could lead to more confusion in the market and decentralization of resources toward solving those issues that most plague reliable charging for electric vehicles. [EPA-HQ-OAR-2022-0829-0780, pp. 45-46]

Certification Data Collection for Improved ZEV Fuel Economy Labels

Based on experience gained to date, CARB has identified several shortcomings in the current fuel economy labels for ZEVs that could be improved to communicate more relevant data to consumers. Internal combustion engine vehicles have a long history with the label and its refinements over the years to present the most meaningful data in a concise format for consumers. For ZEVs in general, and especially for BEVs, however, the current label is insufficient in communicating useful information in an understandable metric to consumers regarding the most important BEV attributes. While modifications to the required label information and format may be out of scope for the current rulemaking proposal, CARB recommends that U.S. EPA include requirements with this proposal to require vehicle manufacturers to disclose additional information that could be used for such an improved label that could be adopted by separate rulemaking in the future. Specifically, CARB recommends that U.S. EPA require that manufacturers report additional test data and vehicle information regarding the vehicle’s range and charging time at the time of certification. [EPA-HQ-OAR-2022-0829-0780, p. 46]

Improved Electric Driving Range Information

Currently, the existing BEV label highlights vehicle efficiency in units of miles per gallons of gas equivalent (MPGe) based on testing across five defined drive cycles. The current label also uses this efficiency for the reported electric vehicle driving range. However, driving range based on city cycle usage or the combined cycle usage is not relevant to drivers who are primarily concerned about range for long distance travel which, by definition, is typically conducted at highway-like speeds. CARB notes that some third parties (including AAA, 75 InsideEVs, 76 and a recent SAE paper 77) have also previously assessed BEV range and noted a mismatch between label reported range and what a typical driver would likely experience in-use. [EPA-HQ-OAR-2022-0829-0780, pp. 46-47]

76 Moloughney, T., “What's The Real World Highway Range Of Today's Electric Cars? We Test To Find Out.” InsideEVs.com. April 22, 2023. https://insideevs.com/reviews/443791/ev-range-test-results/. Accessed June 15, 2023.

77 Pannone, G. and VanderWerp, D., "Comparison of On-Road Highway Fuel Economy and All-Electric Range to Label Values: Are the Current Label Procedures Appropriate for Battery Electric Vehicles?," SAE Technical Paper 2023-01-0349, 2023, https://doi.org/10.4271/2023-01-0349.

CARB recommends that U.S. EPA require manufacturers to collect and report some higher speed highway relevant energy consumption information during ZEV certification to supplement the highway drive cycle information currently submitted. To minimize added test burden to vehicle manufacturers, this data could be collected during the constant speed cycle portion of the already required SAE J1634 certification testing procedure to capture energy consumption rates at 65 mph and perhaps 75 mph to sufficiently bracket expected usage and ensure sufficient data exists to inform a future label. [EPA-HQ-OAR-2022-0829-0780, pp. 46-47]

Additionally, based on experience to date as to information consumers are seeking, CARB recommends U.S. EPA require collection and reporting of additional data to enable calculation of range under cold and hot weather conditions. As an example, collection of both highway-speed energy consumption and total usable battery energy while carrying out required testing for the 20-degree Fahrenheit cold temperature cycle could provide sufficient information to derive a consistent cold temperature estimated driving range. Likewise, during the required supplemental test known as SC03 that represents hot weather driving with high solar load and air conditioning usage, collection of this data could provide the necessary information to allow a more meaningful future label that transparently presents range information to a consumer. Many consumers are aware of battery limitations in cold or hot weather but lack accurate information when making purchase decisions as to the likely magnitude of that impact on any particular vehicle. [EPA-HQ-OAR-2022-0829-0780, pp. 46-47]

Organization: California Attorney General's Office, et al.

Across the country, states have also adopted laws, regulations, and policies that mandate or encourage zero-emission vehicle adoption. These state actions range from state fleet acquisition requirements to zero-emission vehicle purchase incentives and price relief to grants and financial assistance for public and private fleets. For example: [EPA-HQ-OAR-2022-0829-0746, pp. 19-21]

Examples of State Fleet Acquisition Requirements

- In Maine, 50% of all light-duty vehicles acquired by the state shall to the extent practicable be plug-in hybrid electric or zero-emission by 2025, and that requirement increases to 100% by 2030. Maine Revised Statutes, title 5, § 1830(12). [EPA-HQ-OAR-2022-0829-0746, pp. 19-21]

- In Hawai'i and Maryland, 100% of passenger vehicles in the state's fleet must be zero- emission vehicles by 2031, and other light-duty vehicles must be zero-emission by 2036. Hawai'i Revised Statutes § 196-9(c)(11); Maryland Statutes, State Finance & Proc. Code 14-418. [EPA-HQ-OAR-2022-0829-0746, pp. 19-21]

- In Texas, as of 2010, state agency fleets with more than 15 vehicles may purchase only alternative fuel motor vehicles (including electric vehicles), and these fleets must consist of at least 50% alternative fuel vehicles and use those fuels at least 80% of the time they are driven. Texas Statutes, Gov. Code 2158.004-2158.009. [EPA-HQ-OAR-2022-0829-0746, pp. 19-21]

- In Utah, at least 50% of new or replacement light-duty state vehicles must be propelled to a significant extent by alternative fuels, including electricity and hydrogen. Utah Code §§ 63A-9-401, 63A-9-403. [EPA-HQ-OAR-2022-0829-0746, pp. 19-21]

• In Missouri, 50% of new vehicles purchased by state agency fleets in a two-year period must be alternative fuel vehicles. Missouri Revised Statutes §§ 414.410. [EPA-HQ-OAR-2022-0829-0746, pp. 19-21]

• In Connecticut, 100% of all cars and light duty trucks purchased or leased by the state must be battery electric vehicles by 2030. Connecticut Public Act No. 22-25. [EPA-HQ-OAR-2022-0829-0746, pp. 19-21]

• In Rhode Island, 25% of light-duty vehicles purchased and leased by the state must be zero-emission vehicles by 2025. Rhode Island Executive Order 15-17. [EPA-HQ-OAR-2022-0829-0746, pp. 19-21]

• In Pennsylvania, state agencies under the Governor's jurisdiction must replace 25% of the passenger cars in the state fleet with battery electric and plug-in electric hybrid cars by 2025. Pennsylvania Executive Order 2019-01. [EPA-HQ-OAR-2022-0829-0746, pp. 19-21]

• In Washington, state agencies are ordered to electrify their fleets and establish a State Fleets Zero Emission Vehicle Implementation Strategy. Washington Executive Order 21- 04. [EPA-HQ-OAR-2022-0829-0746, pp. 19-21]

Examples of Purchase Incentives

• In Oregon, rebates are available for electric vehicles and plug-in hybrid electric vehicles, including for income-qualified state residents.116 Oregon Revised Statutes §§ 468.422-468.444. [EPA-HQ-OAR-2022-0829-0746, pp. 19-21]

116 Oregon.gov, Requirements for Charge Ahead Applicants, available at https://www.oregon.gov/deq/aq/programs/Pages/Charge-Ahead-Rebate.aspx.

• In California, the Clean Vehicle and Rebate Project for Fleets offers rebates for the purchase of light-duty zero-emission and plug-in hybrid electric fleet vehicles.117 [EPA-HQ-OAR-2022-0829-0746, pp. 19-21]

117 See California Fleet Rebate Project, Fleet Overview, available at https://cleanvehiclerebate.org/en/fleet.

• In Colorado, the Clean Fleet Vehicle and Technology Grant Program offers grants to business and government fleets for the purchase of new electric or fuel cell vehicles, or conversions of vehicles into battery or fuel-cell electric vehicles.118 [EPA-HQ-OAR-2022-0829-0746, pp. 19-21]

4. Lock in a rapid transition to a zero-carbon transportation system, while sending a clear market signal. [EPA-HQ-OAR-2022-0829-0618, p. 2]

Organization: Charles Gordon

REQUEST for EXTENSION of TIME and MEETING

The 2 1\2 months that EPA gave for comments on this massive and complex rulemaking is far too short for anyone who does not have the resources of EPA to add detail to their comments. [EPA-HQ-OAR-2022-0829-0747, p. 2]

I also request a meeting with EPA staff on this rulemaking. That is legally permissible as long as notes are taken and placed in the record. The one group that EPA did not say they met with are private citizens who are most effected by the propose rule [EPA-HQ-OAR-2022-0829-0747, p. 2]

ATTACHMENTS to COMMENTS

I request that the cover to this comment and the attached book be considered as part of these comments. Both make important substantive points. The book is "Unsettled" by Steven E. Kooning. [EPA-HQ-OAR-2022-0829-0747, p. 2]

ALTERNATIVES to DRASTIC REDUCTIONS in CO2

Research is going forward on carbon sequestration with some operations already working. It is true the activists oppose this for no apparent reason. It would be easy to add more sulfur compounds into the atmosphere by burning more soft coal to cool the atmosphere. The power plants would also have to emit a basic substance to prevent lake acidification. That is a challenge, but not Impossible to implement. [EPA-HQ-OAR-2022-0829-0747, pp. 7-8]

Rising sea levels an be contained by sea walls as the Dutch have been doing for centuries. Beach front residences can be moved back. Alternating droughts and torrential rains may not be caused by global warming. But it can be controlled by better water management. Forest fires can be controlled by better forest management. [EPA-HQ-OAR-2022-0829-0747, pp. 7-8]

ACTIVIST ORGANIZATIONS are NOT UNBIASED

Nowadays activist, nonprofit organizations are an industry. They provide well paid jobs for their officers and employees. They lie with statistics just as much as industry. They are never satisfied with regulatory actions that seem to carry out most of their goals because there would be no more grants and jobs for their employees. [EPA-HQ-OAR-2022-0829-0747, pp. 7-8]

When OSHA was considering limiting smoking in the workplace, the antismoking organizations wanted OSHA to regulate based on secret data. When the administration did much to reduce global warming through the IRA and other actions, activist organizations bitterly criticized the administration for permitting a 300-mile pipeline which was necessary to save the IRA and extend the debt ceiling. [EPA-HQ-OAR-2022-0829-0747, pp. 7-8]

Consequently, regulatory agencies need to be as skeptical of activist, non-profit organizations as they are of industry. They certainly should not consider their views as beyond reproach. [EPA-HQ-OAR-2022-0829-0747, pp. 7-8]

Organization: Chevron

It is important for EPA to plan for uncertainty in the feasibility and timing of meeting the standards proposed in the light and medium duty rule. We endorse the recommendation from API in their written comments to implement an interim program review, with provisions for adjustment of the standards if adequate progress is not being demonstrated. These important program elements should be incorporated into any final regulatory action. [EPA-HQ-OAR-2022-0829-0553, p. 6]

Organization: Competitive Enterprise Institute

The proposal purports to give automakers a nudge in the direction the market is already going. However, political coercion is a major factor driving the trend. As the EPA acknowledges:

In 2022, California finalized the Advanced Clean Cars II rule that will require, by 2035, all new light-duty vehicles sold in the state to be zero-emission vehicles, with New York, Massachusetts, and Washington state following suit, likely to be followed by Oregon and Vermont as well. Several other states may adopt similar provisions as members of the International Zero-Emission Vehicle Alliance.73 [EPA-HQ-OAR-2022-0829-0611, p. 19]

73 88 FR 29188.

Consumers now face the real risk that much of the new-car market will be off-limits to gasoline- powered vehicles in the near future. The EPA does not merely ride the EV wave. It launched the wave in January 2013 by withdrawing Clean Air Act preemption of California’s

ZEV program,74 propelled it forward by repealing preemption in March 2022.75 [EPA-HQ-OAR-2022-0829-0611, p. 19]

74 EPA, California State Motor Vehicle Pollution Control Standards; Notice of Decision Granting a Waiver of Clean Air Act Preemption for California's Advanced Clean Car Program and a Within the Scope Confirmation for California's Zero Emission Vehicle Amendments for 2017 and Earlier Model Years, 78 FR 2112, January 9, 2013, https://www.govinfo.gov/content/pkg/FR-2013-01-09/pdf/2013-00181.pdf.

75 EPA, California State Motor Vehicle Pollution Control Standards; Advanced Clean Car Program; Reconsideration of a Previous Withdrawal of a Waiver of Preemption; Notice of Decision, 87 FR 14332, March 14, 2022, https://www.govinfo.gov/content/pkg/FR-2022-03-14/pdf/2022-05227.pdf.

In so doing, the EPA ignored the Energy Policy and Conservation Act's preemption of State laws or regulations "related to" fuel economy standards. ZEV mandates are substantially related to fuel economy standards. As ZEV mandates tighten, fleetwide-average fuel economy increases. Conversely, as the current rulemaking demonstrates, at a certain level of stringency, fleet-average CO2 standards, which are fuel economy standards by another name, function as ZEV mandates. [EPA-HQ-OAR-2022-0829-0611, p. 19]

Organization: Consumer Reports (CR)

8. EPA Should Improve Consumer Information on the Window Sticker for EVs

If enacted, EPA's GHG rule will help support continued growth in EV sales. To help support consumers as they make the transition to EVs, CR asks that EPA open a separate rulemaking to update the consumer information that is provided on the window sticker for EVs. The EV market has evolved immensely in the years since the window sticker was last revised. Updating the sticker with more relevant information can help improve the EV buying experience. CR would suggest the following improvements to the data that is provided to consumers. [EPA-HQ-OAR-2022-0829-0728, pp. 25-27]

8.1. More Useful EV Range Information

As Car and Driver has recently highlighted, EPA's current testing for EV range does not always match with real world vehicle performance.52 A big portion of the problem is the fact that EPA only publishes a combined city/highway EV range number. However, EVs tend to achieve shorter range at real world highway speeds, which is when range is most often relevant to consumers. Also, range is only estimated under ideal weather conditions, leaving consumers with no information about how their vehicle might perform in hot or cold weather. While a single combined number is generally useful in comparing different vehicles against each other, providing consumers with more information including highway range in both hot and cold weather would be most useful in helping consumers understand the true performance they can expect from their vehicle, and better determine if it will meet their needs. [EPA-HQ-OAR-2022-0829-0728, pp. 25-27]

52 Comparison of On-Road Highway Fuel Economy and All-Electric Range to Label Values: Are the Current Label Procedures Appropriate for Battery Electric Vehicles?, SAE International, April 11, 2023, https://www.sae.org/publications/technical-papers/content/2023-01-0349/.

8.2. Consider Alternatives to Mile Per Gallon Equivalent (MPGe)

While MPGe is somewhat useful in helping consumers understand how EVs compare with gas and hybrid vehicles in terms of efficiency, it's not a very useful metric for vehicle owners. EPA should reconsider the use of MPGe on the window sticker and explore replacing or supplementing it with a more useful efficiency metric. In general most modern EVs present efficiency in terms of miles per kilowatt hour on their trip odometers, which is more consistent with how consumers are used to thinking about efficiency in terms of miles per gallon. [EPA-HQ-OAR-2022-0829-0728, pp. 25-27]

8.3. Provide EV Battery Size Information

While manufacturers may choose to include battery size information on the window sticker, it is not required. CR would recommend that manufactures provide the usable battery capacity of the vehicle on the window sticker. This also provides useful information for comparison between vehicles. Two separate vehicles might both have the same rated range, but achieve it with wildly different battery sizes. Providing that information to consumers can help them potentially consider more efficient options. [EPA-HQ-OAR-2022-0829-0728, pp. 25-27]

There may also be some value in manufacturers also providing the basic battery chemistry details as well given that certain types of batteries may perform differently under different conditions. This type of information may become even more important as the market explores more diversity in battery chemistries. [EPA-HQ-OAR-2022-0829-0728, pp. 25-27]

8.4. Develop and Present Standard Metrics for Charging Speeds

Charging speed is becoming an increasingly important differentiator in terms of the convenience of driving an EV longer distances. While the range of EVs is still important, it is charging speed that can most affect how convenient longer trips in EVs will be. CR suggests that EPA develop standardized testing and metrics for EVs' DC-fast charging speeds. Currently automakers provide consumers with cherry-picked charging speeds, often based upon narrow slices of the vehicle's charging curve under ideal conditions. [EPA-HQ-OAR-2022-0829-0728, pp. 25-27]

CR would suggest a standardized test for fast charging speed measuring the time to charge from 10% to 80% state of charge. [EPA-HQ-OAR-2022-0829-0728, pp. 25-27]

However, that metric is only part of the story because it doesn't tell how many miles of range are gained over that time. A separate metric should also be included that measures the average numbers of miles of range gained over a set period of time, potentially average miles per 10 minutes of charging or average miles per minute gained from 10%-80% state of charge. This will give consumers a more standardized way to understand how long they will have to spend charging to cover a specific distance using public fast charging. [EPA-HQ-OAR-2022-0829-0728, pp. 25-27]

Level 2 charging speeds can also be important information, but more information should be provided to consumers about the conditions under which the test was performed. At a minimum EPA should require the amperage of the charger needed to achieve the presented level 2 charging times be provided. [EPA-HQ-OAR-2022-0829-0728, pp. 25-27]

Organization: DENSO Corporation

Appendix 2

DENSO GREEN Technology Examples: ZEV Energy Consumption Reduction

1. Internal Heat Exchanger (SCX): An Internal Heat Exchanger reduces load on the compressor by transferring heat from the high-pressure liquid entering the expansion valve (TXV) to the low- pressure gas exiting the evaporator. [EPA-HQ-OAR-2022-0829-0651, p. 9]

2. Motors Generator (MG): A MG is essential for driving hybrid vehicles/BEVs and generating electricity. It serves as the main power source when starting and driving a vehicle and assists the engine during acceleration. The regenerative energy generated when applying the brakes is used to charge the battery. An MG plays a key role in improving the dynamic performance and fuel efficiency of hybrid vehicles/BEVs. [EPA-HQ-OAR-2022-0829-0651, p. 9]

3. Invertor w/Silicon Carbide (SiC): Inverters convert DC power from the battery to AC power controlling/operating the motor generator for traction/propulsion. During regenerative braking, the inverter converts AC power from the MG to DC (regenerative braking) to recharge the battery. SiC power semiconductors consist of silicon and carbon that significantly reduce power loss compared to silicon (Si) power semiconductors. A cruising test conducted under specific conditions by BEV using SiC semiconductor inverters demonstrated inverters with SiC power semiconductor reduce power loss less than half of ones with Si semiconductor. As a result, the energy efficiency of BEVs is improved and cruising range is extended. [EPA-HQ-OAR-2022-0829-0651, p. 9]

4. Heat Pump System: Highly Efficient Heat Pump Systems extract heat from the air and vehicle systems, and uses it as a heat source for the vehicle battery and climate control system. [EPA-HQ-OAR-2022-0829-0651, p. 9]

5. Radiant Heating System: This technology helps to extend electric driving range when the heating is on. In combination with the heat pump system, the highly heated surface efficiently warms occupants only and reduces the energy required. [EPA-HQ-OAR-2022-0829-0651, p. 9]

6. Battery Management System with Integrated Circuit (IC): This new generation battery- monitoring integrated circuit (IC) for lithium-ion batteries increases the efficiency with which electric and hybrid vehicles use their batteries, improves fuel efficiency and extends driving range. DENSO's was the first IC that can accurately detect battery voltage while monitoring multiple cells, a new capability compared to conventional ICs. [EPA-HQ-OAR-2022-0829-0651, p. 9]

Organization: District of Columbia Department of Energy and Environment (DOEE)

Advanced Clean Cars 2

Given the health and environmental concerns affiliated with vehicle emissions and climate change, DOEE is taking action to mitigate those health and environmental effects. As allowed for under Clean Air Act § 177, DOEE is finalizing efforts to adopt California's Advanced Clean

Cars 2 (ACC2), which will require vehicles to be zero emission by 2035. By adopting ACC2, DOEE takes a crucial step toward improving the health and wellness of District residents. DOEE has also finalized a robust roadmap for transportation electrification, an essential step towards having the capacity to charge vehicles as would be required in the rulemaking.18 Using the roadmap as a guide DOEE and its partners at the District Department of Transportation are working to secure funds through the National Electric Vehicle Infrastructure (NEVI) and Charging and Fueling Infrastructure (CFI) programs. [EPA-HQ-OAR-2022-0829-0550, p. 6]

18 DOEE. Transportation Electrification Roadmap. September 2022. https://doee.dc.gov/sites/default/files/dc/sites/ddoe/service_content/attachments/Final%20DC%20Roadmap%20sm.pdf

While DOEE is finalizing ACC2 and will see improvements following this regulatory change, most of the vehicle traffic in the District of Columbia originates from outside of the District. A DC Travel Pattern Analysis comparing pre-covid and post-covid travel patterns indicated that each day during the work week (Monday through Friday) in 2019, over one million vehicles traveled into the District. In 2022, these numbers dropped to around 700,000 vehicles traveling daily into the District Monday through Friday.19 Ultimately, vehicles traveling from outside of the District also contribute to the pollution traveling to the District from out-of-state. EPA modeling indicates that 95% or more of the District's ozone pollution comes from outside of our borders. Even though the District and other states are electing to adopt ACC2, the District and states which approve ACC2 will still experience the adverse effects of vehicle pollution from the states choosing not to implement ACC2 which travel in and out of the state. [EPA-HQ-OAR-2022-0829-0550, p. 6]

Organization: Elders Climate Action

Commenters understand that additional rulemaking will be required to establish a zero emission standard and phase-in schedule for L/MDV classes not addressed by this rule. However, the current proposal can be revised to incorporate this approach for the L/MDV classes and categories addressed by this proposal. We ask that the Administrator not delay completion of the current proposed rule so that it can apply to 2027-29 MY vehicles. We ask that the Administrator open a rulemaking for the additional vehicle classes to promulgate a zero emission standard and a phase-in schedule that begins with the 2027 MY. [EPA-HQ-OAR-2022-0829-0737, p. 11]

C. Petition for Finding --

Based on these data and other available evidence, we petition the Administrator to find that – climate warming already caused by GHG emissions harms the public health and is causing unacceptable adverse impacts on public welfare and the human environment, and the expected increase in the severity and frequency of harms to health and the public welfare that will be caused by more extreme events that will occur as the global mean temperature advances toward and above the 1.5°C level resulting from growing GHG concentrations in the atmosphere, establish the need for a zero GHG emissions standard for L/MDVs pursuant to section 202(a)(1) and (3)(A) of the Clean Air Act. [EPA-HQ-OAR-2022-0829-0737, p. 20]

We petition the Administrator to make this finding as the predicate for re-opening this rulemaking for the purpose of promulgating a zero emission standard for L/MDVs, and a phase-in schedule that prescribes for each automaker a share of total L/MDV sales that must be ZEVs beginning with the 2027 MY. [EPA-HQ-OAR-2022-0829-0737, p. 20]

Organization: Electric Drive Transportation Association (EDTA)

The Administration has a portfolio of policy initiatives that are essential to accelerating the transition, including the National Electric Vehicle Infrastructure (NEVI) program, the consumer and manufacturing incentives in the Inflation Reduction Act, the Congestion Mitigation and Air Quality program, the Low and No Emissions program, DOE's Loan Programs, Clean Cities, and research and development programs. The broad approach reflects the need for an all-of-government approach to building the EV ecosystem. [EPA-HQ-OAR-2022-0829-0589, p. 1]

Organization: Environmental. and Public Health Organizations

XI. Revisions to Elements of the Compliance and Enforcement Program Are Warranted.

We also urge EPA to revise certain elements of its compliance and enforcement program, as detailed below.

A. Clarifications of EPA's existing enforcement authority are appropriate.

As noted in the Proposal, EPA has the authority to remedy non-compliance with its GHG emissions regulations by correcting credit balances.223 Such action is appropriate under the Clean Air Act, and EPA has utilized such remedies on occasion in the past, including when manufacturers were found to be improperly certifying vehicles to lower emissions.224 [EPA-HQ-OAR-2022-0829-0759, p. 92]

223 88 Fed. Reg. at 29288

224 See "Correction of Greenhouse Gas Emission Credits" in Consent Decree, United States & CARB v. Hyundai Motor Company et al., 14-cv-1837 (D.D.C. Jan. 9, 2015), ECF No. 8, at 9.

EPA's in-use testing program is a critical part of ensuring that the regulatory program yields the reductions anticipated in the real world. Should a manufacturer's in-use testing illustrate deviations from the fleet level certification, particularly those of a systematic nature resulting in higher real-world emissions, it is appropriate for EPA to adjust the manufacturer's regulatory credit balance to reflect this real-world increase. We support EPA's clarification and believe EPA should act swiftly should a need for such enforcement arise. [EPA-HQ-OAR-2022-0829-0759, p. 92]

Unlike other emissions programs, GHG certification is granted at the precise certified test, rather than as a bin, where there is some inherent compliance margin. While EPA has some allowance for in-use values that fall within 10% of the certified value, as discussed in the section immediately below, EPA is proposing to allow manufacturers to voluntarily certify to a higher emissions level to better reflect the range of anticipated in-use emissions from the full configurations of the certified fleet. We support this voluntary approach. [EPA-HQ-OAR-2022-0829-0759, p. 92]

These two actions are complementary to each other, and we support EPA finalizing both together in the final rule. EPA is proposing to allow manufacturers to create their own compliance margin to reflect the full range of plausible in-use emissions from vehicle configurations covered under a given certification level. If, after in-use testing is completed, EPA still determines that the in-use test values do not reflect the emissions levels certified by the manufacturer, EPA is making clear that it has the authority to remedy the manufacturer's balance after the fact. This provides adequate opportunity in advance of the sale of vehicles to preemptively address any concerns about systematic deviation without relinquishing EPA's ultimate authority to ensure that credits for the regulatory program reflect in-use performance. [EPA-HQ-OAR-2022-0829-0759, p. 92]

Organization: Environmental Defense Fund (EDF) (1of 2)

iii. State leadership further supports the feasibility of protective standards.

Along with this market dynamism, state policy leadership has played an important role in advancing ZEV deployment and strongly supports EPA's proposal. As part of California's overall approach to accelerate a large-scale transition to light-, medium- and heavy-duty ZEVs, the state adopted the ACC II rule in November 2022, which requires the sale of an increasing share of new passenger ZEVs starting with MY 2026, ensuring that all new passenger cars, trucks and SUVs sold in California will be zero emission by 2035.62 The program relies on currently available advanced vehicle technologies, including battery-electric, hydrogen fuel cell electric and plug-in hybrid electric vehicles and will help meet the state's air quality and climate change goals. Figure 10 below shows ZEV and PHEV sales percentages required by ACC II.63 [EPA-HQ-OAR-2022-0829-0786, pp. 26-29]

62 https://ww2.arb.ca.gov/our-work/programs/advanced-clean-cars-program/advanced-clean-cars-ii; California's ZEV regulation was first adopted in 1990 as part of LEV I standards and has undergone significant periodic modifications since that time. In January 2012, the state formally adopted the Advanced Clean Cars I program that set requirements for the deployment of electric vehicles at over 10% of new vehicle sales by 2025. Seventeen additional states have since adopted the ACCI regulations. California Air Resources Board, States that Have Adopted California's Vehicle Standards Under Section 177 of the Federal Clean Air Act (May 13, 2022), https://ww2.arb.ca.gov/sites/default/files/2022-05/%C2%A7177_states_05132022_NADA_sales_r2_ac.pdf.

63 ACC II allows manufacturers to sell PHEV50s for up to 20% of the required ZEVs. . Using EPA's updated PHEV utility factors, PHEV50s equal 0.67 of a BEV. When including PHEV50s as two-thirds of a BEV in the calculation to compare EPA's proposal to ACC II, ACC II requires a higher percentage of ZEVs. E.g., in 2030, ACC II requires 68% of vehicles to be ZEVs, with PHEV50s constituting up to 20% of that 68%. Assuming 20% are PHEVs, the true ZEV share drops to 54%, lower than EPA's modeled 60%. When the PHEV50 share is included back at two- thirds, this raises ACC II ZEV share to 64%, higher than EPA's modeled 60%.

[See original attachment for Figure 10: California ACC II ZEV and PHEV Sales] [EPA-HQ-OAR-2022-0829-0786, pp. 26-29]

Source: California Air Resources Board, Advanced Clean Cars II Regulation

The program is expected to provide public health benefits of at least $12 billion over the life of the regulations by reducing premature deaths, hospitalizations and lost workdays associated with exposure to air pollution. Six other states – Massachusetts, New York, Oregon, Vermont, Virginia and Washington – have already adopted ACC II and a number of others are currently considering it. In February 2023, New Jersey Governor Phil Murphy announced a commitment to initiate the process to adopt ACC II.64 And in March 2023, Maryland Governor Wes Moore announced the state would adopt ACC II.65 In December 2022, the District of Columbia released a notice of proposed rulemaking and public hearing for the adoption of California's clean car standards.66 Rhode Island's Department of Environmental Management held a virtual public listening session on May 18, 2023 to review the draft release of the "Rhode Island's Low-Emission and Zero-Emission Vehicle Programs" regulation, which is modeled on ACC II.67 Colorado Governor Jared Polis' administration is also proposing a modified version of ACC II.68 [EPA-HQ-OAR-2022-0829-0786, pp. 26-29]

Organization: Hyundai Motor America

A Federal Advisory Committee Should Be Convened to Help Assess Key Enablers Needed to Support BEV Penetration Requirements.

The Proposed Rule's BEV penetration forecast assumes that all elements critical to the rule's success – such as infrastructure and grid resiliency – come together to support BEV adoption, directly impacting automaker compliance. However, as described above there is much work needed in short order to grow infrastructure and grid capacity. We envision a final rule that includes specific assumptions about infrastructure growth and grid capacity improvements necessary to enable the MY 2030 standards. We recommend the formation of a Federal Advisory Committee ("FAC") to include equitable private and public representation. Starting January 1, 2029 and completed by July 1, 2030, the FAC would assess the state of infrastructure development and grid resiliency against the rule's assumptions and make a recommendation to EPA about the feasibility of the BEV penetration targets. For example, if the assessment concludes that the assumptions are correct, then the final rule could continue as-is. However, if the findings show a shortfall, then EV multipliers would activate for MY 2029 through MY 2032. EV multiplier values should correspond appropriately to the shortfall identified. As a simplified example, a FAC finding of a ten percent infrastructure shortfall compared to the final rule's MY 2030 assumptions would trigger an EV multiplier recommendation of 1.1. In this way, automakers are not penalized for compliance shortfalls directly dependent on enablers necessary for the rule's success. An automaker's compliance shortfall, after accounting for the EV multipliers, would be subject to EPA's normal enforcement protocols. [EPA-HQ-OAR-2022-0829-0599, pp. 8-9]

Recommendations

In summary, we support AFAI's proposal as it aligns with Executive Order 14037. In addition, the final rule should include a: [EPA-HQ-OAR-2022-0829-0599, p. 9]

- Revised No Action case to more adequately account for infrastructure and grid capacity constraints, challenges related to IRA-related supply chain restructuring, and significantly reduced consumer access to EV tax incentives in the near and medium term, [EPA-HQ-OAR-2022-0829-0599, p. 9]

- Confidential and aggregated industry survey to understand real costs associated with supply chain and manufacturing changes caused by the 30D tax credit requirements, [EPA-HQ-OAR-2022-0829-0599, p. 9]

- Off-cycle credit provision consistent with current rules through MY 2030, with a phasedown beginning MY 2031[EPA-HQ-OAR-2022-0829-0599, p. 9]

- Credit incentive for automakers to reduce tailpipe emissions within in disadvantaged communities, and [EPA-HQ-OAR-2022-0829-0599, p. 9]

- Federal Advisory Committee to, by July 1, 2030, assess and issue recommendations regarding the status of key enablers necessary to support the final rule's BEV penetration requirements [EPA-HQ-OAR-2022-0829-0599, p. 9]

Organization: Institute for Policy Integrity at NYU School of Law et al.

Moreover, during the April 2021 "Leaders' Summit on Climate" hosted by the United States, following the announcement of a new U.S. commitment to reduce emissions to 50–52% below 2005 levels by 2030, multiple other countries reciprocally increased the ambition of their own climate targets. Notably, Japan accelerated its reduction goal from 26% to 46–50%; Canada strengthened its target from 30% to 40–45%; South Korea strengthened its target to achieve net zero emissions by 2050; China promised to peak coal use by 2025 and phase down coal consumption after that, and to join the Kigali Amendment to reduce hydrofluorocarbon emissions; Argentina pledged to strengthen its goal by 2.7% and make previously "conditional" targets "unconditional" instead; Brazil committed to a net zero target by 2050 (ten years earlier than its previous 2060 goal) and pledged to end illegal deforestation by 2030; South Africa shifted its emission peak ten years earlier, to 2025; and New Zealand, Bhutan, and Bangladesh all committed to submit more ambitious plans in the near future.45 [EPA-HQ-OAR-2022-0829-0743, pp. 7-8]

45 U.S. Dept. of State, Leaders' Summit on Climate: Day 1, Apr. 22, 2021, https://perma.cc/3X8A-KF4G; Climate Action Tracker, Warming Projections Global Update: May 2021 at 3 (2021), https://perma.cc/7JYN-N2DU.

This flurry of activity is just the latest evidence of reciprocity in international climate actions. Some past reciprocity has been explicit. The Kigali Amendment, for example, is the latest internationally negotiated climate treaty, with more than 120 parties so far committing to common but differentiated responsibilities to phase down hydrofluorocarbons.46 Previously, under the Copenhagen Accord and the Paris Agreement, some parties, including the European Union and Mexico, have at times explicitly made conditional pledges, promising to ratchet up their efforts if other countries make comparable reductions.47 By contrast, when the United States "failed to take action to reduce greenhouse gas emissions during the George W. Bush Administration and during . . . the Trump Administration," as economist Michael Greenstone has testified before the U.S. House of Representatives, "both periods were characterized by little [international] progress, and indeed many instances of backsliding, in reducing emissions globally."48 By failing to take international climate damages into account, in other words, EPA and other U.S. agencies would incentivize other countries to do the same, which in turn would cause greater greenhouse gas pollution originating in other countries that causes climate damage within the United States. [EPA-HQ-OAR-2022-0829-0743, p. 8]

Comm'n, Expression of Willingness to Be Associated with the Copenhagen Accord and Submission of the Quantified Economy-Wide Emissions Reduction Targets for 2020 at 2, Jan. 28, 2010, https://perma.cc/77DD- M4LS (committing to a 20% reduction but "reiterat[ing] its conditional offer to move to a 30% reduction by 2020 compared to 1990 levels, provided that other developed countries commit themselves to comparable emission reductions and that developing countries contribute adequately according to their responsibilities and respective capabilities"); Gov't of Mex. Ministry of Env't & Nat. Res., Nationally Determined Contributions: 2020 Update at 22, https://perma.cc/VF4A-K5HK (making an unconditional pledge of 22% reduction of GHGs and 51% of black carbon by 2030; and making a conditional pledge of up to 36% reduction GHGs and 70% black carbon, conditioned on "an international price for carbon trading, adjustment of tariffs for carbon content" as well as technology transfers and financial resources).

48 Economics of Climate Change: Hearing before the U.S. H. Comm. on Oversight & Reform's Subcomm. on Env't at 6 (Dec. 19, 2019) (testimony of Michael Greenstone), https://perma.cc/H5JS-V4H6.

On several prior occasions—again outside the context of climate change—courts have upheld EPA's authority to consider effects on international reciprocity and cooperation due to domestic pollution standards. In one case, for instance, the D.C. Circuit upheld EPA's decision to set an interim tolerance for the chemical ethylene dibromide under the Food, Drug, and Cosmetic Act (FDCA)—rather than ban the chemical altogether—after EPA concluded that a ban "could damage cooperative [food-safety] efforts," reasoning that "[s]ince effective enforcement of food safety laws depends upon such cooperation, a ban might increase the risk that fruit and vegetables would enter the U.S. treated with unsafe levels of pesticides or infested with pests or diseases."100 The D.C. Circuit similarly upheld EPA's consideration of international harmonization in setting NOx emissions standards for commercial aircraft gas turbine engines, after EPA issued a standard under the Clean Air Act to align U.S. standards with international standards.101 [EPA-HQ-OAR-2022-0829-0743, pp. 15-16]

101 National Ass'n of Clean Air Agencies v. EPA, 489 F.3d 1221 (D.C. Cir. 2007).

Organization: International Council on Clean Transportation (ICCT)

At the state level, policymakers are charging ahead with their own zero-emission vehicle regulations, investments, consumer incentives, planning, and infrastructure deployment. California's Advanced Clean Cars II (ACC II) regulations will require dramatic reductions in light- duty vehicle emissions to 100% zero-emissions by 2035 through the Zero-Emission Vehicle Regulation and the Low-emission Vehicle Regulations. Many other U.S. states follow California's leadership on automotive emissions regulations. As of May 2023, 7 states have adopted ACC II and it is likely that others will follow. By adopting its proposal, EPA can build on ACC II and expand access to cleaner vehicles more broadly across the U.S. [EPA-HQ-OAR-2022-0829-0569, p. 3]

Globally, automakers have already announced over $1.2 trillion in investments in electrification. These investments will lead to greatly expanded model line-ups and production volumes, technological advancements, and reduced costs. [EPA-HQ-OAR-2022-0829-0569, p. 3]

In parallel, states are also adopting their own zero-emission vehicle regulations, investments, consumer incentives, planning, and infrastructure deployment. California's Advanced Clean Cars II (ACC II) regulations will require dramatic reductions in light-duty vehicle emissions to 100% zero-emissions by 2035 through the Zero-Emission Vehicle Regulation and the Low- emission Vehicle Regulations.6 Many other U.S. states follow California's leadership on automotive emissions regulations. As of May 2023, California, Massachusetts, New York, Oregon, Vermont, Virginia, and Washington have adopted ACC II. It is likely that many other states will continue to follow California's leadership and adopt the new ACC II Program to benefit from the anticipated emissions reduction and health benefits of the program.7 Many additional states currently follow the Advanced Clean Cars regulations through model year 2026; as of May 13th, 2022, 17 U.S. states have adopted all or part of California's low-emission and zero-emission vehicle regulations, and about 37% of national new light-duty vehicle sales meet California's emission standards.8 [EPA-HQ-OAR-2022-0829-0569, pp. 7-8]

6 California Air Resources Board. (2023). Advanced Clean Cars II Regulations: All new passenger vehicles sold in California to be zero emissions by 2035. https://ww2.arb.ca.gov/our-work/programs/advanced-clean-cars- program/advanced-clean-cars-ii

8 California Air Resources Board. (May 13, 2022). States that have adopted California’s vehicle standards under Section 177 of the Federal Clean Air Act. https://ww2.arb.ca.gov/sites/default/files/2022-05/%C2%A7177_states_05132022_NADA_sales_r2_ac.pdf

The U.S. share of global automaker electric vehicle investments is increasing, largely driven by these state and federal policies and investments. Research from January 2023 estimates that $210 billion in automaker electric vehicle manufacturing and $54 billion in battery production investments had been announced for the U.S.9 These electric vehicle and battery manufacturing investments will lead to greatly expanded model line-ups and production volumes, technological advancements, and reduced costs [EPA-HQ-OAR-2022-0829-0569, pp. 7-8]

9 Gabriel, N. (2023, January 12). $210 billion of announced investments in electric vehicle manufacturing headed for the U.S. Atlas EV Hub. https://www.atlasevhub.com/data_story/210-billion-of-announced-investments-in-electric- vehicle-manufacturing-headed-for-the-u-s/

MDV data and transparency

EPA’s fuel economy guides, annual certification data, and automotive trends reports are invaluable resources for detailed information on light-duty sales, emissions, fuel consumption, vehicle attributes, and applied technologies. This level of detail is absent for medium-duty vehicles. Public access to this data is necessary for many reasons, including the ability to identify trends in pickup and van sales, possible shifts from light-duty to medium-duty, and technology penetration and effectiveness. ICCT recommends EPA collect and make public these data for MDV as it does for LDV. [EPA-HQ-OAR-2022-0829-0569, pp. 62-64]

Organization: Jaguar Land Rover NA, LLC (JLR)

JLR strongly supports efforts to reduce emissions from passenger cars and light trucks, alongside improving fuel economy and advancing the transition to low emission vehicles. JLR would welcome the opportunity to continue its constructive dialogue with the relevant Government agencies in order to agree a balanced solution based on our unique position. [EPA-HQ-OAR-2022-0829-0744, p. 1]

Additionally, JLR supports the Alliance for Automotive Innovation (Auto Innovators) comments, including those on criteria pollutants emission standards. In this submission, we comment further on regulation stringency and EPA NPRM modeling assumptions in relation to the greenhouse gas (GHG) emission standards. [EPA-HQ-OAR-2022-0829-0744, p. 1]

Relationship to Other Regulations

The targets proposed by EPA are extremely ambitious and the projected BEV penetrations required to meet the standards exceed that of the California Air Resources Board (CARB) Advanced Clean Cars II regulation, with a trajectory to achieve 100% ZEV by 2035MY (as shown in Figure 3 below). [EPA-HQ-OAR-2022-0829-0744, pp. 7-8]

In 2022, California’s ZEV market share was over three times higher than the federal US BEV share.9 It is important that EPA acknowledges the inequality between California and non- S177 states. CARB are a world leader in the pursuit of the 100% ZEV goal, with years of incentives and effort involved to get to this point. EPA cannot assume that all states will follow a similar route and the regulation must balance the various adoption curves across the country. [EPA-HQ-OAR-2022-0829-0744, pp. 7-8]

9 Office of Governor Gavin Newsom - California ZEV Sales Near 19% of All New Car Sales in 2022(Jan 2023) https://www.gov.ca.gov/2023/01/20/california-zev-sales-near-19-of-all-new-car-sales-in-2022/

[See original for graph, Figure 3, titled “EPA Predicted BEV Mix vs California BEV Requirement”] [EPA-HQ-OAR-2022-0829-0744, pp. 7-8]

10 Advanced Clean Cars II (ACC II) Regulations - Section 1962.4, Title 13, California Code of Regulations - https://ww2.arb.ca.gov/sites/default/files/barcu/regact/2022/accii/2acciifro1962.4.pdf

Targets imposed on the automotive industry must be linked to and contingent on the successful roll-out of a comprehensive and accessible charging infrastructure network. The current ratio of public chargers in the US is around 1 charger for every 24 EVs11. While we recognize progress made to date in the roll-out of charging infrastructure, it is vital that this grows proportionally with the increase in uptake of EVs to remain within the EU recommended ratio of 1 public charger per 10 vehicles12 especially as these ratios are based on countries with a much greater population density compared to the United States. With more than 131,200 public chargers across the US, half (65,300) of them are concentrated across five states. (California, New York, Florida, Texas and Massachusetts)13 [EPA-HQ-OAR-2022-0829-0744, pp. 7-8]

11 IEA (2023), Global EV Outlook 2023, IEA, Paris Trends in charging infrastructure - https://www.iea.org/reports/global-ev- outlook-2023/trends-in-charging-infrastructure, License: CC BY 4.0

12 Directive 2014/94/EU of the European Parliament and of the Council of 22 October 2014 on the deployment of alternative fuels infrastructure -https://eur-lex.europa.eu/legal-content/EN/TXT/?uri=celex%3A32014L0094

13 US Department of Energy (Alternative Fuels Data Center (Feb 2023) - U.S. Private Electric Vehicle Charging Infrastructure - https://afdc.energy.gov/data

JLR urges EPA to re-evaluate the proposed stringency of the regulation so that the required BEV share does not exceed CARB’s targets. [EPA-HQ-OAR-2022-0829-0744, pp. 7-8]

Organization: John Graham

Or maybe EPA is suggesting to manufacturers that the agency does not approve of HEV offerings; California has already proposed to ban most hybrids by 2035 and has requested an EPA waiver to move forward with that plan. If it is EPA’s intent to restrict HEVs by regulation, the agency should say so explicitly rather than spread a fiction that HEVs are not cost effective compared to BEVs. [EPA-HQ-OAR-2022-0829-0585, p. 15]

Organization: Kari Ostlie

I am concerned that not enough time is being given for important stakeholders to properly review and adequately comment on these new proposed tailpipe rules. I have read in this docket that the American Petroleum Institute (API), the American Fuel & Petroleum Manufactures (AFPM), and the Alliance for Automotive Innovation’s (AFAI) all requested a time extension be given to do a proper review of this proposed new EPA tailpipe rules. These are important organizations that represent a lot of important companies in the industry, and I believe it is only fair to allow the organizations representing these companies the proper time it takes to adequately give informed responses to all the complex issues in this proceeding.

In their requests the API & AFAI said "we request that EPA grant an additional 90 days for public comment for each proposal. For rules of this scope and complexity, 50 and 60 days for each proposal running concurrently are insufficient. API and AFPM respectfully assert that a 50-day and a 60-day comment period violate EPA's obligation to provide public notice and an opportunity to comment…" The AFAI stated "Moreover, EPA is proposing GHG regulations and criteria regulations for both light- and medium-duty vehicles. Historically, this would have been four separate rulemakings with a combined comment period approaching 250 days."

Recently learning that the EPA denied AFPM's request to extend the comment period in this proceeding is disturbing in light of the fact all these organization felt they needed more time to review the extensive material and provide meaningful comment in this proceeding. If given the proper among of time to analyze and respond, these organizations may have brought up some important points to consider that may have positively affected the outcome of this proceeding. As a citizen of this country, I am shocked that this request for extended time would not be granted. Not giving these organizations the proper time to comment means important perspectives will not even be brought up for discussion before the comment period ends due to time constraints. With such a significant proposal all perspectives should be given the time to bring up the points they need and to be fully heard as the points these organizations bring up may positively affect the outcome of this case for the American public. As it is important to balance all the concerns in this proposal for the best outcome in this proceeding. Thank you for taking my concerns into consideration. [EPA-OAR-HQ-2022-0829-1049]

Organization: Kia Corporation

Kia strongly supports comments submitted by the Alliance for Automotive Innovation (AFAI) on the Multi-Pollutant Emissions Standards proposed rule. Kia incorporates AFAI comments here by reference. Kia also fully endorses comments made by the Hyundai-Kia America Technical Center, Inc. (HATCI). Kia incorporates HATCI's comments here by reference and attaches them as Appendix A. [EPA-HQ-OAR-2022-0829-0555, p. 1]

- Kia continues to support the long-standing goal where EPA, National Highway Traffic Safety Administration (NHTSA), and the California Air Resources Board (CARB) work together to coordinate emissions regulations, strive to align stringency, and reduce unnecessary testing burdens. [EPA-HQ-OAR-2022-0829-0555, p. 3]

Kia supports continuing to collaborate with all levels of the government to ensure complementary policies continue to be implemented so we can work together to meet the goal of fully transitioning to vehicle electrification. The electric renewable identification number (eRIN) component of the Renewable Fuel Standard (RFS) program in 2024 is an example of a policy vital to support the administration's mission of rapidly deploying EVs. It would provide a strong incentive to produce renewable energy that will decarbonize the energy system that supports those vehicles. The eRIN program is unique in its ability to directly support automakers like Kia in its efforts to meet these ambitious goals. However, this program is seemingly in jeopardy and its omission would make it even more difficult to achieve EPA's proposal. [EPA-HQ-OAR-2022-0829-0555, p. 7]

EPA's Program Should Include Mechanism to Adjust Standards if Necessary

EPA's proposal does not include any mechanism to adjust standards or correct course if the various assumptions in the model do not materialize. Market assumptions in EPA's model include adequate charging infrastructure, consumer acceptance and demand, critical mineral supply, manufacturing capacity, power capacity, power rates, and low cost discrepancy between ICE and EVs. All of these elements – market realities and external challenges – are outside the control of automakers. There needs to be a mechanism that allows or requires EPA to revise standards if certain market conditions do not materialize at the level necessary to increase demand for EVs. [EPA-HQ-OAR-2022-0829-0555, p. 7]

Organization: Mass Comment Campaign sponsoring organization unknown (118 signatures)

Additionally, I am concerned about how these new standards could negatively impact the Highway Trust Fund. If implemented without addressing the funding structure, these proposed regulations could strain the already precarious state of transportation funding. It is crucial to consider additional solutions, such as a Low Carbon Fuel Standard, to address the revenue lost by having fewer internal-combustion engines on the road. [EPA-HQ-OAR-2022-0829-1701]

In conclusion, I strongly urge the EPA to reconsider the proposed tailpipe emissions rules. It is crucial that the EPA engage in meaningful collaboration with Congress, automotive manufacturers, and other stakeholders to develop a comprehensive approach that accounts for the current limitations in charging infrastructure, safeguards consumer choice, promotes domestic energy security, and ensures the continued funding of our vital transportation infrastructure. [EPA-HQ-OAR-2022-0829-1701]

Organization: MECA Clean Mobility

EPA should consider incentives and potential future requirements that advance efficiency of electric vehicles.

MECA requests that EPA explore additional incentivization structures that would allow consumers to make informed choices when purchasing electric and fuel cell vehicles. For example, EPA could institute a labeling requirement for electric vehicles with similarities to Energy Star and displaying how an electric vehicle compares to other similar electric vehicles in its class. The simplified Energy Star graphic is recognizable and understood by the majority of consumers who might not be able to interpret the value of an electric vehicle efficiency in kilowatt-hours per 100 miles, which is currently on the window sticker. [EPA-HQ-OAR-2022-0829-0564, pp. 31-32]

Organization: MEMA, The Vehicle Suppliers Associated

The aggressive pace and scope of the proposed rule obliges EPA to work to ensure success throughout the course of this rule's implementation. EPA must follow through on all assumptions in the regulatory impact analysis (RIA), and act accordingly to help make them a reality and reassure manufacturers and consumers along the way. [EPA-HQ-OAR-2022-0829-0644, p. 4]

MEMA urges:

• the Biden Administration to align regulations and priorities in concert with the Joint Office of Energy and Transportation throughout the implementation period of this rule to identify shared concerns and solutions for the many moving parts of the rule. EPA needs this broad support to follow through on all assumptions regarding critical materials, infrastructure, and timing of milestones identified in the rule's analyses. [EPA-HQ-OAR-2022-0829-0644, p. 4]

• EPA work closely with NHTSA to align the CAFE standards rule with the LD/MD Multi-Pollutants rule. [EPA-HQ-OAR-2022-0829-0644, p. 4]

Immigration Reform will Help Address Need for More Skilled Workers

The manufacturing industry continues to invest in solutions to our workforce needs. As the largest employer of manufacturing jobs in the United States, our industry expects to have 2.1

million unfilled jobs by 2030.11[EPA-HQ-OAR-2022-0829-0644, p. 13]

11 Wellener, Paul; Reyes, Victor; Ashton, Heather; Moutray, Chad. "Creating pathways for tomorrow's workforce today". Deloitte Insights, 4 May 2021 https://www2.deloitte.com/us/en/insights/industry/manufacturing/manufacturing-industry-diversity.html

Immigration reform is crucial to the United States developing a new pipeline of talent. MEMA recommends increasing annual quotas for employment-based immigrant and nonimmigrant visas, expanding the scope of essential worker programs, and creating new visa options for international students and other high-demand workers. Immigration reform with a focus on our workforce needs is crucial for our industry to continue its growth and advancement. [EPA-HQ-OAR-2022-0829-0644, p. 13]

MEMA urges:

• EPA to work with other agencies to enable sufficient skilled labor to support national EV deployment and infrastructure transformations. [EPA-HQ-OAR-2022-0829-0644, pp. 14-15]

Organization: Missouri Corn Growers Association (MCGA)

The rule is discriminatory to all farmers and rural America whose economies and way of life depend on agriculture, as well as cars and trucks powered by internal combustion engines (ICE). The impacts of this rule will negatively impact hard-working farmers, their families, and rural communities. But the pain won’t stop with agriculture. [EPA-HQ-OAR-2022-0829-0578, p. 1]

Organization: National Corn Growers Association (NCGA)

Despite the GHG and criteria pollution reduction benefits of FFVs, as well as the low cost to purchase and fuel these vehicles, automakers have cut back on FFV models and now offer very few choices to consumers. Well-structured vehicle credit programs remain an impactful, cost-effective means for the government to encourage the introduction and adoption of new products and technologies. To encourage introduction of a wider range of low emission vehicle choices, NCGA believes EPA must provide equitable crediting across the spectrum of low emission vehicles, including FFVs. [EPA-HQ-OAR-2022-0829-0643, p. 9]

NCGA also urges EPA to take steps to update the F-factor in the fuel economy formula to a forward-looking F-factor of at least 0.2, as we outlined in 2020 comments in response to Docket EPA–HQ–OAR–2020-0104. Furthermore, we urge EPA to reinstate the 0.15 volumetric conversion factor for FFVs. EPA should reharmonize the 0.15 factor for FFVs in these standards, and, if not, in future standards. This change would accurately reflect the significant carbon emissions reductions from FFVs using E85 because the carbon emissions from the fuel are the release of carbon taken up through crop growth. [EPA-HQ-OAR-2022-0829-0643, p. 9]

Organization: Natural Gas Vehicles for America

(2) EPA to the extent it incorporates other technology advancement credits in its vehicle regulations should extend these incentives to natural gas and natural gas hybrid- electric vehicles based on the demonstrated benefits of these vehicles and the need to accelerate the introduction of a diverse mix of cleaner vehicle technologies; [EPA-HQ-OAR-2022-0829-0597, pp. 14-15]

(3) EPA should provide enhanced SmartWay designations for trucks powered by low-NOx engines and fueled by carbon-neutral or even carbon-negative renewable natural gas; [EPA-HQ-OAR-2022-0829-0597, pp. 14-15]

(4) Federal agencies should fund pilot programs and infrastructure development that demonstrate the ways in which natural gas can be used to fuel a variety of different transportation sectors by supporting the purchase of vehicles and equipment at multimodal facilities such as ports and rail facilities; [EPA-HQ-OAR-2022-0829-0597, pp. 14-15]

(5) Federal agencies should ensure that federal funding provided under the CMAQ Program and the DERA Program and other programs enacted as part of the Bipartisan Infrastructure Law and Inflation Reduction Act are competitively awarded for projects that provide the most cost-effective emission reductions and offer increased funding levels for engines and vehicles that are certified to more demanding standards in advance of EPA's adoption of such standards; [EPA-HQ-OAR-2022-0829-0597, pp. 14-15]

(6) Federal agencies should work with state authorities to ensure that transportation policies include performance metrics and consider a variety of different technologies as opposed to only promoting specific technologies regardless of their cost; [EPA-HQ-OAR-2022-0829-0597, pp. 14-15]

(7) The Administration should work with Congress to amend the federal excise tax on new trucks to reduce the impediment to fleets and businesses purchasing cleaner new trucks by either eliminating the tax altogether since it discourages new purchases or amend the tax so that it does not penalize more costly, lower polluting technologies (i.e., eliminate the excise tax on the incremental cost). [EPA-HQ-OAR-2022-0829-0597, pp. 14-15]

Organization: Northeast States for Coordinated Air Use Management (NESCAUM) and the Ozone Transport Commission (OTC)

California's Advanced Clean Cars (ACC) regulations require manufacturers of light-duty cars and trucks to sell increasing percentages of ZEVs. The regulations also include LEV standards to reduce criteria pollutants and GHG emissions from new internal combustion engine (ICE) vehicles. To date, in addition to California, 17 states have adopted the LEV standards, and 15 states have adopted both the LEV standards and ZEV sales requirements.11 [EPA-HQ-OAR-2022-0829-0584, p. 4]

11 A key focus of NESCAUM's clean transportation work is to advise and assist states with respect to adoption and implementation of California's new motor vehicle emissions standards. Through its Mobile Sources Committee, NESCAUM helps the Section 177 states to collaborate and coordinate on shared mobile source regulatory issues.

California's ACC II program, finalized in 2022, requires manufacturers of passenger vehicles (designed to transport 12 persons or less) and light-duty trucks (gross vehicle weight rating less than 8,500 pounds) to produce and deliver for sale an increasing percentage of ZEVs over time and 100 percent ZEVs by 2035. ACC II also establishes increasingly more stringent exhaust and evaporative emission standards for light- and medium-duty ICE vehicles. To date, California, Massachusetts, New York, Oregon, Vermont, Virginia, and Washington have adopted ACC II. These seven states represent over 20 percent of the LDV market.15 Six more jurisdictions—Colorado, Delaware, the District of Columbia, Maryland, New Jersey, and Rhode Island—have announced their intentions to adopt ACC II. More are expected to follow given the anticipated climate, air quality, and economic benefits of the program.16 [EPA-HQ-OAR-2022-0829-0584, p. 5]

15 Recent modeling for select Section 177 states shows that adopting ACC II will result in even greater cumulative NOx and GHG emissions reductions than EPA's proposed standards between 2025 and 2040. Across all of the states modeled, ACC II achieved 30 percent greater well-to-wheel CO2 equivalent reductions and 75 percent greater NOx reductions than EPA's proposed standards. Some states modeled saw even greater reductions. In Connecticut and New Jersey, for example, ACC II would provide an incremental benefit of roughly two times more than EPA's proposal. See Sonoma Technology, ACC II Program – EPA 2027 Proposal Comparison (June 8, 2013), [LINK TO NESCAUM WEBSITE WHEN POSTED].

16 National Automobile Dealers Association, NADA Data 2021 (2022), https://www.nada.org/media/4695/download?inline.

California's Advanced Clean Trucks (ACT) regulation requires manufacturers of Class 2b-8 on- road medium- and heavy-duty vehicles to sell increasing percentages of ZEVs. By model year 2035, 55 percent of sales of Class 2b-3 vehicle sales, 75 percent of class 4-8 vehicle sales, and 40 percent of Class 7-8 truck tractor sales must be ZEVs. In addition to California, seven states— Colorado, Massachusetts, New Jersey, New York, Oregon, Vermont, and Washington—have adopted the ACT regulation. These states have also adopted California's Heavy-Duty Low NOx and Phase II GHG regulations, which are designed to reduce emissions from new diesel fueled heavy-duty vehicles while the market transitions to ZEVs. Many more states are expected to follow. Like the ACC II regulation, state adoption of the ACT regulation creates economies of scale, lowers costs, promotes job creation, and provides the regulatory certainty needed to drive investment in ZEVs and infrastructure. [EPA-HQ-OAR-2022-0829-0584, p. 5]

B. Multi-State Collaboration

The NESCAUM and OTC states have long understood the benefits of a coordinated approach to transportation electrification policy development and implementation. Many are signatories to the 2013 Multi-State Zero-Emission Vehicle Memorandum of Understanding,17 which set light-duty ZEV sales targets for ten states to achieve by 2025; memorialized their commitment to work together to develop policies and programs to achieve those targets; and created the Multi-State ZEV Task Force, facilitated by NESCAUM, to enable states to collaborate and coordinate on ZEV policy. NESCAUM and the Task Force have developed two action plans with recommendations for states to accelerate light-duty ZEV adoption18 and policy guidance on a wide range of related issues and topics. [EPA-HQ-OAR-2022-0829-0584, pp. 5-6]

17 Multi-State Zero-Emission Vehicles Program Memorandum of Understanding (Oct. 2013), https://www.nescaum.org/documents/zev-mou-10-governors-signed-20191120.pdf/.

18 See, e.g., Multi-State ZEV Task Force, Multi-State ZEV Action Plan 2018-2021: Accelerating the Adoption of Zero Emission Vehicles (June 2018), https://www.nescaum.org/topics/zero-emission-vehicles/multi-state-zev-action- plan-2018-2021-accelerating-the-adoption-of-zero-emission-vehicles; Multi-State ZEV Action Plan (May 2014).

Most of the NESCAUM and OTC states are also signatories to the 2020 Multi-State Medium- and Heavy-Duty ZEV Memorandum of Understanding,19 now signed by a diverse coalition of 17 states, the District of Columbia, and the Canadian province of Quebec. Collectively, the U.S. signatories represent 43 percent of the U.S. population, 49 percent of the U.S. economy, and 36 percent of the nation's medium- and heavy-duty vehicles.20 The 2020 MOU commits the signatories to collaborate to accelerate the market for zero-emission trucks, vans, and buses, and sets targets to achieve at least 30 percent medium- and heavy-duty ZEV sales by 2030 and 100 percent ZEV sales by no later than 2050. Some of the signatories have established more ambitious targets. In July 2022, NESCAUM and the Task Force released an action plan with more than 65 strategies and recommendations for state policymakers to support the rapid, equitable, and widespread electrification of MHD vehicles.21 The signatories and other Task Force states are currently working to implement these recommendations. [EPA-HQ-OAR-2022-0829-0584, pp. 5-6]

19 Multi-State Medium- and Heavy-Duty Zero-Emission Vehicle Memorandum of Understanding (July 2020), https://www.nescaum.org/documents/mhdv-zev-mou-20220329.pdf/.

20 Collectively, the U.S. signatories represent 43 percent of the U.S. population, 49 percent of the U.S. economy, and 36 percent of the nation's MHD vehicles. See Census Bureau, 2020 Population and Housing State Data (Aug. 12, 2021), https://www.census.gov/library/visualizations/interactive/2020-population-and-housing-state-data.html; Bureau of Economic Analysis, GDP and Personal Income, https://apps.bea.gov/itable/iTable.cfm?ReqID=70&step=1#reqid=70&step=1&isuri=1 (visited June 23, 2022) (2021 Real GDP); Atlas Public Policy, EV Hub, https://www.atlasevhub.com/materials/medium-and-heavy-duty-vehicle- registrations-dashboard/#06f2a5dfc39daf9cc (visited June 23, 2022) (2019 IHS market data).

21 See Multi-State ZEV Task Force, Multi-State Medium- and Heavy-Duty Zero-Emission Vehicle Action Plan: A Policy Framework to Eliminate Harmful Truck and Bus Emissions (July 27, 2022), https://www.nescaum.org/documents/multi-state-medium-and-heavy-duty-zero-emission-vehicle-action-plan/.

Like ZEV sales regulations, the shared ambition memorialized in these multi-state agreements sends strong and consistent signals to industry and investors and promotes public and private investment in zero-emission technologies and infrastructure. For example, the public utility commissions in the U.S. signatories to the 2022 MOU have already approved more than $2 billion dollars of utility funding for medium- and heavy-duty ZEV infrastructure planning and deployment.22 [EPA-HQ-OAR-2022-0829-0584, pp. 5-6]

Organization: Our Children's Trust (OCT)

There is also no justification, no compelling interest, and no rational basis for not aligning EPA’s rule with California and other states that require 100% of light-duty vehicle sales to be ZEVs by 2035. [EPA-HQ-OAR-2022-0829-0542, p. 1]

Please include all cited evidence in the administrative record. We are also happy to provide any of the cited evidence on request. All Juliana v. United States evidence are in the files of the Department of Justice, which represents EPA and the Administrator in the case, as its clients. Thus, you have access to all of those documents and evidence, along with the legal bases for the comments made herein. However, if you have not been provided with those documents, we are happy to provide them. We would be pleased to meet with you and/or you and your counsel to discuss the constitutional use of EPA’s statutory authority to redress the climate crisis and protect the Nation’s children. Please send us a response to our comments, notification of further comment opportunities, and all analyses and decision documents to the address and email listed below. [EPA-HQ-OAR-2022-0829-0542, p. 6]

Organization: POET, LLC

The complications associated with EPA’s modeling underpinning its Proposed Rule shows the inadequacy of EPA’s 60-day comment period for the Proposed Rule. OnLocation raises significant questions regarding the robustness of EPA’s proposed vehicle GHG regulations and with “more time allowed than the short comment period provided by EPA on the proposal, a more comprehensive analysis of LDV policies using the OMEGA module could be performed leading to a more complete understanding of the consequences of this Proposed Rule.”126 [EPA-HQ-OAR-2022-0829-0609, p. 28]

Additionally, I am concerned about how these new standards could negatively impact the Highway Trust Fund. If implemented without addressing the funding structure, these proposed regulations could strain the already precarious state of transportation funding. It is crucial to consider additional solutions, such as a Low Carbon Fuel Standard, to address the revenue lost by having fewer internal-combustion engines on the road. [EPA-HQ-OAR-2022-0829-0793, p. 1]

Organization: Stellantis

Target Adjustment Mechanisms Needed Based on Market Enablers

Stellantis fully supports the Auto Innovators’ comments proposing a target adjustment mechanism based on key EV market enablers. This mechanism is in addition to making the other revisions needed to address concerns raised with the standards. There is a great deal of uncertainty with how critical mineral and raw material supplies, battery cost improvements, and charging/refueling infrastructure will develop over the next decade. In particular, charging/refueling infrastructure and supply of critical minerals and raw materials from non-countries of concern are well outside the control of either EPA or automakers. We understand

EPA must use projections in its modeling. However, given the uncertainty around these items, large inaccuracies can lead to a final rule that is grossly misaligned with the market. The Auto Innovators' proposal of a market-based target adjustment system would allow for year-by-year adjustments to be made within the framework of a rule that can be finalized on EPA's desired timeline and will minimize the need to be reopened to react to real-world market conditions. [EPA-HQ-OAR-2022-0829-0678, p. 7]

This proposal contains three individual adjustment mechanisms of roughly equivalent magnitude. The first is based on the percentage of the entire U.S. light-duty fleet qualifying for the full $3,750 30D retail tax credit which is tied to extracting and processing critical minerals in the U.S. or a country with a free trade agreement. This is the most simple and direct way to assess whether or not raw material supplies are developing adequately. The second adjustment mechanism is based on actual EV battery costs that could be confidentially disclosed to the EPA by each automaker every model year and compared with EPA's projected battery costs used in the development of this rule. The third mechanism is simply tracking the ratio of public charging/refueling points to the number of light-duty EVs registered and on the road. As the total size of the on-road EV fleet grows, so does the amount of charging/refueling infrastructure. If these three key market enablers develop as envisioned by EPA in this rule, then the impact of these adjustments will be negligible. But if one or more of these key enablers do not develop quickly enough, then this proposed system will allow for simple, objective, and transparent metric-based adjustments to be applied equally to all of industry. These are industry-wide issues and thus should be resolved on an industry-wide basis. [EPA-HQ-OAR-2022-0829-0678, p. 7]

At a House Committee on Energy and Commerce hearing on driving affordability held on June 22, 2023, Rep. Dingell (D-MI) raised concerns with EPA Principal Deputy Administrator Goffman on what happens under the NPRM if companies cannot reach BEV as 67% of new vehicle sales in 2032, consumers cannot afford EVs, the charging stations aren't there, and the assumptions and forecasting EPA relies upon are not viable. Mr. Goffman's response included a reference to a possible market assessment review. Stellantis believes the Auto Innovators' recommended ongoing market-based target adjustment system to be the best embodiment of a direct market review. However, Stellantis could support an additional market-based review that is both objective and transparent in reaching the necessary adjustments to allow this rule to be reasonable and achievable given the large amount of uncertainty with how these key market enablers will develop over the next decade. At a minimum, Stellantis supports EPA adding modules to its annual EPA Automotive Trends Reports that capture important metrics such as the number of public EV charging stations deployed and percent of EVs purchased. [EPA-HQ-OAR-2022-0829-0678, p. 7]

Lastly, this rule is broad in scope and high in complexity, proposing many changes to long-standing processes (i.e., a variety of new phase in requirements). Stellantis would welcome EPA providing industry training on implementation details when the rule is finalized. Stellantis requests that EPA offer classes/training, similar to the material and concise overview provided after the HD GHG Phase 1 rule was published. EPA's simplified slides provided more straight-forward rule interpretation and understanding. It would also be helpful for the training to include compliance calculation examples to resolve any potential ambiguity from the regulation. [EPA-HQ-OAR-2022-0829-0678, p. 25]

Organization: Steven G. Bradbury

Introduction

With these rules, EPA is proposing to interfere with and displace market forces on a massive and unprecedented scale, and the effects of these regulatory edicts on the American people and the U.S. economy will be disastrous if even one of the EPA's many key supporting assumptions turns out to be incorrect. [EPA-HQ-OAR-2022-0829-0647, p. 3]

It seems apparent that the EPA's primary goal is not to improve environmental per- formance of new motor vehicles, but rather to force the industry to transform its production processes and to achieve an artificially rapid transition to zero-emission-vehicle platforms, such as fully electric vehicles, to the extent and on the schedule that President Biden and the California Air Resources Board (CARB) have announced as their goals. Thus, the EPA's proposed rules seem to be guided by and aimed at hitting goals that are more aspira- tional and political in nature; they are not legitimate standards based on an accurate and objective assessment of technological and marketplace realities. [EPA-HQ-OAR-2022-0829-0647, p. 3]

And through these rulemakings, the Agency is proposing to align its regulatory objec- tives with the zero-emission vehicle, or ZEV, mandates recently issued by CARB, the Cali- fornia Air Resources Board, which are designed to phase out the sale of all gas-powered passenger cars and light trucks by 2035 and all medium- and heavy-duty trucks by 2045. The EPA now appears to be committed to a similar trajectory. [EPA-HQ-OAR-2022-0829-0647, p. 6]

It is not surprising the Agency would act to conform its policies to CARB's, since CARB was able to issue its mandates only because the EPA has granted California a special waiver from preemption under the Clean Air Act. Both sets of rules flow from the policy decisions of the EPA in accordance with directions from the White House. [EPA-HQ-OAR-2022-0829-0647, p. 6]

Putting the Highway Trust Fund at risk. The Highway Trust Fund, which covers a large percentage of the costs of state and local highway improvements and main- tenance in the U.S., is currently funded through a gas tax. The gas tax is relatively easy to administer because it is paid at the level of wholesale gasoline and diesel fuel distribution by a small number of large distributors. If more than half of new vehicles sold in the U.S. were EVs, as contemplated in the EPA's proposals, the gas-tax revenues for the Fund would drop dramatically, and the solvency and utility of the Fund would collapse. That would threaten the viability of the national high- way system and the capacity of states to maintain highways in good repair. [EPA-HQ-OAR-2022-0829-0647, p. 19]

If the Fund were to be retained in some form, it would require a new source of revenue, such as a tax on all vehicle miles traveled, or VMT. The idea behind a VMT tax is that it would equitably capture the VMT of EVs, just as well as ICE vehicles. However, a VMT tax is likely to be more complicated and costly to ad- minister than the gas tax. There are significant questions about the design and ad- ministrability of a VMT tax that would need to be worked out and proven—for example, through one or more state-wide pilot programs—before implementation. Since EPA is proposing to adopt rules that would cause a national shift to EVs, which in turn would undermine the revenue basis for the Highway Trust Fund, EPA should recognize and consider as part of these rulemakings the upfront costs and dislocations that would be involved in transitioning to a new revenue basis for the Highway Trust Fund, as well as the ongoing higher costs of administering such an alternative tax. [EPA-HQ-OAR-2022-0829-0647, p. 19]

Increasing highway infrastructure costs. Similarly, the cost of increased wear and tear on highway infrastructure, including the cost of increased frequency of required repairs, should also be recognized in the proposals. If, as EPA envisions, EVs were to comprise more than half of new light-duty vehicle sales, and if a large percentage of new medium- and heavy-duty trucks were battery powered, that would have a definite negative impact on highway infrastructure. The batteries in EVs are heavy, and, as a consequence, EVs tend to be considerably heavier than comparably sized ICE vehicles. The greater weight of EVs would cause faster wear and tear on high- ways if the number of EVs on the road were to increase significantly. [EPA-HQ-OAR-2022-0829-0647, pp. 19-20]

- Increasing the costs and burdens of first responders. There is no mention in EPA's NPRMs or in the accompanying DRIAs of the impact these rules would have on first responders. If EVs come to comprise a greatly increased percentage of the nation's auto fleet, as EPA's proposals are intended to achieve, state and local first responders will inevitably incur significantly higher costs and burdens in the form of specialized fire-suppression chemicals and equipment and additional hazardous- response training requirements. Lithium-ion battery fires are a common occurrence with EVs, and these fires generate intense heat and toxic fluoride gas emissions, making them more difficult to extinguish than conventional vehicle fires and increasing the costs and management challenges of maintaining effective first responder capabilities.56 [EPA-HQ-OAR-2022-0829-0647, pp. 19-20]

56 See Fredrik Larsson, et al., "Toxic fluoride gas emissions from lithium-ion battery fires," Scientific Reports, Nature, August 30, 2017, https://www.nature.com/articles/s41598-017-09784-z (corrected March 22, 2018) (also available at https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5577247/).

EPA should withdraw and reconsider these rulemaking proposals.

In light of the deficiencies in the cost analyses and underlying assumptions laid out above, EPA should withdraw and reconsider both of its proposed tailpipe rules. If EPA had more carefully considered its legal authorities under the Clean Air Act and more thoroughly accounted for the market realities and facts relevant to these proposals, I am confident EPA would not have proposed the radical and far-reaching approach to emissions control reflected in the current proposals. [EPA-HQ-OAR-2022-0829-0647, pp. 21-22]

Even if EPA persists in proposing something along the same lines, at a minimum, it should put these concepts out for public comment in a much more preliminary form—for example, in an advanced notice of proposed rulemaking, or ANPRM. By setting out the general ideas it plans to consider in an ANPRM, EPA could suggest its own preliminary supporting analysis and view of the relevant facts and considerations and then ask for meaningful input on all aspects of the issues, seeking recommendations for alternative approaches from interested parties and the public. That would be more respectful of the American people and all interested stakeholders and would be more accommodating of the need for and the value of greater public input and deliberation. [EPA-HQ-OAR-2022-0829-0647, pp. 21-22]

Such an alternative process would provide the opportunity for EPA to receive deeper and broader information on all sides of the issues raised by these regulatory proposals, as well as a more probing analysis of the scope of EPA's authority to set emissions limits for automobiles and commercial trucks. In that way, an ANPRM process would help redirect EPA's thinking about the true costs, market disruptions, and secondary consequences of its preferred approach and about its authority to undertake these transformational proposals. [EPA-HQ-OAR-2022-0829-0647, pp. 21-22]

Organization: T. Becker Power Systems

5- Both US EPA and California Air Resources Board (CARB) have illegally blocked the study of localized emission reduction strategies that would achieve EPA air quality standards without the need for increasingly stringent motor vehicle emission standards. Those alternative strategies include reducing VMT in California by 55% from a 2019 baseline by 2040, and reducing Port of Los Angeles/Long Beach activity (tonnage) by 75% by 2030 from a 2019 baseline. [EPA-HQ-OAR-2022-0829-0567, p. 1]

Organization: Tesla, Inc.

Additionally, Tesla notes that the 10 MB size limitation on appending supporting documents has prevented the attachment of some supporting materials. As a result, Tesla requests EPA include the following documents in the administrative record: [EPA-HQ-OAR-2022-0829-0792, p. 1]

• Tesla, Impact Report 2022 (Apr. 24, 2023) (full report) available at https://www.tesla.com/impact

• Tesla, Battery Day Presentation (Sept. 22, 2020) available at https://tesla-share.thron.com/content/?id=96ea71cf-8fda-4648-a62c-753af436c3b6&pkey=S1dbei4 [EPA-HQ-OAR-2022-0829-0792, p. 1]

Further, California's recent adoption of the ACC II rule, setting a 100 percent zero-emission vehicle (ZEV) sales standard by 2035, will also accelerate BEV adoption. As EPA recognizes, a number of states have already adopted ACC II and the list is growing.85 New research assessing the impact of additional states adopting California's standards (accounting for the IRA's tax credits) finds that adoption by California and 16 other states would accelerate electric vehicle adoption, cut 1.3 gigatons of carbon emissions (equivalent to closing 13 coal plants), create 300,000 new jobs, save households $230 per year, and prevent 5,000 deaths in 2050.86 [EPA-HQ-OAR-2022-0829-0792, pp. 12-13]

86 Energy Innovation, Nationwide Impacts Of California's Advanced Clean Cars II Rule (April 9, 2023) available at h ttps://energyinnovation.org/publication/nationwide-impacts-of-californias-advanced-clean-cars-ii-rule/

Further, as a growing number of states seek to adopt more robust ZEV requirements, enhancing the ZEV contribution to the establishment of multi-pollutant standards has the potential to significantly enhance nationwide regulatory and market uniformity. Tesla, as do many other manufacturers, strongly supports furthering as much national uniformity as is possible while still acknowledging California and the Section 177 States' innovation and leadership.140 [EPA-HQ-OAR-2022-0829-0792, p. 23]

Organization: Valero Energy Corporation

G. EPA has not adequately considered the consequences of the proposed rule with regard to byproducts and coproducts of petroleum refining.

In its consideration of demand destruction on domestic petroleum refining, EPA fails to consider the full breadth of products made from petroleum that are consumed every day in the United States. A partial list of more than 6,000 products made from oil and gas is provided in Table 6. [EPA-HQ-OAR-2022-0829-0707, pp. 51-54]

EPA fails to consider how the U.S. will source asphalt to pave its roads, tires to support its electrified transportation sector, and a multitude of other consumer products and pharmaceuticals that are integral to day-to-day life of Americans if domestic petroleum refining is phased out or disrupted.281 For example, the amount of asphalt produced is in direct correlation to the amount of liquid transportation fuel refined. Asphalt is a co-product and cannot be independently manufactured.282 The loss of domestic asphalt production would force rail transport of higher volumes and from further distances, driving up costs and GHG emissions, and compounding the burden on communities already impacted by excessive train lengths that in some cases have resulted in fatalities.283 If the United States' asphalt needs were to exceed the potential for railed supplies, incremental asphalt would need to be imported by marine vessel, likely from Asia. EPA's proposal neither accounts for the GHG burdens being outsourced by EPA's policies nor the logistics-related increases in GHG emissions. [EPA-HQ-OAR-2022-0829-0707, pp. 51-54]

283 https://www.washingtonpost.com/nation/interactive/2023/long-trains-block-intersections-paramedics/.

Further, the proposed rule fails to account for how the amount of sulfur available in the United States will be adversely impacted. The chemical can be used in "construction materials, traditional batteries, rubber (vulcanization), pharmaceuticals, paper bleaching, water treatment, cosmetics/skin care, detergents,…and most importantly fertilizers."284 Most of the world's sulfur is now produced through the Claus Recovery Method, which is used at oil and natural gas refineries to keep sulfur dioxide from escaping into the atmosphere.285 On average, this process in the U.S. alone creates 8 million tons of sulfur every year.286 Without this product, there would be a sulfur deficiency in many crops throughout the U.S.287 It is a key ingredient in phosphate fertilizers with nearly 50% of sulfur supply worldwide being used in this manner.288 Total U.S. economic impact is about $130 billion with 487,330 fertilizer industry related jobs in the U.S. with wage earnings of $34.31 billion.289 [EPA-HQ-OAR-2022-0829-0707, pp. 51-54]

Sulfur is also used in manufacturing copper and lithium for batteries. For copper smelting in the U.S., “approximately 1.4 million tons of [sulfur] is required.”290 For the electric vehicle future that some agencies anticipate, an additional 85,000 tons of sulfur would be needed in only two years for copper production alone.291 For lithium, the “crushed ore is leached for several days with diluted [sulfuric] acid.”292 With current projections for the lithium need, it is possible 21% of current sulfur will be used in the process.293 [EPA-HQ-OAR-2022-0829-0707, pp. 51-54]

This list above from the U.S. DOE makes clear that "car battery cases," "car enamel" and "automotive parts" are "products made from oil and natural gas." Petroleum products have been key components of EV innovation, making vehicles lighter and more efficient through the application of plastics, engineered polymers, and fiber-reinforced composites integral to EV design.295 EVs need petrochemicals, and petrochemicals will continue to play a critical role in further reducing the weight of EVs, which will help increase their range.296 The HD Phase 3 GHG Rule should not only account for leakage associated with the production of petrochemicals necessary to produce EVs, but also analyze the impact discontinued oil and refining production will have on the U.S.'s ability to encourage EV production to scale with its proposals. [EPA-HQ-OAR-2022-0829-0707, pp. 51-54]

Organization: Western Energy Alliance

Foreign Justification: Further, EPA cites to other countries as justification for the proposed rule:

"Globally, at least 20 countries, as well as numerous local jurisdictions, have announced targets for shifting all new passenger car sales to zero-emission vehicles in the coming years, including Norway (2025); Austria, the Netherlands, Denmark, Iceland, India, Ireland, Israel, Scotland, Singapore, Sweden, and Slovenia (2030); Canada, Chile, Germany, Thailand, and the United Kingdom (2035); and France, Spain, and Sri Lanka (2040)…In addition, in February 2023 the European Union gave preliminary approval to a measure to phase out sales of ICE passenger vehicles in its 27 member countries by 2035." (p. 29188) [EPA-HQ-OAR-2022-0829-0679, pp. 8-9]

Fundamentally, the fact that foreign countries are dictating EVs is not legitimate justification for U.S. rulemaking. But even were we to concede any relevance to this rulemaking, EPA surely should acknowledge the backtracking on these initiatives as many countries recognize the impracticality of such mandates. While politicians like to decree certain things far into the future, that does not mean such diktats will become reality. There are many examples throughout history of centrally planned economies and nationalized industrial sectors failing, with Venezuela providing the most recent sad example. [EPA-HQ-OAR-2022-0829-0679, pp. 8-9]

EPA has referenced, in footnotes 28 and 29, Reuters articles discussing European Union legislation to ban ICEV sales and mandate new EV car sales goals. In the final rule, EPA must likewise reference the Reuters article shortly thereafter discussing how quickly this legislation was overturned by seven member companies.19 Germany joined France, Italy, Poland, and others in demanding the EU scrap the plan to ban ICEVs and mandate EVs. Insofar as EPA relied on the actions of other countries and the EU in particular to justify this rule, such justification must be reversed in the final rule and references to the EU mandate removed or at least supplemented by the fact that the mandate was nullified. We provide a reference for convenience. [EPA-HQ-OAR-2022-0829-0679, pp. 8-9]

19 “Germany rejects EU plan for ban on new fossil-fuel cars from 2035,” Reuters, June 21, 2023; “E U was set to bani nternal combustion engine cars. Then Germany suddenly changed its mind,” CNN, March 27, 2023.

Organization: Zero Emission Transportation Association (ZETA)

We also encourage EPA to consider standards for MYs 2033-2035 that would result in the same level of emissions reductions as California’s Advanced Clean Cars II regulation. In doing so, we urge the agency to undertake a separate final rulemaking under a different OMB Regulatory Information Number to ensure such standards are severable from these proposed standards for MYs 2027-2032. ZETA notes that there may be useful parallels between the ongoing transition to EVs and EPA’s phaseout of leaded gasoline from 1973 to 1996130 and we encourage the agency to apply any potential lessons learned from that phaseout, recognizing that reducing GHG emissions requires a similar sense of urgency to eliminating lead in gasoline. [EPA-HQ-OAR-2022-0829-0638, p. 26]

130 “EPA History: Lead,” U.S. Environmental Protection Agency, accessed June 20, 2023 https://www.epa.gov/history/epa-history-lead

We also encourage EPA to finalize MDV GHG and multipollutant emissions standards for MY 2033-2035 that align with the stringency of California’s Advanced Clean Trucks regulations for class 2b-3 vehicles. In doing so, we urge the agency to undertake a separate final rulemaking under a different OMB Regulatory Information Number to ensure such standards are severable from these proposed standards for MYs 2027-2032. We recommend finalizing MY 2033-2035 emissions standards for both LDVs and MDVs in the same rulemaking. [EPA-HQ-OAR-2022-0829-0638, p. 28]

Enabling Cleaner Service Calls Through Bucket Truck Technology

Xcel is also taking immediate action on other high-impact emission reduction opportunities, using technologies such as electric power take-off, idle mitigation, and solar systems to power jobsite tools. [EPA-HQ-OAR-2022-0829-0638, pp. 60-61]

- Electric power take-off (ePTO) - An ePTO system is a device that uses battery power. It’s similar to an EV, but instead of moving the vehicle down the road, it powers equipment and tools to avoid engine idling at the job site. These devices are recharged by plugging into the same chargers that EVs use. [EPA-HQ-OAR-2022-0829-0638, pp. 60-61]

- Idle mitigation - An idling truck can consume 1.5 gallons of gas each hour. Idle mitigation on Xcel Energy’s utility bucket trucks works by automatically shutting down the gas-powered engine when the vehicle is not in use or when the engine is idling for too long. This helps to reduce emissions and conserve fuel. [EPA-HQ-OAR-2022-0829-0638, pp. 60-61]

Fleet Electrification Solutions for Customers

Xcel Energy’s experience and expertise with fleet electrification doesn’t stop with their own fleet. They have developed a mix of customer programs across service areas to support fleet electrification for businesses and communities. These customer-centric solutions enable sophisticated planning, lower upfront costs with various rebates and incentives, and minimize impacts to the grid. [EPA-HQ-OAR-2022-0829-0638, p. 61]

Xcel's approach for commercial EV fleet development includes:

- Advisory services: Xcel offers a "white-glove service" to meet customers where they are on their electrification journey by guiding them through customized planning for their infrastructure needs. For fleet operators, this includes a free assessment to help them determine the best path to electrify their fleet and advise them on future electric fleet considerations such as charging best practices. [EPA-HQ-OAR-2022-0829-0638, p. 61]

- Infrastructure installation: Xcel designs and builds EV supply infrastructure to support charging station installations at minimal to no cost to customers. [EPA-HQ-OAR-2022-0829-0638, p. 61]

- Equipment recommendations and rental options: Xcel also provides recommendations for charging equipment and offers customers the option to purchase their own qualifying vehicle chargers or rent them at a monthly fee that includes installation and maintenance. [EPA-HQ-OAR-2022-0829-0638, p. 61]

- Grid continuity: Xcel designs long-term clean energy resource and distribution plans to consider the future impact of new EV load to ensure ongoing grid stability, reliability and affordability. [EPA-HQ-OAR-2022-0829-0638, p. 61]

- Equitable opportunities: Xcel supports EV adoption in higher emissions communities and income-qualified neighborhoods through rebates and incentives. This includes facilitating the electrification of carshare, refuse trucks, school buses, paratransit vehicles, and other fleets operating in these disproportionately impacted communities. [EPA-HQ-OAR-2022-0829-0638, p. 61]

Fleet electrification is a key component of Xcel Energy's larger vision, which includes enabling zero-carbon transportation by 2050 across our eight-state service footprint. This long-term strategy balances affordability with sustainability across the entire grid. It's why Xcel is dedicated to assisting fleet managers across the ecosystem in providing fleet electrification solutions that empower and inspire a clean energy future while also leading by example. [EPA-HQ-OAR-2022-0829-0638, p. 61]

EPA Summary and Response

Summary:

EPA appreciates all the comments received regarding ancillary topics for the proposed rulemaking. By the nature of this section, EPA is summarizing and responding to topics which are related to the proposal and not captured in the other topic specific sections. It also means that the breadth of the comments summarized in this section is wide and somewhat disparate in nature.

Comment:

EPA received comments from the Alliance for Consumers (AFC), Charles Gordon, Kari Ostlie, POET, LLC, and the American Fuel and Petrochemical Manufacturers (AFPM) regarding the length of the comment period.

Response:

Regarding the length of the comment period for EPA's proposal, the proposal was announced on April 12, 2023, and the pre-publication version of the notice of proposed rulemaking was posted to the EPA's website on that same day. The notice was published in the Federal Register on May 5, 2023, and the public comment period was open until July 5, 2023. In addition to the written public comment period, the EPA offered a multi-day virtual public hearing for the public to provide oral comments to the Agency on the proposed rule in May 2023. The EPA considers this a fully adequate amount of time for commenters to provide comments to the Agency regarding the proposed standards for MY 2027 through MY2032 light and medium duty vehicles, and we note that EPA received more than 250,000 public comments on the proposed rulemaking. EPA also considered comments received after the close of the comment period to the extent practicable.

Comment:

The Arizona State Legislature commented that EPA had indicated that it intended to rely on two updated reports for the final rule, following external peer review, a new vehicle tear down study and updated estimates for the social cost of greenhouse gases (SC-GHG) and that EPA should reopen the public comment period to allow commenters the opportunity to comment on the final versions.

Response:

EPA did indicate in the proposal that it was in the process of obtaining updated information on these topics. As part of our efforts to ensure that we use the most accurate, up to date information we often have to update our information in the course of the rulemaking. This information simply expands on the information we included in the docket. We were transparent both in our intention to use updated information and in docketing the vehicle tear down study in Fall, 2023. Moreover, we present benefit-cost analyses for the rule using the same SC-GHG estimates as we used at proposal and, as discussed elsewhere, because of the limited role benefit-cost analysis plays in adoption of the standards (i.e., it is not used for identifying the standards, but rather a positive net benefit is used to confirm the reasonableness of the selection of the standards under section 202), we believe it was reasonable to present benefit-cost figures using both sets of estimates and we do not believe any commenter was prejudiced by our decision not to reopen the comment period to allow further comment.

Comment:

ICCT, Northeast States for Coordinated Air Use Management (NESCAUM) and the Ozone Transport Commission (OTC), EDF, Tesla, and the Institute for Policy Integrity at New York City School of Law, the Environmental Defense Fund all pointed towards policies and regulations made at the state and international level that support EPA's proposal. Commenters expressed that state and international policies support both the feasibility of the proposed standards but also could be used by EPA as the basis for regulations. Our Children's Trust (OCT) and Zero Emission Transportation Association (ZETA) commented similarly and with the former commenting that there was no reason for EPA not to adopt the CARB ACC II program and ZETA recommending that EPA initiate a new rulemaking for MY's 2033 to 2035. On the other hand, commenters such as Jaguar Land Rover and the Western Energy Alliance recommended that EPA not adopt standards that resulted in BEV penetrations beyond those adopted by CARB or commented that EPA was wrong to point to international regulations to support our feasibility analysis. The California Attorney General's office also took the opportunity to note various fleet purchase requirements and incentives.

Response:

EPA appreciates the comments regarding ways to address state and regulatory programs in the final rule. While references to state and international programs are certainly helpful in informing the public of similar efforts to reduce vehicle emissions, EPA has not based the final standards on state and international programs. We only note that EPA's final rule, while not based on state and international programs, is similarly attempting to address emissions from light- and medium-duty vehicles and, as noted in EDF's comments, such programs help to support our feasibility conclusions.

Comment:

EPA received comments from the American Council for Energy-Efficiency (ACEEE) and Consumer Reports that vehicle labeling should be improved, both for BEVs and MDVs. ACEEE, ICCT and CARB specifically commented on the need for a consumer label for MDVs, while the Manufacturers of Emission Controls Association (MECA) and CARB both commented on the need for improved labeling in general. In addition to labeling, CARB commented on the need for standard serviceability requirements, standard DC fast charging, and standardized charging inlets. CARB also suggested that EPA collect and report additional data for BEVs in cold weather operation. Consumer Reports added recommendations regarding improved range estimates, alternative metrics other than miles per gallon, providing battery size information and for EPA to develop standards for battery charging speed metrics.

Response:

EPA appreciates the comments received regarding labeling, serviceability, and charging. While EPA recognizes the importance of each of these provisions, however, we did not propose changes or other reopen any provisions regarding the MDV or BEV labeling, serviceability, and charging, issues raised by the commenters. Therefore these topics are out of scope for this FRM.

Comment:

EPA received comments regarding a mid-rulemaking check-in and/or tying the standards to the development of infrastructure from the Alliance for Vehicle Efficiency (AVE), the American Petroleum Institute (API), Chevron, and Stellantis. API and Stellantis both suggested that the final rule includes provisions for adjustments with API also recommending that we base the standards on life-cycle analysis (LCA). AVE also noted that due to political uncertainty, suppliers were lacking in assurance. Hyundai commented in a related fashion and recommended that a Federal Advisory Committee should be convened to help assess key enablers.

Response:

EPA appreciates comments received regarding a midterm evaluation and tying standards to infrastructure development, with potential provisions for standard adjustments. EPA is not finalizing a midterm evaluation or provisions for monitoring infrastructure development. The Administrator has the authority to initiate a new rulemaking if he or she finds that there is an appropriate need to do so without establishing midterm evaluation provisions. Note that similar comments are addressed in RTC section 3.4. Additional detail on the request for tying standards to infrastructure can be found in RTC section 17. Comments on LCA are addressed in RTC 19.2.

Regarding AVE's comment on political uncertainty, EPA has closely engaged with stakeholders in formulating this rulemaking, consistent with AVE's comment. AVE claims there is opposition to EPA's "recent rulemakings in Congress." EPA addresses this topic in RTC 2.

Comment:

EPA received several comments regarding the Highway Trust Fund and the potential changes to fuel revenues that support road maintenance and construction. Commenters included American Highway Users Alliance, a mass comment campaign, and citizens Ray Littlefield IV and Steven G. Bradbury. Mr. Bradbury also used the opportunity to note potential increases in costs for first responder training that might be required for emergencies involving electric vehicles. Commenters had pointed out that EPA had failed to consider these costs.

Response:

Please see Section 8.3 regarding comments on fuel revenue changes. Regarding comments that training costs for first responders may increase, we first note that even in the absence of this rule, PEVs are being purchased at used at increasing rates. With respect to the costs of training first responders, we note that this is out of scope for this rule.

Comment:

EPA also received several comments on a broad range of topics. The American Chemical Council Product Approval Protocol Task Group recommended that EPA consider the benefits of improved lubricants. CALSTART encouraged EPA to "lock in" a rapid transition to zero carbon transportation while sending a clear signal to the market. Denso Corporation provided a list of technologies which could be applied to improve EV efficiency while Elders Climate Action encouraged EPA to initiate a zero-emission rulemaking. The Electric Drive Transportation Association (EDTA) recommended an all-government approach to for EPA's FRM. Environmental and Public Health Organizations took the opportunity to recommend improvements to enforcement of emission standards and improvements for in-use testing. General Motors encouraged the agency to maintain a strong dialogue between stakeholders and EPA. The Zero Emissions Transportation Association (ZETA) recommended that EPA consider electric bucket trucks.

Response:

EPA appreciates all the comments received on these topics. EPA has considered a broad array of technologies in its technical assessment for this FRM. Technologies, such as improved lubricants, are part of our ALPHA simulation, and while electric bucket trucks are not specifically covered, electrification is certainly well captured in our analysis for the light- and medium-duty vehicle sectors. EPA appreciates the comments which support this rulemaking as a clear signal to the market. At this time EPA is not able to respond to the nature of future rulemakings for the light and medium duty vehicle sector.

Comment:

Several fuel interests also provided comments related to a variety of topics. Valero commented on that EPA had not considered what impact a reduction in refining may have on other products that depend on refined petroleum. Valero also noted the potential reduction in the availability of sulphur as the result of reduced petroleum refining. The Missouri Corn Growers Association (MCGA) commented that the proposed rule was discriminatory against farmers that depend on ICE-based powertrains and that the agency had not considered the negative impacts on farmers. The National Corn Growers Association recommended that EPA update the F-Factor, used for flex fuel vehicle compliance, to 0.2 and to re-establish the 0.15 divisor for fuel economy calculations. Natural Gas Vehicles of America provided a variety of suggestions regarding natural gas incentives and distribution.

<u>Response:</u>

EPA appreciates the comments received regarding these topics. Regarding Valero's comment that EPA has erroneously failed to consider the alleged broader impacts of petroleum refining on sulphur, asphalt, and other more than 6,000 other products, we disagree. As we discuss in RTC 2, given the global nature of today's supply chain, any significant action, whether by the government or industry, may have indirect impacts on other entities. EPA acknowledges that the petroleum industry, along with the motor vehicle industry and numerous other industries, is a significant part of the global supply chain. This does not mean, however, that prior to issuing any regulation that potentially and indirectly affects the petroleum sector, EPA must evaluate the impacts on 6,000 different products. As we explain in preamble III.B and RTC 2, CAA section 202(a) directs EPA to promulgate emission standards based on the statutory criteria, including the costs of compliance on regulated entities. While EPA may consider other factors, the agency is certainly not obligated to evaluate economic impacts on 6,000 different products, particularly where the commenter has failed to adduce with reasonable specificity what are the actual impacts of the regulation on those products.

Moreover, the commenter's concern appears highly exaggerated. While the final rule is estimated to reduce demand for refined petroleum products in the US, much of that reduction is associated with reductions in US net oil imports, that is reductions in oil imports from foreign countries or increases in exports of US oil. Further, as Valero itself notes, refineries produce many different kinds of products, including gasoline, diesel fuel, aviation fuels, and other products, that are used by many sectors of the economy, further mitigating the possible refinery impacts associated with the rule. We further discuss the uncertainty surrounding how changes in domestic demand for liquid fuel may or may not impact domestic refining of liquid fuel in RIA 8 and preamble VI.

Further, even assuming impacts on domestic refining, it is entirely unclear there will be any impact on availability of the 6,000 products alleged by Valero. For example, while Valero claims the rule will adversely impact the amount of sulphur available in the US, it provides no data or analysis to show that this is likely to happen. As Valero itself acknowledges, there are multiple methods to produce sulphur, including methods that are unrelated to petroleum refining, for example the refining of natural gas.

Regarding standards discriminating against farmers, EPA is establishing performance-based standards for both GHG and criteria pollutant emissions. EPA expects that ICE-based powertrain equipped vehicles will remain available throughout the timeframe of this rulemaking. EPA did not propose any changes to the F-factor or the fuel economy calculation, as it relates to the use of E85, and flex fuel vehicles, therefore changes to the F-factor and 0.15 divisor are out of scope. EPA is not finalizing any revised provisions regarding natural gas vehicles, and the commenters requests regarding natural gas incentives and distribution are beyond the scope of the rulemaking.

Comment:

Stellantis recommended that EPA conduct an industry training event after the rulemaking is finalized.

Response:

EPA appreciates this suggestion. We agree that an industry training event may be valuable in ensuring the regulated industry understands the scope and details of the regulations, and will consider establishing such an event.

Comment:

The Motor and Equipment Manufacturers Association commented on the need for immigration reform to address skilled worker availability.

Response:

This comment is out of scope for this vehicle emission regulation, though we note that issues concerning the labor work force are further addressed in RTC Section 20.

Comment:

John Graham commented on the future of HEVs in EPA regulations.

Response:

HEVs are in no way restricted under this rulemaking. Under EPA's performance-based GHG standards, manufacturers are free to build HEVs as part of their compliance strategy.

28 - Out of scope

Comments by Organizations

Organization: A. Longo

Thank you for considering my detailed comments on this matter of great importance. By adopting a balanced and evidence-based approach, I believe we can develop effective regulations that address environmental concerns without unduly burdening the transportation sector and jeopardizing economic stability. Further, I recommend the EPA evaluate incentive-based programs, which accelerate the adoption of technology and serve to lower the cost of implementing such technology providing greater benefits in the achievement of improvements to air quality versus the imposition of regulations that mandate arbitrary timelines and force increased manufacturing cost, which can cascade into most areas of the economy. A great example of this would be the use of tax credits in the industry. The brownfield redevelopment tax credit program and the alternate fuel vehicle rebates and incentives programs are examples of successful implementations. The Alternate Motor Fuels Act (AMFA) or 1988 successfully promoted the use of ethanol and natural gas, a similar stimulus to the industry could serve to accelerate electronic vehicle production targeting the light to medium-duty vehicle segments. The EPA should invest more in industry-wide tax credit programs incenting both manufacturers and consumers to achieve the desired outcome of cleaner air quality. [EPA-HQ-OAR-2022-0829-0517, p. 2]

Organization: Alex Stavis

[*From Hearing Testimony, May 9, 2023*] I employ you good people to do whatever is needed to meet the climate change requirements that have been met by international and national requirements. As the President just said we are the leader and must set the best example possible for which we have the tools to do, be it with a cash for clunkers buy back program, be it with education, be it with sanctioning, be it with more electric vehicles made in a clean way and disposed of when finished in a clean way and in a way that the public will buy into, i.e., getting the public to say yes, this is what I want, not only do I want it, I can afford it. It is up to all of us, the government setting the standards, the EPA setting the standards to do such. [From Hearing Testimony, EPA-HQ-OAR-2022-0829-5115, Day 1]

Organization: American Fuel & Petrochemical Manufacturers

Finally, EPA also ignored the advances being made in carbon capture and sequestration (CCS) as an alternative means of reducing GHG emissions. While EPA touts available incentives for ZEVs in federal legislation, it overlooks federal incentives and private sector support for CCS technology. Many AFPM members are investing heavily in CCS technology to reduce their GHG emissions.192 This promising technology has the potential to decrease emissions. EPA arbitrarily ignored the promise of this technology. [EPA-HQ-OAR-2022-0829-0733, pp. 41-42]

192 AFPM members ExxonMobil, Chevron, Valero, and INEOS have been at the forefront of CCS. ExxonMobil invested in CCS for more than 30 years and maintains an equity stake in roughly one-fifth of all carbon capture projects worldwide. These projects "captured approximately 40 percent of all the captured anthropogenic carbon dioxide (CO2) in the world." Exxon's current carbon capture capacity of about nine million metric tons annually is the equivalent of planting 150 million trees every year.

Organization: Brian Russo

[*From Hearing Testimony, May 10, 2023*] I want to speak a little bit about vehicle manufacturers. The first vehicle was made to runoff of peanut oil. Ford made a vehicle that ran off of hemp biofuel and was made with hemp body panels. So at some point we started burning fossil fuels and became dependent on fossil fuels and seems it's by design because vehicles could have been made to be powered by alternatives. You may be familiar with some of the alternative lower emission fuels. Some states are using biofuels to mix with our gasoline for the purposes of lowering emissions and they have been successful. Diesel vehicles can be powered with hemp biofuel -- bio diesel without any modifications so I can't help but wonder if it would be easier to power these vehicles with hemp bio diesel rather than replace fleets of vehicles. So I worked in the auto industry for over ten years and I can tell you that vehicle manufacturers have no regard for their waste. During the Obama administration when vehicle manufacturers were required to lower emissions, they introduced composite materials that are not going to be biodegradable or recyclable. When I asked the engineer if there was any consideration for the environmental impact, they say no. I say what's the point. We can no longer be burying batteries or tires in the ground, it's contaminating our soil. I live in the land of Lenape where Ford has contaminated our land and killed many people. They may have paid a small lawsuit but it's nowhere near the destruction they caused to the environment and the death of the Lenape people. So I support strong limits on emissions but I don't think it goes far enough. I think we need to be regulating the vehicle manufacturers as far as the overall environmental impact when it comes to the sourcing of the materials and produce a responsibility when it comes to their waste. They could be making the vehicles with hemp body panels and using -- they could be powered off of biofuel and everything should be recyclable rather than ending up in a junkyard. So I became a climate activist when I realized I would not be able to retire and most likely die from catastrophic climate events. So I am asking the EPA to support a strong emission standard but also take it one step further and protect us from the vehicle manufacturers. [From Hearing Testimony, EPA-HQ-OAR-2022-0829-5115, Day 2]

Organization: California Air Resources Board (CARB) (Part 1 of 5)

Running Loss Standards

Running loss emissions are a type of evaporative emissions that occur when fuel vapors escape from the vehicle during driving. Manufacturers are required to certify vehicles to the running loss standard by driving a vehicle over a prescribed drive cycle on a dynamometer and measuring the resulting evaporative emissions as captured in a sealed enclosure around the vehicle during testing. Under ACC II, California lowered the running loss standard from 0.05 g/mi to 0.01 g/mi. Based on manufacturers' 2021 MY California certification data, 92 percent were certified as already emitting at or below 0.01 g/mi of hydrocarbons. 46 To ensure vehicles continue to perform at those levels and to further reduce emissions from the small proportion of vehicles that are currently certifying at higher emission levels, CARB recommends that U.S. EPA align with CARB by tightening its current running loss standard from 0.05 g/mi down to 0.01 g/mi. [EPA-HQ-OAR-2022-0829-0780, p. 35]

46 CARB. ACC II. Attachment O - Additional Documents or Incorporated Documents Added to the Record, MY2021 Evaporative Running Loss Emission Certification Data. July 2022. This is a spreadsheet of the data which was used to support the proposed new running loss standard of 0.01 g/mi, CARB 2022j. https://ww2.arb.ca.gov/sites/default/files/barcu/regact/2022/accii/atto.pdf.

Certification Data Collection for Improved ZEV Fuel Economy Labels

Based on experience gained to date, CARB has identified several shortcomings in the current fuel economy labels for ZEVs that could be improved to communicate more relevant data to consumers. Internal combustion engine vehicles have a long history with the label and its refinements over the years to present the most meaningful data in a concise format for consumers. For ZEVs in general, and especially for BEVs, however, the current label is insufficient in communicating useful information in an understandable metric to consumers regarding the most important BEV attributes. While modifications to the required label information and format may be out of scope for the current rulemaking proposal, CARB recommends that U.S. EPA include requirements with this proposal to require vehicle manufacturers to disclose additional information that could be used for such an improved label that could be adopted by separate rulemaking in the future. Specifically, CARB recommends that U.S. EPA require that manufacturers report additional test data and vehicle information regarding the vehicle's range and charging time at the time of certification. [EPA-HQ-OAR-2022-0829-0780, p. 46]

Organization: Consumer Reports (CR)

8. EPA Should Improve Consumer Information on the Window Sticker for EVs

If enacted, EPA's GHG rule will help support continued growth in EV sales. To help support consumers as they make the transition to EVs, CR asks that EPA open a separate rulemaking to update the consumer information that is provided on the window sticker for EVs. The EV market has evolved immensely in the years since the window sticker was last revised. Updating the sticker with more relevant information can help improve the EV buying experience. CR would suggest the following improvements to the data that is provided to consumers. [EPA-HQ-OAR-2022-0829-0728, pp. 25-27]

8.1. More Useful EV Range Information

As Car and Driver has recently highlighted, EPA's current testing for EV range does not always match with real world vehicle performance.52 A big portion of the problem is the fact that EPA only publishes a combined city/highway EV range number. However, EVs tend to achieve shorter range at real world highway speeds, which is when range is most often relevant to consumers. Also, range is only estimated under ideal weather conditions, leaving consumers with no information about how their vehicle might perform in hot or cold weather. While a single combined number is generally useful in comparing different vehicles against each other, providing consumers with more information including highway range in both hot and cold weather would be most useful in helping consumers understand the true performance they can expect from their vehicle, and better determine if it will meet their needs. [EPA-HQ-OAR-2022-0829-0728, pp. 25-27]

52 Comparison of On-Road Highway Fuel Economy and All-Electric Range to Label Values: Are the Current Label Procedures Appropriate for Battery Electric Vehicles?, SAE International, April 11, 2023, https://www.sae.org/publications/technical-papers/content/2023-01-0349/.

8.2. Consider Alternatives to Mile Per Gallon Equivalent (MPGe)

While MPGe is somewhat useful in helping consumers understand how EVs compare with gas and hybrid vehicles in terms of efficiency, it’s not a very useful metric for vehicle owners. EPA should reconsider the use of MPGe on the window sticker and explore replacing or supplementing it with a more useful efficiency metric. In general most modern EVs present efficiency in terms of miles per kilowatt hour on their trip odometers, which is more consistent with how consumers are used to thinking about efficiency in terms of miles per gallon. [EPA-HQ-OAR-2022-0829-0728, pp. 25-27]

8.3. Provide EV Battery Size Information

While manufacturers may choose to include battery size information on the window sticker, it is not required. CR would recommend that manufactures provide the usable battery capacity of the vehicle on the window sticker. This also provides useful information for comparison between vehicles. Two separate vehicles might both have the same rated range, but achieve it with wildly different battery sizes. Providing that information to consumers can help them potentially consider more efficient options. [EPA-HQ-OAR-2022-0829-0728, pp. 25-27]

There may also be some value in manufacturers also providing the basic battery chemistry details as well given that certain types of batteries may perform differently under different conditions. This type of information may become even more important as the market explores more diversity in battery chemistries. [EPA-HQ-OAR-2022-0829-0728, pp. 25-27]

8.4. Develop and Present Standard Metrics for Charging Speeds

Charging speed is becoming an increasingly important differentiator in terms of the convenience of driving an EV longer distances. While the range of EVs is still important, it is charging speed that can most affect how convenient longer trips in EVs will be. CR suggests that EPA develop standardized testing and metrics for EVs' DC-fast charging speeds. Currently automakers provide consumers with cherry-picked charging speeds, often based upon narrow slices of the vehicle's charging curve under ideal conditions. [EPA-HQ-OAR-2022-0829-0728, pp. 25-27]

CR would suggest a standardized test for fast charging speed measuring the time to charge from 10% to 80% state of charge. [EPA-HQ-OAR-2022-0829-0728, pp. 25-27]

However, that metric is only part of the story because it doesn't tell how many miles of range are gained over that time. A separate metric should also be included that measures the average numbers of miles of range gained over a set period of time, potentially average miles per 10 minutes of charging or average miles per minute gained from 10%-80% state of charge. This will give consumers a more standardized way to understand how long they will have to spend charging to cover a specific distance using public fast charging. [EPA-HQ-OAR-2022-0829-0728, pp. 25-27]

Level 2 charging speeds can also be important information, but more information should be provided to consumers about the conditions under which the test was performed. At a minimum EPA should require the amperage of the charger needed to achieve the presented level 2 charging times be provided. [EPA-HQ-OAR-2022-0829-0728, pp. 25-27]

Dirt track Racing is a sport that a lot of people love. There is nothing better than going to the dirt track on a saturday night in the summer. Racing is in the blood of a lot of people and you can't take it away. The smell of racing alcohol is amazing; it is not hurting the environment in any way. If you try to take it away there will be a lot of people very angry. Racing is a sport like soccer, football, etc.

Organization: Fuel Freedom Foundation

The EPA's rationale for phasing out FFV credits within the GHG program was to defer to the Renewable Fuel Standard (RFS) for upstream decarbonization.5 While the GHG requirements under the RFS have indeed driven down lifecycle carbon intensity of ethanol to between 44 and 52% of the gasoline it replaces according to the GREET model and recent independent research, the RFS program does not extend to incentivizing the vehicles that enable greater displacement of petroleum fuels with a lower-carbon alternative.6 Consequently, OEM automakers have no incentive to incorporate FFVs within their product plans. Incorporating an FFV credit within the GHG Standards program will amplify the progress in reducing CI upstream by enabling wider use of lower carbon ethanol as a substitute for high-carbon gasoline for the in-use phase. [EPA-HQ-OAR-2022-0829-0711, p. 2]

5 75 FR 25434, "EPA recently finalized its RFS2 rulemaking which life cycle emissions from ethanol and the upstream GHG benefits of E85 use are already captured by this program."

6 Environmental Research Letters, "Carbon intensity of corn ethanol in the United States: state of the science" (2021) accessed at https://iopscience.iop.org/article/10.1088/1748-9326/abde08

Encouraging the production of FFVs will not impede EPA's aggressive goal of rapid light-duty electrification. Instead, promoting the use of lower-carbon liquid fuels will diversify EPA's portfolio of decarbonization strategies to more quickly, broadly, and cost-effectively decarbonize the light-duty transportation sector. [EPA-HQ-OAR-2022-0829-0711, p. 2]

There are multiple public policy rationales for crediting FFVs within the GHG program:

Maximize cost effectiveness of GHG reductions. As GHG reduction targets are strengthened over time to achieve Net Zero carbon emissions in transportation, economic costs will inevitably increase. However, the total economic burden can be lessened, and the social benefits maximized, by keeping the door open to the most cost-effective fuel pathways. Fuel Freedom funded a study by Lifecycle Associates to evaluate possible scenarios for achieving an 80% fuel cycle reduction in light-duty vehicle GHG emissions for the U.S. and for California by 2050.7 The analysis used government estimates8 of fuel carbon intensity, vehicle efficiency improvements, and incremental costs for each fuel-vehicle combination, to develop feasible market penetrations for various pathways, including high-octane fuels with high-compression-ratio ICEs coupled with electrification, biofuels used in ICEs with and without hybridization, hybrid and plug-in hybrid vehicles, fuel cell EVs, and battery electric vehicles, to compare both feasibility and relative cost effectiveness for carbon reductions.9 Long-term results to 2050 show that it is critical to provide market flexibility for both electrification and liquid pathways in the near term to promote long-term feasibility and cost-effectiveness of GHG reductions. Regulations should therefore encourage and/or facilitate all feasible vehicle-fuel pathways that can 1.) immediately reduce carbon intensity in the transportation sector and, 2.) maximize long-term GHG reductions by transitioning to renewable sources, including electricity, hydrogen, and increasingly lower-carbon and advanced biofuels. [EPA-HQ-OAR-2022-0829-0711, pp. 2-3]

7 Life Cycle Associates, "Assessing Greenhouse Gas Emission and Petroleum Reduction Scenarios for the U.S. and California Transportation Sectors Final Report" (March 2019) – Submitted in conjunction with previous comments at Docket EPA–HQ– OAR–2021–0208

8 EIA Annual Energy Outlook 2016; Argonne National Laboratory (ANL), Greenhouse Gasses, Regulated Emissions and Energy Use in Transportation (GREET) Model, VISION2015, and Cradle-to-Grave Lifecycle Analysis of U.S. Light Duty Vehicle Fuel Pathways (2016);); National Academies of Science Transitions report (2013); EPA-NHTSA Draft Technical Assessment Report, EPA Fuel Economy Guide; CARB VISION2.1 and CA-GREET2 models

9 Each pathway centered on a dominant vehicle technology, constrained by practical limitations and the attributes of cars versus trucks or SUVs. Vehicles not suitable for battery electric propulsion were assumed to be ICEs.

Realize GHG reductions sooner rather than later. Given the urgency to forestall the increasing effects of climate change, the EPA should not foreclose pathways that can immediately reduce GHG emissions. With a signal from EPA that FFVs will be recognized for their decarbonization value, higher blends of low-carbon ethanol can be made quickly available in the marketplace to immediately displace higher-carbon gasoline. Today, more than 20 million FFVs are already on the road, compared to 3.8 million plug-in EVs. FFVs are a mature vehicle technology that can quickly be reintegrated into OEM offerings at virtual price parity to existing internal combustion engine (ICE) vehicles. E85 also has widely available distribution and dispensing infrastructure to deliver the fuel to retailers and consumers. Another key finding of the Lifecycle Associates analysis is that policies accelerating a decrease in the carbon intensity of fuels reduce total GHGs sooner. As EPA has noted, "future [GHG] emissions are expected to produce larger incremental damages as physical and economic systems become more stressed in response to greater climatic change."10 Given the uncertainties in measuring the long-term impacts of GHG emissions,11 and the accumulated impacts of carbon emissions,12 EPA should not discount the benefits of pathways with significant promise to reduce emissions more quickly in the near-term. Organization: Growth Energy

One way to recognize the GHG benefits of biofuels would be to reinstate the Vehicle Conversion Factor ("VCF") for FFVs. Through 2015, EPA used the following formula through which the carbon emissions of FFVs were multiplied by the VCF to reflect the lifecycle greenhouse gas benefits of ethanol use. The formula, which was phrased in terms of Carbon Related Exhaust Emissions ("CREE"), was:

CREE = (F x CREEE85 x VCF) + ((1 −F) x CREEgas)

[EPA-HQ-OAR-2022-0829-0580, p. 11]

40 CFR 600.510-12(j)(2)(iv)(B). Through model year 2015, the VCF was established at .15. This is appropriate given that the tailpipe emissions from the ethanol portion of E85 (nominally 85% of the fuel) can be considered to net out with the carbon sequestered by the corn used to produce the ethanol. As noted above, RFS calculations have assumed no tailpipe GHG emissions for ethanol when calculating lifecycle emissions for that reason. EPA should therefore use a VCF of .15 (based on the Congressional level set under the CAFE standards) or such other level as EPA considers reflects the lifecycle greenhouse gas benefits of ethanol. [EPA-HQ-OAR-2022-0829-0580, p. 11]

Reinstating VCF for FFVs would be only one potential step. EPA should ensure that it accounts for the GHG emissions reductions of all biofuels, including those used in lower blends like E10, E15, and E30. The best way to do that would be to conduct a lifecycle analysis for EVs and a lifecycle analysis for ICE vehicles that examines the impact of different blends of biofuels, including projecting an increase in biofuel blending in future years. [EPA-HQ-OAR-2022-0829-0580, p. 11]

VI. EPA Should Establish or Expand Credits for Biofuels and Should Consider Other Measures to Encourage Greater Biofuel Use.

A. Credits and Other Measures Under Section 202

Simply addressing EPA's errors regarding the lifecycle emissions of biofuels and EVs will not sufficiently drive biofuel use in a manner consistent with Section 202 and the RFS. EPA should also establish credits that specifically reward auto manufacturers for taking measures to incentivize increased biofuel use. [EPA-HQ-OAR-2022-0829-0580, pp. 15-16]

EPA clearly has authority to issue such credits under Section 202. It has for years issued credits for various measures that reduce emissions that are not reflected in tailpipe emissions, including credits for efficient air conditioning and off-cycle credits. 88 Fed. Reg. at 29,246. [EPA-HQ-OAR-2022-0829-0580, pp. 15-16]

The simplest type of credits to incentivize biofuels are those that allow greater biofuel use in vehicles, such as flex-fuel vehicles ("FFVs") that can use E85 and higher blends of ethanol. EPA, along with the National Highway Traffic Safety Administration ("NHTSA"), has already established credits both under CAFE and Section 202 that provide an incentive for E85 use. 77 Fed. Reg. at 62,829. Those credits were initially awarded to FFVs regardless of the fuel they actually used, but were later adjusted to account for the amount of fuel actually used. In its 2012 rulemaking for MY 2017 and later years, EPA explained that: [EPA-HQ-OAR-2022-0829-0580, pp. 15-16]

In the final rulemaking for MYs 2012-2016, EPA promulgated regulations for MYs 2012-2015 ethanol FFVs that provide significant GHG emissions incentives equivalent to the long-standing "CAFE credits" for ethanol FFVs under EPCA, since many manufacturers had relied on the availability of these credits in developing their compliance strategies. Beginning in MY 2016, EPA ended the GHG emissions compliance incentives and adopted a methodology based on demonstrated vehicle emissions performance. This methodology established a default value where ethanol FFVs are assumed to be operated 100 percent of the time on gasoline, but allows manufacturers to use a relative E85 and gasoline vehicle emissions performance weighting based either on national average E85 and gasoline sales data, or manufacturer-specific data showing the percentage of miles that are driven on E85 vis-[a]-vis gasoline for that manufacturer's ethanol FFVs. [EPA-HQ-OAR-2022-0829-0580, pp. 15-16]

EPA should, at a minimum, extend and expand upon existing credits for FFVs. Existing credits are limited in several ways—they do not provide an incentive for other technologies that facilitate biofuel use in vehicles, they do not incentivize investments in blending infrastructure or other non-vehicle equipment for biofuel use, and they do not incentivize greater use of biofuels in standard, non-FFV engines. EPA therefore should also develop additional credits that can further reduce GHG emissions by incentivizing greater biofuel use. To begin with, EPA could expand credits to include technologies that facilitate different biofuel blends, like E30, and investments that help facilitate fueling of vehicles with higher blends. [EPA-HQ-OAR-2022-0829-0580, pp. 15-16]

An even better system of credits would be to provide credits based on overall biofuel use in the manufacturer's fleet, regardless of whether the manufacturer manufactures FFVs or any specific technology. That type of credit would give manufacturers incentives to increase biofuel use in their fleet in any way possible—everything from making more FFVs, to making it easier for non-FFVs to run on higher blends, to facilitating investments in fueling with higher blends. [EPA-HQ-OAR-2022-0829-0580, pp. 15-16]

Given the discussion of various credit programs in the proposal and past FFV incentive programs, EPA can finalize a credit program based on biofuel use in this rule. But to the extent that EPA believes it would require an additional rulemaking proposal, EPA should propose and finalize such an incentive program as quickly as possible—it need not wait until the end of its currently proposed standards to develop an important additional mechanism for reducing greenhouse gas emissions while continuing to maintain options for multiple types of vehicles in our transportation system. [EPA-HQ-OAR-2022-0829-0580, pp. 15-16]

Tax credits would be the best incentive for this type of program as more people would be more likely to make the switch. In my city, Littleton, Colorado, we have incentives to switch to solar energy for a tax write-off, this made me more likely to switch. This incentive cannot be little either, you are asking people to change their vehicle in for something more expensive, and potentially less suitable. In this link: https://www.littletonco.gov/Business/Incentives-Financing/State-Incentives-Tax-Credits , you can see the incentives and the buzz around them. [EPA-HQ-OAR-2022-0829-0489, p. 2]

Organization: Minnesota Corn Growers Association (MCGA)

LOW CARBON ETHANOL: MOVING TO NET ZERO

The Renewable Fuel Standard (RFS) has already resulted in more 1 billion metric tons of cumulative GHG savings from 2008-2021, exceeding original projections largely due to the reduced carbon intensity of corn ethanol, highlighting the importance of using biofuels like ethanol to enhance the GHG emissions reductions from transportation with the right policies.18 [EPA-HQ-OAR-2022-0829-0612, pp. 7-9]

18 Unnasch, S. & Parida, D., Healy, B. "GHG Emissions Reductions due to the RFS2: A 2022 Update," February 2023; chrome-extension://efaidnbmnnnibpcajpcglclefindmkaj/https://d35t1syewk4d42.cloudfront.net/file/2424/GHG%20Emissions%20Reductions%20due% 20to%20the%20RFS2%20-%20Feb%202023.pdf.

The most recent assessment from the Department of Energy's Argonne National Laboratory concludes corn ethanol's carbon intensity decreased 23 percent from 2005 to 2019 due to increased corn yield, reduced fertilizer intensity and improved ethanol production efficiency, with corn ethanol now between 44 and 52 percent lower in carbon intensity (CI) than the gasoline it replaces.19 Argonne's conclusions are similar to analysis from Environmental Health and Engineering finding ethanol now results in 46 percent fewer GHG emissions compared to gasoline, due to improved corn production, ethanol production efficiencies and land productivity.20 [EPA-HQ-OAR-2022-0829-0612, pp. 7-9]

19 Lee, Uisung & et al. ANL, "Retrospective Analysis of the U.S. Corn Ethanol Industry for 2005–2019: Implications for Greenhouse Gas Emission Reductions," (2021). https://onlinelibrary.wiley.com/doi/10.1002/bbb.2225.

20 Scully, Melissa J., et al, "Carbon intensity of corn ethanol in the United States: state of the science," (2021) Environmental Research Letters 16 043001. https://iopscience.iop.org/article/10.1088/1748-9326/abde08.

Corn-based ethanol can reach net zero emissions with continued on-farm improvements and soil carbon sequestration, along with carbon capture technology and new efficiencies in ethanol production. Corn farmers are proud of our leadership in adopting conservation and best management practices. NCGA's recently released Corn Sustainability Report21 details corn farmers' history of improvements and our commitment to further sustainability achievements by 2030. [EPA-HQ-OAR-2022-0829-0612, pp. 7-9]

21 National Corn Growers Association Corn Sustainability Report: chrome-extension://efaidnbmnnnibpcajpcglclefindmkaj/https://dt176nijwh14e.cloudfront.net/file/392/NCGA%20Sustainability%20Report_final_digital_ 07_29_21.pdf.

Sustainable production means corn farmers today are producing more corn using less land and fewer resources. For example, planted corn acres in 2022, at 88.6 million acres, were less than planted acres in 2007, the year the RFS was expanded, at 93.5 million acres. USDA data also shows the area planted to principal crops in the United States is not expanding overall. Corn production has increased primarily because crop yields have increased from an average of 150 bushels per acre in 2007 to 173 bushels in 2022. With the average yield in 1980 at just 91 bushels per acre, productivity growth is a long-term trend. [EPA-HQ-OAR-2022-0829-0612, pp. 7-9]

Using the expertise of Argonne's scientists and the U.S. Department of Agriculture's data, we believe Argonne's Greenhouse Gases, Regulated Emissions, and Energy Use in Technologies (GREET) model is the federal government's most accurate tool for evaluating biofuel and energy lifecycle emissions. Because GREET is regularly updated, this model captures GHG emissions reductions from farmers' improved production practices and will incorporate the ongoing, voluntary climate-smart improvements in agriculture production this Administration supports, ensuring further carbon intensity reductions are accounted for in the LCA. [EPA-HQ-OAR-2022-0829-0612, pp. 7-9]

Corn production has improved across all measures of resource efficiency, including higher crop yields per acre, resulting in greater corn production using less land and fewer inputs, further fortifying ethanol as a sustainable, low-carbon renewable fuel. This progress is reflected in Argonne's most recent analysis, which builds on and is consistent with other recent reviews. [EPA-HQ-OAR-2022-0829-0612, pp. 7-9]

For example, a 2018 USDA study shows that ethanol then resulted in 39 to 43 percent fewer GHG emissions than gasoline.22 Building on this progress, additional improvements on farms and in ethanol production supported by expanding markets for low carbon fuels could result in ethanol with up to 70 percent fewer GHG emissions than gasoline, according to USDA's analysis. Furthermore, according to California Air Resources Board (CARB) data, the CI of ethanol is more than 40 percent lower than the CI of gasoline.23 [EPA-HQ-OAR-2022-0829-0612, pp. 7-9]

22 Lewandrowski, Jan, and et. al, "The Greenhouse Gas Benefits of Corn Ethanol - Assessing Recent Evidence," (202) Biofuels, 11:3, 361-375. https://www.tandfonline.com/doi/full/10.1080/17597269.2018.1546488.

23 California Air Resources Board, Low Carbon Fuel Standard Reporting Tool Quarterly Summaries, based on data through Q3 2020 at https://ww3.arb.ca.gov/fuels/lcfs/lrtqsummaries.htm.

These increasing benefits have occurred without accounting for corn's ability to sequester carbon in the soil. Corn as a crop can serve as a carbon sink. As a photo-synthetically superior C4 plant, corn has an extraordinary ability to sequester carbon and move fertilizer nutrients back to the surface for plant growth rather than polluting ground water. Corn's extensive, deep root system makes it one of the few plants with this important capability to make crop production sustainable. [EPA-HQ-OAR-2022-0829-0612, pp. 7-9]

High-yield corn—combined with the steady adoption of best practices such as reductions in tillage intensity—is sequestering carbon from the atmosphere into the soil. This sequestration is increasing soil carbon levels and reducing atmospheric CO2. Although GHG lifecycle models do not currently account for this direct GHG reduction from corn production, NCGA believes the effect of corn crops on soil carbon sequestration, among other considerations, should be incorporated into current lifecycle analysis. This increase in soil carbon from corn production, when included, could result in a 20 gram/MJ carbon credit for corn-based ethanol.24 Fully accounting for corn's carbon sequestration would further demonstrate significant low-carbon advantages of a high-octane midlevel ethanol blend. [EPA-HQ-OAR-2022-0829-0612, pp. 7-9]

24 American Coalition for Ethanol, The Case for Properly Valuing the Low Carbon Benefits of Corn Ethanol, 2018.

FLEX FUEL VEHICLES and CREDITING

Beyond ethanol's utility in all gasoline engines to reduce GHG emissions, other alternative vehicle technologies can also harness the GHG reductions and air quality benefits of ethanol, such as Flex Fuel Vehicles (FFVs). FFVs utilizing higher blends of low carbon ethanol, such as E85, can provide immediate emissions reductions without tangibly altering the price of the vehicle and reducing fuel costs. In fact, E85 is typically sold at a substantially lower price than gasoline, translating to monetary savings in addition to the significant air pollution savings. [EPA-HQ-OAR-2022-0829-0612, p. 11]

Compared to gasoline, E85 leads to significant reductions in NOx and GHG emissions. E85 avoids use of toxic hydrocarbon aromatics in gasoline that are precursors to secondary organic aerosols that result in harmful fine particulate matter emissions that cause serious respiratory, cardiovascular, and other health harm, including premature death, according to the American Lung Association. [EPA-HQ-OAR-2022-0829-0612, p. 11]

Incentivized to reduce emissions through the state's Low Carbon Fuel Standard (LCFS), in California some FFVs are even powered by a blend of 15 percent renewable naphtha with 85 percent ethanol. These vehicles use zero fossil fuels, have improved air emissions profiles, and have an extremely low carbon intensity. [EPA-HQ-OAR-2022-0829-0612, p. 11]

Despite the GHG and criteria pollution reduction benefits by use of FFVs, as well as the low cost to purchase and fuel these vehicles, automakers have cut back on FFV models and now offer very few choices to consumers. Well-structured vehicle credit programs remain an impactful, cost-effective means for the government to encourage the introduction and adoption of new products and technologies. To encourage introduction of a wider range of low emission vehicle choices, NCGA believes EPA must provide equitable crediting across the spectrum of low emission vehicles, including FFVs. [EPA-HQ-OAR-2022-0829-0612, p. 11]

NCGA also urges EPA to take steps to update the F-factor in the fuel economy formula to a forward-looking F-factor of at least 0.2, as we outlined in 2020 comments in response to Docket EPA–HQ–OAR–2020-0104. Furthermore, we urge EPA to reinstate the 0.15 volumetric conversion factor for FFVs. EPA should reharmonize the 0.15 factor for FFVs in these standards, and, if not, in future standards. This change would accurately reflect the significant carbon emissions reductions from FFVs using E85 because the carbon emissions from the fuel are the release of carbon taken up through crop growth. [EPA-HQ-OAR-2022-0829-0612, p. 11]

Organization: Natural Gas Vehicles for America

NGVAmerica believes that by its own admission EPA has sought to create an unlevel and anti-competitive advantage for electric vehicles over other technologies including NGVs. Natural gas vehicles involve significant cost due to their low-volume and the cost of the storage vessels and systems. Like electric vehicles, natural gas vehicles when powered by RNG deliver significant greenhouse emission reductions and therefore should have been similarly encouraged. Thus, EPA has every reason to treat natural gas vehicles like electric vehicles when providing regulatory incentives – moreover, since natural gas vehicles have largely not qualified for these incentives, it is reasonable to extend similar size incentives for natural gas technology at least for a short-period of time to allow natural gas trucks to increase in market share. [EPA-HQ-OAR-2022-0829-0597, p. 13]

Thus, in addition to proposing a mechanism for crediting biofuels based on their upstream emissions, EPA must provide equal treatment with respect to any future incentives offered to manufacturers to assist them in overcoming market hurdles, and, moreover, EPA should take corrective action to address the harm that has been done by its past actions. [EPA-HQ-OAR-2022-0829-0597, p. 13]

Developing a Credit Mechanism for Biofuels

For greenhouse gas emissions, NGVAmerica previously requested that EPA use the 0.15 factor for greenhouse gas emissions to give credit to manufacturers for RNG use and to create an efficient method of calculating the benefit of renewable natural gas until EPA moves to adopt a well-to-wheels regulatory approach for all fuels, or until EPA can develop a detailed assessment and emission factor specific to RNG use. A benefit of the 0.15 factor is that it is consistent with the fuel efficiency credits and has been used in the past in EPA's regulations. [EPA-HQ-OAR-2022-0829-0597, pp. 13-14]

Given the recent state of developments and based on the increasing amount of carbon negative RNG that is being used in transportation, a factor of 0.15 may not adequately represent the credit that is warranted for RNG use. A factor of 0.15 would represent an 85 percent reduction and therefore is not carbon neutral or carbon negative. Developing a precise factor based on WTW comparisons of different fuels is complicated for various reasons: moving baseline targets; year-over-year changes in fuel mix; truck lifetimes, etc. That is probably part of the reason that EPA decided to abandon developing factors for electric vehicles and retained the 0 g/mi factor. [EPA-HQ-OAR-2022-0829-0597, pp. 13-14]

One solution might be to adopt a similar approach for NGVs as has been adopted for electric vehicles. Such a concept has been developed and is explained in the attached European Biogas and NGVA Europe documents. NGVA Europe has proposed using a carbon correction factor (CCF) that treats biomethane as having a carbon content of zero, and then providing an emission offset related to the percentage of biomethane distributed in a country. In the example provided in the NGV Europe document, 10 percent displacement with biomethane equates to a CCF discount of 10 percent that is applied to a vehicle's tailpipe emissions of CO2. In the case of the U.S., the CCF for 2022 would be 69 percent if the national average were used or 97 percent if the

California average were used and credits were assigned based on state registration of motor vehicles. [EPA-HQ-OAR-2022-0829-0597, pp. 13-14]

One limitation of this approach is the fact that if RNG levels go up in the future manufacturers selling trucks today would not receive the full benefit of future increases, and thus the credit or CCF used would underrepresent the benefit of their trucks. This could be addressed by periodically revising the levels of RNG use projected to occur during a vehicle's lifetime and using that level of displacement to offset emissions. EPA previously proposed a similar concept for electric vehicles that would have based emissions on future EIA forecasts of renewable electricity. [EPA-HQ-OAR-2022-0829-0597, pp. 13-14]

(1) EPA should amend its greenhouse gas regulations for all types of vehicles including light-, medium-, and heavy-duty motor vehicles and incorporate the well-to-wheel benefits of natural gas and renewable natural gas as part of the engine and vehicle certification regulations; [EPA-HQ-OAR-2022-0829-0597, pp. 14-15]

(2) EPA to the extent it incorporates other technology advancement credits in its vehicle regulations should extend these incentives to natural gas and natural gas hybrid- electric vehicles based on the demonstrated benefits of these vehicles and the need to accelerate the introduction of a diverse mix of cleaner vehicle technologies; [EPA-HQ-OAR-2022-0829-0597, pp. 14-15]

(3) EPA should provide enhanced SmartWay designations for trucks powered by low-NOx engines and fueled by carbon-neutral or even carbon-negative renewable natural gas; [EPA-HQ-OAR-2022-0829-0597, pp. 14-15]

(4) Federal agencies should fund pilot programs and infrastructure development that demonstrate the ways in which natural gas can be used to fuel a variety of different transportation sectors by supporting the purchase of vehicles and equipment at multimodal facilities such as ports and rail facilities; [EPA-HQ-OAR-2022-0829-0597, pp. 14-15]

(5) Federal agencies should ensure that federal funding provided under the CMAQ Program and the DERA Program and other programs enacted as part of the Bipartisan Infrastructure Law and Inflation Reduction Act are competitively awarded for projects that provide the most cost-effective emission reductions and offer increased funding levels for engines and vehicles that are certified to more demanding standards in advance of EPA's adoption of such standards; [EPA-HQ-OAR-2022-0829-0597, pp. 14-15]

(6) Federal agencies should work with state authorities to ensure that transportation policies include performance metrics and consider a variety of different technologies as opposed to only promoting specific technologies regardless of their cost; [EPA-HQ-OAR-2022-0829-0597, pp. 14-15]

(7) The Administration should work with Congress to amend the federal excise tax on new trucks to reduce the impediment to fleets and businesses purchasing cleaner new trucks by either eliminating the tax altogether since it discourages new purchases or amend the tax so that it does not penalize more costly, lower polluting technologies (i.e., eliminate the excise tax on the incremental cost). [EPA-HQ-OAR-2022-0829-0597, pp. 14-15]

Organization: National Association of Clean Air Agencies (NACAA)

NACAA supports … lower[ing] the running loss standard from the current 0.05 gm/mi to the ACC standard of 0.01 gm/mi.

Organization: National Corn Growers Association (NCGA)

NCGA also urges EPA to take steps to update the F-factor in the fuel economy formula to a forward-looking F-factor of at least 0.2, as we outlined in 2020 comments in response to Docket EPA–HQ–OAR–2020-0104. Furthermore, we urge EPA to reinstate the 0.15 volumetric conversion factor for FFVs. EPA should reharmonize the 0.15 factor for FFVs in these standards, and, if not, in future standards. This change would accurately reflect the significant carbon emissions reductions from FFVs using E85 because the carbon emissions from the fuel are the release of carbon taken up through crop growth. [EPA-HQ-OAR-2022-0829-0643, p. 9]

As NCGA recommended to EPA in 2020 comments on Docket EPA–HQ–OAR–2016-0604, actual tailpipe carbon emissions, regardless of the test fuel, must continue to be the only measure of vehicle emissions performance in vehicle testing. CO2 test adjustments would needlessly complicate vehicle test procedures. Relying solely on test results eliminates uncertainty, averaging and potential for inaccuracies in procedures to adjust emission test results for the fuel. [EPA-HQ-OAR-2022-0829-0643, p. 10]

Lower GHG emissions from vehicles benefit consumers, our environment, and our energy security. Just as updating the test fuel from E0 to E10 reduced GHG emissions by blending cleaner, renewable ethanol with gasoline, E15 and future clean, high-octane fuels that blend more ethanol will further reduce emissions and improve fuel economy when used with optimized engines. Vehicle test procedures for Tier 3 fuel, or any future certification fuel, must not create impediments to low carbon fuels such as E15 and higher blends and the vehicle technologies that help reach our mutual goal of lower GHG emissions. Stringency of the standards is best maintained through the Administrator’s authority to adjust the standards, as EPA is using in this proposal, not by adjusting emission test results. [EPA-HQ-OAR-2022-0829-0643, p. 10]

Update the F-factor in the fuel economy formula to a forward-looking F-factor of at least 0.2. [EPA-HQ-OAR-2022-0829-0643, p. 10]

Reinstate the 0.15 volumetric conversion factor for FFVs. [EPA-HQ-OAR-2022-0829-0643, p. 10]

Organization: Pearson Fuels

h. Argonne National Laboratory has studied the lifecycle GHG emissions of ethanol extensively and found an average carbon intensity reduction of 44- 52% compared to gasoline in 2019, and that this represented a 23% carbon intensity reduction between 2005 and 2019 [EPA-HQ-OAR-2022-0829-0577, pp. 13-14]

A study conducted by researchers at the U.S. Department of Energy’s (“DOE”) Argonne National Laboratory (“Argonne”) determined that corn ethanol is reducing its carbon footprint and diminishing greenhouse gases as compared to gasoline. The study analyzed corn ethanol production in the United States from 2005 to 2019, when production more than quadrupled.

Scientists assessed corn ethanol's GHG emission intensity (also referred to as carbon intensity, or CI) during that period and found a 23% reduction in CI.25 The study found that U.S. corn ethanol has 44%–52% lower GHG emissions as compared to conventional gasoline. [EPA-HQ-OAR-2022-0829-0577, pp. 13-14]

25 Kathryn Jandeska, Argonne National Laboratory, "Corn ethanol reduces carbon footprint, greenhouse gases," (May 24, 2021), at https://www.anl.gov/article/corn-ethanol-reduces-carbon-footprint-greenhouse-gases. See also Valerie Sarisky-Reed, Director DOE Bioenergy Technologies Office, "Ethanol vs. Petroleum-Based Fuel Carbon Emissions," (June 23, 2022), at https://www.energy.gov/eere/bioenergy/articles/ethanol-vs-petroleum-based-fuel- carbon-emissions.

The time has come for EPA to revisit this decision based on several recent developments in the international campaign to mitigate climate change [EPA-HQ-OAR-2022-0829-0577, p. 2]:

- the increasing lifecycle GHG reductions that modern U.S. ethanol provides as compared to petroleum-based gasoline that now constitute a sound policy basis for the integration of a GHG emissions factor,

- the significant and rapidly increasing GHG reductions that California has achieved by leveraging its existing FFV fleet to rapidly scale E85 use,

- the potential of advanced feedstocks, carbon capture and sequestration and climate smart agriculture to enable production of carbon neutral ethanol, and,

- the clear need to deploy strategies that can further decarbonize internal combustion engines ("ICE") given the long useful life and expensive costs of vehicles. [EPA-HQ-OAR-2022-0829-0577, p. 2]

With the support of EPA, California has instituted a comprehensive program to decarbonize its economy to achieve 40% GHG reduction below 1990 levels by 2030, and to achieve carbon neutrality by 2045. President Biden has announced similar goals for the nation and has succeeded in passing sweeping laws including the Inflation Reduction Act to begin to achieve these goals. Regarding FFVs, California's Low Carbon Fuel Standard ("LCFS") recognizes the tremendous value of GHG reductions from biofuels as well as reductions achieved by battery electric vehicles ("BEVs"). As a result, E85 use in California FFVs has been growing at an average annual rate of 33% with a usage rate in FFVs of 16% in 2022. California's E85 use in 2022 grew over 65% and exceeded 100 million gallons, as determined by the California Air Resources Board ("CARB"). [EPA-HQ-OAR-2022-0829-0577, p. 2]

In the GHG rulemaking for model years ("MY") 2012-2016, EPA explained its decision to phase down FFV crediting as attributable to the utility of the Renewable Fuel Standard program ("RFS2") as an effective upstream decarbonization policy.3 While RFS2 does recognize the life cycle emissions reductions that ethanol and other low carbon fuels provide, RFS2 does not provide any direct or indirect incentive for automakers to manufacture FFVs. To enable these potential GHG emissions reductions, EPA must reintegrate FFV crediting into the GHG policy framework at a level commensurate with the GHG reductions achieved. Specifically, EPA should establish a GHG emissions factor for E85 utilized in FFVs that is derived from the most recent determination of the carbon intensity of ethanol used in the United States, as determined by Argonne National Laboratory's Greenhouse Gases, Regulated Emissions, and Energy Use in Technologies ("GREET") model. [EPA-HQ-OAR-2022-0829-0577, p. 2]

3 See 75 FR 25434, “EPA recently finalized its RFS2 rulemaking which life cycle emissions from ethanol and the upstream GHG benefits of E85 use are already captured by this program.”

Given the current and future devastating impacts of climate change that EPA foretold in its 2009 Endangerment Finding, U.S. federal policy must immediately leverage the GHG reducing benefits of all viable transportation fuels and technologies including FFVs that can utilize E85. [EPA-HQ-OAR-2022-0829-0577, p. 2]

f. An analysis of the current scale and rate of growth of E85 in California establishes that the use of E85 is a highly effective GHG reduction strategy that could be deployed nation-wide to provide a new and annually expanding source of GHG reductions from ICE vehicles.

Utilizing the Argonne GREET lifecycle analysis of corn starch ethanol, the carbon intensity of ethanol is 45 gCO2e/MJ.16 This compares with a 100.82 gCO2e/MJ carbon intensity for California gasoline blendstock, and a 90 gCO2e/MJ carbon intensity for E10.17 Thus, each gallon of corn starch ethanol utilized in E85 provides approximately 55% GHG reduction compared to California gasoline blendstock. Consistent with California regulations, E85 marketers in California supply at an actual blend rate of 83% ethanol with 17% California gasoline blendstock such that a blended gallon of California E85 from corn starch ethanol has a carbon intensity of 54.9 gCO2e/MJ carbon intensity. [EPA-HQ-OAR-2022-0829-0577, pp. 10-11]

16 Lee, U., Kwon, H., Wu, M., Wang, M., Retrospective analysis of the U.S. corn ethanol industry for 2005-2019: implications for greenhouse gas emission reductions, Biofuels, Bioprod. Bioref. 15:1318–1331 (2021), at 1, available at https://onlinelibrary.wiley.com/doi/epdf/10.1002/bbb.2225.

However, Pearson Fuels does not limit its supply to corn starch ethanol-based E85 blended with gasoline. Instead, Pearson Fuels has pioneered the use of 100% renewable E-85 fuel into the California marketplace as well as sourcing ethanol produced from cellulosic feedstocks. Wherever possible, Pearson replaces the 17% gasoline blendstock for its E85 with renewable naphtha. Thus the only remaining fossil-based product supplied is the de minimus portion of denaturant.18 Some of the renewable naphtha is produced by World Energy in its Paramount, California facility that also produces renewable diesel and sustainable aviation fuel from a variety of feedstocks including rendered animal fat. Pursuant to the California LCFS, World Energy’s renewable naphtha from rendered animal fat fuel pathway is certified at 25.08 gCO2e/MJ.19 Utilizing the Argonne GREET CI score for the corn starch ethanol of 45g gCO2e/MJ and the CARB score of 25 gCO2e/MJ for the renewable naphtha, Pearson Fuels’ E85 provides approximately 60% GHG reduction as compared to California gasoline blendstock. [EPA-HQ-OAR-2022-0829-0577, pp. 10-11]

Pearson Fuels’ E85/ renewable naphtha blend produced with cellulosic ethanol performs even better in terms of GHG reduction. [EPA-HQ-OAR-2022-0829-0577, pp. 10-11]

II. EPA SHOULD TAKE THE OPPORTUNITY IN THIS RULEMAKING TO RECOGNIZE THE TRUE GHG POLICY VALUE OF FFVS BY RESTORING MEANINGFUL GHG CREDITING FOR FFVs

We encourage the Agency to re-affirm the policy value of FFVs and American ethanol production and use by restoring meaningful GHG crediting for the manufacture of FFVs by modifying the methodology for determining GHG crediting for FFVs beginning MY 2027. EPA has authority to better harmonize crediting between the GHG and CAFE standards and thereby expand FFV manufacturing through two alternative means both of which are supported by Pearson Fuels. [EPA-HQ-OAR-2022-0829-0577, p. 16]

a. EPA should re-integrate the methodology that continues to exist in the CAFE program by re-establishing its use of the 0.15 multiplier in the EPA's GHG Standards, or,

b. EPA should establish a new GHG Emissions Factor for the GHG Standards that recognizes the lifecycle emissions reductions of E85 as compared with conventional gasoline.

Crediting based on lifecycle GHG emissions reductions can be accomplished simply by establishing a GHG Emissions Factor that is based on the average GHG emissions reduction provided by ethanol as compared to petroleum gasoline on a lifecycle basis. This GHG Emissions Factor would be subject to adjustment based on a determination by Argonne National Laboratory regarding the average lifecycle emissions of U.S. used as a transportation fuel as compared to the average lifecycle emissions of the U.S. gasoline used as a transportation fuel. [EPA-HQ-OAR-2022-0829-0577, p. 16]

As previously noted, utilizing the Argonne GREET lifecycle analysis of corn starch ethanol, the carbon intensity of ethanol is 45 gCO2e/MJ.33 This compares with a 93 gCO2e/MJ carbon intensity for the U.S. average petroleum gasoline blendstock.34 Thus, utilizing only corn starch ethanol as an example, the CI Reduction Factor would be 0.48. To date, there does not appear to be a comprehensive analysis of the average CI of U.S. ethanol but the Alternative Fuels Data Center states that 94% of ethanol produced in the U.S. is corn ethanol.35 For illustrative purposes, if one were to assume that the other 6% share of U.S. ethanol consisted solely of cellulosic ethanol with a carbon intensity score of 20 gCO2e/MJ, that would reduce the average CI score of U.S. ethanol to 44 gCO2e/MJ. This would reduce the GHG Emissions Factor to 0.47, and will be utilized for illustrative purposes. [EPA-HQ-OAR-2022-0829-0577, pp. 16-17]

Pearson Fuels would request that EPA consider modifying the equation for measuring the CO_2 emissions of FFVs for light-duty GHG program purposes as follows [EPA-HQ-OAR-2022-0829-0577, pp. 16-17]:

CO_2 = (E85 Tailpipe GHG Emissions x F Factor x E85 GHG Emissions Factor) + [Gasoline Tailpipe GHG Emissions x (1- F Factor)]

E85 GHG Emissions Factor (2021) = 0.47 (illustrative based on above parameters) [EPA-HQ-OAR-2022-0829-0577, pp. 16-17]

Organization: Porsche Cars North America (PCNA)

Policy makers and the auto industry must also continue to find wins in other regulatory programs. EPA's recently finalized Renewable Fuel Standard for 2023-2025 regrettably was unable to finalize the innovative and robust proposal for "eRINs". This proposal that was supported by Porsche could have opened the door for continued growth in electricity derived from biogas and used transportation fuel and to further incentivize growth in the electric vehicle market. Porsche appreciates the need for EPA to consider the wide range of input they received on this proposal and will work proactively to support near-term regulatory actions to finalize this valuable, supportive policy. [EPA-HQ-OAR-2022-0829-0637, p. 3]

Organization: Renewable Fuels Association (RFA)

VII. If EPA Maintains its Zero Gram per Mile Incentive for EV Production, the Agency Should Allow for a Similar Incentive for FFV Production

For the reasons described in detail above, RFA objects to the continued use of a 0 g/mile compliance value for EVs for the purposes of calculating fleet averages. However, if EPA ultimately finalizes a permanent incentive of 0 g/mile for EVs, then it must consider applying a similar incentive for other low-carbon vehicle technologies, including FFVs that can operate on E85 and other higher ethanol blends. [EPA-HQ-OAR-2022-0829-0602, pp. 12-13]

EPA's proposed approach for BEVs (i.e., using a value of 0 grams/mile) essentially assumes every BEV produced by automakers will only use zero-carbon renewable electricity over the entire lifespan of the vehicle. In other words, EPA's proposal credits all BEVs for their maximum potential CO_2 benefit, without requiring any evidence that such a benefit is actually achieved. [EPA-HQ-OAR-2022-0829-0602, pp. 12-13]

In order to create an equitable opportunity for biofuels to contribute to the effort to decarbonize light-duty transportation, EPA should institute a CO_2 emissions compliance value that similarly recognizes the potential carbon benefits of light-duty vehicles designed to operate on liquid fuels containing high levels of renewable ethanol. [EPA-HQ-OAR-2022-0829-0602, pp. 12-13]

EPA's final rule should adopt an assumption that FFVs operate on E85 all the time, just as the proposed 0 g/mile value effectively assumes BEVs operate on zero-carbon electricity all the time. Automakers who manufacture FFVs should be allowed to use a CO_2 emissions compliance value that reflects the lifecycle CO_2 savings from using E85. [EPA-HQ-OAR-2022-0829-0602, pp. 12-13]

According to the latest Argonne National Laboratory GREET model results, E85 made with average corn ethanol reduces full lifecycle CO2-equivalent GHG emissions by 31% per mile compared to gasoline.29 This estimate includes hypothetical/potential emissions from direct and indirect land use changes. Accordingly, for the purposes of calculating fleet averages, EPA should allow automakers to use a CO2 compliance value for an FFV that is 31% lower than the compliance value for a corresponding non-FFV model. As an example, if a non-FFV car is determined by the automaker to have a CO2 value of 181 g/mile, the automaker should be allowed to use a compliance value of 125 g/mile for an FFV version of that same car. [EPA-HQ-OAR-2022-0829-0602, pp. 12-13]

29 The GREET2022 model shows that E0 gasoline results in fleet average full lifecycle GHG emissions of 421 g/mile, compared to fleet average emissions of 291 g/mile for the use of E85 in an FFV. Results verified via personal communication between RFA and Longwen Ou of Argonne National Laboratory.

This approach to incentivizing FFVs would be no different than the approach EPA has used historically, and is proposing to continue, for incentivizing EV production. This FFV mechanism would create a more level playing field for low-carbon liquid fuels and would provide a meaningful incentive for automakers to manufacture FFVs in addition to BEVs. Increased production of FFVs would unlock increased use of lower-carbon liquid fuel blends containing higher levels of ethanol, such as E85 and E30. [EPA-HQ-OAR-2022-0829-0602, pp. 12-13]

Alternatively, EPA could allow auto manufacturers to use the same 0 g/mile compliance value for ethanol's portion of FFV operation, given that the ethanol-related "tailpipe" CO2 emissions from an FFV are biogenic in nature and fully offset by atmospheric CO2 removal by the biomass feedstock at the beginning of the lifecycle. That is, if EPA remains committed to focusing only on tailpipe emissions (and ignoring upstream fuel production and supply chain emissions), then biofuels like ethanol should be treated as "zero emissions" fuels because CO2 emissions from the vehicle are fully offset by CO2 uptake by the feedstock. [EPA-HQ-OAR-2022-0829-0602, pp. 12-13]

Organization: Sandra Thomas

I applaud the new regulations on EV cars and trucks. However one essential thing is missing for me. As a middle class person with low income I have no use for a $7500 tax credit – or any tax credit. In order to owe that much in taxes a person has to be very wealthy, which excludes most residents of the United States. Seven year ago when I paid off my current car, I continued saving the payment amount and now I have enough saved to buy one of the cheaper EV's with cash – but I will get no tax credit deduction if I do. So I am not buying an EV although I would VERY much like to help our planet survive.

I hope that you would re-consider a refundable tax credit – or purchase credit, so that this benefit extends to the average American. We want to do our part for the climate along side the rifh, but the current policy makes that impossible. Please respond. [EPA-HQ-OAR-2022-0829-5088]

Organization: South Coast Air Quality Management District

3. Set a minimum range for ZEVs. ACC II requires a minimum certification range of 200 miles for zero emission vehicles. This is to ensure that new ZEVs will provide useful EV miles

to meet the everyday needs of consumers, which will lead to higher acceptance and uses, and greater reductions of emissions from on-road vehicles. This range is also easily achievable with technologies that are currently available. We concur with the need for a minimum range requirement and recommend a similar range limit for the proposed rule. Setting a 200-mile range minimum threshold will prevent manufacturers from producing ZEVs with limited ranges simply for the sake of compliance with State and federal regulations, including the Corporate Average Fuel Economy (CAFÉ) standards. [EPA-HQ-OAR-2022-0829-0659, p. 3]

Organization: Toyota Motor North America, Inc.

Therefore, it is disappointing that EPA removed the e-RIN proposal from the RFS set rule as it is one of the few measures for which EPA has direct authority to provide at least some level of assistance in supporting the EV shares required in the GHG proposal. After a muti-year collaboration with the auto industry, a valuable policy tool for establishing PEV markets and promoting clean energy has been lost. [EPA-HQ-OAR-2022-0829-0620, pp. 25-26]

Organization: Volvo Car Corporation (VCC)

Many uncertainties remain that are critical to implementing the proposal. The impact of the new separate Department of Energy proposal on the methodology for determining energy consumption of an EV is pending. This creates uncertainty about the number of EVs that VCC would need to sell prior to 2030. [EPA-HQ-OAR-2022-0829-0624, p. 2]

Organization: Wisconsin Automobile and Truck Dealers Association

The EPA predicts unprecedented increases in non-hydro renewable energies. This is identified as primarily wind and solar. Northern Wisconsin has vast expanses of trees and forests making the non-hydro renewable energies debate the benefits of trees and forests versus the benefits wind and solar. [EPA-HQ-OAR-2022-0829-0494, p. 2]

EPA Summary and Response

Summary:

Commenters described various concerns and suggestions which were on topics that EPA did not specifically propose or seek comment on in the light-duty and medium-duty vehicle proposal.

Response:

Comments describing additional incentives, other programs, and other considerations are unrelated to anything we proposed or analyzed in developing the proposed rule, and we have determined they are outside the scope of the rule.

28.1 - Directed to the heavy-duty Phase 3 proposal

Comments by Organizations

Organization: Ceres Corporate Electric Vehicle Alliance (CEVA)

- Heavy-duty vehicle phase 3 GHG emissions standards that are at least as strong as those proposed, but ideally are stronger to ensure at least 50% zero-emissions vehicle (ZEV) sales across all market segments by 2032. California's Advanced Clean Trucks (ACT) rule,4 manufacturer commitments,5 and the Inflation Reduction Act (IRA) funding are all consistent with such a goal.6 [EPA-HQ-OAR-2022-0829-0511, p. 1]

5 https://theicct.org/wp-content/uploads/2023/04/hdv-phase3-ghg-standards-benefits-apr23.pdf

6 https://theicct.org/wp-content/uploads/2023/01/ira-impact-evs-us-jan23-2.pdf

Heavy-Duty Vehicle Standards:

Similarly, strong heavy-duty vehicle standards that lead to 50% ZEV sales across all market segments by 2032 will drive the electrification of the heavy-duty sector by building on the momentum created by state regulations, manufacturers' commitments, and IRA and Infrastructure Investment and Jobs Act funding. Taken together (in concert with modal shifts) these actions will spur rapid decarbonization of the sector and ensure a diverse supply of ZEVs that meets the needs of commercial fleets and carriers.8 [EPA-HQ-OAR-2022-0829-0511, p. 2]

8 https://www.atlasevhub.com/data_story/210-billion-of-announced-investments-in-electric-vehicle-manufacturing-headed-for-the-u-s/#:~:text=Vehicle%20manufacturers%20and%20battery%20makers,than%20in%20any%20other%20country.

While medium- and heavy-duty trucks represent only 5% of vehicles on the road, their GHG emissions represent 23% of the transportation sector's carbon footprint, which grew 75% over the last three decades.9 They are also largely responsible for the harmful pollutant emissions that disproportionally impact historically low-income and BIPOC communities located near fleet depots, major transportation corridors, distribution centers, and ports.10
In fact, the American Lung Association found that one in three Americans live in places with unhealthy air pollution, largely due to transportation sector emissions. As such, vehicle emissions standards serve as a crucial mechanism to protect public health and advance environmental justice.11 Further, with many major companies aiming to deploy 50-100% zero-emission trucks by 2030, EPA's proposed standards fail to stimulate the rate of commercial electric truck production that commercial fleet operators seek.12 By strengthening the proposed Phase 3 standards to ensure at least 50% ZEV sales across all market segments by 2032, EPA will accelerate the industry's necessary investments in heavy-duty ZEV manufacturing and the accompanying investments in charging infrastructure. [EPA-HQ-OAR-2022-0829-0511, pp. 2-3]

Organization: GreenLatinos et al.

For Greenhouse gas (GHG) Phase 3 HDV standards, we urge the U.S. EPA to finalize the strongest possible cleaner trucks standards. The standards must require tighter limits on diesel vehicles, so that we're making diesel trucks increasingly cleaner as manufacturers transition to zero pollution vehicles. [EPA-HQ-OAR-2022-0829-0789, p. 1]Organization: Mayor Becky Daggett, City of Flagstaff, Arizona et al.

On behalf of the 52 undersigned local officials, we urge the EPA to protect the health of our cities' residents and fight climate change by finalizing the strongest clean car and truck vehicle emission standards before the end of 2023. [EPA-HQ-OAR-2022-0829-0732, p. 1]

EPA should finalize the most stringent standards possible for the Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles (LDV) and the Greenhouse Gas Emissions Standards for Heavy-Duty Engines and Vehicles Phase 3 (HDV). We recommend these car and truck standards: [EPA-HQ-OAR-2022-0829-0732, p. 1]

- Be aligned on rulemaking timelines; [EPA-HQ-OAR-2022-0829-0732, p. 1]

- Account for technological advances and cost-savings in zero-emission technologies, including those made possible by recent legislation; [EPA-HQ-OAR-2022-0829-0732, p. 1]

- Achieve critically necessary reductions in greenhouse gases (GHGs) and other pollutants; and [EPA-HQ-OAR-2022-0829-0732, p. 1]

- Be developed with thorough stakeholder involvement that ensures all affected communities can engage in the rulemaking process. [EPA-HQ-OAR-2022-0829-0732, p. 1]

Ambitious federal standards, coupled with actions we are taking in our cities and towns to accelerate the use of clean vehicles, will enable our localities to more quickly cut transportation pollution and help ensure our residents and businesses have access to zero-emission technologies. [EPA-HQ-OAR-2022-0829-0732, p. 1]

Organization: Senator Shelley Moore Capito et al.

In addition, there remains a lack of support infrastructure capacity to implement the sweeping transition envisioned in these proposals, particularly for the heavy-duty vehicle category. While the Infrastructure Investment and Jobs Act provides states funding for electric vehicle charging infrastructure, charging technology and deployment continues to focus on passenger and commercial vehicles, not on heavy-duty vehicles. The White House has noted that 72 percent of goods in this country are moved by truck, placing the industry and the center of our critical supply chains and economic competitiveness.5 Efficient and reliable charging infrastructure for heavy-duty vehicles is essential for the sort of transition to electric trucks that the EPA has proposed. However, the technology is nowhere near ready to meet the demand necessary to keep our supply chain moving at the same rate it is today. Charging heavy-duty vehicles requires significantly more expensive conduits and transformers, and consumes vastly more electricity, than what is necessary for charging light- and medium-duty vehicles. Heavy-duty vehicle charging takes longer and is required more frequently than liquid fueling due to electric trucks having reduced range compared to conventional diesel vehicles. This proposal will result in increased curb weight for heavy-duty vehicles due to the significant weight of batteries, leading to reduced payload capacity and ultimately more heavy-duty vehicles on our roadways to move the same amount of freight. This shift may have highway safety implications and create increased congestion on our nation's roadways. In short, the charging technology for heavy-duty vehicles is not readily available and it will take many more years to develop and deploy if it is even economically feasible, making compliance with the EPA' s proposal for heavy-duty vehicles unattainable for the foreseeable future. [EPA-HQ-OAR-2022-0829-5083, p. 2]

5 The Biden-Harris Administration Trucking Action Plan to Strengthen America's Workforce, The White House (Dec. 16, 2021).

Organization: South Dakota Department of Agriculture and Natural Resources (DANR)

Public Safety

This past year South Dakota had a long, harsh winter. During the previous two winters the South Dakota Department of Transportation (DOT) maintenance crews covered about 1.4 million miles and used about 540,000 gallons of diesel fuel. This past winter, DOT totaled 3.2 million miles, used about one million gallons of fuel, and clocked approximately 178,000 man-hours to keep our roads safe. DANR is concerned the proposed emissions standards and push to heavy-duty vehicle EV use could significantly limit DOT's and South Dakota municipalities' ability to keep our roads safe during winter conditions. [EPA-HQ-OAR-2022-0829-0523, p. 2]

Organization: TCW Inc.

We currently operate 320 day cab tractors in the southeast, with 434 drivers. So, we "slip-seat" trucks, assigning a day shift and night shift driver in many trucks. With BEV's, we would need down time to charge, so we would need to purchase an additional 114 trucks to provide a tractor for every driver. Most of the freight we haul is international intermodal, with gross weight ranging from 70,000 to 90,000. With current electric truck capacity, we would have a service radius of 125 miles vs. a current radius of 250+ miles. Additional relay points would be required, and with the 50% reduction in service radius, we would need twice the number of trucks to service lanes that exist today. Electric trucks cost in excess of three times the amount we currently pay for a new Peterbilt day cab. Those additional expenses would be passed along in transportation expenses, astronomically impacting our already existing inflation issues related to supply chain constraints. [EPA-HQ-OAR-2022-0829-0452, p. 1]

Organization: Texas Public Policy Foundation (TPPF)

The HD Tailpipe Rule Will Devastate Trucking

Former Supreme Court Justice Breyer stated in Whitman v. Am. Trucking, 531 U.S. 457 (2001), that the Clean Air Act “does not require the EPA to eliminate every health risk, however slight, at any economic cost, however great, to the point of ‘hurtling’ industry over ‘the brink of ruin.’” Id. at 494. In the Whitman case the Supreme Court vacated the 1997 NAAQS because of the poor science and lack of discernable criteria underlying them. Likewise here, no scientific data requires the EPA to enact the most stringent tailpipe emission limits conceivable. [EPA-HQ-OAR-2022-0829-0510, pp. 4-5]

Electric trucks typically have a higher upfront purchase price compared to traditional diesel trucks. The HD Tailpipe Rule will effectively bar diesel trucks from sale, forcing trucking companies seeking to replace their fleet to take on more costs to do so. This will strain the financial resources of some companies, especially smaller ones. Shifting from diesel trucks to electric ones will also require adapting to new technologies and training drivers to effectively operate electric vehicles. This transition period will likely lead to disruptions in the supply chain and additional costs — both temporal and monetary — for trucking companies. [EPA-HQ-OAR-2022-0829-0510, pp. 4-5]

Moreover, the availability of charging stations for electric trucks is currently poor and still developing. It is certainly not as extensive as refueling stations for diesel trucks, and retrofitting existing truck stops for electric charging will place immense strain on electrical infrastructure and the national grid, especially in rural communities often frequented by truckers traveling the nation's highways, causing prices to skyrocket for average Americans. [EPA-HQ-OAR-2022-0829-0510, pp. 4-5]

The resulting chaos will limit the range and flexibility of electric trucks for long-haul journeys. Electric trucks already have limited range compared to diesel trucks, particularly when fully loaded. This will mean more frequent charging, adjustment to trucking routes, and overall shipping delays, negatively affecting operational efficiency. And even if the myriad infrastructure issues involved in getting power to truck refueling stations were solved or mitigated, the electricity used to charge electric trucks would still primarily come from America's most reliable and abundant power source: fossil fuels. [EPA-HQ-OAR-2022-0829-0510, pp. 4-5]

In effect, the HD Tailpipe Rule will force truckers to spend substantial financial and human resources to comply with ultra vires government regulations that fail to make even a marginal dent in global issue of changing climate. [EPA-HQ-OAR-2022-0829-0510, pp. 4-5]

EPA Summary and Response

Summary:

Commenters provide ideas and observations related to the electrification of heavy-duty vehicles and related issues such as charging infrastructure.

Response:

This rule is limited to light-duty and medium-duty vehicles. As a result, the comments related to heavy-duty vehicles are outside the scope of this rule. Interested readers should refer to the Agency's action, *Greenhouse Gas Emissions Standards for Heavy-Duty Vehicles - Phase 3*, which can be found at https://www.epa.gov/regulations-emissions-vehicles-and-engines/regulations-greenhouse-gas-emissions-commercial-trucks. Note that some of the comments included in this section were also submitted to the docket for the heavy-duty vehicle rulemaking (EPA-HQ-OAR-2022-0985).

29 - Additional comments

The Agency has been, is, and will continue to be committed to considering timely comments received on proposed rules. Although the comment period for this rule closed on July 5, 2023, EPA was able to also consider late comments received through December 15, 2023 for this final action. Comments received that provide specific information and feedback about particular data or assumptions used in EPA's analysis supporting the proposal or other aspects of the program and that were received after the end of the comment period through August 27, 2024, are included in the various sections of this RTC document. Additional comments received after that date and up to December 15, 2023, and that provide detailed information are included in this section. Comments received after the close of the comment period that express general support for or opposition to the proposal and/or contain opinions or statements about issues but without detailed data, information, or comment relating to specific provisions of the proposal or EPA's supporting analysis are not included in this RTC document. In the interest of transparency, we have included all comments we received after the close of the comment period in the docket; however, we were not able to consider comments received after December 15, 2023 and do not consider them part of the administrative record for this rulemaking.

Organization: AESI et al.

The 29 undersigned organizations write to express our strong support for the Environmental Protection Agency's (EPA) proposal to strengthen standards for harmful particulate matter (PM) emissions within the Agency's proposed Multi-Pollutant Emissions Standards for Model Year 2027 and Later Light-Duty and Medium-Duty Vehicles, 88 Fed. Reg. 29184 (May 5, 2023).

Many of our organizations previously submitted comments to EPA in support of the multipollutant standards during the open comment period of the proposed rulemaking. Finalizing strong PM standards that drive the deployment of off the shelf, low-cost gasoline particulate filters (GPFs) will save lives and reduce asthma attacks and cancer risk, all while saving our nation billions of dollars in avoided healthcare costs.

Exposure to PM can affect both the lungs and the heart. Numerous peer-reviewed scientific studies have linked particle pollution exposure to significant heath harms, including premature death in people with heart or lung disease, nonfatal heart attacks, aggravated asthma, decreased lung function, and increased respiratory symptoms.1 People with heart or lung diseases, children, and older adults are especially vulnerable to particle pollution exposure.

1 https://www.epa.gov/pm-pollution/health-and-environmental-effects-particulate-matter-pm

Strong standards will also protect vulnerable communities. People of color in the United States are exposed to disproportionately high levels of ambient PM pollution, including from motor vehicle emissions. One study finds that on a national level, people of color are exposed to 46 percent more ambient PM2.5 from light-duty gasoline vehicles than white people.2

2 Tessum, C et al. (2021). PM2.5 Polluters Disproportionately and Systemically Affect People of Color in the United States, Science Advances 7, no. 18: eabf4491, https://doi.org/10.1126/sciadv.abf4491.

EPA's proposed PM limit of 0.5 mg/mile would greatly reduce particulate emissions from new gasoline vehicles. These proposed standards are critical as there is growing evidence of increases in particulate emissions from recent model year gasoline vehicles. A June 2023 ICCT analysis looking at remote sensing data shows that recent model year light-duty vehicles (2015-2020) show a marked increase in UV smoke, a proxy for particulates, while other pollutants, like carbon monoxide and ozone-forming nitrogen oxides, showed clear and consistent downwards trends.3 The issue of elevated particulate emissions from some gasoline vehicles and the need for more protective PM standards was identified before EPA finalized its Tier 3 standards nearly a decade ago.4

3 Meyer, M., Khan, T., Dallmann, T., Yang, Z. Particulate matter emissions from U.S. gasoline light-duty vehicles and trucks: TRUE Initiative U.S. remote sensing database case study. ICCT, June 2023. https://theicct.org/publication/true-pm-emissions-jun23/

EPA states that the strengthened PM emissions limit will likely be met through the installation of gasoline particulate filters (GPFs).5 GPFs are a mature technology and studies have demonstrated they can reduce particulate emissions by 97% to 100% compared to vehicles without filters.6 According to EPA they have been used in series production on new gasoline vehicles in Europe since 2017 and are now being used by U.S., European, and Asian manufacturers, with several manufacturers currently assembling vehicles equipped with GPFs in the U.S. for export to other markets.7 GPFs are also cost-effective devices – EPA estimates per vehicle manufacturing costs of $51–$166.8 Other independent studies conducted over a decade ago found similar GPF costs of $50–$184, indicating that current costs could be significantly lower.9

Particle number emission limits for Euro 6 positive ignition vehicles. https://www.nanoparticles.ch/archive/2011_Steininger_PR.pdf

A June 2023 report from the Manufacturers of Emission Controls Association (MECA) found tremendous health benefits of GPFs, even with significant deployment of zero-emission vehicles projected by EPA.10 According to the analysis, the health benefits of more protective PM standards would effectively double the benefit of electrification alone. The cumulative benefits of standards that drive more GPF use in the combustion vehicle fleet through 2050 include:

- 58,000 to 112,000 tons of particulate matter emissions eliminated;
- 42,000 to 81,000 tons of climate-forcing black carbon emissions eliminated;
- $18 to $163 billion in healthcare cost savings;
- Up to 22,000 premature deaths prevented; and
- Up to 314,000 asthma attacks avoided.

10 MECA Clean Mobility. Impacts Analysis of a Revised Federal Light-Duty On-Road Particulate Matter Standard. June 2023, https://www.meca.org/wp-content/uploads/2023/06/LDV_PM_Standard_Final_Report_06272023.pdf. See also MECA presentation to OMB, March 6, 2023. https://www.reginfo.gov/public/do/eoDownloadDocument?pubId=&eodoc=true&documentID=210843

By finalizing the proposed standards, EPA will bring the U.S. in line with other major vehicle markets. According to MECA, by 2023, four years ahead of EPA's proposed particulate standard implementation, two-thirds of the automotive manufacturing markets, including Europe, India and China, will be meeting tighter PM emission standards similar to those now proposed by EPA.11

[11] *Id.*

EPA's proposed updated standard would provide cost-effective and much needed health benefits through reduced particulate matter emissions. We urge the Administration to finalize its Multi- Pollutant Emissions Standards, including the strong health-protecting particulate standards, without delay. [EPA-HQ-OAR-2022-0829-5106]

Organization: Alliance for Automotive Innovation

The Alliance for Automotive Innovation submitted comments to EPA on the subject rulemaking.1 In those previous comments we noted concerns with the availability of adequate critical mineral supplies to support the market share of electric vehicles that would effectively be required under EPA's proposed light-duty vehicle greenhouse gas and criteria pollutant regulations, particularly given global demand for such materials. We now bring to EPA's attention recently updated analysis from Benchmark Minerals Intelligence (BMI) on lithium supplies in the context of automaker production goals and global regulatory policies. Please consider this a supplemental comment on the proposed rule and update to the section in our comments that compared an earlier BMI study with EPA's projected lithium ion battery cell demand to its proposed standards,2 and place this letter in the rulemaking docket.

1 See Alliance for Automotive Innovation Comments, available at Docket Id No. EPA-HQ-OAR-2022-0829-0701.

2 Id. at pp. 10-16.

In an article titled "Lithium industry needs over $116 billion to meet automaker and policy targets by 2030",3 Benchmark Minerals Intelligence (BMI) describes its analysis of lithium needs to meet its "high case" demand under vehicle electrification targets set by automakers and governments across the world, including a 50% electric vehicle share in the United States by 2030. BMI raises the following points that we feel are potentially informative to the subject rulemaking.

3 Benchmark Source, "Lithium industry needs over $116 billion to meet automaker and policy targets by 2030" (August 4, 2023). Available at https://source.benchmarkminerals.com/article/lithium-industry-needs-over-116-billion-to-meet- automaker-and-policy-targets-by-2030 by subscription.

- "The lithium industry needs to invest $116 billion by 2030 if the world is to meet the ambitions targets set by governments and the largest automakers.
- "Even if every asset in the pipeline came online on time and hit their projected lithium production capacities, the world would still need 1.8 million tonnes on top of that to meet the high case demand."
- "The high case scenario, which encompasses data from Rho Motion on automakers' passenger EV targets as well as data from the International Energy Agency on enacted country-level policies, would require 5.3 million tonnes of lithium carbonate equivalent (LCE). This is compared to the 915,000 tonnes LCE production in operation today."
- According to a BMI analyst, "It's almost impossible, and definitely a race against time . . . The players with skin in the game are the least likely to rush their spending . . . They don't want to flood the market with lithium too quickly. They want to release it slowly to maximise their return . . . As a carmaker, consumer, or EV policy maker, should I be alarmed? Yes."

The article described above is available by subscription. Much of the content of that article may also be obtained from Green Car Congress.4

4 Green Car Congress, “Benchmark: Lithium industry needs more than $116 billion to meet automaker and policy targets by 2030” (August 5, 2023). Available at https://www.greencarcongress.com/2023/08/20230805-benchmark.html.

EPA projects that its proposed light-duty vehicle greenhouse gas standards will be met with a 60% battery electric vehicle market share in 2030,5 10 percentage points higher than the “high case” demand scenario examined by BMI (which includes PHEVs), and beyond the goals of President Biden’s Executive Order 14037.6 EPA’s proposal also projects that BEV sales will continue to grow to 67% by 2032. As detailed in our original comments, the proposed greenhouse gas targets far exceed the capabilities of internal combustion engine vehicles.7 Therefore, failing to achieve the EPA-projected BEV market share, whether due to battery material availability or other issues, will have serious consequences for automakers and consumers alike. Data such as that highlighted above casts serious doubts on the feasibility of EPA’s proposed rule and is significantly different from assumptions EPA made in its proposal. EPA should take a deeper look into these supply chain challenges, including on-going efforts by other federal agencies responsible for carrying out President Biden’s Executive Order 14037 pertaining to vulnerabilities in our nation’s critical mineral and battery supply chains. EPA needs to address these significant shortcomings as it develops a final rule, rely on data from respected expert analysts such as Benchmark Minerals Intelligence, and use this data in reassessing the feasibility of the proposed greenhouse gas standards.

5 88 Fed. Reg. 29333 (May 5, 2023), Table 99.

6 We also note that EPA’s projections are premised on only battery electric vehicles, excluding plug-in hybrids, whereas Executive Order 10437 was inclusive of battery electric, plug-in hybrid electric, and fuel cell electric vehicles.

7 See comments of the Alliance for Automotive Innovation at Regulations.gov, Docket ID EPA-HQ-OAR-2022-0829-0701, at 90.

[EPA-HQ-OAR-2022-0829-5085]

Organization: American Free Enterprise Chamber of Commerce

This letter supplements the American Free Enterprise Chamber of Com- merce (“AmFree”) July 5, 2023 comment on EPA’s notice of proposed rule- making “Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles,” 88 Fed. Reg. 29,184 (May 5, 2023).

Since our previous comment, there have been several developments that affect the validity of the proposed rule’s estimate of compliance costs. Of note is Toyota’s announcement that Model Year 2025 and later Camrys—the best- selling passenger car in the United States—will be exclusively hybrids. Joseph White, Toyota’s Camry, best-selling car in US, goes all-hybrid, Reuters (Nov. 15, 2023), https://www.reuters.com/business/autos-transportation/toyotas- camry-best-selling-car-us-goes-all-hybrid-2023-11-15. David Christ, the head of the Toyota brand in North America, explained that the decision to move to an all-hybrid vehicle line, dropping four- and six-cylinder combustion models that made up about 85% of sales in the current model year was motivated primarily by the need to comply with tougher U.S. fuel economy rules. Id. And because “any rule that limits tailpipe [greenhouse gas] emissions is effectively identical to a rule that limits fuel consumption,” they presumably had EPA’s proposal in mind as well. Delta Constr. Co. v. EPA, 783 F.3d 1291, 1294 (D.C. Cir. 2015).

But this isn't a cost-free shift: the cheapest Camry hybrid model currently sells for about $2,400 more than the most inexpensive combustion Camry. Toyota Camry, Toyota, https://www.toyota.com/camry/ (last accessed Nov. 20, 2023) (showing the Camry LE Hybrid costing $2,435 than its conventional counterpart, the Camry SE Hybrid costing $2,430 more than its conventional counterpart, and the Camry XLE costing $2,575 more than its conventional counterpart.).

As discussed in our previous comments, Section 202(a) requires EPA to consider whether compliance with the proposed emissions standards is feasible, giving appropriate consideration to the cost of compliance. 42 U.S.C.

§ 7521(a)(2) ("Any regulation prescribed . . . shall take effect after such period as the Administrator finds necessary to permit the development and application of the requisite technology, giving appropriate consideration to the cost of com- pliance within such period."). The agency must explain why its projections are "reason[able]" and defend "its methodology for arriving at numerical esti- mates." Id.

In undertaking this task, EPA implausibly calculates that achieving its in- credibly aggressive greenhouse gas standards will raise the average cost of pas- senger cars by only $844 per vehicle in 2032, as compared to the no-action al- ternative, and that Toyota's new vehicles are projected to be hundreds of dollars cheaper than in the no-action alternative in Model Years 2027 through 2030. DRIA at 13-26. As we emphasized in our initial comments, these numbers were highly implausible when EPA calculated them. Now, just six months later, they have already been proved incorrect.

As our initial comments explained, EPA's vehicle cost estimates are flawed in many ways, and failing to account for these costs violates the agency's stat- utory obligations and at the very least renders the rule arbitrary and capricious. Because of these errors, EPA's proposed standards must be withdrawn. [EPA-HQ-OAR-2022-0829-5107]

Organization: Center for Biological Diversity et al.

Center for Biological Diversity, Clean Air Task Force, Environmental Law & Policy Center, National Parks Conservation Association, Public Citizen, and Sierra Club respectfully submit these comments in response to the Environmental Protection Agency's (EPA) Proposed Rule titled Greenhouse Gas Emissions Standards for Heavy-Duty Vehicles—Phase 3, 88 Fed. Reg. 25926 (Apr. 27, 2023). As additional support for a strong final rule, we are providing EPA with important materials that were published after the close of the comment period:

1. Attachment 1: Electric Power Research Institute, *EVs2Scale2030 Program Overview*, https://publicdownload.epri.com/PublicAttachmentDownload.svc/AttachmentId% 3D84807
    a. EVs2Scale is a data-driven, multi-stakeholder initiative to help prepare the electric grid for expanded deployment of EV charging infrastructure, including for heavy-duty vehicles. Participants include fleet operators, truck manufacturers, electric utilities, charging infrastructure providers, government institutions, and national laboratories. Among other

projects, the initiative will provide a secure data exchange platform to help utilities efficiently plan grid investments, and will identify location-specific EV loads, grid impacts, lead times, workforce needs, and costs across the 50 states.

b. Further information on EVs2Scale2030 is available at https://msites.epri.com/evs2scale2030.

2. Attachment 2: Calstart, *Phasing in U.S. Charging Infrastructure* (Aug. 22, 2023), https://calstart.org/wp-content/uploads/2023/08/Phasing-in-U.S.-infrastructure-bri ef-082223.pdf

   a. This report presents a model and roadmap for a geographically-targeted, phased approach to heavy-duty charging infrastructure buildout, showing that the charging needs of those vehicles (in volumes even higher than associated with the Phase 3 proposal) can be met feasibly and cost-effectively.

We urge the Agency to consider these materials and include them in the record for this rulemaking. [EPA-HQ-OAR-2022-0829-5087]

Organization: Environmental Defense Fund (EDF)

Environmental Defense Fund (EDF) respectfully submits the attached report, "U.S. Electric Vehicle Manufacturing Investments and Jobs: Characterizing the Impacts of the Inflation Reduction Act after 12 Months," as supplemental comments on EPA's Proposed Rule, Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles, 88 Fed. Reg. 29184 (May 5, 2023), and on EPA's Proposed Rule, Greenhouse Gas Emissions Standards for Heavy-Duty Vehicles, 88 Fed. Reg. 25926 (April 27, 2023). The attached analysis, released by EDF and WSP in August 2023, focuses on the impacts of the Inflation Reduction Act in dramatically accelerating U.S. investments in EV manufacturing and job growth.

The analysis finds:

- Investments in the EV manufacturing ecosystem over the last eight years total more than $165 billion with 56% of that investment occurring since the passage of the IRA.
- These investments support 179,000 direct jobs and are expected to create more than 800,000 additional jobs in the broader economy.
- By 2026, U.S. manufacturing facilities will be able to make 4.7 million new EVs annually (36% of new vehicles sold last year) and by 2027, enough batteries to supply 12.1 million new passenger vehicles (95% of new vehicles sold last year).

[Two PowerPoint attachments:

- U.S. Electric Vehicle Manufacturing Investments and Jobs Characterizing the Impacts of the Inflation Reduction Act after 1 Year August 2023

- EDF Meeting on EPA's Proposed Multipollutant Standards for New Light-, Medium-, and Heavy-Duty Vehicles, August 23, 2023]

[EPA-HQ-OAR-2022-0829-5084]

Organization: Environmental Defense Fund (EDF)

Environmental Defense Fund submits the following information for inclusion in the docket for EPA's Proposed Rule, Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles, 88 Fed. Reg. 29184 (May 5, 2023).

On Friday, October 20, the Colorado Air Quality Control Commission voted unanimously to adopt the Advanced Clean Car II (ACCII) standards – second-generation safeguards that will expand sales of new zero-emitting cars and passenger trucks in Colorado. The standards will be implemented beginning in 2027 and run through 2032. During that time, the standards will require increasing sales of new zero-emitting vehicles and will strengthen protections against emissions from internal combustion engine vehicles. Under the new standards, 82% of new passenger vehicles sold in Colorado will be zero-emission in 2032.

The Colorado Air Quality Control Commission also voted to require a state agency to bring a proposal no later than July 31, 2029 for the Commission to consider extending the standards through 2035. Colorado joins eight other states that have now adopted the Advanced Clean Car II standards – California, Maryland, Vermont, Washington, Oregon, Massachusetts, Virginia, and New York – and becomes the first state in the Mountain West to adopt them. New Mexico and Connecticut are among the states now considering adopting the standards.

The standards will expand consumer choice in the state, furthering current trends. Colorado saw a 55% increase in electric vehicle sales between 2021 and 2022. New data released by the Colorado Automobile Dealers Association shows that the YTD market share of electric vehicles (BEV + PHEV) in the state is 14.5%, up from 10.1% this time last year, and a record 17.1% of total vehicle purchases were electric the last full quarter of 2023. [EPA-HQ-OAR-2022-0829-5116]

Organization: Environmental Defense Fund (EDF)

We wanted to share an analysis EDF did on alternative pathways OEMs could use to comply with the LD proposed standards using a low level of or no BEVs. We have also submitted this document to the docket.

The analysis finds that EPA's proposed LD standards can be met with zero BEVs and still result in significant net benefits ($770B-$900B). The analysis also looks at compliance pathways with low-BEV baselines ranging from 7% (roughly today's BEV sales) to 40% (EPA's No Action Case BEV sales in 2032). We find no additional BEVs are needed to comply with the standards and these compliance pathways result in significant net benefits. [EPA-HQ-OAR-2022-0829-5118]

[Attached study:]

Environmental Defense Fund (EDF) respectfully submits supplemental comments on EPA's Proposed Rule, *Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles*, 88 Fed. Reg. 29184 (May 5, 2023) ("Proposal" or "Proposed Standards"). Since the close of the comment period, EDF evaluated additional alternative technology pathways for manufacturers to meet the Proposed Standards. Our analysis reinforces and expands on findings submitted in our earlier comments and concludes that there are numerous additional pathways that are technologically feasible and cost beneficial even in counterfactual scenarios of very low and no baseline deployment of battery electric vehicles (BEVs). The analysis underscores the technology neutrality of the standards and further demonstrates that there is no single technology necessary to meet the standards (though certainly not a requirement for standards established under section 202 of the Clean Air Act).

EPA has long established performance-based light-duty vehicle greenhouse gas standards that allow manufacturers to comply with a range of emissions-improving technologies. The Proposed Standards are no exception – they are performance-based and can be met using a range of internal combustion engine vehicle (ICEV) improvements and/or electrification technologies.

In our comments submitted on July 5, 2023, EDF evaluated 3 pathways – in addition to those that EPA modeled – to demonstrate that EPA's proposed standards can be met with a range of technologies, including battery BEVs, plug-in hybrid electric vehicles (PHEVs) and ICEV improvements.[1] EDF contracted with Roush to project the relative cost of PHEVs and BEVs in the 2024-2035 timeframe.[2] EDF then used Roush's cost projections for PHEVs in conjunction with EPA's costs for BEVs and ICEVs to conduct an analysis of compliance costs under possible scenarios in which PHEV and ICEV sales represent a greater proportional share of manufacturers' sales than EPA modeled while still meeting the emissions targets set in EPA's Proposal. The original alternative pathways EDF modeled included:

- Pathway 1 (ICEV Pathway): assumed the greatest possible GHG control from ICEVs using EPA's OMEGA 2 model; assumed no PHEV technologies
- Pathway 2: set PHEV and BEV sales to roughly equivalent levels leaving ICEV emissions at the level projected in EPA's compliance simulation of its Proposed Standards
- Pathway 3: held ICEV sales at the level found in Pathway 2; increased PHEV sales further than Pathway 2 by maximizing ICEV emission controls as in Pathway 1

1 Comments of the Environmental Defense Fund, EPA-HQ-OAR-2022-0829-0786, https://www.regulations.gov/comment/EPA-HQ-OAR-2022-0829-0786.

2 Vishnu Nair, Himanshu Saxena, Sajit Pillai, Alternative Powertrain Pathways for Light-Duty and Class 3 Vehicles for MYs 2024, 2027, and 2035 to Meet Future CO2 Emission Targets, Roush for EDF (June 2023).

Each of these pathways provided a viable example of compliance pathways automakers could choose to take—one relatively more reliant on ICEVs, one more so on PHEV controls and the third on both—all of which demonstrating the flexibility afforded manufacturers to cost-effectively reduce emissions using a mix of technologies with lesser reliance on BEV sales than was shown in EPA's cost-minimizing modeling.

Since our original analysis and comment submission, some stakeholders have asserted or implied that the Proposed Standards could not be met without significant BEV sales.3 EDF has performed a follow-up detailed analysis, set forth below, assessing additional pathways to compliance through fuller reliance on PHEVs, hybrids, and ICE efficiency improvements with zero to moderate levels of battery electric vehicles (BEVs). Our analysis concludes that EPA's proposed standards can be met with varying levels of technology and that no particular technology is required – in whole or in part – to meet the fleet-average standards. This is true even in exceedingly unrealistic low- and no-BEV baseline scenarios. Our analysis also finds that even a zero-BEV pathway would result in significant net benefits, and as BEV sales increase so do the net benefits.

Analysis: Feasibility of low- to zero-BEV pathways

This analysis investigates manufacturers' ability to comply with EPA's standards with fewer BEVs compared to EPA projections or even no BEVs at all, substituting further ICEV emissions control and PHEVs compared to our previous pathways analysis. Starting with four different levels of BEV sales, we evaluate the PHEV sales required to comply with the standards under two levels of ICEV emissions control—a MY2022 average level of control as estimated by the National Highway Traffic Safety Administration (NHTSA) in its recent proposed rule,[4] and an advanced level of emissions control for a vehicle powered entirely by gasoline. This analysis included calculations for two model years, MY2027 and MY2032. The different levels of BEVs included are 0% BEVs, 7% BEVs - roughly the share of BEV sales in the US today, 17% BEVs – EPA's projection in the final rulemaking for its MY 2023-2026 standards, and finally the level of BEV sales projected under the current EPA Proposal No Action Case, 27% in 2027 and 40% in 2032. In all the scenarios presented below, no additional BEVs are deployed beyond the above-stated baseline sales levels.

[4] Corporate Average Fuel Economy Standards for Passenger Cars and Light Trucks for Model Years 2027–2032 and Fuel Efficiency Standards for Heavy-Duty Pickup Trucks and Vans for Model Years 2030–2035, 88 Fed. Reg. 56128 (August 17, 2023).

MY2022 ICEV Technology Scenario:

The MY2022 ICEV control scenario reflects the ICEV performance of the current fleet. In its modeling for the Proposal, EPA projected that minimal ICEV improvement would occur and compliance with vehicle emission standards would be mostly achieved using BEVs. As a result, MY2022 ICEVs are consistent with all the ICEVs used in EPA's modeling for MY2027 through MY2032. For reasons described below, we decided to use the level of MY2022 vehicle emissions as estimated by NHTSA and obtained from the CAFE Compliance and Effects Model (CCEM) used in NHTSA's recent proposed rule.[5] Over half of these vehicles had advanced engines (turbocharged, with cylinder deactivation, or high compression ratio). Nearly half had transmissions with more than 8 speeds or continuously variable. Just under 7% and 2% were strong hybrids or PHEVs.

[5] We did not use EPA's OMEGA 2 model to estimate the emission impact of advanced ICEV emission control technology because the OMEGA 2 model does not include P2 strong hybrid technology.

Advanced ICEV Technology Scenario:

We also evaluated an advanced level of emission reductions available from ICEV technologies, which includes nearly complete conversion to strong hybrid technology and is also taken from a CCEM run. EDF conducted a run of CCEM in which BEV and PHEV technologies were strictly limited resulting in all ICEV emission control technology available in the model being applied, converting 94% of ICEV sales to strong hybrids. The use of the CCEM to estimate the benefit of ICEV technology necessitated the use of 2022 MY emissions from the CCEM to maintain technical consistency. These strong hybrids include advanced engines, high or continuously variable transmissions and additional weight reduction in glider mass. Fleetwide, the application of all ICEV technologies present in CCEM has a significant impact on emission reductions, reducing carbon dioxide (CO_2) emissions for passenger cars by 30% and light trucks by 28% compared to MY 2022 ICEV control levels. Together, the two ICEV control scenarios are intended to bookend the realistic and feasible emissions from ICEVs in the near term.

Methodology and Assumptions

In this analysis we assume PHEVs to have an onroad range of 50 miles. Per EPA's Proposal, PHEV50s have a utility factor of 0.68.[6] PHEVs also must have a minimum range over the two-cycle test of 70 miles (equivalent to an onroad range of 50 miles) to qualify as ZEVs under California's Advanced Clean Cars II program. Therefore, we assumed that a manufacturer intending to comply with EPA's proposed standards using PHEVs would aim for an onroad range of roughly 50 miles.[7] PHEV50s are assumed to have the same CO2 emissions as an ICEV with advanced emissions control technology when they are operating on gasoline.

[6] Fed. Reg. 88 at 29441 (May 5, 2023), Tables 1 and 2.

[7] Even those PHEVs sold outside of California and the states that have adopted California's ACC2 program.

We separate new vehicle sales into their two regulatory classes - cars and light trucks - and apply ICEV technology and conversion to PHEV and BEV technology proportionately to both vehicle classes.[8] In this portion of our analysis, we focus on compliance with EPA's standards in MYs 2027 and 2032, the first and last model years covered under the Proposed Rule.

[8] While EPA allows unrestricted trading of CO2 credits from one category to the other, their emissions need to be tracked separately due to differences in assumed lifetime mileages.

Manufacturer sales projections for MY 2027 and 2032 are available from both EPA's and NHTSA's modeling supporting their respective proposed rules. We use EPA's sales projections for each manufacturer's total sales of cars and light trucks to maintain consistency with the focus on compliance with EPA's emission standards.

Manufacturer-specific compliance with EPA's proposed CO_2 standards is accomplished with a spreadsheet model. Neither OMEGA 2 nor the CAFE model are designed to allow the user to specify the mix of technology to be applied as an input to the model. This model is very accurate in projecting compliance in MY 2032 with a BEV-heavy strategy.[9]

[9] The model indicates that BEV sales in 2032, assuming 2022 ICEV technology, would need to be 66%. EPA, using OMEGA 2, projected BEV sales of 67% to meet the proposed standards with 1% strong hybrid sales (i.e., ICEV emissions essentially consistent with the 2022 ICEV fleet).

Results

The first two tables below show the level of PHEV sales in 2027 that would be required to meet EPA's proposed standards given various levels of assumed BEV baseline penetration and the two ICEV technology scenarios described above (2022 ICEV technology and advanced ICEV control). Table 1 assumes ICEVs with 2022-levels of emission control technology, while Table 2 assumes advanced application of technology to ICEVs, including strong hybridization.

Our analysis shows that there are many feasible pathways to compliance and no particular technology is required to meet the standards. Column one in both tables shows that meeting the proposed standards in 2027 with baseline BEV sales at 0% would require the incremental sale of 36% to 61% PHEVs on a fleetwide basis, depending on the level of ICEV control technology applied. At a 7% BEVs baseline sales rate, only a quarter to a half of all sales would need to be PHEVs to meet the proposed 2027 vehicle standards. And assuming BEV sales of 17%, manufacturers could meet the proposed 2027 vehicle standards with PHEV sales of 11-39%.

Finally, our analysis shows that if BEV sales reach 27% in 2027, then manufacturers would only need to sell 3% PHEVs if they choose to adopt advanced control technology on all ICEVs and a quarter PHEVs if they do not. We recognize that 0% and 7% baseline ZEV sales are either counterfactual (0%) or overly pessimistic (7%) given the current rate of ZEV sales and their upwards trend. In our earlier comments to EPA, EDF included an analysis that indicates EPA's projection of high BEV adoption over the next decade is justified and likely an underestimate greatly lessening the likelihood that any of the low-BEV scenarios would occur.[10] We have nonetheless included them to demonstrate that the same conclusions that no additional BEV sales are required to meet the standards hold under the full range of possible assumptions regarding baseline ZEV deployment, including for lower assumed baseline levels that are not reasonably likely to occur.

Tables 3 and 4 below show the level of PHEV sales that would be required to meet EPA's proposed standards in 2032 at varying levels of baseline BEV sales and ICEV technology adoption. The tables show that on average, manufacturers could meet the proposed 2032 standards by selling zero BEVs if they instead sell somewhere between 86% and 91% PHEVs, depending on the degree of ICEV control technology. Alternatively, if just 7% of sales are BEVs in 2032 (roughly today's current rate of BEV sales), PHEV sales could drop to 76% if advanced ICEV technology is used (Table 4) or 82% if 2022 ICEV technology is assumed (Table 3). And assuming BEV sales of 40%, in line with EPA's "No Action" projections for 2030-2032,[11] fleet average PHEV sales could be as low as 28% to 40% in 2032. As above, we underscore that the zero and seven percent BEV baselines are unrealistic; we include them to demonstrate the robustness of our conclusions.

[11] The BEV sales under the No Action Case are 40% in 2030 and 2031 and 39% in 2032. 88 Fed. Reg. 29184 (May 5, 2023) Table 81.

Analysis: Costs and benefits of low- to zero-BEV pathways

In addition to evaluating the feasibility of meeting EPA's Proposed Standards through different technology pathways, we estimated the net benefits of compliance for the lowest (0% BEV sales) and highest (40% BEV sales in 2032) BEV scenarios presented above. As shown in Table 7 below, all of the alternative scenarios evaluated are projected to produce significant net benefits compared to a No Action scenario, with net benefits ranging from $767 billion to $1.4 trillion.

Methodology

To estimate net benefits, we assessed the differences in the cost of compliance technology, adjusting the No Action scenario to be consistent with the compliance strategy to which it was being compared. Vehicle technology is the largest cost associated with the Proposal. The largest savings or benefits, in order of magnitude, are from reduced fuel costs, health and climate change impacts, and reduced maintenance and repair costs.

Alternative Scenarios for No Action Case and Proposal

To estimate net benefits, EDF evaluated the costs and benefits of EPA's Proposal in three alternative compliance scenarios with corresponding No Action cases. The scenarios are summarized in Table 5 below. We considered the two Proposal scenarios with the lowest and highest levels of ZEVs described above and shown in Table 4. In the Zero-BEV sales scenario we assess the net benefits of compliance with the Proposal using higher sales of PHEVs and ICEVs with advanced emissions control technology (Scenario 2). In the 40% BEV sales scenario we assess the net benefits where BEV sales are 40%, and the remaining sales are a combination of PHEVs and ICEVs with advanced technology (Scenarios 3 and 4).

Table 5: Alternative Scenarios Evaluated

	Scenario	No Action Case				Proposal			
		BEV	PHEV	MY2022 ICEV	Adv. ICEV Tech	BEV	PHEV	MY2022 ICEV	Adv.ICEV Tech
1	EPA Proposal	40%	0%	60%	0%	67%	0%	33%	0%
2	Zero BEV	0%	33%	67%	0%	0%	86%	0%	14%
3	No Incremental BEVs	40%	0%	60%	0%	40%	28%	0%	32%
4	Proportional BEVs	16%	11%	73%	0%	40%	28%	0%	32%

For Scenarios 2, 3 and 4 we assumed different starting points (No Action Case) from that assumed by EPA (line 1of Table 5). We assume that a manufacturer would use a similar strategy to comply with the current standards under the No Action case as with the Proposed Standards. For example, as shown in row 1 of Table 5, EPA projected that manufacturer's will use BEVs to comply with both the current standards and the Proposed standards, in their evaluation of the Proposal's costs and benefits. Consistent with this approach, in our Zero-BEV scenario as shown in row 2 of Table 5, in which we assume manufacturers use only PHEVs and ICEVs to comply with the Proposal, EDF also assumes that these manufacturers will use only PHEVs and ICEVs to comply with the current standards.[12]

[12] For the purposes of evaluating the net benefits of the zero-BEV compliance pathway, we use a zero-BEV reference case as well, though extremely unlikely given current BEV sales, and though the 40% BEV scenario uses a different reference case.

For the 40% BEV scenarios (rows 3 and 4 in Table 5), we used two separate No Action cases for comparison. These two cases allow for an evaluation of the net benefits of compliance with the Proposed Standards following manufacturers' compliance with the current standards using two possible fleet mixes. In the "No Incremental BEVs" scenario at row 3 of Table 5, we assume the same No Action case that EPA used for the Proposal, with the Proposal leading to increased sales of PHEVs and improved ICEVs. In the "Proportional BEVs" scenario at row 4, we assume that manufacturers would sell a mix of BEVs and PHEVs under the No Action case in a similar ratio to that projected for the Proposal.

Calculation of Costs and Benefits

To calculate the costs and benefits of these alternative pathways EDF started with EPA's Proposal and No Action Case costs and benefits to account for the differences. The primary driver of the differences in benefits from these alternative compliance pathways is the change in vehicle costs due to the different fleet technology mix.

Emission Benefits

Both tailpipe CO_2 emissions and fuel costs are the same whether PHEVs and cleaner ICEVs or BEVs are used to comply with the GHG standards.[13][14] We assumed that criteria pollutant emissions under the Zero-BEV scenario are also the same as under EPA's Proposal. This is a conservative assumption as a higher use of PHEVs will result in lower overall criteria pollutant emissions.[15]

[13] While all the scenarios modeled use the same amount of gasoline, scenarios with a higher level of strong hybrids or PHEVs use slightly less electricity than a scenario of all BEVs and conventional ICEVs like the ones EPA projected. This means the assumption that the alternative compliance scenarios modeled here have the same level of emission reductions is conservative since they will have lower EGU emissions.

[14] This analysis used a discount rate of 3%. OMB recently released a revised version of Circular A-4 which lowers the recommended discount rate to be used by agencies in the cost benefit analyses. If this analysis used the new values, the benefits would likely be higher. Circular No. A-4, Office of Management and Budget, November 9, 2023. https://www.whitehouse.gov/wp- content/uploads/2023/11/CircularA-4.pdf.

[15] EPA's current non-methane organic gases plus nitrogen oxides (NMOG+NOx) emission standards do not adjust PHEV emissions through use of the utility factor. One result of this is PHEVs must have the same emission control technology as ICEVs. This is consistent with Roush's approach to estimating the cost of a PHEV, which includes the same aftertreatment system costs for PHEVs as ICEVs. Thus, any PHEV travel using electricity will reduce NMOG+NOx emissions relative to those resulting from a BEV strategy to GHG compliance.

Maintenance Costs

We also assume that maintenance costs would be the same under all the alternative scenarios evaluated in this analysis as EPA's Proposal. While smaller than climate and health-related benefits and fuel savings, maintenance cost savings are a significant factor in the estimation of the net benefits of the Proposal. EPA estimates that PHEVs will have lower maintenance costs than ICEVs (and higher costs than BEVs), but not to the degree indicated by the utility factor. At the same time, EPA projected roughly the same maintenance cost savings for strong hybrids as PHEVs, and very few strong hybrids were projected to be sold in EPA's modeling of the No Action and proposed standards cases. Thus, our assumption may overestimate maintenance cost savings assuming ICEVs remain at 2022 emission levels, but both over- and underestimate maintenance cost savings assuming advanced technology ICEVs. However, any overestimation of maintenance savings in the former case would be much smaller than the value of reduced NMOG+NOx emissions resulting from a fleet consisting mostly of PHEVs.

Vehicle Costs

The average cost of MY2022 ICEVs and BEVs were taken directly from EPA's analysis supporting the Proposal. We then developed incremental costs of 1) a PHEV50 over a BEV300 and 2) of an ICEV with all of the available technology applied over the cost of a MY 2022 ICEV.

EPA does not include PHEV costs in its modeling for the Proposal. To determine reasonable PHEV50 cost estimates to use in conjunction with EPA's BEV cost estimates, we adjusted Roush's PHEV50 costs to match the ratio of PHEV50 to BEV300 costs projected by Roush. [16] Roush projected that PHEV50s would cost $4,800 to $8,100 more than BEV300s across 5 vehicle classes in MYs 2027 and 2032 with fleet average costs of $5,700 and $7,400, respectively, in MYs 2027 and 2032.[17] Adjusting Roush's incremental PHEV costs (relative to BEVs) to match EPA's methodology reduces the incremental PHEV costs by 30%, to $4,000 in 2027 and $5,200 in 2032. [18]

[16] Vishnu Nair, Himanshu Saxena, Sajit Pillai, Alternative Powertrain Pathways for Light-Duty and Class 3 Vehicles for MYs 2024, 2027, and 2035 to Meet Future CO2 Emission Targets, Roush for EDF (June 2023).

[17] This is using vehicle segment sales from EPA's OMEGA 2 modeling for the Proposal.

[18] We adjusted Roush's incremental costs for PHEV50s to harmonize with EPA's BEV cost estimates. EPA's and Roush's accounting for engine, transmission and aftertreatment removal with full electrification are similar, so no adjustment was necessary. However, EPA's battery capacities for BEV300s[18] are 23% larger than Roush's estimates.[18] We increased Roush's projected battery capacities for both PHEV50s and BEV300s by 23% to match EPA's methodology. And while EPA and Roush battery direct manufacturing costs for BEVs are comparable, EPA applies a 1.5 RPE factor to BEVs, while Roush applies a factor of 1.2 in 2027 and beyond to the entire electric powertrain. Similarly, we adjusted Roush's battery RPEs for both PHEV50s and BEVs to reflect EPA's RPE factor of 1.5. There was no need to do this for non-battery powertrain costs, as these are essentially the same for both BEVs and PHEVs. Both adjustments reduce the incremental cost of PHEV50s over BEVs. Combining these two

factors, the PHEV50 battery savings are 54% higher using EPA's battery capacities and battery RPEs than originally projected by Roush.

We obtained the incremental cost of a vehicle with advanced ICEV emission control technology from the CAFE model.[19] The incremental ICEV cost of a MY 2032 vehicle with all available ICEV technology applied was $1,267 above average MY 2022 costs.

[19] This used the same run used to estimate the emission benefits of the advanced application of ICEV technology described above. Specifically, we modelled a scenario beyond NHTSA's proposal without allowing any ZEV technologies to be used to ensure that all available ICEV technology was applied.

We then combined these costs for the four vehicle technologies into a single fleetwide cost for the No Action and Proposal scenarios for each of the alternative pathways being evaluated here.

The average incremental vehicle costs (on a fleetwide basis) of the four scenarios are shown in Table 6. These fleetwide estimates were developed from the incremental costs for each of the four vehicle types described above: 1) 2022 ICEVs, 2) advanced ICEV technology, 3) PHEV50s, and 4) BEV300s.

Table 6: Average Incremental Vehicle Costs

	Scenario	Incremental Vehicle Costs
1	EPA Proposal	$1,200
2	Zero BEV	$3,200
3	No Incremental BEVs	$2,900
4	Proportional BEVs	$2,600

As shown in Table 6, a greater reliance on PHEV sales increases the fleetwide cost of complying with the Proposal. The average fleetwide cost is highest under the Zero BEV scenario, as the increase in PHEV sales is 55 percentage points. It is lowest under the Proportional BEV scenario as the increase in PHEV sales is only 16 percentage points.

No Action Case Costs and Benefits

While EPA projected a significant degree of over-compliance in its modeling of the No Action scenario,[20] the Zero-BEV and Proportional BEV No Action cases are assumed to strictly comply with the MY2026 vehicle standards. To account for this, EDF developed a second set of costs and benefits for the case where manufacturers strictly complied with the current MY 2026 standards, the binding regulations under EPA's No Action scenario for the Proposed Standards.[21]

[20] This is due to the expected favorable economics of BEVs leading to more BEV sales than required for manufacturers to comply with the current regulations.

[21] We did this by reducing the number of BEVs sold in EPA's No Action scenario to the level where manufacturers just complied with the standards. Sales of ICEVs were increased accordingly. As EPA's OMEGA 2 model provides outputs for BEVs and ICEVs separately, all outputs were adjusted to reflect the increase or decrease in vehicle sales. This resulting set of OMEGA 2 outputs was then input to EPA's OMEGA 2 Effects Model to develop an alternative set of costs and benefits for the Proposal where manufacturers just complied with the current standards. The net benefits from this analysis could then serve as the basis for estimating the net benefits of the Zero BEV and Proportional BEV scenarios shown in Table 6. The net benefits of the Proposal relative to the "just complying" No Action scenario from calendar year (CY) 2027-2055 are about $150 billion higher than EPA's estimates, as the costs and benefits of some of the BEVs sold under EPA's No Action scenario now contribute to the incremental costs and benefits of the Proposal.

Net Benefit Results

Table 7 shows the estimated net benefits of EPA's proposed standards for MY 2027 and beyond under different compliance pathways. As described above, we assume that manufacturers that intend to comply with the proposed standards using PHEVs would already be deploying PHEVs to comply with the current standards.

Table 7: Net Benefits of EPA's Proposed Emission Standards from CY 2027-2055, Discounted at 3%/year to 2027, Per EPA Methodology ($ Billion)

	Scenario	Net Benefits
1	EPA Proposal	$1,400-$1,600
2	Zero BEV	$770-$900
3	No Incremental BEVs	$970-$1,100
4	Proportional BEVs	$1,300-$1,400

As shown in Table 7, all of the alternative scenarios evaluated here are projected to produce significant levels of net benefits relative to their No Action scenarios. The net benefits of the Proportional BEV scenario are the highest of the three alternative scenarios. They approach those of EPA's Proposal due to the fact that sales of both BEVs and PHEVs increase between the No Action and Proposal scenarios. The net benefits are the lowest for the No BEV scenario due to its reliance on PHEV sales, though they are still very substantial. The net benefits of the No Incremental BEV sales fall in between those of the other two alternative scenarios.

Conclusion

Our follow-up detailed analysis assessing additional pathways to compliance through fuller reliance on PHEVs, hybrids, and ICE efficiency improvements and less reliance on BEVs concludes that EPA's proposed standards can be met with varying levels of technology and no particular technology is required – in whole or in part – to meet the fleet-average standards.

Our analysis also finds that even a zero-BEV pathway would result in significant net benefits of more than $770 billion and as BEV sales increase so do the net benefits. This analysis reinforces the performance-based nature of EPA's Proposed Standards and the technology flexibility manufacturers have toward compliance. [EPA-HQ-OAR-2022-0829-5118]

[EPA-HQ-OAR-2022-0829-5119]

[Attached study:]

U.S. Electric Vehicle Battery Manufacturing on Track to Meet Demand

The announced U.S. electric vehicle (EV) battery production capacity is more than on track to meet the projected demand for EV batteries that may occur under the Environmental Protection Agency's (EPA) proposed emission standards for light- medium- and heavy-duty vehicles with $92 billion of investment in batteries announced in the U.S.[i] Over 1,000 gigawatt hours (GWh) per year of U.S. battery production capacity has already been announced to come online by 2028 – enough to meet all of EPA's projected demand in 2030 and 85% of the projected demand in 2032.

[i] EPA's standards are technology neutral: vehicle manufacturers can use any combination of technologies they choose to reduce emissions from their vehicles. Likely the most cost-effective pathway is using ZEVs, as EPA modeled in its proposed rules.

Projected Demand for EV Batteries from EPA Proposed Standards

EDF used the EPA's projections for EV adoption and associated battery demand through 2030.[ii] Roughly 90% of the potential EV battery demand is from light-duty (passenger) vehicles. Potential demand for batteries in medium-duty vehicles (large pickup trucks and vans) and heavy-duty vehicles (delivery trucks, step vans, semi-trucks, buses, etc.) is much smaller.

[ii] Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles, 88 Fed. Reg. 29184 (May 5, 2023); Greenhouse Gas Emissions Standards for Heavy-Duty Vehicles—Phase 3, 88 Fed. Reg. 25926 (April 27, 2023).

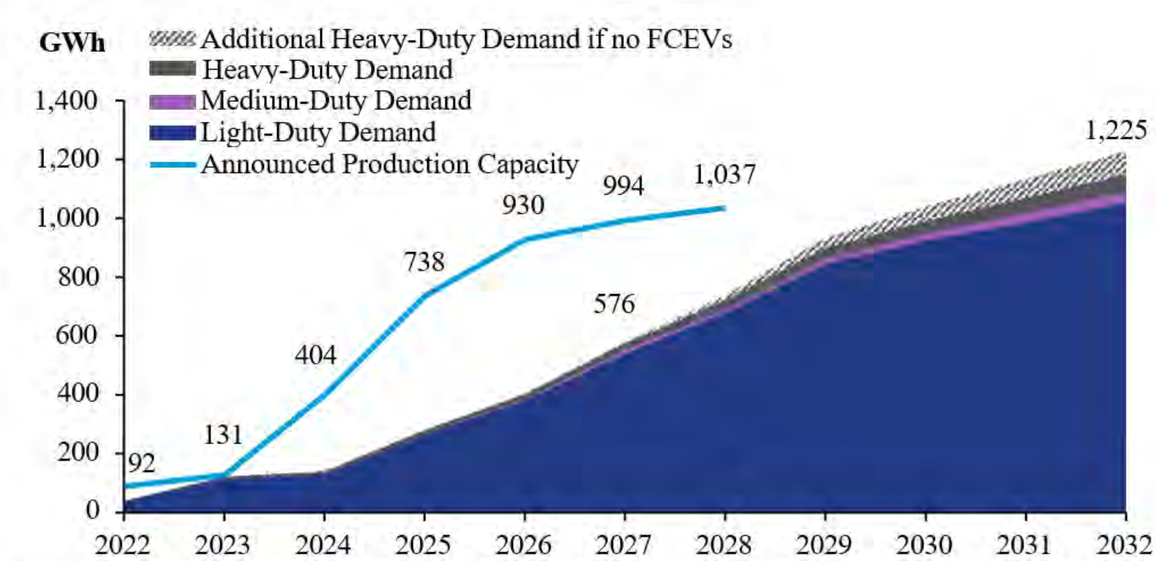

Figure 1: Projected U.S. EV Battery Demand and Announced Battery Production Capacity (2022-2032)

Figure 1 shows EPA projected battery demand by segment:

- Light-duty: 539 GWh per year in 2027 growing to 1,053 GWh per year by 2032.
- Medium-duty: 13 GWh per year in 2027 and only 38 GWh per year in 2032.
- Heavy-duty: 23 GWh per year in 2027 growing to between 59 GWh to 134 GWh per year in 2032, depending on whether heavy-duty EV adoption is met with a combination of fuel cell electric vehicles (FCEVs) and battery electric vehicles (BEVs) or solely BEVs (which would require more batteries). The additional batteries for an all-BEV compliance with EPA's heavy-duty proposal are labeled as "Additional Heavy-Duty Demand if no FCEVs".

Combined, U.S. EV battery demand is projected to be 576 GWh per year in 2027 and 1,151 GWh – 1,225 GWh per year in 2032. Even if heavy-duty EV battery demand increased twofold, overall battery demand would only increase to 1,359 GWh in 2032.

Announced Battery Manufacturing Capacity in the U.S.

As shown by the blue line in Figure 1, based solely on announced EV battery manufacturing plants, the U.S. will have an estimated capacity of 1,037 GWh per year by 2028, consistent with projections made by other sources.iii This includes 45 battery manufacturing facilities with an average production capacity of 23 GWh per year. Table 1 shows states with the most announced battery production capacity. To estimate the nation's battery manufacturing capacity, EDF used publicly announced battery manufacturing plant information, including total monetary investment, battery capacity, and production start date.

[iii] A DOE estimate from January 2023 found 1,000 GWh of announced battery capacity expected to come online by 2030. https://www.energy.gov/eere/vehicles/articles/fotw-1271-january-2-2023-electric-vehicle-battery-manufacturing-capacity Tech Crunch in August 2023 estimated 1,200 GWh per year of battery

capacity by 2030. https://techcrunch.com/2023/08/16/tracking-the-ev-battery-factory-construction-boom-across-north-america/?guccounter=1&guce_referrer=aHR0cHM6Ly93d3cuZ29vZ2xlLmNvbS8&guce_referrer_sig=AQAAACQ3fpohOwikg9 1T2WLv1r2F04jRtHJDtRVn8x0POx4Nz9XSKaYfKo6VDeVTY9Qgtb2X1MT1iiNwW2Zsoi8Owel0pZeKtL- M6tKgad7jbJsInS3C6TGxfX9gTHeWX7ZbKQtH5gHEk79lt0NqGsUzWt73wa0_Vb7Xw2ulgzY15X22 In July 2023, Digi Times Asia estimated the announced battery capacity for 2030 was 900 GWh per year. https://www.digitimes.com/news/a20230726VL202/us-battery-electric-vehicle-meet-the-analyst.html

Table 1: States with Highest Announced Battery Manufacturing

State	Number of Facilities	Battery Production (GWh)
Michigan	6	140
Georgia	5	136
Tennessee	3	128
Kentucky	4	119
Indiana	3	97
Ohio	2	75
South Carolina	5	67
Arizona	4	56
California	1	54
Illinois	1	40
Other	11	125
Total	45	1,037

The announced capacity for battery production outpaces EPA's projected demand through 2028, the last year for which any of the concrete current announcements project production will begin. Shifting consumer demand together with tax credits and incentives in the Inflation Reduction Act provide a strong case for battery manufacturers to build EV batteries in the U.S.

Even if construction delays shift production, there would still be enough battery supply. The average time between announcement and expected start of production for the battery facilities is 2.7 years, indicating that many of the facilities that would come online in 2027 and beyond have not yet been announced.

Plants Provide Capacity for Passenger EVs and Commercial EVs

As shown in Figure 1, EPA projects that roughly 90% of projected battery demand will power light-duty BEVs. While the relative demand for heavy-duty batteries is small, it will likely grow as demand for heavy- duty EVs grows. A recent announcement by Cummins, Daimler and PACCAR to build a joint battery plant in the U.S. indicates that heavy-duty manufacturers are already moving to supply this market.[iv]

[iv] *Accelera by Cummins, Daimler Truck, and PACCAR form a joint venture to advance battery cell production in the United States*, Cummins Newsroom, (September 6, 2023), https://www.cummins.com/news/releases/2023/09/06/accelera-cummins- daimler-truck-and-paccar-form-joint-venture-advance.

There can also be significant sharing of vehicle batteries and components across light- and heavy-duty EVs, including cell modules.[v] For example, Tesla uses the same batteries for its electric semi-truck and Model Y passenger car.[vi] And many of the same battery chemistries are being used and explored for both vehicle segments, including Nickel Manganese Cobalt Oxide (NMC) and Lithium-Iron Phosphate (LFP).[vii] [viii]

viii A Million-Mile Battery From China Could Power Your Electric Car, Bloomberg News, (June 7, 2020), https://www.bloomberg.com/news/articles/2020-06-07/a-million-mile-battery-from-china-could-power-your-electric-car

Methodology

EPA's OMEGA2 model tracks fleetwide battery usage by model year. EDF used EPA's OMEGA2 model outputs for the light- and medium-duty runs for the proposed rule, Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles, to quantify the projected battery need. We summed the battery pack size for each vehicle by EPA's projected sales for a given year for all years between 2022 and 2032.

For the proposed heavy-duty rule, Greenhouse Gas Emissions Standards for Heavy-Duty Vehicles—Phase 3, EPA used the HD TRUCS model to project EV adoption, including number of vehicles and size of battery packs. EPA modeled two years, 2027 and 2032. EPA also included two types of EVs – battery electric vehicles (BEVs) and fuel cell electric vehicles (FCEVs). EDF multiplied the projected BEV adoption in 2027 and 2032 (in percentage terms) for each of the 101 vehicle categories in HD TRUCS by the annual sales and estimated battery pack size. HD TRUCS includes 2019 sales. To project HDV sales in later years, EDF assumed a 0.8% compound annual growth rate consistent with AEO2023.ix Heavy-duty battery demand in 2022 was assumed to be 10% of the demand in 2027. The battery demand was linearly interpolated for the years between 2022, 2027 and 2032.

[ix] U.S. Energy Information Administration's Annual Energy Outlook 2023, Table 49. Freight Transportation Energy Use, (March 2023), https://www.eia.gov/outlooks/aeo/supplement/excel/suptab_49.xlsx.

To account for a more conservative scenario in which the projected heavy-duty EV adoption might be met with all BEVs instead of a mix of BEVs and FCEVs as EPA projects, we calculated the battery demand if adoption projections are met entirely with BEVs. The largest group of vehicles projected to be FCEVs are sleeper cab tractors. EPA projects sleeper cab tractors would have very large battery packs, if BEVs were the chosen compliance path versus FCEVs, with the largest being more than 2 MWh per vehicle. EDF believes that EPA overestimates the battery pack size needed for many heavy- duty vehicles as explained in more detail in our comments,x but for purposes of this analysis, we used the EPA projected battery pack sizes. Assuming all heavy-duty EVs are BEVs results in the same 2027 battery demand because EPA does not project any FCEVs to be deployed then. Heavy-duty battery demand increases in 2030 to 90 GWh per year as a result of more BEVs, doubling EPA's projected demand for heavy-duty vehicles with BEVs and FCEVs of 45 GWh. This additional battery demand is labeled as "Additional Heavy-Duty Demand if no FCEVs" in Figure 1.

[x] Comments of the Environmental Defense Fund, EPA-HQ-OAR-2022-0985-1644, https://www.regulations.gov/comment/EPA- HQ-OAR-2022-0985-1644.

To determine the announced U.S. battery manufacturing capacity, EDF updated a previous analysis performed by WSP in August 2023 for EDF.xi EDF confirmed all plants produced batteries and not battery components to ensure no double counting. In cases where plans had changed for battery plants and the timelines for production were uncertain, the battery facilities were removed from the list. Some of the facilities like the North Carolina Toyota plant have announced investments ($13.9B) that would likely support much more battery production than they have announced (30GWh). Due to the conservative measures we took, this is likely an underestimate of the battery production capacity from already announced plants.

[EPA-HQ-OAR-2022-0829-5119]

Organization: Hyundai Motor America

Hyundai Motor America ("Hyundai") would like to provide supplemental comments to those submitted on July 5, 2023, for the U.S. Environmental Protection Agency's ("EPA") notice of proposed rulemaking entitled, "Multi-Pollutant Emission Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles." There are two specific areas that we wish to supplementally comment on: (1) Slowing EV Sales Rate and (2) Community Energy Savings Credit. These comments were not included in our previous letter because they are based on recent activity.

1. Slowing EV Sales Rate

A slowdown in EV Sales across the industry has been making headlines recently. Hyundai echoes these concerns. Our comment letter, submitted July 5, 2023, provides a balanced solution that allows EPA to regulate at levels it deems appropriate today while acknowledging that the unprecedented push to EVs hinges on the materialization of key enablers in just six short model years from now. The solution: A newly created Federal Advisory Committee (FAC) that would be charged with assessing, in the 2029-2030 calendar years, key enablers such as but not limited to the state of market demand, EV infrastructure development, and grid resiliency against the final rule's assumptions. The FAC is authorized to activate proportional EV multipliers as a regulatory cure for model years 2029-2032 if it finds there is a shortfall in the assumptions for key enablers supporting the rule's stringency and EV-equivalent penetration rates. Please see pages 8 and 9 of Attachment 1.

2. Community Energy Savings Credit

This is regarding our proposed incentive program for automakers who increase the volume of plug-in electric vehicles ("PEV") into disadvantaged communities. This concept was refined in response to the National Highway Traffic Safety Administration's ("NHTSA") notice of proposed rulemaking entitled, "Corporate Average Fuel Economy Standards for Passenger Cars and Light Trucks for Model Years 2027–2032."1 Specifically, we narrowed its scope and made it easier to implement while still yielding noteworthy fuel economy improvements and emissions reductions particularly among America's equity communities. Please see pages 6-7 and the last page of Attachment 2.

1 88 Fed. Reg. 56,371-56,374 (Aug. 17, 2023)

We appreciate EPA's thoughtful consideration of these supplemental comments and would be more than happy to discuss further. [EPA-HQ-OAR-2022-0829-5102; 2 attachments]

Organization: Toyota Motor North America, Inc. (submits 2 additional studies)

Toyota Motor North America, Inc. (Toyota) appreciates the opportunity to provide supplemental comments on the above-referenced Notice of Proposed Rulemaking (NPRM). We are submitting to the docket the recent correction to the Plötz et al (2021) paper, "From lab-to-road: real-world fuel consumption and CO_2 emissions of plug-in hybrid electric vehicles" (2021 Environ. Res. Lett. 16 054078).

As the only peer reviewed paper referenced in the NPRM in support of the proposed revisions to the SAE J2841 Utility Factor Curves, we believe it is incumbent upon EPA to incorporate the published corrections in their analysis of the Final Rule. See, e.g., Motor Vehicle Mfrs. Ass'n v. State Farm Mut. Auto. Ins. Co., 463 U.S. 29, 43 (1983) ("[T]he agency must examine the relevant data and articulate a satisfactory explanation for its action including a rational connection between the facts found and the choice made.") (internal quotation marks omitted).

The corrigendum notes that there were errors in the original conventional fuel consumption (FC) measures based on EPA's data, which now have been substituted with EPA label (window sticker) values. The resulting correction brings the Plötz work in line with the Toyota/Hamza et al (2022) paper, "On inferred real-world fuel consumption of past decade plug-in hybrid electric vehicles in the US." (2022 Environ. Res. Lett. 17 104053); suggesting strong correlation between real world data and the existing SAE J2841 Utility Factor Curves.

This important correction provides additional rationale in support of Toyota's July 5, 2023 comments that EPA should maintain SAE J2841 for determining utility factor curves for PHEVs. [EPA-HQ-OAR-2022-0829-5100]

EPA Summary and Response

AESI et al., a group of 29 organizations, commented in support of strong standards to control particulate matter (PM) emissions from light- and medium-duty vehicles. These commenters discussed the public health needs for further PM emissions control, the benefits of emissions standards, and the feasibility and availability of gasoline particulate filter technology in being effective in controlling tailpipe emissions. EPA appreciates these additional comments, and we are finalizing the proposed PM standards, with an extension of the phase-in to provide manufacturers with additional lead time. Section 4.1.3 addresses comments on the PM standard.

The Alliance for Automotive Innovation (Alliance) expressed concerns with the availability of adequate critical mineral supplies to support the market share of EVs under the proposed standards, given global demand for such materials. The Alliance submitted additional analysis from Benchmark Minerals Intelligence (BMI) on lithium supplies in the context of automaker production goals and global regulatory policies. EPA addresses comments related to critical minerals are addressed in Section 15.

The American Free Enterprise Chamber of Commerce (AmFree) provided comments regarding EPA's estimated per-vehicle costs in the proposed rule. EPA has responded to comment on our cost analysis, which has been updated since the proposal in consideration of comments and based on the best available information in the public record. Our final analysis includes several possible pathways toward compliance including pathways that rely on varying combinations of ICE, HEV, PHEV and BEVs (see Sections IV.F and G of the preamble to this final rule). We believe that manufacturers could choose to meet these multiple potential technology pathways at costs that are reasonable. Also see further responses to comments regarding our technology cost estimates in Section 12.2.7.

Center for Biological Diversity et al provided two additional studies for the record. One study, by EPRI, relates to aiding utilities efficiently plan investment to prepare the electric grid for expanded deployment of EV charging infrastructure. We discuss electric grid impacts further in Section 18. The second report is related to phasing in charging infrastructure and focuses on the heavy-duty vehicle sector. While heavy-duty infrastructure issues are out of scope for this rule, we have also included the CBD et al comment in the heavy-duty GHG rulemaking docket (EPA-HQ-OAR-2022-0985-2672).

EDF provided a follow-up detailed analysis, in which it assessed additional pathways to compliance through fuller reliance on PHEVs, hybrids, and ICE efficiency improvements with zero to moderate levels of battery electric vehicles (BEVs). EDF's analysis concluded that the proposed standards could be met with varying levels of technology and that no particular technology would be required (in whole or in part) to meet the fleet-average standards. EDF noted that this finding was true even in what it considered exceedingly unrealistic low- and no-BEV baseline scenarios. EDF further found that even a no-BEV pathway would result in significant net benefits, and as BEV sales increase so do the net benefits. EDF also shared additional information on state adoption of clean vehicle programs. EPA appreciates the additional information provided by EDF. We note that EDF's analysis of alternative pathways supports EPA's analysis that there is a wide range of feasible technology pathways for auto manufacturers to choose in complying with the standards, including pathways that rely to varying degrees of ICE, HEV, PHEV and BEVs, including pathways that include low levels or even no additional BEVs beyond those in the marketplace today, or beyond the No Action case.

Hyundai provided information on EV sales rates and community energy savings credits. Hyundai expressed concern with what they view as a slowing of EV sales in recent months, and put forward a suggestion to create a Federal Advisory Committee that would be charged with assessing, in the 2029-2030 calendar years, key enablers such as but not limited to the state of market demand, EV infrastructure development, and grid resiliency against the final rule's assumptions. As discussed further in Sections 3.4 and 28, EPA is not finalizing any form of a midterm evaluation or provisions for formally monitoring development of market demand, infrastructure or other factors. The Administrator has the authority to initiate a new rulemaking if he or she finds that there is an appropriate need without establishing these provisions. Hyundai also suggests an incentive program for automakers who increase the volume of PEVs into disadvantaged communities. EPA does not believe that further incentive credits are appropriate under the final standards, and because we neither proposed nor sought comment on such an approach we consider it out of scope.

Toyota submitted additional information regarding the PHEV utility factor. Specifically, Toyota submitted a correction to a published paper that EPA had referenced in the NPRM. EPA has considered the corrections to this paper in our final analysis of the PHEV UF, as further discussed in Section 3.1.6.

Appendix A: Other comments received, not reproduced verbatim in RTC text

This appendix contains a list of comments that are general in nature and do not require detailed EPA response beyond provided elsewhere in this document, and/or contain opinions or statements about issues that are raised without reasonable specificity. There are about 4,300 individual comments that fall into this category. The commenters are listed in Table A-3, below.

EPA Summary and Response:

Summary:

We characterize the nature of each of the comments not reproduced verbatim elsewhere in this document by classifying their statements along eight dimensions (one comment may contain statements on more than one dimension). The topics are as follows:

- General Support
- Want more stringent
- Oppose
- Environmental and/or health concerns
- Environmental Justice concerns
- Business and/or cost concerns
- Infrastructure and/or resource availability, supply chain concerns
- Incentives Available (IRA, BIL)

As shown in Table A-1, of the 4,300 unique non-detailed comments, 17.8% did not include a codable statement one of these 8 topics. Most of the comments included statements on 2 or 3 topics.

Table A-1: Number of Topics Raised in Other Comments Received, Not Reproduced Verbatim in RTC Text

No. Issues Raised	% of Commenters
0	17.8%
1	26.0%
2	33.5%
3	17.4%
4	4.1%
5	1.1%
6	0.1%
Total	100.0%

Table A-2 sets out the general themes raised in these comments. It should be noted that aside from the categories of "general support," "want more stringent," or "oppose," the coding does not distinguish between positive and negative comments on a particular theme. So, for example, comments on business and costs cover both those comments expecting decreased costs and those expecting increased costs. The purpose of the analysis is not to tally the comments per se, but rather to form an impression of the themes these commenters are most concerned about.

Table A-2: Themes Raised in Other Comments Received, Not Reproduced Verbatim in RTC Text

Theme	% of Comments Raising Theme
General support	0.7%
Want more stringent	7.5%
Oppose	25.0%
Environmental, Health	19.8%
Environmental Justice	1.9%
Business, Costs	27.1%
Infrastructure, Supply Chain	16.1%
Incentive Availability	2.0%
Total	100.0%

Response:

As noted above, these comments are general in nature and do not require detailed EPA response beyond provided elsewhere in this document, and/or contain opinions or statements that are raised without reasonable specificity. EPA's responses included throughout this RtC document address each of the general topics raised in these comments.

Table A-3: List of Comments Not Reproduced Verbatim in RtC

Appendix B: Mass comment campaigns

EPA received 46 mass mail campaigns commenting on the proposal, representing 247,767 signatures. These mass comment campaigns are in the form of either a cover letter with many signatures; individual letters that are identical or nearly identical; or a cover note with a spreadsheet containing many individual comments. The mass mail campaigns are listed in Table B-1, organized by the sponsoring organization (if known), along with the number of signatures. Also reproduced verbatim below is the docketed example of each mass mail campaign or one excerpt from the associated spreadsheet or attachments.

Sixteen of the mass mail campaigns contain detailed comments and are included verbatim in the RtC document. These are also noted in Table B-1. The remaining 30 comments are reproduced below.

Comments by Organizations

EPA-HQ-OAR-2022-0829-0505 - Mass Comment Campaign sponsored by E2 Environmental Entrepreneur Business Leaders. (web) (124 signatures)

As business leaders and supporters of E2, we are writing to urge you to ensure that both the medium/light duty and heavy-duty vehicle emission standards are as strong as possible.

Specifically, we believe that it is vital the Environmental Protection Agency (EPA):

1. Quickly finalize a standard for Light and Medium-duty vehicles that achieves at least a 75% reduction in greenhouse gas emissions by model year 2030.

2. Finalize Heavy Duty Vehicle/clean truck standards by the end of 2023 that puts the nation on a path to all new heavy-duty vehicle sales being zero emissions by 2035.

E2 is a national, nonpartisan group of more than 11,000 business leaders, investors, and professionals from every sector of the economy. Our members have founded or funded more than 2,500 companies, created more than 600,000 jobs and manage more than $100 billion in venture and private equity capital.

We recognize and appreciate that this administration has driven incredible and unprecedented federal clean energy investments across a broad range of sectors including vehicles. E2 has been proud to actively support key components of your agenda including the passage of the Inflation Reduction Act, the Infrastructure Investment and Jobs Act and the Chips and Science Act.

As businesspeople from a broad cross-section of the economy, we value these investments and are seeing, firsthand, the positive benefits. However, we also recognize that without strong light/medium and heavy-duty vehicle emission standards, the U.S. risks ceding global economic leadership to other nations and regions such as Asia, Europe or India. These global competitors have plans in place advancing their transition to zero-emission vehicles in the coming decades.

As of September 2022, automakers and battery manufacturers worldwide will spend more than $626 billion through 2030 to develop new electric cars, passenger trucks, freight trucks and buses. That is a $110 billion increase from projections in April of 2022.

To be globally competitive, the US must accelerate the rate that our auto sector is transitioning to clean vehicles. Strong EPA standards will provide the clear market certainty needed to support commitments that are already being made by many in the industry and will provide regulatory support to ensure those commitments are met.

Furthermore, many of our businesses are trying to lower emissions in our supply chains and lower costs for our consumers. Most businesses are dependent on third party delivery truck operators. Stronger vehicle emissions standards will drive the availability of lower emission, lower cost, options in a way that businesses with small market-share cannot.

Strengthening tailpipe emissions and advancing a transition to zero-emission vehicles is a win for America and all those looking to protect public health, spur job creation, economic growth, as well as family and business cost savings.

Please redouble your efforts to ensure that the very strongest light-, medium-, and heavy-duty vehicle emission standards are finalized this year. Doing so will allow us to tackle the climate crisis and address air pollution. It will also allow us to fully leverage the recent federal clean energy investments and historic investments from Congress, accelerate the vehicle sector's shift to a zero-emission future, increase U.S. global competitiveness, save consumers money, and create good American jobs.

EPA-HQ-OAR-2022-0829-0512 - Mass Comment Campaign sponsored by Moms Clean Air Force - Arizona. (web) (40 signatures)

The transportation sector is the largest source of climate pollution in the US, and cleaning up this pollution is one of the most important things we can do to fight climate change and protect our children's future. Tailpipe pollution can also harm the health of our families and communities. Clean Car Standards are a critical tool to fight climate change and reduce dangerous air pollution. They help protect public health nationwide.

EPA has proposed Clean Car Standards that are a significant step forward In the transition to zero-emission vehicles. This rule would put us on a path to boosting the electric passenger vehicle market share to 67% by 2032.

We the undersigned urge the EPA to move quickly to finalize the strongest possible standards for tailpipe pollution from passenger cars and trucks.

EPA-HQ-OAR-2022-0829-0535 - Mass Comment Campaign sponsored by Moms Clean Air Force - Arizona Chapter (14 signatures)

The transportation sector is the largest source of climate pollution in the US, and cleaning up this pollution is one of the most important things we can do to fight climate change and protect our children's future. Tailpipe pollution can also harm the health of our families and communities. Clean Car Standards are a critical tool to fight climate change and reduce dangerous air pollution. They help protect public health nationwide.

EPA has proposed Clean Car Standards that are a significant step forward In the transition to zero-emission vehicles. This rule would put us on a path to boosting the electric passenger vehicle market share to 67% by 2032.

We the undersigned urge the EPA to move quickly to finalize the strongest possible standards for tailpipe pollution from passenger cars and trucks.

EPA-HQ-OAR-2022-0829-0543 - Mass mail campaign submitted Alliance of Nurses for Healthy Environments (web) (54 signatures)

The transportation sector is the largest source of greenhouse gasses in the United States, making up nearly 30% of our country's emissions. Emissions from passenger vehicles and trucks pollute the air we breathe causing adverse health impacts and contributing to the increasingly urgent issue of climate change. Nurses applaud EPA for finalizing robust clean car standards through model year 2026 and for taking the important next steps to finalize stricter clean car and truck standards through model year 2027.

It is critical that EPA finalize the strongest possible clean car and truck standards to drive a rapid transition to zero emissions vehicles. Numerous studies show that poor health outcomes and higher incidences of chronic conditions, like asthma, lung disease, and cancer, are linked to tailpipe pollution from passenger vehicles. In 2020, the national passenger vehicle fleet represented approximately 94 percent of the nation's on-road vehicles and generated over one million tons of ozone- and particle-forming NOx emissions, and over 33,400 tons of fine particles annually. Further, freight truck pollution harms especially those who live near highways, ports, freight hubs and other high traffic areas. We know that clean car standards are the most effective policy to reduce dangerous air pollution and protect public health nationwide.

Climate change poses serious threats to the health and lives of all Americans, especially children, older adults, low-wealth communities, communities of color and people living with chronic diseases. When poor air quality due to vehicle emissions coincides with climate-related risks, such as extreme heat or ground-level ozone, adverse health effects are further amplified.

By finalizing the strongest possible clean car standards for cars and trucks, EPA will help the communities, who often are more exposed to air pollution and the hardest hit by effects of climate change and will align with the Biden Administration's environmental justice goals.

The Biden Administration has an opportunity to protect public health and fight the climate crisis with strong long-term clean cars standards. As we transition nationwide to zero-emission vehicles, we urge EPA to move swiftly to enact the strongest possible long-term standards for light-, medium-, and heavy-duty trucks to clean our air, keep Americans healthy, and combat the climate crisis.

EPA-HQ-OAR-2022-0829-0691 - Mass Comment Campaign sponsored by The Climate Reality Project. (web) (7,367 signatures)

On behalf of more than 7,300 Americans who want to improve their communities' health and protect the planet we share, The Climate Reality Project strongly urges you to enact historic climate regulation by implementing the strongest possible proposed vehicle pollution standards.

We have attached the comment letter we have asked our followers, friends, and volunteers in the region to sign as well as each signatory's name. As you tabulate the number of comments, we hope you count each and every one of these signatories as an individual comment.

Thank you for your work and commitment to climate action.

Transportation makes up the largest share United States greenhouse gas (GHG) emissions—28%—due to the fossil fuels we burn for cars, trucks, and other modes of transport.i This must change if we are to achieve our climate and justice goals. In combination with recent historic provisions in the Bipartisan Infrastructure Law (BIL) and Inflation Reduction Act (IRA), the proposed standards for light-, medium-, and heavy-duty vehicles could accelerate emission reductions, while significantly growing the electric vehicle (EV) sector.ii We are encouraged by the EPA's proposal and urge you to enact the strongest possible limits on vehicle pollution.

Communities of color are more likely to reside near highways, and subsequently experience the brunt of associated negative health impacts, including impaired lung function, cardiovascular diseases, and premature death.iii The new standards could address these issues by potentially reducing emissions for harmful pollutants, such as particulate matter, by over 95%.iv Not only would this lessen burden of pollution on vulnerable communities, but the standards could yield up to $1.6 trillion in net benefits from cleaner air to lower vehicle operating costs and fuel savings.v

EVs made up an estimated 5.6% of cars and trucks sold in 2022.vi To achieve President Biden's goal of cutting climate pollution in half by the end of the decade, the number of EVs on the road must significantly increase; the strongest proposed limits could lead to an estimated

69% of new light-duty passenger vehicles sold being electric by 2032.vii Once out of reach for the average American, EVs popularity is expected to grow as a result of recent incentives making these vehicles more accessible.viii According to the International Council on Clean Transportation, EVs could reach cost parity with traditional cars in the next two years.ix Between the climate and economic benefits, we cannot afford to delay this transition with less stringent standards.

IPCC recently warned that rapid and deep GHG emission reductions must be executed to keep warming below the critical 1.5 degrees Celsius threshold.x In 2021, President Biden signed an Executive Order setting a target for half of all vehicles sold to be zero emission vehicles by 2030.xi We applaud EPA's efforts to exceed this directive and implement ambitious regulation that will help us to meet our climate targets.

Under the BIL and IRA, Congress showcased its commitment to transitioning toward a clean energy economy. If we are serious about unlocking the full potential of these laws, we must end our dependence on dirty fossil fuels. We urge you to enact historic climate regulation by implementing the strongest possible proposed vehicle pollution standards. Our just energy transition and the health of our communities depends on it.

EPA-HQ-OAR-2022-0829-0693 - Mass Comment Campaign sponsored by Evangelical Environmental Network (EEN). (web) (2,5303 signatures)

As pro-life Christians, we have a special concern for the unborn and believe all human life is sacred and worth defending. Children deserve the hope and expectation of a healthy, vibrant, and full life, unhindered by the ravages of pollution. Tailpipe emissions from passenger vehicles fills the air we breathe where we live, work, and play with toxic pollution, like soot (PM2.5) and ozone. Traffic is preventable and puts God's creation and our families - especially pregnant mothers and the unborn - in harm's way. Medical research links traffic pollution to serious harms to human health, including asthma, lung cancer, dementia, and pre-term birth.

As pro-life Christians, we have duty to defend life. We urge the EPA to set the strongest standards possible for tailpipe pollution from passenger vehicles. To create the healthy future our children deserve, we need the strongest possible long-term standards—beyond model year 2026—that will reduce car and light truck pollution by 75% by 2030 and put us on a path to a 100% zero-emission new vehicle sales target by 2035. Our kids deserve clean air and the right to an abundant life.

EPA-HQ-OAR-2022-0829-0717 - Mass Comment Campaign sponsored by Natural Resources Defense Council (NRDC). (web) (24,038 signatures)

Please accept these public 24,038 comments from members and online activists of the Natural Resources Defense Council (NRDC) asking you to finalize the strongest possible standards to reduce pollution and help ensure the transition toward zero-emission vehicles.

Transportation accounts for the largest share of climate pollution in the U.S. and is also a major source of other harmful pollutants that significantly impact public health, causing deadly diseases such as asthma, heart problems, and cancer.

Cleaner vehicles are a winner all around. They help clean up the air, deliver savings on fuel, support domestic job creation, and protect the climate.

Please finalize a strong vehicle standard that would do the following:

• A strong EPA standard for cars, SUVs, pickup trucks, and cargo vans should be finalized by the end of the year and must lead to significant reductions in carbon emissions by being at least as strong as the most stringent alternative in the agency's proposal.

EPA-HQ-OAR-2022-0829-0719 - Mass Comment Campaign sponsored by Interfaith Power & Light (IPL). (web) (190 signatures)

As faith leaders from diverse religious and spiritual traditions, we speak with one voice in support of bold and just climate solutions. Climate change is a moral issue that is most harmful to those least responsible for creating the problem. People of faith and conscience recognize the need for bold, new transportation solutions, and clean cars and light trucks are an integral step towards addressing the climate crisis. Today we write to ask you to move swiftly to enact robust light-duty vehicle multi-pollutant emissions standards. As a nation, we have a moral imperative to enact the most stringent light-duty vehicle standards in order to address our historically unsafe pollutant emissions and to protect our public health and Shared Home.

Transportation is currently the single largest source of climate pollution in the United States. In 2020, the national passenger vehicle fleet represented approximately 94% of the nation's onroad vehicles and generated over one million tons of ozone- and particle-forming NOx emissions, which create dangerous smog. In order for the U.S to meet our Paris Climate

Agreement goals we need the strongest possible long-term standards—beyond model year 2026 — that will put the country on a path to a 100% zero-emission new vehicle sales target by 2035.

It is critical to remember that the climate crisis is a challenge of racial, economic, and generational justice, and these rules target air pollution that disproportionately harms marginalized communities of color and low-wealth communities that reside in counties closest to major freeways. Implementing the strongest light-duty vehicle standards is a matter of environmental justice, and these standards would deliver massive emission reductions and lifesaving relief to frontline communities.

In addition, electrifying cars and light trucks will be key to improving air quality and saving lives across the nation. More than 119 million American residents currently live in areas with unhealthy levels of air pollution. According to research from Harvard University, more than 8 million people died from the effects of fossil fuel combustion in 2018, meaning that fossil fuels like oil and coal are linked to 1 in 5 deaths worldwide. Pollutants caused by burning fossil fuels have been linked to early death, heart attacks, respiratory disorders, stroke, and asthma.

It is of the utmost importance that standards require tighter limits on internal combustion engine vehicles in order to continually make these vehicles cleaner as manufacturers transition to zero-emission cars.

Now is the time to maximize the impact of our national clean car standards—the most effective policy that the federal government has to reduce dangerous air pollution, lower greenhouse gas emissions, and save consumers money at the pump. As policymakers, you have a critical and sacred role in helping to achieve these goals. As faith leaders, we urge you to establish strong light-duty vehicle multi-pollutant emissions standards that put our nation on a trajectory to a zero-emissions transportation future, and we ask you to redouble efforts to announce the draft rule before the end of 2023. For more than a decade, people of faith and conscience have advocated for strong safeguards on greenhouse gas pollution from transportation. Since then, the climate crisis has only accelerated, taking an enormous toll on human life, our communities, and our world. We have a moral responsibility to act right now as a nation to do all we can to address climate change for our communities, future generations, and our Sacred Earth.

EPA-HQ-OAR-2022-0829-0720 - Mass Comment Campaign sponsored by Union of Concerned Scientists. (web) (1,030 signatures)

We, the over 1000 undersigned scientists, researchers, health professionals, economists, engineers, and planners respectfully submit this comment in support of standards for heavy-duty vehicles and passenger vehicles that put us on a trajectory to eliminate tailpipe pollution.

The Environmental Protection Agency (EPA) has made explicit commitments to climate, clean air, and environmental justice under this administration. The transportation sector is the largest contributor to global warming emissions in the United States. And while heavy-duty trucks make up only 10 percent of vehicles on the road, they produce 28 percent of global warming emissions from on-road transportation, as well as 45 percent of nitrogen oxide emissions and 57 percent of particulate matter emissions, which disproportionately harm environmental justice communities living near ports and freight corridors. Thus, we believe that the light- and medium-duty vehicle multipollutant rule and the global warming emissions proposal for heavy-duty trucks should live up to these important stated commitments and to set us on an accelerated path to a zero-emission transportation future.

The light- and medium-duty vehicle rule is on the right track to reduce climate-harming, smog-forming, and particulate pollution, but the heavy-duty rule trails passenger vehicles, leaving environmental justice communities in harm's way.1 The science and technology, as well as the urgent need to protect public health and address the climate crisis, are clear on this front: zero-emission vehicles are available today and must be the number one priority.2

1 https://www.movingforwardnetwork.com/zero-emissions

2 https://www.ucsusa.org/resources/electrify-trucks

New state standards adopted by several states across the country will ensure more than 50 percent of new heavy-duty vehicle sales are electric vehicles by 2030. Also, new tax incentives for commercial trucks are predicted to push electrification even further.3 As the EPA acts to accelerate the deployment of zero-emission passenger vehicles, it must also eliminate toxic tailpipe emissions from heavy-duty trucks and ensure that 100 percent of all new vehicles sales are electric by 2035 to maximize clean air to breathe. This has also long been an ask of environmental justice communities across the country.

3 https://theicct.org/wp-content/uploads/2023/04/hdv-phase3-ghg-standards-benefits-apr23.pdf

The urgency of these issues demands a strong response. For far too long, vehicle pollution has been devastating for the health of communities across the country and the climate.4 The solutions are here – and we urge the EPA to stand up to this moment, pass the strongest possible version of the light- and medium-duty standards, and eliminate tailpipe pollution from heavy-duty trucks and cars.

4 https://www.ucsusa.org/resources/diesel-engines-public-health

EPA-HQ-OAR-2022-0829-0721 - Mass Comment Campaign sponsored by Evergreen Collaborative. (web) (8,119 signatures)

Thank you for the proposed light-duty multi-pollutant emissions rule for 2027-2032 (Clean Car Standards). I want to applaud EPA for using the full force of Clean Air Act authorities to address climate pollution and public health impacts by proposing the most ambitious standards yet. It's wonderful to see EPA affirming its commitments to prioritize environmental justice by proposing standards that will reduce soot and smog in our communities.

Specifically, I am supportive of EPA's proposed "Alternative 1," which sets the most stringent emissions reduction standards. While these proposed standards are technology neutral, electric vehicles present the best option for compliance as they emit zero tailpipe pollution, resulting in improved public health and climate outcomes. Based on the current and growing uptake of electric vehicles, paired with the investments in charging and manufacturing from the Inflation Reduction Act and the Infrastructure Investment and Jobs Act, these standards should be achievable under the model years covered.

And, I would be supportive of EPA further strengthening Alternative 1 to increase the stringency of the rule after 2030, as the market will likely be prepared for stronger standards at that time.

I am also supportive of EPA adopting clean car standards that last through 2035, as requested by auto manufacturers to create market stability. Locking in clean car standards now, and for the next decade, will give manufacturers, investors, and consumers greater confidence in the direction of the vehicle market.

We urgently need tailpipe emissions standards that clean up the air we breathe and protect the climate, and by locking in the strongest possible proposal, EPA can best protect communities that have long been harmed by transportation pollution.

Please move quickly to finalize the strongest possible Clean Car Standards that align with the level of ambition needed to protect public health and the planet.

EPA-HQ-OAR-2022-0829-0723 - Mass Comment Campaign sponsored by American Lung Association (ALA). (web) (1,371 signatures)

We urge the U.S. Environmental Protection Agency to finalize strong emissions standards for heavy-duty, light-duty and medium-duty vehicles this year. These emissions standards are critical for addressing climate change, improving public health and promoting environmental justice.

We appreciate your proposal to strengthen greenhouse gas emissions limits for new heavy-duty vehicles. We urge you to ensure that they are finalized this year, as new diesel trucks have long lifespans on our roads. We also urge you to make the final rule even stronger than the proposal. The final standards should be at least as stringent as the state-level Advanced Clean Trucks program currently in place in many states.

We also appreciate your proposal to strengthen limits on greenhouse gases and other air pollutants for new light-duty and medium-duty vehicles in Model Years 2027-2032. We call on you to ensure these standards for all pollutants are finalized this year as well. We appreciate that in the proposal, you included alternative levels, and urge you to build off Alternative 1 – the most stringent option – in the final rule. This alternative will yield the most health benefits from pollution reductions.

Emissions from vehicles powered by gasoline and diesel pose immediate harm to health. In the heavy-duty vehicle sector, pollution from diesel-powered trucks and buses drive health harms including asthma attacks, heart attacks and strokes, and premature death. Seventy-two million people are estimated to live near truck freight routes, and they are more likely to be people of color and with lower incomes.

Pollution from light- and medium-duty vehicles powered by gasoline and diesel, like passenger cars, SUVs, pickup trucks and package delivery vans, also harms public health and is driving climate change. Particulate matter can cause immediate health harm, including respiratory and cardiovascular disease and even premature death.

Transportation is the single biggest source of greenhouse gas emissions in the U.S. and transitioning to zero-emission cars is a critical part of addressing climate change. Climate change is a health emergency, leading to more frequent and intense extreme weather events like flooding, excessive heat, drought, and wildfires; longer and more intense allergy seasons; increased risks from water-borne and vector-borne diseases like Lyme Disease; and worsening air quality.

Stronger limits on emissions from cars, vans, buses and trucks will help drive a nationwide transition to zero-emission vehicles, which is crucial for not only addressing climate change, but also for improving public health and equity.

EPA-HQ-OAR-2022-0829-0725 - Mass Comment Campaign sponsored by National Religious Partnership for the Environment. (web) (10,890 signatures)

As Black church leaders, we urge the Environmental Protection Agency (EPA), the agency responsible for protecting the health and environment of communities across the United States, to finalize robust clean car standards that protects human health and the sanctity of God's creation. Since transportation is the largest source of carbon pollution in our country, strong pollution standards will protect families from dangerous vehicle pollution and fight climate change.

Addressing pollution and climate change is a moral and justice matter. Our communities have traditionally borne an undue burden from pollution and climate change; a burden levied on us from redlining and other discriminatory practices. Our communities are often located closest to highways and other sources of vehicle pollution. It is no surprise that black communities are disproportionately impacted by asthma and other respiratory illnesses. Stronger vehicle emission standards will help address these unequal health impacts.

For the health and wellbeing of our communities, it is imperative that the EPA deliver emission standards for cars that set us on the path to zero-emission vehicles by 2035. These tailpipe emission standards, which will help drive us towards a clean energy future, must be done in partnership with an investment in infrastructure that will allow all communities access to zero-emission vehicles.

As Christians, we are called to protect God's creation and care for God's people. The EPA has an opportunity to help address the injustice of pollution and climate change by enacting the strongest possible federal clean car standards.

EPA-HQ-OAR-2022-0829-0726 - Mass Comment Campaign sponsoring organization unknown. (web) (22 signatures)

I'm writing to urge the EPA to quickly finalize the strongest possible air pollution safeguards on emissions from passenger cars and light trucks. The EPA's current proposal is a good start, but it must be stronger to limit climate change and improve public health significantly. I appreciate that the EPA has said it will consider more stringent alternatives and ask the agency to implement air pollution safeguards on cars and light trucks that are at least as strong as the standards outlined in Alternative 1 of the EPA's proposal.

For the U.S. to meet its Paris Climate Agreement goals, the EPA must set the strongest possible long-term standards that will reduce car and light truck greenhouse gas emissions 75% by 2030, putting the country on a path to a 100% zero-emission new vehicle sales target by 2035. According to the EPA's own analysis, the transportation sector accounts for 27% of greenhouse gas emissions and is the fastest growing emitter of greenhouse gases.

Greenhouse gas emissions accelerate climate change, which poses a serious threat to Americans' health and well-being, affecting everything from the air we breathe to the places we live. Extreme weather events worsened by climate change create more air and water pollution, destabilize food sources, and put our homes and lives at risk. According to the American Lung Association, a nationwide transition to zero-emission cars, light trucks, and heavy-duty vehicles –coupled with a transition to zero-emission electricity – would result in 110,000 premature deaths prevented (nationwide, 2020-2050); $1.2 trillion in health benefits (nationwide, 2020-2050); and $1.7 trillion in additional climate benefits (global, 2020- 2050).

The strongest possible air pollution safeguards on cars and light trucks would also deliver massive emission reductions and life-saving relief to frontline communities that are often closest to highways and bear the greatest burden from vehicle pollution. Low-wealth and BIPOC (Black, Indigenous, People of Color) communities experience disproportionate harm from dirty vehicle pollution, leading to increased rates of asthma and other respiratory illnesses.

I ask that the EPA move quickly to finalize air pollution safeguards on cars and light trucks that are at least as strong as the standards set forth in Alternative 1 of the agency's proposal. There is no time to lose. The EPA has the opportunity–and responsibility–to deploy the strongest possible safeguards to clean up deadly car pollution, limit catastrophic climate change, and improve public health. Thank you for the opportunity to provide input.

EPA-HQ-OAR-2022-0829-0727 - Mass Comment Campaign sponsored by Climate Hawks Vote Civic Action. (web) (5,035 signatures)

Enclosed and attached, please find the comments of 5,035 Climate Hawks Vote Civic Action members and supporters encouraging you to finalize the strongest possible clean vehicle standards. On behalf of all of us, we thank you for your work to promote electric vehicle adoption, and your recent car emissions standards, which will help America get to 67% clean cars by 2032. But we, and you, know that America can do more to clean up our cars and protect Americans' health, as well as the health of our climate. We're writing to ask you to finalize the strongest possible clean vehicle standards, now.

Transportation is the biggest source of US climate pollution, accounting for roughly a third of all US Greenhouse Gas emissions. Tailpipe pollution is also a major source of other pollution that harms public health, such as ozone, smog, and more. These pollutants are known by the EPA to cause climate chaos, as well as deadly diseases such as asthma, heart disease, and cancer.

Now is the time to protect our climate, and public health, by finalizing the strongest possible standards for cars and light duty trucks. Here's how your current proposed rule can be improved:

First, new EPA standard for cars, SUVs, pickup trucks, and cargo vans must be finalized by the end of 2023, and must lead to significant reductions in carbon emissions.

Second, new EPA standards must put us on a trajectory to cut all pollution, including global warming pollution, 75% by 2030, and to zero emissions by 2035. These targets are significantly stronger than the most stringent alternative in the EPA's current proposal.

Finally, you must study and publish estimates in the federal record that show that tougher emissions standards and the transition to electric cars will not only reduce pollution, but save consumers money. Only by showing that clean, green, climate action to clean up our cars is also an investment in cheaper, more affordable transportation for all Americans will we build the support needed to finalize this rule.

On behalf of climate hawks everywhere, thank you.

EPA-HQ-OAR-2022-0829-0728 - Comment submitted by Consumer Reports (CR) - Mass Mail Campaign Included. (web) (18,817 signatures; mass mailer was submitted as Attachment 1 to their main comments)

Petition to the Environmental Protection Agency: 18,817 Consumers Want More Clean Vehicles for a Better Climate Future

We're urging the EPA to adopt the strongest possible rules to reduce climate- and health-damaging vehicle emissions and greatly reduce fuel consumption, while helping consumers save an estimated $12,000 over the lifetime of a new vehicle. The rules will rapidly accelerate the number of cleaner vehicles like EVs and hybrids in production over the next decade; save lives due to a dramatic decrease in tailpipe pollution; and put us on the route towards a zero emissions future. These rules are a win-win for the climate, consumers' wallets, and our health!

EPA-HQ-OAR-2022-0829-0730 - Mass Comment Campaign sponsored by Sierra Club. (web) (16,273 signatures)

Sierra Club has collected 16,273 public comments. We have highlighted a selection of comments below. The names of the individuals submitting comments are listed under the selected comments. Each of the individuals signed onto the following text:

Please deliver a strong clean cars standard!

We appreciate Administrator Regan and the Environmental Protection Agency for proposing an updated standard to address light and medium duty vehicle pollution, which contributes to poor air quality and drives the climate crisis.

This proposal moves our vehicles in the right direction. However, the EPA must finalize the strongest possible standards this year to accelerate the adoption of zero-emission cars, pickup trucks, and delivery vans.

The standards must reduce greenhouse gas emissions by 75 percent by 2030 and put the country on a path so that all new vehicle sales are zero emission by 2035.

Thank you for finalizing these standards as swiftly as possible and delivering public health and climate benefits.

Thank you for considering this public input

EPA-HQ-OAR-2022-0829-1697- Mass Comment Campaign sponsoring organization unknown (5,581 signatures)

I am aggravated by the Environmental Protection Agency's (EPA) proposed rule change on emissions that would require up to two-thirds of new vehicles sold in the U.S. to be electric by 2032, the strictest standards ever proposed. The EPA is once again exceeding their authority by attempting to dictate national policy without congressional authorization. I believe that the proposal ignores America's market dynamics, fails to consider current supply chain limitations, and and violates the market dynamics which have made the US the greatest nation the world has ever known. You appear to be poised to destroy that greatness.

Forced compliance with stricter emissions regulations will increase costs for business equipment and operations, particularly for small businesses in the transportation industry. The EPA has acknowledged that compliance costs for manufacturers would be $6 billion and could include businesses spending thousands of additional dollars per business on zero-emissions vehicles. These burdensome regulations could lead many small businesses to cut jobs or even face bankruptcy, creating spillover effects that harm the rest of the economy. Increased transportation costs, for instance, could further drive up the cost of food for families across America at a time when they are already being crushed by record inflation.

Furthermore, China controls many critical materials for electric vehicle (EV) batteries, including inputs such as cobalt, graphite, manganese, and lithium. One question is whether you expect to participate financially in this rule, since it has been rumored, unverifiable, that the Bidens own 10% of a lithium mine, necessary to make electric vehicles possible. While rules issued under the so-called “Inflation Reduction Act” exclude sourcing from “foreign entities of concern,” it is unclear how the stimulated increased demand for EVs will be met without relying on China’s production of critical minerals or EV batteries. While the Biden Administration might be attempting to incentivize domestic supply chain production, the mining and processing of critical minerals such as lithium remain time-consuming and constrained by strict domestic environmental laws – one of many significant regulatory barriers that will remain in place even after this rule goes into effect. I fear that implementing this rule will ultimately harm our domestic industry while enriching one of our chief geopolitical rivals.

Ultimately, Americans and their families are hurt by this rule because it seeks to increase the cost of gas-powered vehicles enough to make the less-affordable EVs more appealing.

In an already inflationary environment, it is unconscionable to force American families to choose between owning a car or putting food on the table. I ask that you withdraw this poorly considered proposal.

EPA-HQ-OAR-2022-0829-1698 - Mass Comment Campaign sponsoring organization unknown (132 signatures)

American families are counting on you and the EPA to set strong vehicle emissions standards for cars and light- and medium-duty trucks as soon as possible. Strong tailpipe regulations that move the U.S. toward a zero-emissions vehicle future will protect public health and fight the climate crisis. We need the strongest possible long-term standards—beyond model year 2026—that will reduce car and light truck emissions by 75% by 2030, putting the country on a path to a 100% zero-emission new vehicle sales target by 2035.

EPA-HQ-OAR-2022-0829-1699 - Mass Comment Campaign sponsoring organization unknown (2,937 signatures)

As an environmental educator and field biologist as well as a parent and grandparent who cares deeply about the health of our planet and all its inhabitants, I am writing to urge you to move quickly to finalize the strongest possible standards for tailpipe pollution from passenger cars and light trucks.

The transportation sector is the largest source of climate pollution in the US, and cleaning up this pollution is one of the most important things we can do to fight climate change and protect our childrens future.

Not only does tailpipe pollution contribute to the climate crisis, but it can also harm the health of our families and communities. Exposure to pollution from cars and trucks can cause asthma, lung infections, heart attacks, stroke, premature death, low birth weight, and cancer. Clean car standards are a critical tool to fight climate change, and they help reduce dangerous air pollution. They help protect public health nationwide.

Our families want to see a rapid transition to zero-emitting cars and trucks, and we urgently need cleaner air for our children and our communities. Please move quickly to finalize the strongest possible Clean Car Standards. [EPA-HQ-OAR-2022-0829-1699]

EPA-HQ-OAR-2022-0829-1703 - Mass Comment Campaign sponsoring organization unknown (60 signatures)

Im writing to urge you to prioritize the implementation of robust vehicle emissions standards for cars and light trucks and medium-duty vehicles. American families are relying on your leadership to protect public health and combat the climate crisis through stringent safeguards.

The transportation sector alone accounts for a staggering 27% of greenhouse gas emissions, as highlighted in the EPA's own 2020 study. This makes cleaner vehicles absolutely crucial in safeguarding our communities from harmful tailpipe pollution.

While the proposed standards for model year model years 2027 through 2032 represent a crucial first step, we cannot afford to stop there. I implore you to finalize standards at least as strong as Alternative 1 and set standards that go beyond 2032. By reducing car and light truck emissions by 75% by 2030, we can set our nation on a trajectory toward achieving a 100% zero-emission new vehicle sales target by 2035.

To accomplish this, it is essential to increase the pace of progress after 2030 toward cleaner new vehicles in 2032 and beyond. We also need to ensure that gas cars become even cleaner and more efficient. By going with stronger final standards, we can create a more sustainable future while protecting public health and the environment.

Thank you for your attention to this urgent matter. I strongly urge you to take decisive action by finalizing the strongest possible vehicle emissions standards this year.

I appreciate your consideration in doing whats necessary to move towards cleaner air, healthier communities, and a more sustainable future.

EPA-HQ-OAR-2022-0829-1705 - Mass Comment Campaign sponsoring organization unknown (223 signatures)

As a supporter of healthy outdoor opportunities for all, I strongly urge the EPA to finalize the clean car proposal and final rule for cleaner vehicles as soon as possible. This rule is an essential piece of reducing greenhouse gas and ozone-forming emissions under the Clean Air Act and will protect waterways, clean, healthy air, and ecosystems across the nation.

Clean air is vitally important for our health. Vehicles are responsible for 30-40% of greenhouse gas emissions. It could be a much more beautiful world!

Strengthening national emission standards for vehicles on our roadways will also advance environmental justice. A significant body of research has established that people of color in this country breathe more particle-polluted air, on average than White people because communities of color tend to be located near sources of this deadly pollutant, including major roadways. For example, a recent study found that Black, Latino, and Asian Americans across the country were consistently exposed to more soot pollution than White Americans, in both rural and urban settings, and at all income levels.

I urge EPA to finish this rulemaking process expeditiously and retain the strong emission standard targets proposed. The EPAs work to implement and enforce the Clean Air Act has yielded enormous public health benefits and saved countless lives over the years. It is essential that the agency continue that work by setting the strongest science-based air quality emission standards to protect our air and the public welfare and advance environmental justice, and safeguard our health.

EPA-HQ-OAR-2022-0829-1706 - Mass Comment Campaign sponsoring organization unknown (1,982 signatures)

My family is directly impacted by the air pollution in Salt Lake City. Personally, I would like to move to an area with cleaner air, but now with wildfire smoke spreading across North America, there is no safe area. Already our family suffers from COPD, bronchitis, and frequent respiratory illnesses. Animals don’t soil their dens. Why are we humans soiling the air we breathe?!

As a person of faith and conscience, I recognize that we have a moral obligation to cut carbon emissions that harm our Shared Home. People of faith and conscience are ready for bold, new transportation solutions, and cleaner cars and light trucks are an integral step towards addressing climate change for our communities, future generations, and our Sacred Earth.

I am asking EPA to move quickly and finalize the strongest possible light-duty vehicle (LDV) standards. This proposal is a first step and the EPA needs to finish the job by finalizing the strongest possible standards this year.

In order for the U.S. to meet our Paris Climate Agreement goals we need the strongest possible long-term standards—beyond model year 2026— that will put the country on a path to a 100% zero-emission new vehicle sales target by 2035. Not implementing the strongest possible light-duty vehicle standards would create major negative implications for our country’s climate goals.

We must also keep in mind that these rules target air pollution that disproportionately harms marginalized communities of color and low-wealth communities. For example, “Black and Hispanic Americans are exposed to 56 and 63 percent more particulate matter pollution, respectively, than they produce.” This is especially concerning for people of faith, as all religions call on us to treat our neighbors with respect, dignity, and compassion. Implementing the strongest LDV standards is a matter of environmental justice, and these standards would deliver massive emission reductions and life-saving relief to frontline communities.

In addition, electrifying passenger vehicles will be key to improving air quality and saving lives across the nation. More than 119 million American residents currently live in areas with unhealthy levels of air pollution. In 2020, the national passenger vehicle fleet represented approximately 94% of the nation's on-road vehicles and generated over 33,400 tons of fine particles annually, which are so small that they easily enter our bloodstream and harm our health. It is also critical that standards require tighter limits on internal combustion engine vehicles in order to continually make these cars cleaner as manufacturers transition to zero-emission vehicles.

So again, on behalf of millions of people of faith and conscience around the country, I urge the EPA to move quickly and finalize the strongest possible light-duty vehicle standards in order to reap the benefits of light-duty vehicle electrification and accelerate the transition to zero-emission vehicles.

Thank you for this opportunity to comment.

EPA-HQ-OAR-2022-0829-1708 - Mass Comment Campaign sponsoring organization unknown (3,105 signatures)

Over the centuries, most jobs become obsolete; why should it be any different for people who work in fossil fuels?

As someone who loves and cares about our national parks, I know that the clock is ticking for us to curb climate pollution. We need bold climate action now.

We certainly do need bold action and must end all use of fossil fuels!

With the transportation sector now the largest source of climate-altering greenhouse gas pollution in the U.S., the U.S. Environmental Protection Agency (EPA) must put us on a clear path to make all on-road vehicles zero emissions as soon as possible.

Vehicle pollution harms the health and well-being of individuals, affects ecosystems and visibility in our treasured national parks, and exacerbates the global climate crisis. EPAs proposals to reduce greenhouse gas emissions from light, medium, and heavy-duty vehicles will provide our communities with cleaner air and can prevent the worst effects of climate change.

For this reason, I urge EPA to move forward quickly with ambitious new rules for on-road vehicles. Specific to EPAs clean cars proposal, I ask that you implement the stronger Alternative 1. For EPAs clean trucks proposal, more must be done sooner, and EPA should follow the lead of states that have already committed to 100 percent zero-emission truck sales by no later than 2045.

Following significant investments in the Inflation Reduction Act to support transportation electrification, now is the time for aggressive action to tackle vehicle emissions and deliver cleaner air and a livable climate for our communities and national parks.

EPA-HQ-OAR-2022-0829-1711 - Mass Comment Campaign sponsoring organization unknown (44 signatures)

My children and grandchildren are looking to our government (not big business) to make our country and planet habitable for all kinds of fauna & flora for centuries to come.

And we implore the EPA to take the strongest actions right now before all hope is gone...

So we urge EPA to create the strongest possible limits on medium and light-duty vehicle pollution. The proposal for Alternative 1 constitutes a strong start to regulating dangerous air pollution for the first three years, but EPA should increase the pace starting in 2030 to require only zero-emission vehicle sales after 2035. Additionally, gas cars should be made cleaner and more efficient along the way.

Tailpipe pollution causes tens of thousands of premature deaths nationwide each year, especially in communities of color. Exposure to air pollution can lead to health problems including increased risk of asthma attacks, strokes, heart attacks, cancer, and premature deaths. The EPA can further its commitment to environmental justice this year by issuing stronger and longer term clean car standards.

Strong tailpipe regulations that move the U.S. toward a zero-emissions vehicle future will protect public health and fight the climate crisis. We need the strongest possible long-term standards that will reduce car and light truck emissions by 75% by 2030, putting the country on a path to a 100% zero-emission new vehicle sales target by 2035.

Increasingly strong clean car standards are the signal the industry needs to provide more, and more affordable, zero-emission vehicles, along with the infrastructure to support them. EPA should also require that manufacturers make any combustion engine vehicles that are on the road increasingly cleaner and more efficient.

Alternative 1 is good for the first 3 years, but we need to increase the pace starting in 2030 to stay on the route to zero emissions.

EPA-HQ-OAR-2022-0829-1712 - Mass Comment Campaign sponsoring organization unknown (3,164 signatures)

I dont know why you have this job if you cant do the obvious things the Environmental Protection Agency SHOULD AND MUST DO. Your corporate corrupt backround is clowding your understanding of this JOB!

EPA must create the strongest possible limits on medium and light-duty vehicle pollution. The proposal for Alternative 1 constitutes a strong start to regulating dangerous air pollution for the first three years, but EPA should increase the pace starting in 2030 to require only zero-emission vehicle sales after 2035. Additionally, gas cars should be made cleaner and more efficient along the way.

Tailpipe pollution causes tens of thousands of premature deaths nationwide each year, especially in communities of color. Exposure to air pollution can lead to health problems including increased risk of asthma attacks, strokes, heart attacks, cancer, and premature deaths.

The EPA can further its commitment to environmental justice this year by issuing stronger and longer term clean car standards.

Strong tailpipe regulations that move the U.S. toward a zero-emissions vehicle future will protect public health and fight the climate crisis. We need the strongest possible long-term standards that will reduce car and light truck emissions by 75% by 2030, putting the country on a path to a 100% zero-emission new vehicle sales target by 2035.

Increasingly strong clean car standards are the signal the industry needs to provide more, and more affordable, zero-emission vehicles, along with the infrastructure to support them. EPA should also require that manufacturers make any combustion engine vehicles that are on the road increasingly cleaner and more efficient.

Alternative 1 is good for the first 3 years, but we need to increase the pace starting in 2030 to stay on the route to zero emissions.

Use this space to type out a comment for the EPA explaining what more expensive vehicles would mean for your family's budget.

UNA FORDABLE

EPA-HQ-OAR-2022-0829-1715 - Mass Comment Campaign sponsoring organization unknown (14,249 signatures)

I am opposed to this regulation.

The American spirit built the auto industry and defined the 20th century; the open road became a symbol of freedom. Now, this regulation threatens to take away our freedoms by taking away our cars.

These new vehicle regulations proposed by the Environmental Protection Agency (EPA) are clearly intended to limit the production and sale of gas cars. And it’s very clear that President Biden and the far Left would like to ban gas cars altogether. But this is NOT what the American people want. We like gas cars and we like being able to buy gas cars. We do not need the Socialist state to regulate our choice of car.

Regulating gas cars out of existence is extremely unpopular—it’s why this policy would never make it through Congress. It is why the President is instead pushing this policy via the federal bureaucracy.

This regulation will limit my options when I go to buy my next car. I will be stuck with a car or truck that is more expensive, of lower quality, dependent on rare Chinese materials, dependent on the vulnerable electric grid, and otherwise unable to meet my needs. We will be forced to replace our gas cars with electric cars—which are more expensive, have shorter ranges, take more time to refuel, and line the pockets of the Chinese Communist Government because of the lithium mining needed.

This regulation is the big-government Socialist state at its worst; it hurts Americans and helps our adversaries. It raises the key question: what does this Administration have against American citizens?

Let's keep America free—let us buy the car or truck that we want.

EPA-HQ-OAR-2022-0829-1718 - Mass Comment Campaign sponsoring organization unknown (email) (57 signatures)

Thank you for your recently announced proposals to address pollution from light and medium-duty vehicles. I am worried about the impacts of the climate crisis and dangerous air pollution on the health of our communities, which is why I hope that you'll finalize this rule by the end of the year.

With your support we can ensure that all new vehicles are zero-emission in 2035.

The transportation sector is the leading source of climate pollution in the US and is responsible for significant NOx and particulate matter emissions. The climate crisis and air pollution are harming our families and our communities today, and vehicle emissions are a major contributor to this pollution. This is especially true for passenger cars and trucks, which are responsible for 57% of the total climate pollution from the transportation sector.

EPA's proposed standards will be crucial in addressing this pollution. EPA estimates that the proposed standards would avoid approximately 7.3 billion metric tons of greenhouse gas emissions from 2027 through 2055, and would significantly reduce NOx, PM, and VOC emissions during that time.

It is vital for EPA to finalize the most protective multipollutant standards possible that are consistent with and build from the proposals, helping to ensure that at least two-thirds of new light-duty vehicles and at least 40% of new medium-duty vehicles sold in 2032 are zero-emitting. These standards must put us on a path for all new vehicles to have zero emissions no later than 2035. Standards at this level are eminently achievable, accounting for the progress already underway thanks to manufacturer and fleet investments and commitments, federal spending, and state policies like the Advanced Clean Cars II rule. According to a report by EDF and WSP, U.S. manufacturing will be capable of producing an estimated 4.3 million new passenger EVs every year by 2026 (a third of all new vehicles sold in 2022). U.S. manufacturing facilities will also be able to produce enough batteries to supply up to 11.2 million new passenger EVs every year by 2026.

Please take action to ensure that EPA finalizes the most protective standards possible that are consistent with, and build from the proposals, to put us on the path to zero emissions from new vehicles in 2035.

EPA-HQ-OAR-2022-0829-1719 - Mass Comment Campaign sponsoring organization unknown (email) (261 signatures)

I support the EPA's proposed standards for light-, medium-, and heavy-duty vehicles. These standards should significantly reduce emissions and grow the electric vehicle sector, helping us reach important climate goals.

The EPA's proposals reflect the desires of a majority of Americans. Seven in ten Americans want tougher fuel efficiency standards.

Congress committed to transitioning toward a clean energy economy under the Bipartisan Infrastructure Law and Inflation Reduction Act. To unlock the full potential of these laws, we must end our dependence on fossil fuels.

I urge you to implement the strongest possible proposed vehicle pollution standards. Our energy transition and the health of our communities depend on it.

EPA-HQ-OAR-2022-0829-1720 - Mass Comment Campaign sponsoring organization unknown (email) (19,816 signatures)

I have lived with Los Angeles smog my whole life. As an EV driver, I am trying to do my part to reduce emissions and am glad that you have proposed strong emissions standards for light- and medium-duty vehicle pollution that move us forward in addressing harmful air pollutants and global warming emissions.

These standards will be a good step in the right direction to limit dangerous smog forming and particulate emissions that can increase the risk of asthma attacks, strokes, and heart attacks, and lowering global warming emissions. Transportation is the number one contributor to global warming emissions in the United States, and curbing these emissions will be critical to addressing the climate crisis.

However, we can go farther. We need to see the strongest possible standards finalized this year. The EPA's Alternative 1 is a good start, but we need the agency to set more stringent standards after Model Year 2030 to accelerate our transition to zero-emissions and continue to make gas cars cleaner.

Please finalize a regulation at least as strong as Alternative 1 and continue working to make cars cleaner.

In order to limit dangerous NOx emissions and other air pollutants, and reduce global warming emissions to address the climate crisis, the EPA needs to pass the strongest possible cleaner cars standards. Thank you for your consideration.

EPA Summary and Response:

Summary:

Many of these mass mail campaigns are supportive of EPA's proposed program or request EPA to issue more stringent standards to address climate change and other environmental issues, as well as Environmental Justice concerns. Some, however, raise concerns about potential adverse impacts of the rule.

Response:

The mass mail campaign comments reproduced verbatim above are general in nature and do not require detailed EPA response beyond provided elsewhere in this document, and/or contain opinions or statements that are raised without reasonable specificity. EPA's responses included throughout this RtC document address each of the general topics raised in these comments. The mass mail campaign comments that are not reproduced above and that contain detailed comments on specific issues are addressed under the relevant topics of this RtC document.

Appendix C: List of testifiers at public hearings

This appendix contains a list of individuals who testified at a virtual public hearing on the proposal, which was held on May 9-11, 2023. The hearing transcript can be found in the docket for this rule (EPA-HQ-OAR-2022-0829-5115). Over the three days of the hearings, 217 testifiers provided statements voicing their support for or concerns about the proposal: 88 testifiers on May 9, 89 testifiers on May 10, and 49 testifiers on May 11. The testifiers are listed in Table C-3, below.

<u>EPA Summary and Response:</u>

Summary:

We characterize the nature of each of these comments by classifying their statements along eight dimensions (one comment may contain statements on more than one dimension). The topics are as follows:

- General support
- Want more stringent
- Oppose
- Environmental and/or health concerns
- Environmental Justice concerns
- Business and/or cost concerns
- Infrastructure and/or resource availability
- Incentive availability (IRA, BIL, etc.)

As shown in Table C-1, each of the testifiers testified on at least one of these 8 topics. Most of the testifiers made statements on 2 or 3 topics (36% and 30%, respectively).

Table C-1: Number of Topics Raised in Hearing Testimony

No. Issues Raised	% of Testifiers
0	0%
1	26%
2	36%
3	30%
4	6%
5	1%
Total	100%

As shown in Table C-2, the most commonly raised topics were statements raising concerns about the climate change and the environment (29%), general support (24%), and Environmental Justice (13%).

Table C-2: Themes Raised in Hearing Testimony

Themes of Non-Detailed Comments	% Testifiers Raising Theme
General support	24%
Want more stringent	11%
Oppose	3%
Environmental, Health	29%
Environmental Justice	13%
Business, Costs	11%
Infrastructure, resource availability	5%
Incentive availability	4%
Total	100%

<u>Response:</u>

Hearing statements that are specific in nature and are not included in written comments submitted by the testifier or the testifier's organization are included verbatim in sections of this document above and responded to by EPA.

Some of the testimony statements are general in nature and do not require detailed EPA response beyond those provided in the sections above in this document, and/or they contain opinions or statements about issues without reasonable specificity. EPA's responses included throughout this RtC document address each of the general topics raised in these general comments.

Appendix D: EPA's request for comment on potential fuels controls for future rulemaking such as gasoline PM standards

This appendix contains the responses received to EPA's request for comment on including potential fuels controls in a future rulemaking.

<u>Comments by Organizations</u>

Organization: Alliance for Automotive Innovation

A. EPA Should Act Now to Improve Fuels

EPA should act now to:

- Implement a nationwide clean fuel standard to lower GHG emissions; [EPA-HQ-OAR-2022-0829-0701, pp. 260-261]

- Regulate the particulate forming tendency of market gasoline by eliminating the heavy aromatic fraction of gasoline, thereby reducing PM emissions from all ICE vehicles, equipment, and engines to improve air quality for all; [EPA-HQ-OAR-2022-0829-0701, pp. 260-261]

- Lower the sulfur cap of gasoline from 80 ppm to 10 ppm at the refinery gate to further reduce non-GHG emissions from ICE-equipped vehicles and engines to improve air quality; [EPA-HQ-OAR-2022-0829-0701, pp. 260-261]

- Adjust Tier 3 certification fuel specifications to align with current market fuel composition and to enable fuel suppliers to target a particulate matter index of 1.5 to 1.6; [EPA-HQ-OAR-2022-0829-0701, pp. 260-261]

- Cap summer vapor pressure of gasoline at 9.0 psi or less, regardless of ethanol content, to further reduce evaporative emissions as E10 fuel is ubiquitous in the market; [EPA-HQ-OAR-2022-0829-0701, pp. 260-261]

- Immediately eliminate sub-87 anti-knock index ("AKI") octane fuels from the market to increase fuel efficiency and reduce GHG emissions; [EPA-HQ-OAR-2022-0829-0701, pp. 260-261]

- Transition to a higher minimum-octane gasoline (i.e., minimum 95–98 research octane number) to facilitate higher engine efficiency; and [EPA-HQ-OAR-2022-0829-0701, pp. 260-261]

- Limit air toxics, e.g., olefins and aromatics, and their precursors from the fuel to improve air quality for all. [EPA-HQ-OAR-2022-0829-0701, pp. 260-261]

In addition to a comprehensive fuels rulemaking, Auto Innovators recommends that EPA also proceed with finalizing its eRINs proposal from the Renewable Fuel Standard Set Rule for Renewable Volume Obligations for 2023-2025 NPRM.404 This proposal provides a complementary approach to EPA's proposed multipollutant rule, including supporting and encouraging both EVs and renewable sources of energy, as well as to the overall goal of decarbonizing the transportation sector. [EPA-HQ-OAR-2022-0829-0701, pp. 260-261]

404 Renewable Fuel Standard Set Rule for Renewable Volume Obligations for 2023-2025, https://www.govinfo.gov/content/pkg/FR-2022-12-30/pdf/2022-26499.pdf

E. EPA Should Regulate the Particulate Forming Tendency of Market Gasoline

1. Regulatory Authority

All major global regulatory agencies (EPA, CARB, the European Union, China) have taken steps to reduce vehicle particulate emissions as demonstrated by their regulations limiting tailpipe emissions of particulate mater (“PM”).409,410 While establishing and tightening particulate emissions standards for future vehicles may lower future PM emissions from those new vehicles, reducing heavy aromatic content in gasoline will reduce PM emissions today from the on-road fleet as well as from new vehicles. EPA recognizes that it has the authority to address gasoline composition as a mechanism to address the in-use fleet, citing the sulfur standards for gasoline and diesel.411 [EPA-HQ-OAR-2022-0829-0701, pp. 263-266]

411 NPRM at 29402

2. High Leverage for PM Emissions Reduction

We agree with EPA’s position that removal of heavy aromatic compounds from gasoline has a very high leverage to reduce PM emissions from vehicles fueled by gasoline.412 These compounds have a disproportionate contribution to PM formation in vehicle exhaust, particularly aromatic hydrocarbons with 10 or more carbons. As discussed by EPA, removing these heavy aromatic hydrocarbons from gasoline greatly reduces PM emissions from vehicles.413,414 A regulatory change in fuel requirements to reduce or limit the amount of heavy aromatic hydrocarbons in gasoline would also reduce PM emissions from off-road equipment fueled by gasoline (e.g., lawn care equipment, generators, snowmobiles, outboard motors, etc.). [EPA-HQ-OAR-2022-0829-0701, pp. 263-266]

414 Coordinating Research Council, “Evaluation and Investigation of Fuel Effects on Gaseous and Particulate Emissions on SIDI In- Use Vehicles,” Report No. E-94-2, March 2016.

Many studies have shown the contribution of heavy aromatics to tailpipe PM. Early papers of particular importance were published by Honda and include the development of a PM index (PMI) for gasoline. PMI values correlate well with tailpipe PM emissions.415,416 The PMI calculation is based on data from a laboratory technique known as detailed hydrocarbon analysis

(DHA). Other methods of measuring heavy hydrocarbon content and PM-forming tendency beyond the DHA method may be more readily implemented.417,418,419,420 Improvements to one such method, known as Simulated Distillation or SimDis, were recently reported by EPA.421 Auto Innovators 2018 and 2019 market fuel DHA study reveals the high PMI fuels are from high molecular weight aromatic hydrocarbons, those with 10 or more carbon atoms (e.g., C10+ aromatics).422 Therefore, an upper limit for C10+ aromatics is needed. [EPA-HQ-OAR-2022-0829-0701, pp. 263-266]

Several Coordinating Research Council (CRC) research projects have been conducted to investigate the impacts of PMI, ethanol, and octane ratings on vehicle emissions.423,424,425 The data show a direct and strong correlation between increased fuel PMI and increased tailpipe PM. Detailed hydrocarbon analysis of the fuels showed that the high molecular weight aromatic hydrocarbons in the fuel, C10+ hydrocarbons, are particularly significant contributors to increased tailpipe PM. The greater the C10+ aromatic hydrocarbon content, the greater the increase in PM emissions. [EPA-HQ-OAR-2022-0829-0701, pp. 263-266]

423 Coordinating Research Council Report No. E-94-1. Evaluation and Investigation of Gaseous and Particulate Emissions on SIDI In-Use Vehicles with Higher Ethanol Blend Fuels (2014), htp://crcsite.wpengine.com/wp- content/uploads/2019/05/03-17589_CRC-E94-1_Final-Report_6-2-2014_Lobato_Morgan.pdf (accessed Sep. 24, 2021).

content/uploads/2019/05/CRC_2017-3-21_03-20955_E94-2FinalReport-Rev1b.pdf (accessed Sep. 24, 2021).

425 Coordinating Research Council, “An Improved Index for Particulate Matter Emissions (PME),” Report No. RW-107-2, March 2021.

Figure 87 shows that fuels with high PMI values have higher proportions of heavy aromatics (C10+ aromatics).

[See original for box plot titled “Figure 87: 2018 and 2019 Summer U.S. Market Gasoline C10+ and PMI”] [EPA-HQ-OAR-2022-0829-0701, pp. 263-266]

Figure 88 below shows that limiting the content of total aromatic hydrocarbons doesn’t necessarily control against high PMI market fuels, however, limiting the amount of C10+ aromatics would do so.

[See original for graph titled “Figure 88: 2018 and 2019 Summer U.S. Market Gasoline PMI and Total Aromatics”] [EPA-HQ-OAR-2022-0829-0701, pp. 263-266]

More recently, as described in Section IX of the NPRM, a study of this fuel impact on vehicle PM emissions was conducted by EPA, Environment Canada and several automotive OEMs.426 The program included 10 test vehicles of model years 2015 to 2022. Three test fuels, two E10 and one E15 (fuels B, C, and D respectively), were constructed that contained a reduced heavy aromatic content relative to a baseline E10 test fuel (fuel A). The baseline fuel represented a U.S. market fuel with high C10+ aromatic content whereas the base fuel and the three test fuels represented fuels with C10+ aromatic content typical of average U.S. gasoline. The fuels therefore had similar composition except that test fuels B, C, and D had replaced 3 %vol (all C10+ aromatics) with other lighter hydrocarbons or ethanol (each intended to replace the octane value of the removed C10+ aromatics). As summarized in Figure 89 below, the three fuels incorporating this 3 %vol change in composition led to major (25-40%) reductions in average PM emissions across the test vehicle fleet (40% on the FTP drive cycle and by 25% on US06). [EPA-HQ-OAR-2022-0829-0701, pp. 266-268]

426 USEPA, "Exhaust Emission Impacts of Replacing Heavy Aromatic Hydrocarbons in Gasoline with Alternate Octane Sources," April 2023. Document EPA-420-R-23-008.

[See original for graph titled “Figure 89: FTP Composite and US06 PM Emissions Results”]

Above figures adapted from EPA-420-R-23-008 (Figures ES.1 and ES.2) [EPA-HQ-OAR-2022-0829-0701, pp. 266-268]

As these multiple studies and others have conclusively shown, the removal of heavy aromatic hydrocarbons from gasoline, particularly those in the C10+ range, has very high leverage in reducing tailpipe PM emissions from gasoline vehicles. In particular, the 2023 study by EPA and others427 showed that a 3% change in gasoline formulation (replacing these heavy hydrocarbons) yielded tailpipe PM emissions reductions averaging 40% and 25% on the FTP and US06 regulatory drive cycles, respectively. [EPA-HQ-OAR-2022-0829-0701, pp. 266-268]

427 USEPA, "Exhaust Emission Impacts of Replacing Heavy Aromatic Hydrocarbons in Gasoline with Alternate Octane Sources," April 2023. Document EPA-420-R-23-008.

The Worldwide Fuel Charter, Sixth Edition,428 published as a cooperative effort between global vehicle and engine manufacturers, discusses fuel quality needs commensurate with meeting emissions control requirements in different global markets. This document gives a suggested PMI maximum in the range of 1.5-1.8 for markets with highly advanced emission control requirements, such as the United States (Tier 3 Bin 30) and California regulations. However, as shown in Figure 42 of the NPRM, approximately 20% of U.S. gasoline still has a PMI of 1.8 or greater.429 The Charter also notes that "Various fuel-sampling efforts have shown that many areas of the developed world have achieved a PMI value of 1.5 in their commercially available gasoline without actively trying to minimize PMI. Setting a maximum PMI value of 1.5 for all grades of commercially available gasoline will reduce and help control the particulate emissions from legacy, current, and future vehicles." We note that the same outcome can be achieved through an alternative control metric that achieves the same result (e.g., distillation or simulated distillation cut point), as discussed in the NPRM.430 [EPA-HQ-OAR-2022-0829-0701, pp. 266-268]

428 htps://www.acea.auto/files/WWFC_19_gasoline_diesel.pdf

429 NPRM at 29401.

430 NPRM at 29402

Therefore, EPA should proceed with controlling the particulate-forming tendency of market gasoline by requiring the removal of the heavy aromatic components to lower PM emissions throughout the fleet and improve air quality. Based on the body of information presented above, we recommend an approach that would limit market fuels to a maximum PMI value of 1.5. [EPA-HQ-OAR-2022-0829-0701, pp. 266-268]

3. Reduction of Heaviest Gasoline Aromatics will have little to no impact on the Octane Rating

Evaluation of API research report 45,431 where the octane ratings of individual hydrocarbons have been measured, shows that octane ratings start to tail-off as boiling points increase. A plot of these data shows the following trends. [EPA-HQ-OAR-2022-0829-0701, pp. 266-268]

431 Knocking Characteristics of Pure Hydrocarbons. American Society for Testing Methods, Developed Under American Petroleum Institute Research Project 45.

[See original for graph titled "Figure 90: API Project 45 Octane and Boiling Points"] [EPA-HQ-OAR-2022-0829-0701, pp. 266-268]

4. Addresses Entire On-Road Fleet and Off-Road Equipment

We agree with EPA that a new fuel-based PM regulation for gasoline is the only mechanism to reduce PM emissions from all gasoline engines, both old and new, in on-road vehicles and off-road equipment. The average lifespan of light duty vehicles has increased over time. S&P Global Mobility reports that the average lifespan for U.S. light duty vehicles has risen to 12.5 years (13.6 years for cars, and 11.8 years for SUVs, crossovers, and light duty trucks).432 The on-road LDV fleet consists of 290 million vehicles of varying age,433 whereas new vehicles are produced at a rate of only 14-17 million per year over the last decade.434 A fuel-based solution to address PM emissions from the on-road fleet will have a broad impact. [EPA-HQ-OAR-2022-0829-0701, pp. 269-270]

432 htps://www.cnbc.com/2023/05/15/americans-are-keeping-their-cars-longer-amid-rising-interest-rates.html

433 U.S. Vehicle Registration Statistics, Hedges & Company, htps://hedgescompany.com/automotive-market- research-statistics/auto-mailing-lists-and-marketing/ (accessed May 23, 2023).

434 htps://www.epa.gov/system/files/documents/2022-12/420r22029.pdf

A fuel-based PM regulation is the ONLY option to reduce PM emissions from the on-road fleet and has a particularly high impact on those vehicles with the highest tailpipe PM emissions (older vehicles that were subject to higher emissions limits). A fuel-based regulation would also yield tailpipe PM reductions for new vehicles. [EPA-HQ-OAR-2022-0829-0701, pp. 269-270]

5. Improves Resistance to Abnormal Combustion

Additionally, it is well known that Stochastic Preignition (SPI), also commonly known as Low- Speed Preignition (LSPI), is an abnormal combustion issue that can adversely impact downsized, boosted spark-ignition engines that now dominate the light-duty vehicle market. SPI is more than just engine “knock,” for which fuel solutions and engine controls strategies exist. SPI involves early combustion of the air-fuel mixture which can lead to catastrophic engine damage. Improving fuel economy of future vehicles to meet more stringent requirements will require that automakers further increase the efficiency and power density of future engines. However, these engine improvements are constrained by the increased occurrence of SPI under those conditions. The presence of high boiling point aromatic compounds and high fuel PMI value have been shown to be positively correlated to the SPI occurrence frequency from engines. Heavy compounds in gasoline that do not easily vaporize will impinge on the wall, which can produce SPI events in the current or next combustion cycle. Various papers have been published about the relationship, 435,436,437,438,439 and on-going studies are in process to confirm it.440 The described fuel-based regulation controlling high boiling point compounds would beneficially reduce the occurrence of SPI in U.S. gasoline vehicles. [EPA-HQ-OAR-2022-0829-0701, pp. 269-270]

435 Swarts, A., Chapman, E., and Costanzo, V., "Detailed Analyses and Correlation of Fuel Effects on Stochastic Preignition," SAE Int. J. Adv. & Curr. Prac. in Mobility 2(6):3248-3267, 2020, https://doi.org/10.4271/2020-01- 0612

436 Chapman, E., Davis, R., Studzinski, W., and Geng, P., "Fuel Octane and Volatility Effects on the Stochastic Pre- Ignition Behavior of a 2.0L Gasoline Turbocharged DI Engine," SAE Int. J. Fuels Lubr. 7(2):379-389, 2014, doi:10.4271/2014-01-1226.

440 CRC Project AVFL-33 Phase 1 and Phase 2 - htps://crcao.org/wp-content/uploads/2023/03/Final-2022-CRC- Annual-Reportv2.pdf

Unlike SPI mitigation strategies employed by automakers today, which are reactive in nature, reducing heavy aromatic hydrocarbons in gasoline would also help address one of the root causes of SPI. [EPA-HQ-OAR-2022-0829-0701, pp. 269-270]

6. Addresses Proposed Changes to National Ambient Air Quality Standards (NAAQS)

A new fuel-based PM regulation, which will reduce tailpipe PM emissions from the on-road fleet, particularly in areas with high tailpipe PM emissions from gasoline vehicles, would also help states to meet the proposed lower annual PM2.5 standard that EPA proposed for the NAAQS earlier this year.441 A fuel-based PM regulation is the only option for reducing PM across the light-duty vehicle fleet and from gasoline-powered equipment. [EPA-HQ-OAR-2022-0829-0701, p. 270]

441 htps://www.federalregister.gov/documents/2023/01/27/2023-00269/reconsideration-of-the-national-ambient- air-quality-standards-for-particulate-mater

7. Environmental Justice Considerations

We agree with EPA that a reduction in heavy aromatics in gasoline will produce beneficial reductions in PM emissions that will further national environmental justice goals. EPA notes in the NPRM that people living and working near roadways will benefit from fuel improvements that reduce PM formation, that those individuals are more likely to be people of color and/or have a low socioeconomic status (SES), and that lower-SES neighborhoods are likely to have more vehicles with higher emissions than higher-SES neighborhoods.442 A fuel-based regulation to reduce PM emissions would do so for all vehicles in the on-road fleet. Importantly, the greatest absolute emissions reductions will occur in and benefit lower-SES communities, as those communities are more likely to have the highest-emitting vehicles, i.e., a higher proportion of older vehicles with the highest emissions levels (due to their vehicle's age). [EPA-HQ-OAR-2022-0829-0701, pp. 270-271]

442 NPRM at 29393

EPA also uses this same rationale (proximity of low-SES communities to roadways) in support of a proposed lower tailpipe PM emissions limit, but the distribution of ages of vehicles on roadways is not discussed. The emissions reductions from the proposed tailpipe emissions rule will only reduce emissions for the newest vehicles, which in the near-term benefits higher-SES communities more than lower-SES communities. Moreover, these new vehicles will tend to replace vehicles of more recent vintage that already adhere to the newest, most stringent PM emissions limits. A fuel-based regulation targets all vehicles and is the only approach that immediately reduces emissions from older, higher-emitting vehicles more often found in low-SES communities. [EPA-HQ-OAR-2022-0829-0701, pp. 270-271]

5. Limit Air Toxics from Market Fuels

The emissions from an average light duty vehicle have been reduced by over 99% since the introduction of emissions control technology. The reduction has been such that, according to CARB, in the California south coast air basin, lawn and garden equipment is a greater contributor to poor air quality than light-duty vehicles.453 The best approach to limiting toxic emissions is to remove toxics from the fuel prior to distribution. EPA recognized and applied this approach to limiting benzene emissions. Going forward, EPA must broaden its approach and limit air toxics, e.g., olefins and aromatics, and their precursors from the fuel prior to distribution. [EPA-HQ-OAR-2022-0829-0701, pp. 277-278]

453 SORE Fact Sheet, California Air Resources Board, https://www.arb.ca.gov/msprog/offroad/sore/sm_en_fs.pdf?_ga=2.125314186.1460474514.1631206544-48095875.1631206544 (accessed Sep. 24, 2021).

Organization: American Chemistry Council, Fuel Additives Task Group (FATG)

In the Program Announcement 2, EPA states that,

2 EPA-420-F-23-009. https://nepis.epa.gov/Exe/ZyPDF.cgi?Dockey=P1017626.pdf

…advanced gasoline technologies are expected to play an important role in the future… [EPA-HQ-OAR-2022-0829-0663, pp. 1-2]

EPA is also seeking comment on potential future gasoline fuel property standards, aimed at further reducing PM emissions, for consideration in a possible subsequent rulemaking. These could provide an important complement to the vehicle standards being proposed in the current action. [EPA-HQ-OAR-2022-0829-0663, pp. 1-2]

The proposed standards are performance-based, allowing each manufacturer to choose what set of emissions control technologies is best suited for their vehicle fleet to meet the standards. [EPA-HQ-OAR-2022-0829-0663, pp. 1-2]

The FATG supports EPA's recognition that multiple technologies can lead to a reduction in emissions and supports the use of performance-based standards. The longevity of the internal combustion engines (ICE) of the current car parc means that they, and carbon-based liquid fuels, will continue to play an important role in the transportation needs of the United States. Fuel additives have and will continue to play a vital role in the optimization of the fuel and engine system with the aim of reducing particulate matter (PM) emissions. [EPA-HQ-OAR-2022-0829-0663, pp. 1-2]

Fuel Additive Benefits

Fuel additives provide benefits to the environment and the consumer3. Additive technologies help enhance desired performance attributes beyond the base capabilities of the fuel and help ensure fitness for use, leading to improved function and performance. [EPA-HQ-OAR-2022-0829-0663, pp. 1-2]

3 Additive Technical Committee, "Fuel Additives: Use and Benefits," Document 113, September 2013. [Embedded link: https://www.atc-europe.org/public/Doc113%202013-11-20.pdf]

Gasoline deposit control additives play a significant role in engine cleanliness and performance. They help to control the formation of deposits in port fuel injectors and on intake valves. In doing so, they help maintain optimum fuel delivery to minimize exhaust emissions and limit fuel economy degradation. [EPA-HQ-OAR-2022-0829-0663, pp. 1-2]

Fuel additives help to optimize the functional efficiency of the internal combustion engine leading to the reduction of fuel consumption. [EPA-HQ-OAR-2022-0829-0663, pp. 1-2]

Recognizing the benefits of treating gasoline with detergents, the Clean Air Act Amendments of 1994 require all gasoline sold in the United States to contain additives to limit the formation of intake valve and port fuel injector deposits and avoid a negative impact on emissions. The lowest additive treat rate that passes the required certification testing can be registered with the EPA as the Lowest Additive Concentration (LAC) for the detergent additive. The performance standards in the voluntary TOP TIERTM Detergent Gasoline program result in deposit control additive treat rates that are at least as high - and typically higher - than those required to meet EPA standards. [EPA-HQ-OAR-2022-0829-0663, pp. 1-2]

As a stakeholder regarding EPA's potential subsequent rulemaking on future gasoline property standards, the FATG would welcome a meeting with EPA to detail the role additives can play in further reducing PM emissions. The additive industry will respond to regulatory and technology trends to continue to enable the level of performance required of current and future fuels. [EPA-HQ-OAR-2022-0829-0663, pp. 1-2]

Organization: American Coalition for Ethanol (ACE)

We welcome EPA specifically identifying fuel and the opportunity to address particulate matter (PM) emission reductions from sources of liquid fuels in a separate future rulemaking. Given the inescapable link between vehicle emissions and the fuel used to power the engines in those vehicles, we strongly recommend the Agency not wait for a future rulemaking but rather address fuel quality and PM reductions as part of the final rule for 2027 and later model year vehicles. EPA's proposal explains the complications facing refiners with respect to reducing the content of high-boiling point compounds in gasoline given the need to meet market octane requirements (since removing aromatics from gasoline requires a method to replace the octane those aromatics contained). This presents another opportunity for the Agency to rely on greater concentrations of ethanol in gasoline because ethanol delivers the highest-octane rating for fuel at the lowest cost, allowing automakers to benefit by continuing to develop high-compression and fuel-efficient engine technologies to reduce vehicle GHG emissions. We believe high octane, low carbon blends comprised of 25 to 30 percent ethanol would enable more fuel-efficient vehicles, reduce GHG emissions, and reduce other pollutants. [EPA-HQ-OAR-2022-0829-0613, pp. 4-5]

There are approximately 25 million FFVs in the U.S. today. The ideal way to transition from today's legacy fleet of internal combustion engines to new vehicles with advanced engine technologies designed to run optimally on a high-octane fuel is to utilize FFVs as bridge vehicles that can provide immediate demand for midlevel ethanol blends. [EPA-HQ-OAR-2022-0829-0613, pp. 4-5]

As a matter of fact, the Department of Energy Oak Ridge National Lab has investigated the use of high- octane ethanol blends such as E25 and E30 in FFVs that are designed and compatible with ethanol blend levels from 0 to 85 percent and can therefore seamlessly and with OEM approval utilize midlevel ethanol blends.9 Key findings from Oak Ridge include: "Experiments were performed with four FFVs using an E10 (92 RON) and E30 (100 RON) fuel. The two direct-injection FFVs demonstrated performance improvements for E30 compared to E10 of 2.5 to 3 percent, based on the 15-80 wide- open throttle acceleration time. Three of the four FFVs showed performance improvement with high- octane E30 compared to regular E10. (…) Marketing E25 or E30 to FFV owners as a performance fuel may enable greater utilization of ethanol in the near term and could help establish the refueling infrastructure to enable manufacturers to build dedicated vehicles designed for a high-octane midlevel ethanol blend." [EPA-HQ-OAR-2022-0829-0613, pp. 4-5]

> 9 Effects of High-Octane Ethanol Blends on Four Legacy FFVs and a Turbocharged GDI Vehicle." Thomas, J, West, and Huff, S, U.S. DoE ORNL. March 2015.

The full lifecycle GHG emissions analysis in the final rule must be based upon the latest version of the Greenhouse Gases, Regulated Emissions, and Energy Use in Technologies (GREET) model developed by U.S. Department of Energy's Argonne National Laboratory.

GREET is considered the gold-standard for calculating energy use, GHGs, and other regulated emissions that occur during the full lifecycle production and combustion of all transportation fuels and sources. GREET is used by the California Low Carbon Fuel Standard program and the Oregon Clean Fuels program and has more than 40,000 registered users worldwide. Congress directed the Treasury Department to use GREET for the new 45Z clean fuel production tax credit in the Inflation Reduction Act (IRA). [EPA-HQ-OAR-2022-0829-0613, pp. 5-6]

While it may be an inconvenient truth for some to accept, corn ethanol is a proven and cost-effective low carbon fuel playing an important role in reducing GHG emissions and air pollution from the transportation sector. In fact, the RFS has cut GHG emissions by nearly 600 million metric tons since 2007, exceeding EPA's original expectation of 444 million metric tons.10 [EPA-HQ-OAR-2022-0829-0613, pp. 5-6]

10 Unnasch. S. (2019) GHG Reductions from the RFS2 – A 2018 Update. Life Cycle Associates Report LCA. LCA.6145.199.2019 Prepared for Renewable Fuels Association.

Organization: American Free Enterprise Chamber of Commerce (AmFree) et al.

EPA's projected increase in electric-vehicle adoption also rests on unrealis- tic expectations of increased future sales. In addition to assuming that "con- sumer uptake" will increase as more models become available and charging infrastructure develops—issues addressed elsewhere in this comment—the agency asserts that growing interest and satisfaction with electric-vehicle tech- nology, as well as decreasing costs, will play a substantial role in turning the tides toward electrification. See 88 Fed. Reg. at 29,189, 29,312; Draft RIA at 4- [EPA-HQ-OAR-2022-0829-0683, pp. 21-22]

17. Available data, however, demonstrate that these assumptions suffer from critical flaws.

Consumer Interest and Satisfaction. Although nearly 95 percent Americans in the market for a new car chose not to purchase an electric vehicle last year, EPA claims that American consumers are increasingly interested in, and satisfied with, electric-vehicle technology. That assertion rests on a collection of un- justified inferences. [EPA-HQ-OAR-2022-0829-0683, pp. 21-22]

First, EPA cites one recent survey reporting that more than one-third of Americans said that they would either "seriously consider or definitely buy or lease" a battery-electric model today if they were in the market for a new vehicle. 88 Fed. Reg. at 29,189. But other data undermine EPA's reliance on abstract consumer "affinity" (id.) for electric vehicles. Other polls show that, even when there is an expressed interest in purchasing an electric vehicle, consumers often do not follow through. For example, "[a] 2022 CarGurus survey found that 35 percent of new car buyers expressed an interest in purchasing a hybrid, but only 13 percent eventually did." Robert N. Charette, Convincing Consumers to Buy EVs: How Range, Affordability, Reliability, and Behavioral Changes Figure into Purchase Decisions, IEEE Spectrum (Jan. 23, 2023) ("Convincing Consumers"), https://tinyurl.com/3p26536j. "Similarly, 22 percent expressed interest in a battery electric vehicle . . . , but only 5 percent bought one." Id. Just as manu- facturer announcements are not a reliable indicator of actual future production, abstract consumer surveys are not a reliable indicator of actual future purchase. [EPA-HQ-OAR-2022-0829-0683, pp. 21-22]

Organization: American Fuel & Petrochemical Manufacturers

VI. EPA's Consideration of Fuel Controls

EPA requested comment on potential changes to fuel controls to address PM emissions in the existing fleet. EPA specifically stated that it "has not undertaken sufficient analysis to propose changes to fuel requirements under CAA section 211(c) in this rulemaking and considers such changes beyond the scope of this rulemaking."284 Since EPA has declared it is not actually proposing to change fuel controls in this Proposal, AFPM respectfully asserts that it cannot provide detailed comments on this issue at this time; however, we are more than willing to work with the Agency on this issue. [EPA-HQ-OAR-2022-0829-0733, pp. 63-64]

284 Proposed Rule at 29,397.

As noted above, AFPM sought a brief extension to the comment period, which EPA denied.285 AFPM does not have adequate time to thoroughly review and comprehend EPA's supporting materials, conduct additional research into the unrealistic assumptions and conclusions embedded in the Proposed Rule, and provide informed comment on each aspect of a rule that has significant implications for our industry and the nation while also reviewing, researching, and providing comments on potential changes to fuel controls. [EPA-HQ-OAR-2022-0829-0733, pp. 63-64]

285 See Section V.

That said, at an extremely high level, we would have significant concerns about the adverse impacts this would have on the supply of gasoline and the minuscule PM benefits that might be achieved. For example, EPA's assessment must include the significant impacts to refineries and the gasoline pool such potential measures would entail. The potential fuel controls measures would cut a significant amount of the gasoline pool that is not contributing to PM generation. This would translate into both economical and logistical impacts (e.g., alternate disposition, or blending into diesel pool) that impacts costs to consumers. EPA should consider the significant contribution to PM from tire wear and entrained road dust, which account for a majority of the total PM2.5 emissions associated with traffic.286 EPA also must revise its flawed methodologies. For instance, the ASTM D7096 simulated distillation by gas chromatography (SimDis) proposed to either calculate PMI or to set high boiling point limits is not adequately precise to use as a control method and would generate significant errors. We also question the Agency's legal authority to move forward with these fuel controls, which have no environmental benefit for new motor vehicles. [EPA-HQ-OAR-2022-0829-0733, pp. 63-64]

286 See https://www.epa.gov/air-emissions-inventories.

Please contact the undersigned to explore these issues in greater detail. AFPM is happy to bring its members' technical expertise to this complex issue to help inform EPA's decision-making in this area. [EPA-HQ-OAR-2022-0829-0733, pp. 63-64]

Organization: American Honda Motor Co., Inc.

EPA is deferring consideration of fuel specifications that would better enable 0.5 mg/mi emissions compliance] [EPA-HQ-OAR-2022-0829-0652, p. 17]

Finally, important fuel specifications changes could assist automakers' abilities to comply with tighter PM standards, but the agency has chosen to defer action. [EPA-HQ-OAR-2022-0829-0652, p. 17]

C. Fuels Issues

In addition to vehicle emissions reductions, the agency also notes the opportunity for additional PM reductions through fuel specification changes:

The emissions standards for new vehicles (MY 2027 and later) proposed in this rule would achieve significant air quality benefits. However, there is an opportunity to further address PM emissions from the existing vehicle fleet, the millions of vehicles produced during the phase-in period, as well as nonroad engines, through changes in market fuel composition… EPA requests comments on aspects of a possible future rulemaking aimed at further PM emission reductions from these sources via gasoline fuel property standards. Such future fuel standards could be an important complement to EPA's proposed vehicle PM standards.31 [EPA-HQ-OAR-2022-0829-0652, p. 18]

31 88 Fed. Reg. 29397 (May 5, 2023)

Honda supports these efforts and believes strongly that the removal of heavy hydrocarbons from market gasoline would have a sizable impact in reducing PM emissions — not only from new vehicles moving forward, but also from the majority of cars and trucks operating on U.S. roads today.32 It will be important for EPA to consider changes to fuel property standards for both market fuel and certification test fuel, as applying changes to both fuels would far better align compliance requirements with real- world emissions performance. [EPA-HQ-OAR-2022-0829-0652, p. 18]

32 It would also have an emissions benefit of reducing PM emissions from all internal combustion engines, including motorcycles, marine engines, and small engine products such as lawn mowers, generators and ICE-based power tools.

The importance of including these changes in certification fuel is clear: removal of heavy hydrocarbons would have a significant impact on the viability of reaching 0.5 mg/mi levels. Because it appears the agency will only consider gasoline fuel property standards as part of "a possible future rulemaking," we strongly urge the agency to maintain alignment with California LEV IV standards at this time, and revisit mg/mi PM stringency when fuel specifications can better accommodate such performance standards. [EPA-HQ-OAR-2022-0829-0652, p. 18]

Tailpipe emissions are inherently an input-output function. With the entire car parc already subject to existing fuel regulations at the pump for RVP, octane, lead and other requirements, reducing the PM potential of market fuel would have a significant impact on our nation's PM inventory. If market fuel regulation can drive reductions in tailpipe PM, it seems only logical to also update certification fuel and MOVES modeling to reflect the real-world inventory impacts. This would also have an ancillary benefit in helping OEMs comply with, as proposed, a significantly more stringent (than CARB LEV IV) PM requirement. [EPA-HQ-OAR-2022-0829-0652, p. 18]

The Honda PM Index (PMI), calculated via a detailed hydrocarbon analysis (DHA) of a gasoline, has become an established parameter associated with tailpipe particulate matter.33 34 Low-volatility aromatics have huge leverage on the PMI value and also on measured tailpipe PM emissions; a percent or two of these heavy aromatics are responsible for a large portion of PM emissions. Although PMI should remain the "gold standard," Honda realizes that its use as the only compliance method will meet resistance due to the method's time and technical requirements. Therefore, alternative compliance methods should be allowed, with the caveats that (1) any such alternatives would require approval from EPA and (2) all approved methods should have compliance standards of equivalent stringency. [EPA-HQ-OAR-2022-0829-0652, p. 19]

33 Aikawa, K., Sakurai, T., and Jetter, J., "Development of a

Predictive Model for Gasoline Vehicle Particulate Matter Emissions," SAE Int. J. Fuels Lubr. 3, no. 2 (2010): 610-622 [EPA-HQ-OAR-2022-0829-0652, p. 19]

34 Aikawa, K. and Jetter, J.J., "Impact of Gasoline Composition on Particulate Matter Emissions from a Direct- Injection Gasoline Engine: Applicability of the Particulate Matter Index," International Journal of Engine Research 15, no. 3 (2014): 298-306

One promising alternative, as noted in the agency's proposed rule and associated documents,35 36 is simulated distillation (SimDis) by ASTM D7096. This method is short, usually requires no post-analysis review, and is sufficiently precise to quantify the heavy tail of a fuel sample. Although it is based on the volatility of the gasoline and not the fuel's chemistry, data show that the heavy tail consists primarily of aromatics. This makes it a potential surrogate for PMI. Also noted in the proposed rule is the vacuum- ultraviolet (VUV) method. Honda agrees with EPA's assessment that more VUV data on market fuels will be needed to complete a correlation with DHA-derived PMI values. An example of such work is currently in progress within the Coordinating Research Council (CRC). [EPA-HQ-OAR-2022-0829-0652, p. 19]

36 Butler, A, et al., US EPA, "Supplemental Information Related to Potential Fuel Control for Gasoline PM - EPA-HQ- OAR-2022-0829," April 2023

Recommendation: Reduce PM emissions by reducing the PM potential of fuel. Update fuel property standards to remove heavy hydrocarbons from both market fuel and certification fuel. [EPA-HQ-OAR-2022-0829-0652, p. 19]

Organization: American Petroleum Institute (API)

viii. EPA lacks authority to set limits on aromatics and other high-boiling material.

The proposed rule asks for comments on whether EPA should engage in a rulemaking to address potential limits on aromatics and high-boiling material as fuel standards under CAA § 211(c). Although EPA has not proposed to engage in a rulemaking at this time, API urges the agency to avoid a costly and burdensome rulemaking effort that would exceed its authority. [EPA-HQ-OAR-2022-0829-0641, pp. 33-34]

The proposed rule acknowledges that fuel standards would not assist the new vehicle fleet to comply with the new standards, but suggests the agency is thinking about them to reduce particulate matter from the existing fleet. However, EPA lacks authority to set fuel standards to address vehicle emissions from the existing vehicles, which are already able to comply with their applicable particulate matter standards. [EPA-HQ-OAR-2022-0829-0641, pp. 33-34]

EPA's authority to regulate vehicle emissions applies only prospectively. EPA may only set standards for classes of "new motor vehicles." CAA § 202(a)(1). In turn, EPA may only consider controlling or regulating fuel after it has determined there are no other "economically feasible means of achieving emissions standards under section [202]." Regulating fuel cannot be needed to achieve the Section 202 standards for existing vehicles because those vehicles already meet their applicable particulate matter standards without any additional fuel regulation. Any attempt to rely on the inability of existing vehicles to comply with the particulate matter standards for new vehicles because of lack of alternative controls would be contrary to the Act's focus on prospective standards. [EPA-HQ-OAR-2022-0829-0641, pp. 33-34]

In any event, EPA may not issue standards under CAA § 211(c) at this time because, as the proposed rule readily admits, EPA has not "considered all relevant medical and scientific evidence available to [it], including consideration of other technologically or economically feasible means of achieving" the standards under section 202. See § 202(c)(2)(A). Unless and until EPA completes that analysis and allows stakeholders an opportunity to comment on it, EPA may not set new standards under CAA § 211(c). [EPA-HQ-OAR-2022-0829-0641, pp. 33-34]

i. Additional Concerns.

EPA must address several aspects of their analysis of vulnerabilities associated with critical minerals as outlined in Appendix A and related to cost, modeling, and assumptions as outlined in Appendix B. [EPA-HQ-OAR-2022-0829-0641, p. 34]

j. Response to EPA Request for Information on Particulate Matter Fuel Controls.

In Appendix C we respond to EPA's request to review the Agency's rationale for considering fuels controls in a future rulemaking to reduce PM emissions. API finds the Agency has not appropriately considered all data and issues raised by a potential rulemaking. Furthermore, EPA needs to reconsider their analytical conclusions, limitations of SimDis, refinery modeling specifications, and that tire wear and entrained road dust related PM emissions are significant. Please note that due to the compressed comment period for such a complex request for information, coupled with the lack of an extension, API may supplement the docket. [EPA-HQ-OAR-2022-0829-0641, p. 34]

8. Cost and Impacts on Refining

EPA's qualitative description of refining impacts from restriction of gasoline heavy-boiling components is over-simplified and incomplete. EPA asserts an easy shift of gasoline heavy-ends to distillates; in the experience of API members, it is often challenging to make such shifts while keeping distillate fuel properties on specification, especially flashpoint. In addition, EPA's analysis focuses on octane loss as the only detriment to segregating heavy-ends from the gasoline pool, neglecting the value of these components' low volatility as a volatility "sink" which allows blending of butanes and other light components. Eliminating heavy-ends would result in a significant loss of light components to the gasoline pool as well to meet maximum RVP requirements. Finally, EPA considers only one refinery configuration where fluid catalytic cracking (FCC) dominates gasoline production, augmented by alkylation to upgrade FCC light olefins. Among API member refineries are plants which have neither FCC or alkylation units; impacts on these refineries are neglected in EPA's analysis. [EPA-HQ-OAR-2022-0829-0641, pp. 36-37]

EPA correctly identifies LP optimization as a useful tool for estimating refinery cost impacts of process changes, and provides results from a Haverly optimization program. Unfortunately, the Agency does not describe how it modeled the single refinery configuration considered. Although challenging to review without knowing key assumptions, correlations, and constraints used in the Haverly model, the results presented raise several concerns to API members. Among these concerns are the apparent lack of proper constraints, allowing the LP to make up lost gasoline heavy-ends with increased isomerization and alkylation; in practice, these units are likely fully utilized without headroom for increased production. Also, the results fail to discuss the light-ends utilization impact from eliminating the heavy-ends as RVP soak. [EPA-HQ-OAR-2022-0829-0641, pp. 36-37]

Finally, the results are again limited to a single, simple refinery configuration. API members routinely use LP models for refinery planning and preliminary optimization, but the models required to accurately represent a real refinery are highly complex and unique to a specific plant; a one-size-fits-all Haverly model is highly insufficient to quantify refining impacts of EPA's proposed restriction of gasoline heavy-ends blending. EPA should provide access to the model files with the assumed correlations to allow the public to fully analyze the results. [EPA-HQ-OAR-2022-0829-0641, pp. 36-37]

While the preliminary results suggest some directional relationship, API has concerns with: [EPA-HQ-OAR-2022-0829-0641, pp. 36-37]

(1) The accuracy of the correlation between PMI and the 99% SimDis by D7096; and

(2) Whether the minimum distillate flash and minimum gasoline T50 limits were modeled sufficiently. [EPA-HQ-OAR-2022-0829-0641, pp. 36-37]

Adding a restrictive max 99% point specification to gasoline, which already has a limiting minimum T50 specification, puts gasoline blending in a tight box which has the potential to increase costs to society. Similarly, our ability to shift transitional molecules from gasoline to distillate is limited by the flash specification. [EPA-HQ-OAR-2022-0829-0641, pp. 36-37]

EPA states, "The estimated costs for the 5°F, 10°F, and 15°F reductions in T90 were 0.5, 2.2, and 3.0 cents per gallon, respectively." These relative costs are questionable, as the cost per degree should be monotonically increasing as the reduction becomes more severe. An economic model should be graduated, beginning with the lower-cost steps first. The EPA model seems to contradict this economic fundamental when its 5°F to 10°F reduction costs 1.7 cpg (=2.2-0.5), while the 10°F to 15°F reduction costs only 0.8 cpg (=3.0-2.2). [EPA-HQ-OAR-2022-0829-0641, pp. 36-37]

Appendix C:

Consideration of Potential Fuels Controls for a Future Rulemaking

EPA notes in the NPRM that the Agency "…has not undertaken sufficient analysis to propose changes to fuel requirements…"130 and has not provided enough support to set limits at this time. In reviewing EPA's rationale for considering fuels controls in a future rulemaking to reduce PM emissions, API finds the Agency has not appropriately considered all data and issues raised by a potential rulemaking. In the ten sections below, API provides detailed comments on EPA's analysis, finding generally that such a rulemaking on potential fuels controls is unnecessary. If EPA plans to continue to review this issue, API and its members would like the opportunity to meet with the agency to work on this topic. [EPA-HQ-OAR-2022-0829-0641, p. 52]

130 88 Fed. Reg. 29397 (May 5, 2023).

1. Impacts of High-Boiling Components on Emissions

EPA acknowledges that fuel standards would not assist the new vehicle fleet comply with the new standards, but suggests the agency is thinking about reducing particulate matter from the existing fleet, which are already able to comply with their current particulate matter standards. While vehicle technologies have proven to be the primary means to control vehicle emissions, fuels quality can enable and support vehicle emissions systems performance. Fuels quality contributions, however, are smaller than those achieved by vehicle technologies. For instance, Tier III engine technologies such as higher fuel injection pressures, for gasoline direct injection (GDI), and future technologies with gasoline particulate filter (GPF), that can be used for both GDI and port-fuel injection (PFI), are capable to meet the very stringent 2025 LEV III 1 mg/mi mass particulate emissions standards or beyond131. Current vehicle technologies, without a GPF, are capable of reducing significantly PM emissions, and further constraints on the fuel will have limited impact on further reducing these emissions. The 2023 EPA certification vehicle test data shows that there were approximately 83 carline models (out of approximately 376 carlines tested on US06) that achieved a certification level of emissions of 0 gm/mile (and a rounded emission test results level below 0.5 mg/mile) of PM on the US06 drive cycle. These carlines were able to meet a 0.5 mg/mile PM emissions level using current certification gasolines, without the need for specialty lower PMI fuels. Additionally, newer vehicle technologies without GPFs have been demonstrated to have minimal sensitivity to fuel changes.132 In regard to future vehicles, EPA's DRIA states that GPF technologies are more effective at reducing PM emissions than fuel controls (e.g., PMI limit or T99 limits). Specifically, Figure 3-19 of the DRIA describes that PM emissions can be reduced by 99%, 96% and 96% for the testing cycles -7°C FTP, 25°C FTP, and US06, respectively. In contrast when considering a fuel control approach, the NPRM points to studies where it was found that there was a 1-2 percent PM emissions increase for each percent PMI increase. When assessed together, fewer PM emission reductions are gained through fuel controls compared to vehicle hardware approaches. [EPA-HQ-OAR-2022-0829-0641, p. 52]

131 https://doi.org/10.1016/j.scitotenv.2022.161225.

132 Citation: Singh, R., Voice, A., Fatouraie, M., and Levy, R., "Fuel Effects on Engine-out Emissions Part 1 - Comparing Certification and Market Gasoline Fuels," SAE Int. J. Adv. & Curr. Prac. in Mobility 3(6):3121-3137, 2021, https://doi.org/10.4271/2021-01-0541.

Furthermore, even if fuel controls were required to significantly reduce PM emissions from existent and future vehicles, which they are not, EPA's proposed methodology is flawed. PMI equations were developed on early, light duty vehicles with Tier 2 technology. New Tier 3 vehicles used advancements in fuel pressure, injector nozzle design and combustion strategy. PMI calculations are not necessarily correlated with modern vehicle technology. PMI equations were developed on Tier 2 gasolines, current EPA gasoline would not be expected to have the same emissions profile. [EPA-HQ-OAR-2022-0829-0641, p. 52]

PM indices also have proven biased for alcohol molecules and are not accurate for current vehicle and fuels technologies. "PMI was found to perform well if the fuels being evaluated had the same ethanol content, but it proved to be a biased indicator when applied to groups of fuels with varying ethanol content – i.e., E0 (neat), E10 (10% ethanol by volume), and higher ethanol-content fuels. LA92 Phase I PM emissions from fuels with ethanol were found to be consistently greater than emissions from nonoxygenated fuels of the same PMI" [CRC Project No. RW-107-2]. [EPA-HQ-OAR-2022-0829-0641, p. 52]

A study133 presented at the 33rd CRC Real World Emissions Workshop134, demonstrated and concluded that PMI was not predictive of engine out (or tailpipe) PM emissions. Further, it was concluded that FBP performed somewhat better predictor than PMI, but was still a weak indicator. [EPA-HQ-OAR-2022-0829-0641, p. 52]

2. Survey of High-Boiling Materials in Market Gasoline

EPA discusses their assessment of the trends of T90 from ASTM D86 (high-boiling material) over the past two decades, followed by a summary of available PMI data. [EPA-HQ-OAR-2022-0829-0641, p. 52]

The PMI Profile of Market Gasoline discussion in this section also points out that median PMI is 1.6 for US fuels with 10% remaining above 2.0, suggesting an opportunity to reduce PMI. However, Figure 42135 in the NPRM shows two-time frames (2008-12) and (2021-2022) but no source for the data. When conducting industry projects (i.e., CRC) where higher PMI fuels are being solicited, it has become almost impossible to find these in real-world fuels.136 [EPA-HQ-OAR-2022-0829-0641, p. 52]

135 88 Fed. Reg. 29397 (May 5, 2023).

136 One API member recently surveyed its gasoline BOB production (i.e., gasoline prior to blending ethanol) and found 95% of BOBs with PMI below 2.0.

3. Sources of High-Boiling Compounds in Gasoline Production and How Reductions might Occur – Refinery Impacts

EPA's analysis of high-boiling components in gasoline production is over-simplified and neglects significant effect of proposed reduction technologies. It should be pointed out that high boiling point does not necessarily mean high aromatic content. Reducing the gasoline high boiling point as a surrogate for heavy aromatic content would cut a significant amount of the gasoline pool that is not contributing to PM generation. This would translate into both economical and logistical impacts (e.g., alternate disposition, or blending into diesel pool). that would ultimately impact costs to consumers. Segregation of gasoline heavy-ends to distillates may impact octane, and replacement of octane is more complex than claimed. A potential impact resulting in a reduction of octane would reduce vehicle fuel economy limiting the advantages of higher octane. Work from the Department of Energy's Co-optima concluded, for downsize boosted engine technology, RON and octane sensitivity (enabled through high aromatic fuels) have the most potential to improve efficiency among all fuel properties.137 For naturally aspirated, port fuel- injected legacy vehicles, CRC138 showed that decreases in energy consumption of up to 2% for a small SUV was possible through the use of a 97 RON fuel compared to 91 RON fuel on a US06 drive cycle. [EPA-HQ-OAR-2022-0829-0641, p. 52]

137 https://doi.org/10.1016/j.pecs.2020.100876.

138 https://crcao.org/wp-content/uploads/2020/12/CRC-Project-AVFL-20a_SAE-Paper-2020-01-5117.pdf.

Shifting boiling points of naphtha produced on the fluid catalytic cracker (FCC), reformer, and coker to produce lighter distillate or kerosene may cause potential market issues, including:

- Overall gasoline production may fall if fuel producers are required to shift gasoline molecules to distillates, which may lead to higher gasoline prices for consumers. [EPA-HQ-OAR-2022-0829-0641, p. 52]

- There may be equipment constraints that prevent shifting of the cut point without restricting overall refining capacity, which could lead to higher consumer prices if overall production falls. [EPA-HQ-OAR-2022-0829-0641, p. 52]

- The value of alkylate and ethanol (non-aromatic high octane blend components) may increase. The alkylate production would probably fall if FCC units were constraint because of tightened specifications. [EPA-HQ-OAR-2022-0829-0641, p. 52]

- There may also be constraints in aromatics content and cetane number for putting these aromatic molecules into jet fuel or distillate, which may further reduce capacity or cause increased shipping of diesel blend components to maintain distillate specifications. [EPA-HQ-OAR-2022-0829-0641, p. 52]

- There are some capital projects that refiners may pursue to help mitigate the impacts, but these too could result in increased cost of supply to gasoline consumers. [EPA-HQ-OAR-2022-0829-0641, p. 52]

4. Methods of Compliance Determination

ASTM D7096 Simulated Distillation by GC Analysis: EPA proposes to use ASTM D7096 simulated distillation by gas chromatography (SimDis) to control / reduce gasoline particulate matter index (PMI) because the actual analytical method needed to calculate PMI --- detailed hydrocarbon analysis (DHA) --- is too costly and time-consuming to use as a production control. While API members agree that DHA is inappropriate for the reasons cited by the Agency, our experience indicates SimDis is not a reasonable alternative because (1) SimDis cannot distinguish between heavy gasoline constituents that contribute to PMI from those that do not, (2) SimDis results are not well correlated to PMI by DHA, and (3) SimDis is not adequately precise to use as a control method. [EPA-HQ-OAR-2022-0829-0641, pp. 52-53]

ASTM D7096 SimDis identifies the carbon number of hydrocarbons and estimates boiling point ranges, but it does not differentiate molecules that contribute highly to PM emissions (and PMI) from molecules in the same boiling point range that have minimal contribution to PM emissions. If EPA were to place limits on gasoline blending by using a SimDis constraint, a significant part of the available gasoline pool would be eliminated without sound technical reasoning. [EPA-HQ-OAR-2022-0829-0641, pp. 52-53]

Measurements by API members shows poor correlation between PMI and/or C10+ aromatics and Simulated Distillation Endpoint, T98, T95, or T90. While the heavy aromatics which contribute to PM emissions are in the high end of the distillation, many other non-PM formers are also present. Consequently, SimDis is too crude in its selectivity to use as a control method for reducing PMI. [EPA-HQ-OAR-2022-0829-0641, pp. 52-53]

ASTM D7069-19 states reproducibility of the method to be 8.3°F for T95 and 18.5°F for FBP. At EPA's proposed control point of T99 by SimDis, the reproducibility would be more closely represented by that of FBP stated in the method. Subsequently, a fuel specification with a SimDis T99 cut-off of 450 °F or 425 °F would result in an indefinite and inconsistent portion of heavy gasolines removed from the gasoline pool. From a compliance standpoint, fuel qualities that can be measured with greater precision are optimal because they can be tightly correlated with unit operations. [EPA-HQ-OAR-2022-0829-0641, pp. 52-53]

VUV Methods: EPA's analysis of VUV as a compliance tool contains errors regarding the appropriate methods, and inappropriately dismisses VUV as being insufficiently available for use as a control method. [EPA-HQ-OAR-2022-0829-0641, pp. 52-53]

EPA cities ASTM D8071 as the applicable method to substitute for DHA and use in PMI calculation, but this is incorrect. The D8071 method only gives compound classifications, not detailed component analysis needed for PMI calculation. The most suited VUV method for this application is D8369. [EPA-HQ-OAR-2022-0829-0641, pp. 52-53]

API disagrees with EPA's finding that VUV is insufficiently mature and available for consideration as a method to quantity gasoline PMI. When using the appropriate method D8369, API members find the VUV results are equivalent to PMI calculated from DHA but at a fraction of the analysis cost and time. In addition, most API members companies and many commercial laboratories have already implemented VUV analysis. [EPA-HQ-OAR-2022-0829-0641, pp. 52-53]

The proposed 99% SimDis specification would significantly reduce the molecules that can swing between gasoline and diesel, which is the primary model the industry uses to adapt to changing demands and inventory imbalances. With reduced blending flexibility, refiners will have much less ability to increase gasoline yields. Restricting gasoline end points could lead to gasoline price spikes in periods of market volatility. [EPA-HQ-OAR-2022-0829-0641, p. 53]

5. Statutory Authority

The proposed rule asks for comments on whether EPA should engage in a rulemaking to address potential limits on aromatics and high-boiling material as fuel standards under CAA § 211(c). Although EPA has not proposed to engage in a rulemaking at this time, API urges the agency to avoid a costly and burdensome rulemaking effort that would exceed its authority. [EPA-HQ-OAR-2022-0829-0641, p. 53]

The proposed rule acknowledges that fuel standards would not assist the new vehicle fleet to comply with the new standards, but suggests the agency is thinking about them to reduce particulate matter from the existing fleet. However, EPA lacks authority to set fuel standards to address vehicle emissions from the existing vehicles, which are already able to comply with their applicable particulate matter standards. [EPA-HQ-OAR-2022-0829-0641, p. 53]

EPA's authority to regulate vehicle emissions applies only prospectively. EPA may only set standards for classes of "new motor vehicles." CAA § 202(a)(1). In turn, EPA may only consider controlling or regulating fuel after it has determined there are no other "economically feasible means of achieving emissions standards under section [202]." Regulating fuel cannot be needed to achieve the Section 202 standards for existing vehicles because those vehicles already meet their applicable particulate matter standards without any additional fuel regulation. Any attempt to rely on the inability of existing vehicles to comply with the particulate matter standards for new vehicles because of lack of alternative controls would be contrary to the Act's focus on prospective standards. [EPA-HQ-OAR-2022-0829-0641, p. 53]

In any event, EPA may not issue standards under CAA § 211(c) at this time because, as the proposed rule readily admits, EPA has not "considered all relevant medical and scientific evidence available to [it], including consideration of other technologically or economically feasible means of achieving" the standards under section 202. See § 202(c)(2)(A). Unless and until EPA completes that analysis and allows stakeholders an opportunity to comment on it, EPA may not set new standards under CAA § 211(c). [EPA-HQ-OAR-2022-0829-0641, p. 53]

Please note that due to the compressed comment period for such a complex request for information, coupled with the lack of an extension, API may supplement the docket. [EPA-HQ-OAR-2022-0829-0641, p. 53]

6. Structure and Level of the Standard

As mentioned at the beginning of Appendix C, vehicle technologies have proven to be the primary means for controlling vehicle emissions. Fuels quality can improve vehicle emissions systems and help achieve air quality objectives, but fuels contributions are smaller than those achieved by vehicle technologies. [EPA-HQ-OAR-2022-0829-0641, p. 53]

To the extent a structure and level of standard may be considered, an averaging, banking, and trading solution has worked well for mogas sulfur and benzene. Much like a Low Carbon Fuels Standard program, it allows the industry to meet the goals of the program at the lowest possible cost while providing flexibility to blend fuel under abnormal operations. This would be preferrable to a price per gallon cap which could be difficult to both measure and design controls to ensure operations are below required thresholds. [EPA-HQ-OAR-2022-0829-0641, p. 53]

7. Impact of PMI on Engine Design and Efficiency

EPA mentions that another potential reason to consider a PMI limit is related to low- speed preignition (LSPI) and requests comments on the impact of PMI on engine design and effciency. References below point to other factors that impact LSPI that need to be considered. Fuel specification changes may not be sufficient to reduce LSPI occurrences. [EPA-HQ-OAR-2022-0829-0641, p. 53]

CRC Project CM-137-17-1 139 [Link: https://crcao.org/wp-content/uploads/2019/07/CM-137-17-1_FinalReport-June-2019.pdf] (Review of Low-Speed Pre-Ignition Literature) makes clear that one single LSPI initiation mechanism cannot be derived from the published literature. However, the report did allow for the general statement that "improved oil formulation and oil ignitability as well as a design that leads to reduced oil intrusion from, for example, the crankcase ventilation system or past the piston rings is of benefit. Further the report went on to indicate that low calcium and High ZNDTP or MODTC oil formulations are linked to low LSPI counts. [EPA-HQ-OAR-2022-0829-0641, p. 53]

139 “REVIEW OF LOW-SPEED PRE-IGNITION LITERATURE,” CRC Report No. CM-137-17-1, June 2019, (https://crcao.org/wp-content/uploads/2019/07/CM-137-17-1_FinalReport-June-2019.pdf).

ILSAC GF-6A and GF-6B 140 [Link: https://www.api.org/products-and-services/engine-oil/eolcs-categories-and-classifications/oil-categories#tab-ilsac] specifications represent the latest performance requirements for gasoline engine oils set by the International Lubricant Specification Advisory Committee (ILSAC). GF-6A and GF-6B were introduced in May 2020 and are designed to provide protection against low-speed pre-ignition (LSPI) in engines operating on ethanol-containing fuels up to E85. [EPA-HQ-OAR-2022-0829-0641, p. 53]

140 ILSAC Standard For Passenger Car Engine Oils. (https://www.api.org/products-and-services/engine-oil/eolcs- categories-and-classifications/oil-categories#tab-ilsac).

For automotive gasoline engines, the latest engine oil service category includes the performance properties of each earlier category. Therefore, the latest engine oil specifications will provide full protection for automotive engines where an earlier oil category is recommended by the engine manufacturer. [EPA-HQ-OAR-2022-0829-0641, p. 53]

SAE paper 2017-24-0061 141 [Link: https://www.sae.org/publications/technical-papers/content/2017-24-0061/] shows that high aromatic and high sensitivity fuels help to mitigate knock under high load for boosted SI engines. Similarly, in SAE paper 2011-01-0342142 low-aromatics fuel blends showed an increase tendency to auto-ignition and knock (traditional engine knock, not LSPI) characterized by the presence of a low-temperature heat release regime prior to the main combustion phase. It should be noted that LSPI, autoignition, and knock are different phenomenon and not related. [EPA-HQ-OAR-2022-0829-0641, p. 53]

141 Szybist, J., Wagnon, S., Spliter, D., Pitz, W. et al., "The Reduced Effectiveness of EGR to Mitigate Knock at High Loads in Boosted SI Engines," SAE Int. J. Engines 10(5):2305-2318, 2017, https://doi.org/10.4271/2017-24-0061.

142 Amann, M., Mehta, D., and Alger, T., "Engine Operating Condition and Gasoline Fuel Composition Effects on Low- Speed Pre-Ignition in High-Performance Spark Ignited Gasoline Engines," SAE Int. J. Engines 4(1):274-285, 2011, https://doi.org/10.4271/2011-01-0342.

The LSPI phenomenon is complex with some mechanisms strictly related to lubricants formulation. Fuel specification changes may not reduce LSPI occurrences. Proposed PMI limits could reduce the aromatic content of the gasoline pool and potentially result in an unintentional increase of knock or autoignition events for the current on-road carpark. [EPA-HQ-OAR-2022-0829-0641, p. 53]

8. Cost and Impacts on Refining

EPA's qualitative description of refining impacts from restriction of gasoline heavy- boiling components is over-simplified and incomplete. EPA asserts an easy shift of gasoline heavy-ends to distillates; in the experience of API members, it is often challenging to make such shifts while keeping distillate fuel properties on specification, especially flashpoint. In addition, EPA’s analysis focuses on octane loss as the only detriment to segregating heavy-ends from the gasoline pool, neglecting the value of these components’ low volatility as a volatility “sink” which allows blending of butanes and other light components. Eliminating heavy-ends would result in a significant loss of light components to the gasoline pool as well to meet maximum RVP requirements. Finally, EPA considers only one refinery configuration where fluid catalytic cracking (FCC) dominates gasoline production, augmented by alkylation to upgrade FCC light olefins. Among API member refineries are plants which have neither FCC or alkylation units; impacts on these refineries are neglected in EPA's analysis. [EPA-HQ-OAR-2022-0829-0641, p. 53]

EPA correctly identifies LP optimization as a useful tool for estimating refinery cost impacts of process changes, and provides results from a Haverly optimization program. Unfortunately, the Agency does not describe how it modeled the single refinery configuration considered. Although challenging to review without knowing key assumptions, correlations, and constraints used in the Haverly model, the results presented raise several concerns to API members. Among these concerns are the apparent lack of proper constraints, allowing the LP to make up lost gasoline heavy-ends with increased isomerization and alkylation; in practice, these units are likely fully utilized without headroom for increased production. Also, the results fail to discuss the light-ends utilization impact from eliminating the heavy-ends as RVP soak. [EPA-HQ-OAR-2022-0829-0641, p. 53]

Finally, the results are again limited to a single, simple refinery configuration. API members routinely use LP models for refinery planning and preliminary optimization, but the models required to accurately represent a real refinery are highly complex and unique to a specific plant; a one-size-fits-all Haverly model is highly insufficient to quantify refining impacts of EPA's proposed restriction of gasoline heavy-ends blending. EPA should provide access to the model files with the assumed correlations to allow the public to fully analyze the results. [EPA-HQ-OAR-2022-0829-0641, p. 53]

While the preliminary results suggest some directional relationship, API has concerns with: [EPA-HQ-OAR-2022-0829-0641, p. 53]

(1) The accuracy of the correlation between PMI and the 99% SimDis by D7096; and

(2) Whether the minimum distillate flash and minimum gasoline T50 limits were modeled sufficiently. [EPA-HQ-OAR-2022-0829-0641, p. 53]

Adding a restrictive max 99% point specification to gasoline, which already has a limiting minimum T50 specification, puts gasoline blending in a tight box which has the potential to increase costs to society. Similarly, our ability to shift transitional molecules from gasoline to distillate is limited by the flash specification. [EPA-HQ-OAR-2022-0829-0641, p. 53]

EPA states, "The estimated costs for the 5°F, 10°F, and 15°F reductions in T90 were 0.5, 2.2, and 3.0 cents per gallon, respectively." These relative costs are questionable, as the cost per degree should be monotonically increasing as the reduction becomes more severe. An economic model should be graduated, beginning with the lower-cost steps first. The EPA model seems to contradict this economic fundamental when its 5°F to 10°F reduction costs 1.7 cpg (=2.2-0.5), while the 10°F to 15°F reduction costs only 0.8 cpg (=3.0-2.2). [EPA-HQ-OAR-2022-0829-0641, p. 53]

The proposed 99% SimDis specification would significantly reduce the molecules that can swing between gasoline and diesel, which is the primary model the industry uses to adapt to changing demands and inventory imbalances. With reduced blending flexibility, refiners will have much less ability to increase gasoline yields. Restricting gasoline end points could lead to gasoline price spikes in periods of market volatility. [EPA-HQ-OAR-2022-0829-0641, p. 53]

9. Estimated Emissions and Air Quality Impacts

EPA has failed to assess particulate matter impacts from tire wear or entrained road dust. Tire wear and entrained road dust emissions account for a majority of the total PM2.5 emissions associated with traffic.143 There is a high correlation between both tire wear, and entrained road dust emissions, and vehicle weight. Studies have also found electric vehicles to be heavier than the equivalent class/size of ICEVs due to the inclusion of the battery. Therefore, converting ICEVs to ZEVs, as a result of the proposed regulation on “Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light- Duty and Medium-Duty Vehicles” would significantly increase the average vehicle weight on roadways, which in turn would increase tire, brake, and entrained road dust emissions. Including these emissions144, 145, 146,147 in the analysis could potentially change EPA’s conclusions and significance findings in the DRIA. Hence, EPA must evaluate these emissions and their impacts. [EPA-HQ-OAR-2022-0829-0641, p. 53]

143 https://www.epa.gov/air-emissions-inventories.

144 https://ww3.arb.ca.gov/ei/areasrc/fullpdf/2021_paved_roads_7_9.pdf.

145 https://doi.org/10.1016/j.scitotenv.2022.156961.

146 htp://dx.doi.org/10.1016/j.atmosenv.2016.03.017.

147 https://doi.org/10.1016/j.scitotenv.2022.161225.

There are several sources in the literature that raise questions as to the absolute and relative magnitude of the potential reductions to PM concentrations, and subsequent health benefits, that reducing PMI could have that are not included in the proposed rule: that EPA needs to evaluate: [EPA-HQ-OAR-2022-0829-0641, p. 53]

- The 2019 OECD report lays out the relative contribution of primary PM emissions from road transport, showing approximately 1/3 PM2.5 from non-exhaust (tires, brakes, road wear) in 2014 148 (Figure 2.1). [EPA-HQ-OAR-2022-0829-0641, p. 53]

148 OECD (2020), Non-exhaust Particulate Emissions from Road Transport: An Ignored Environmental Policy. Challenge, OECD Publishing, Paris, https://doi.org/10.1787/4a4dc6ca-en.

- The 2019 OECD report also includes data from EPA (2019 NEI) that shows that less than half of primary PM2.5 from road transportation is from vehicles, and this represents 3% of total primary PM2.5. See Table 2.3 [EPA-HQ-OAR-2022-0829-0641, p. 53]

- Total PM 2.5 is a combination of primary PM 2.5 emissions plus secondary species (inorganic and organic). Secondary aerosols often dominate. Primary PM can range from 10% to 70%, and is often less than 50%.149,150 [EPA-HQ-OAR-2022-0829-0641, p. 53]

149 https://www.science.org/doi/10.1126/science.1180353.

150 https://www3.epa.gov/tnchie1/conference/ei13/mobile/hodan.pdf.

- Mobile sources of secondary organic aerosols are a small fraction of the total in both absolute and population weighted terms.151 On-road sources already a generally small fraction without limiting to just light duty/passenger (Figure 7).152 [EPA-HQ-OAR-2022-0829-0641, p. 53]

10. Analysis of the references to CRC studies

Comments on references used in Section IX153: Consideration of Potential Fuels Controls for a Future Rulemaking. [EPA-HQ-OAR-2022-0829-0641, pp. 53-63]

153 **The focus of section IX is PM emissions reduction, and therefore will serve as the focus of comments.

Proposed Rule Statement:

Statement: "Numerous emissions studies have associated high-boiling compounds in gasoline with increased tailpipe PM emissions."154 [EPA-HQ-OAR-2022-0829-0641, pp. 53-63]

154 88 Fed. Reg. 29398 (May 5, 2023).

Statement references 155: [EPA-HQ-OAR-2022-0829-0641, pp. 53-63]

155 Statement reference numbers refer to footnote numbering in the proposed rule.

868 Coordinating Research Council, "Evaluation and Investigation of Fuel Effects on Gaseous and Particulate Emissions on SIDI In-Use Vehicles," Report No. E–94–2, March 2016. [EPA-HQ-OAR-2022-0829-0641, pp. 53-63]

869 USEPA "Assessing the Effect of Five Gasoline Properties on Exhaust Emissions from Light-Duty Vehicles Certified to Tier 2 Standards: Analysis of Data from EPAct Phase 3 (EPAct/V2/E–89)," April 2013. Document EPA–420–R–13–002. [EPA-HQ-OAR-2022-0829-0641, pp. 53-63]

Background: references 868 (CRC report E-94-2) and 869 (EPA EPAct study) refer to large fuel effects-emissions studies seeking to determine what gasoline properties drive vehicle emissions (mainly PM). E-94-2 looked at emissions across a mix of Tier 2, GDI vehicles (12) running match-blended gasoline fuels that approximated market gasoline fuels (PMI, AKI, and ethanol levels were varied). In the EPAct work, ethanol, T50, T90, aromatics, and RVP were varied. For the study, 27 fuels were developed (i.e., match-blended) and tested in 15 light-duty vehicles (Tier 2, MY2008, all PFI). [EPA-HQ-OAR-2022-0829-0641, pp. 53-63]

API Comment: Although PMI was strongly correlated with increasing PM emissions in E-94-2, PM increased with increasing C10+ aromatics in EPAct, both studies contain faults. E-94-2, for example, used match-blended fuels, which received criticism when the final report was released for not being representative of market fuels. In addition, EPAct results are no longer relevant due to the MY2008 test fleet. In short, the references are dated, and more-recent attempts by CRC to study emissions impacts of newer, Tier 3 vehicles with injection pressures approaching 350 bar are inconclusive, warranting further study. Generally, higher injection pressures lower PM emissions; and the positive correlation between PMI and PM is less clear (CRC E-135). [EPA-HQ-OAR-2022-0829-0641, pp. 53-63]

Statement: "…analysis of a large number of market fuel samples has shown that the high-boiling tail of gasoline contains a high proportion of aromatics, and that the heaviest few percent of this material has very high leverage on PM emissions."156 [EPA-HQ-OAR-2022-0829-0641, pp. 53-63]

156 88 Fed. Reg. 29393 (May 5, 2023)

Background: Honda published the SAE paper introducing the PMI concept in 2010 (873), and while it took a few years to gain notoriety, its dependency on DHA has motivated others to find alternative, easier pathways towards a predictive PM emissions metric (GM in 870; Toyota in 871). Regardless of metric, heavier fuel components tend to lead to higher PM emissions. [EPA-HQ-OAR-2022-0829-0641, pp. 53-63]

API Comment: So much of the supporting work is based on assessments using Tier 2 technology. We know Tier 3 vehicles are transitioning to higher injection pressures (which lowers PM, generally), but many fuel effects studies are ongoing or in development. Lastly, it would be unfortunate if some type of fuel distillation cut limited potential use of low-carbon feedstocks for future fuels. [EPA-HQ-OAR-2022-0829-0641, pp. 53-63]

Statement: PMI has been used in several emission studies and modeling analyses correlating fuel parameters to PM, and our assessment of potential impacts of fuel formulation changes on PM emission inventories, presented in Section IX.7, rely heavily on PMI.”157 [EPA-HQ-OAR-2022-0829-0641, pp. 53-63]

157 88 Fed. Reg. 29398 (May 5, 2023).

880 Coordinating Research Council, “Alternative Oxygenate Effects on Emissions,” Report No. E–129–2, October 2022. [EPA-HQ-OAR-2022-0829-0641, pp. 53-63]

Background: Reference 879 refers to an SAE paper authored by EPA staff members involved in the EPAct study (2015-01-1072). The authors work to integrate PMI into the EPAct data, while also observing ethanol-PM interactions. 10 of 15 vehicles used in the EPAct study showed a correlation between PM and PMI; in addition, the authors postulated that ethanol addition appears to exacerbate the inability of heavier components to volatilize, resulting in increased PM (it should be noted that the remaining 5 vehicles did not exhibit any PM sensitivity to PMI or ethanol). Reference 880 is a CRC report covering results from E-129-2, a program run out of NREL on a single cylinder research engine running a couple of base gasolines (low- and high-PMI) blended with various alcohols. The primary objective of this program was to develop data to better understand competing effects between heat of vaporization (as mentioned above in reference to the EPAct study) and dilution (i.e., diluted gasoline results in lower emissions). While PM emissions generally increased with increasing PMI, correlation strength was highly variable across multiple test conditions. [EPA-HQ-OAR-2022-0829-0641, pp. 53-63]

API Comment: While PMI has become the most 'robust' parameter for indicating a fuel's propensity for PM formation, it has limitations. For example, in E-129-2, ethanol blended into the 'low' PMI (1.21) fuel appeared to show HOV effects dominated. In the 'high' PMI blend (2.75), HOV effects dominated at the high-speed condition, but dilution seemed to dominate at the low-speed condition (i.e., PM decreased with increasing ethanol content). The choice to include this reference is interesting as the results are far from absolute, and beg more questions for future study. For the SAE EPA paper (reference 879), I have concerns with the age of the vehicle fleet used in the study (MY2008), technology (PFI), as well as 1/3 of the fleet exhibiting no sensitivity to PMI and/or ethanol with respect to PM emissions. [EPA-HQ-OAR-2022-0829-0641, pp. 53-63]

Organization: Chevron

5. Potential future fuel controls.

In Section IX. (Consideration of Potential Fuels Controls for a Future Rulemaking) of the proposed rule, EPA discusses an opportunity to address particulate matter emissions from the existing and future fleet through changes in fuel compositions. Chevron has extensive technical expertise in fuel formulation, emissions testing, and analytical methodology. Based on our experience, we believe EPA's suggested approach to controlling particulate matter may not be cost effective or necessary. We offer the following comments on Section IX. [EPA-HQ-OAR-2022-0829-0553, p. 7]

Specifically, Chevron recommends against EPA's consideration of Particulate Matter Index (PMI) methodology as an option to control particulate matter (PM) emissions from gasoline. The PMI methodology was developed over 10 years ago and is based on testing with Tier 2 vehicles and fuels. The transition to Tier 3 vehicles and fuels has greatly reduced PM emissions from the vehicle fleet. Vehicle hardware technology advancements, such as gasoline direct injection and higher fuel injection pressures are better suited to manage the remaining PM emissions rather than changing the gasoline composition. When the PMI methodology is used to evaluate current gasoline samples, Tier 3 gasoline has shown a steady reduction in calculated PMI compared to Tier 2 gasoline, even where the Tier 3 samples have higher final distillation boiling temperatures. The combination of advanced vehicle technology and improved Tier 3 gasoline quality suggests that the PMI methodology may no longer be effective at identifying future PM control measures. [EPA-HQ-OAR-2022-0829-0553, p. 7]

As an alternative to PMI, EPA suggests that ASTM D7096 SIMDIS may be the best technology to evaluate candidate gasoline fuels and to determine a new standard to address PM emissions. Chevron does not believe the use of SIMDIS is appropriate because it does not distinguish between molecules that contribute to PM formation and molecules that do not form particulates. Use of the SIMDIS methodology will result in a fairly imprecise reduction in the final boiling point of gasoline. Changing the gasoline distillation specification in this way will eliminate many non-PM forming molecules, like heavy alkylate species, which are valuable components for gasoline octane, vapor pressure, and economics. [EPA-HQ-OAR-2022-0829-0553, p. 7]

In lieu of using the SIMDIS analytical method, Chevron prefers the vacuum-UV (VUV) technology. Chevron has developed gasoline characterization methods using VUV and believes that it is well suited to identifying particulate-forming molecules. Chevron is available to work with EPA in identifying analytical techniques that could be used in evaluating PM formation from gasoline. [EPA-HQ-OAR-2022-0829-0553, p. 7]

The API comments on the proposed rule contain an extensive discussion of the technical issues related to particulate matter formation. Chevron made significant contributions to the API comments. We endorse the API comments on Section IX. in their entirety. We recommend that EPA should work closely with industry prior to any decision to proceed with a formal rulemaking to address gasoline particulates. [EPA-HQ-OAR-2022-0829-0553, p. 7]

Organization: Clean Fuels Development Coalition (CDFC)

SOA from Gasoline Aromatics. On p. 591, EPA noted that “Mobile sources are an important contributor to secondary aerosols formed from nitrate, sulfate and organic precursors. Studies have shown that secondary organic aerosol (SOA) formation from gasoline vehicle exhaust can exceed directly emitted (tailpipe) PM emissions, and that changes to gasoline formulation can have impacts on SOA that are larger than the associated shifts in direct PM emissions.” [EPA-HQ-OAR-2022-0829-0630, p. 8]

This statement seems at odds with the Agency’s claim that the proposed rule would reduce PM emissions by “more than 95 percent”. In fact, EPA historically has vastly understated the substantial contributions mobile sources—especially gasoline BTEX— make to SOA + PAH formation. [EPA-HQ-OAR-2022-0829-0630, p. 8]

Former OTAQ Director Grundler offered this explanation to SDFU President Sombke: “With respect to your concern that the EPA’s models incorrectly predict the contribution of light-duty gasoline vehicles to PM (e.g., as compared to leaf blowers) it is important to note that the EPA estimates cited in the Wall Street Journal refer only to directly emitted PM. We agree that ambient levels of PM are a result of secondarily formed particles in addition to direct PM emissions, and that light-duty gasoline vehicles are important sources of precursors to PM formation.”4 [Emphasis supplied] [EPA-HQ-OAR-2022-0829-0630, p. 8]

4 Supra, Grundler letter to Sombke, March 15, 2018.

It took several exchanges to elicit this admission five years ago. It is clear from EPA’s claim that the proposed rule would reduce PM emissions by “more than 95 percent” that the Agency continues to downplay the disproportionate role SOA plays in fine and ultrafine particulate emissions. [EPA-HQ-OAR-2022-0829-0630, p. 8]

Leading experts are convinced that aromatics ("organics") are the primary culprit. "An important recent study, co-authored by the Nobel Prize winner Mario Molina, concluded that reducing the smallest (ultrafine) particles "without simultaneously limiting organics from automobile emissions is ineffective and can even exacerbate this problem". [Detchon/Modlin 2021 comments, p. 2.] This has implications not only for GDI engine emissions effects, but also for the NPRM's gasoline particulate filter (GPF) strategies. [EPA-HQ-OAR-2022-0829-0630, p. 8]

Detchon and Modlin went on to note that "Emissions from aromatic compounds in gasoline were thought to be short-lived, thus posing little threat to human health. But that was wrong. A recent General Motors study found that nearly 96% of the fine particle emissions from gasoline are caused by the aromatics in the fuel". [Ibid., p. 1] [EPA-HQ-OAR-2022-0829-0630, p. 8]

In a letter to Acting OAR Administrator Joseph Goffman, former Senate Majority Leader Tom Daschle cited these experts and then cautioned EPA that failure to control BTEX would severely compromise, perhaps doom, EPA's PM control strategies DaschleGoffmanHOLCAexecutedjune2021.pdf: [Link: file:///C:/Users/dehbi/AppData/Local/Microsoft/Windows/INetCache/Content.Outlook/OFSN24IW/DaschleGoffmanHOLCAexecutedjune2021.pdf] [EPA-HQ-OAR-2022-0829-0630, p. 8]

"Given the role of aromatic hydrocarbons in PM formation and given the propensity of GDI engines to increase emissions of UFPs, EPA's strategies for regulating fine particle pollution in urban areas are doomed to failure unless they significantly reduce gasoline aromatics." A prescient statement that is proving itself to be even more true as GDI engines dominate the U.S. fleet. [EPA-HQ-OAR-2022-0829-0630, p. 8]

EPA Experts Have Warned About "Atmospheric Transformation Products" from Aromatics for Many Years. Outside of OTAQ, EPA experts have been clear about EPA's duty under the Clean Air Act to control carcinogenic and mutagenic atmospheric reaction products, the predominant precursors of which are gasoline aromatics. [EPA-HQ-OAR-2022-0829-0630, p. 9]

"Although oxidized VOCs can be components of primary emissions from a variety of sources, most result from secondary reactions of hydrocarbons emitted into the atmosphere, making them late-generation atmospheric reaction products. Assessments of health effects based solely on direct emissions are incomplete if potentially important contributions from such products are neglected, as has been noted by the Clean Air Act, which mandates consideration of atmospheric transformation products. [EPA-HQ-OAR-2022-0829-0630, p. 9]

5. Conclusions and implications for control strategies

Other than 1,2,4- and 1,3,5-trimethylbenzene, all of the precursor aromatic VOCs investigated here are classified as hazardous air pollutants by the U.S. EPA, and therefore emissions of these species from industrial activities are controlled under the Clean Air Act (U.S. EPA, 2015a). Nonetheless, of the 8 VOCs that produced mutagenic atmospheres, all did so only under irradiation. Thus, only late-generation reaction products were responsible for the mutagenicity, not the precursor VOCs, raising an interesting point regarding potential control strategies when the photochemistry of certain chemical species is similar to those described here. Non-mutagenic primary compounds may be less likely to be controlled; however, the resulting late-generation products may be more likely to be mutagenic. Therefore, consideration should be given to precursor compounds based not only on their intrinsic health concerns but also on those of their potential late-generation atmospheric photochemical products. It seems that these products, which are typically not monitored or controlled, account for much of the gas-phase direct-acting mutagenicity. Based on these limited studies, reducing the concentrations of primary VOCs would likely result in a corresponding reduction in the concentrations of the products, with a parallel reduction in atmospheric mutagenicity."5 [EPA-HQ-OAR-2022-0829-0630, p. 9]

5 "Mutagenic atmospheres resulting from the photooxidation of aromatic hydrocarbon and NOx mixtures", Theran P. Riedela,∗ , David M. DeMarinib , Jose Zavalac , Sarah H. Warrenb , Eric W. Corsed , John H. Offenberga , Tadeusz E. Kleindiensta , Michael Lewandowski]

[Dr. Riedel is a senior scientist at EPA's National Exposure Research Lab in Research Triangle Park, NC. He and his colleagues published this study in 2018 ResearchGate https://www.researchgate.net/publication/315864231_Mutagenicity_and_Carcinogen icity] [EPA-HQ-OAR-2022-0829-0630, p. 9]

Conclusion. Thus, the NPRM presents us with "insurmountable opportunities", as Pogo would say. Recognizing that EPA's primary thrust with this rulemaking is to drive the U.S. to an electrified transport system, we must also recognize that trillions of miles will be driven by ICEs powered by gasoline. Unless EPA moves urgently to improve the quality of that gasoline by substantially reducing gasoline BTEX content— as required by Congress—tens of millions of Americans will have their health unnecessarily damaged and die premature deaths. The Detchon/Modlin comments said it best: [EPA-HQ-OAR-2022-0829-0630, pp. 8-10]

"It doesn't have to be this way. Technologies and products have come together to define a new solution for what the Clean Air Act requires: "the greatest degree of emission reduction achievable through the application of technology which will be available." Along with a rapid transition to electric vehicles, a complementary program should include adoption of higher ethanol blends, which have been shown by U.S. National Laboratories to enable higher fuel economy and vehicle performance. Such blends would enable a 40% reduction in the use of toxic aromatics in gasoline. An important recent study, co-authored by the Nobel Prize winner Mario Molina, concluded that reducing the smallest (ultrafine) particles "without simultaneously limiting organics from automobile emissions is ineffective and can even exacerbate this problem." (p. 2) [EPA-HQ-OAR-2022-0829-0630, pp. 8-10]

OTAQ's exclusive reliance on vehicle technology improvements was not only a violation of clear Congressional directives, it has proven to be a colossal scientific miscalculation. The rapid adoption of gasoline direct injection (GDI) engines—absent a parallel reduction in gasoline BTEX levels—will increase emissions of the most harmful UFP + PAH carcinogens by more than a "septillion" particles over the next decade. [EPA-HQ-OAR-2022-0829-0630, pp. 8-10]

Detchon/Modlin conclude: "Test programs in the rural Midwest have shown that today's vehicles operate well on higher levels of ethanol blended with conventional gasoline. Automakers have affirmed that such benefits would be realized by both new and existing internal combustion engines and therefore should be encouraged as additional solutions as soon as possible." [EPA-HQ-OAR-2022-0829-0630, pp. 8-10]

The nation has waited 35 years for EPA/OTAQ to act. The nation's public health and environment cannot afford to wait any longer. Higher ethanol blends cost less than gasoline BTEX, they are here today, they would save the nation hundreds of billions of dollars every year in reduced oil imports and health costs, and automakers require the additional octane. More importantly, EPA has a nondiscretionary duty to act—one it has ignored for far too long. [EPA-HQ-OAR-2022-0829-0630, pp. 8-10]

[See original submission for Supporting Documentation and End Notes] [EPA-HQ-OAR-2022-0829-0630, pp. 8-10]

Organization: Colorado Energy Office, Colorado Department of Transportation, and Colorado Department of Public Health and Environment

In response to EPA's request for comments on specific aspects of the rule, we offer the following suggestions to ensure the rule is as successful as possible: [EPA-HQ-OAR-2022-0829-0694, pp. 2-3]

- EPA requested comment on what levels of carbon dioxide (CO2) emissions stringency to pursue between 2026 and 2032, and suggested one recommended stringency schedule and three alternative schedules. We believe that the federal government needs to streamline widespread adoption of EVs to avoid the inefficiency that comes with significantly varied markets across the country. At times, it has been hard to get the products consumers want in Colorado, because the initial stock of popular models gets sent to larger states like California even though our state is an ideal market with strong EV incentives. For example, the State of Colorado put in an order for over 100 Ford F-150 Lightnings, but only four have been delivered thus far. Similarly, it has been challenging for consumers to access popular models with great potential for mountain driving, such as the Toyota RAV-4 Prime. Thankfully, delivery times are starting to improve, but as the supply chain normalizes, it is critical that states like Colorado have equal access to the full range of vehicle choices, and that will be enhanced by the federal government taking the lead on regulations that normalize production and delivery across the country. Alternative 1 would provide the most consistency with what Colorado is already pursuing. We urge the federal government to place even greater focus on consistency and streamlining of regulations in order to help us accelerate EV adoption with the urgency that we need. [EPA-HQ-OAR-2022-0829-0694, pp. 2-3]

- Regarding criteria pollutants, we urge EPA to consider ways to align these proposed standards with California, and in doing so to avoid any backsliding in remaining conventional vehicles sold, while avoiding a scenario in which OEMs are forced to divert investment away from transportation electrification and towards technology advancement on conventional vehicles. We are concerned that the criteria standards in the EPA draft rule could have this unintended effect. [EPA-HQ-OAR-2022-0829-0694, pp. 2-3]

- We urge EPA to consider investments in charging infrastructure as an option for manufacturers to achieve compliance credit. For years, EPA has included a broad range of crediting options to add flexibility to the program in ways that support its underlying goals. At the state and local level, one of the greatest challenges we face is completing robust and varied networks of public and private charging infrastructure so that travelers can travel where they want to go without range anxiety. We appreciate new funding in IIJA, but achieving this goal will require all the tools in the toolbox. We strongly urge EPA to utilize its credit program to incentivize companies investing in the charging networks which benefits consumers and will facilitate more public private partnership around this critical need. [EPA-HQ-OAR-2022-0829-0694, pp. 2-3]

- We encourage EPA to coordinate its EV battery durability and warranty requirements with the maintenance and durability requirements of the ACC II program to the greatest extent possible. These provisions are critical for ensuring consumer confidence in the performance and durability of EVs in the new and used market, and alignment to the greatest extent possible can help avoid confusion for consumers, dealers, and other key stakeholders. [EPA-HQ-OAR-2022-0829-0694, pp. 2-3]

- EPA requested comment on whether to consider a future rulemaking for gasoline fuel property standards to further reduce PM emissions. Colorado supports EPA exercising its authority under CAA 211(c) to develop gasoline property standards in a future rulemaking. Cleaner fuel standards will complement the vehicle emissions standards proposed in the current rulemaking by addressing emissions from the existing ICE vehicle fleet, as well as the vehicles that will be produced during the phase-in and operative periods of the proposed vehicle emissions standards. [EPA-HQ-OAR-2022-0829-0694, pp. 2-3]

Organization: Hyundai America Technical Center, Inc. (HATCI)

HMG supports AFAl's public comments regarding criteria pollutant standards related to low carbon fuels [EPA-HQ-OAR-2022-0829-0554, p. 7]

Under the Proposed Rule, EPA seeks comment on fuel property standards proposed to further reduce PM emissions, and specifically proposed improvements regarding when heavy hydrocarbon series are reduced. [EPA-HQ-OAR-2022-0829-0554, p. 7]

AFAI cites in its public comments multiple industry and agency studies demonstrating the effect of fuel composition on PM. Indeed, fuel properties contributing to the reduction of PMI are thoroughly analyzed and well understood. As a result, HMG supports the demand for strengthening the specifications for both commercial and certification fuels in future rulemaking to further reduce PMI. HMG also supports additional industry positions on fuels as reflected in AFAl's public comments. [EPA-HQ-OAR-2022-0829-0554, p. 7]

Organization: Illinois Corn Growers Association

Section IX. of the proposed Multi-Pollutant Emissions Standards entitled “Consideration of Potential Fuels Controls for a Future Rulemaking” states: [EPA-HQ-OAR-2022-0829-0756, pp. 7-8]

“The emissions standards for new vehicles (MY 2027 and later) proposed in this rule would achieve significant air quality benefits. However, there is an opportunity to further address PM emissions from the existing vehicle fleet, the millions of vehicles produced during the phase-in period, as well as nonroad engines, through changes in market fuel composition. Given the current population of vehicles and nonroad equipment, we expect that tens of millions of gasoline-powered sources will remain in use well into the 2030s. Although EPA has not undertaken sufficient analysis to propose changes to fuel requirements under CAA section 211(c) in this rulemaking, and considers such changes beyond the scope of this rulemaking, EPA has begun to consider the possibility of such changes and in this section, EPA requests comments on aspects of a possible future rulemaking aimed at further PM emission reductions from these sources via gasoline fuel property standards. Such future fuel standards could be an important complement to EPA's proposed vehicle PM standards." (emphasis added) [EPA-HQ-OAR-2022-0829-0756, pp. 7-8]

As previously discussed, the potential technological pathways for automakers for reducing CO2 tailpipe emissions have dwindled from 34 in the 2012 rulemaking to just 9 in the current rulemaking. Moreover, most of the 9 pathways discussed in the Regulatory Impact Analysis have already been employed across many automakers' product line. While the proposed standards have the appearance of being "technology neutral," the only potential option that an automaker could employ to achieve the called-for massive emission reductions is electrification of at least half their 2032 model year light and medium duty product line. [EPA-HQ-OAR-2022-0829-0756, pp. 7-8]

Given that the vehicle technology pathways have dwindled to just one, it seems reasonable that the next most viable pathway would be with improving the liquid fuels that could be used by the half of the 2032 new vehicle fleet that is not expected to be electrified. Yet EPA is only proposing future fuel changes that might help automakers meet one small part of the Multi-Pollutant Emissions Standards – the standards for PM emissions. [EPA-HQ-OAR-2022-0829-0756, pp. 7-8]

EPA should strongly consider opening the scope of any future rulemaking regarding fuel standards to include a detailed analysis of the benefits and costs of implementing a HOLC fuel program and compare those costs and benefits to the limited rulemaking discussed in Section IX of the current Multi-Pollutant Emissions Standard rulemaking. [EPA-HQ-OAR-2022-0829-0756, pp. 7-8]

EPA has responded to past requests to use its authority to set octane standards and revise their testing requirements to encourage the use of HOLC fuel with the position that automotive manufacturers have many other options to comply with the greenhouse gas standards and do not need a HOLC fuel. With only one viable pathway available to meet the proposed standards, EPA should expand the scope of the proposed future rulemaking on potential fuel controls to include the explicit consideration of HOLC fuel and, like was done in the 1970's with unleaded gasoline, make the regulatory changes to make widespread use of HOLC fuel a reality. [EPA-HQ-OAR-2022-0829-0756, pp. 7-8]

Costs and Benefits of Potential Future Fuel Controls

The focus of Section IX of the current proposed rulemaking (Consideration of Potential Fuels Controls for a Future Rulemaking) is a future rulemaking to set a cap on aromatic compounds in gasoline to help automakers comply with the proposed particulate standards. [EPA-HQ-OAR-2022-0829-0756, p. 9]

EPA identifies the biggest challenge to doing this in gasoline at the refinery level: aromatic compounds are used to increase the octane rating of gasoline and removing them would cause the octane rating to fall. [EPA-HQ-OAR-2022-0829-0756, p. 9]

As EPA explains it:

"If heavy aromatics were to be removed from gasoline, then not only their volume, but their octane would have to be replaced. One source for additional octane is via increased reformer severity or throughput to generate additional light aromatics. This action may require other adjustments to maintain compliance with gasoline benzene standards or rebalance naphtha streams. A refinery may also be able to increase high-octane isoparaffin production through additional alkylation and/or isomerization operations. Finally, a refinery may opt to further increase reliance on ethanol as a source of octane."6 [EPA-HQ-OAR-2022-0829-0756, p. 9]

6 Pg 584, Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles

Cost of Alternatives to Aromatics Compared to Ethanol. Refineries currently consider aromatics as the low-cost means of increasing the octane rating of gasoline blend stock. By limiting their consideration of reducing aromatics at the refinery level, EPA will inevitably see an increase to the price of gasoline if aromatic levels are reduced. If, on the other hand, EPA would expand the scope of their future rulemaking beyond the refinery to include gasoline blends that use more ethanol than is the case today, the price of gasoline would likely be reduced and the capital costs to refineries would be essentially zero. This fact alone should justify a more expansive view of fuel controls than reflected in Section IX. One way to illustrate this is to compare the difference in cost between a gallon of blend stock and a gallon of various octane boosting alternatives to aromatics. The Oil Price Information Service's weekly reports includes spot prices for regular and premium grade reformulated and conventional gasoline blend stocks, ethanol (which only the sales-weighted average is used in this analysis), alkylates and MTBE on a per gallon basis.7 Assuming the same amount of each aromatic alternative is required to provide the same octane boost as aromatics,8 then a positive [EPA-HQ-OAR-2022-0829-0756, pp. 9-10]

7 MTBE is not used in the U.S. as an octane booster, although it is used elsewhere.

8 Since ethanol has the highest blending octane the alternatives, this assumption underestimates the value of ethanol.

[See original attachment for "Figure 2. Relative Costs of Alternatives to Aromatics"] difference indicates that the alternative will raise the cost of gasoline blend stock and a negative value indicates the alternative will lower the cost. As shown in Figure 2, page 9, only ethanol provides a cost savings. [EPA-HQ-OAR-2022-0829-0756, pp. 9-10]

Furthermore, the price advantage of ethanol over gasoline blend stock may well be greater in the future. The Nebraska Energy Board has been publishing the monthly rack9 price of fuel ethanol and regular grade gasoline in their state since 1982. These monthly prices are expressed in nominal dollars (i.e., not adjusted for inflation). After the Defour Group adjusted the annual average data to reflect 2022 dollars, calculated the implied blend stock price and computed the difference between the price of a gallon of ethanol and gasoline blend stock, the relationship between ethanol and gasoline blend stock prices over a 40-year period can be established. This is shown in Figure 3. [EPA-HQ-OAR-2022-0829-0756, p. 10]

9 The rack price is the price paid by fuel blenders for the blend stock and ethanol they receive from oil and bio refineries.

There is a statistically significant linear correlation between fuel ethanol and gasoline blend stock, with the price of ethanol becoming more favorable over time. If this correlation remains consistent, ethanol's price advantage over gasoline blend stock could increase to $1.66 a gallon by 2032. [EPA-HQ-OAR-2022-0829-0756, p. 10]

[See original attachment for "Figure 3 Ethanol and Figure 4. Gasoline Ethanol Blendss: 1982-2021"] [EPA-HQ-OAR-2022-0829-0756, p. 10]

The Greenhouse Gas Benefits of Using HOLC Fuel. What is referred to as "gasoline" is a blend of a fossil fuel (gasoline blend stock) and a renewable fuel (ethanol). Nearly all such blended fuel consists of 90% gasoline blend stock and 10% ethanol known as E10. As shown in Figure 4, the total volume of gasoline blend fuels peaked just prior to the Covid pandemic. [EPA-HQ-OAR-2022-0829-0756, pp. 10-11]

Thus, due to the blending of ethanol into gasoline, the fossil fuel component of liquid fuel peaked in 2006 while total gasoline blend usage peaked in 2018. [EPA-HQ-OAR-2022-0829-0756, pp. 10-11]

The first substantital reduction in the use of fossil fuels in the transportation sector occurred over a relatively short period of time. While the overall use of motor fuel began to stabilize starting in 2005, the replacement of gasoline blend stock by ethanol reduced fossil fuel use enough to turn the trend downward. This was due primarily to the enactment of the Renewable Fuel Standards (RFS) which dictated the annual volume of biofuel that must be blended into gasoline and diesel fuels. [EPA-HQ-OAR-2022-0829-0756, pp. 10-11]

[See original attachment for "Figure 5. Impact of Proposed GHG Emission Reductions on U.S. Fuel Consumption" and "Figure 6. Benefits from a Possible HOLC Fuel"] [EPA-HQ-OAR-2022-0829-0756, pp. 10-11]

Figure 5 illustrates what these trends would look like if the current rulemaking would achieve the results shown in Table 1. Note that while overall liquid fuel use goes down, the amount of ethanol used also declines because the concentration of ethanol in gasoline has remained unchanged at 10%. Thus, the full potential of the proposed shift to electric vehicles is blunted by the decreased use of ethanol. [EPA-HQ-OAR-2022-0829-0756, pp. 10-11]

If, on the other hand. EPA were to adopt changes to the regulations to bring about widespread use of HOLC fuel with triple the ethanol that is in today's fuel, an additional 8% to 16%10 of the fossil fuel portion of the fuel (the gasoline blend stock) would be displaced by 2055. Figure 6 illustrates what the trends would look like if the current rulemaking would achieve the results shown in Table 1. [EPA-HQ-OAR-2022-0829-0756, pp. 10-11]

10 This assumes a 2% reduction in mpg due to ethanol after energy density, heat of vaporization and optimization impacts are considered.

To illustrate the difference, consider that the amount of petroleum used for light and medium duty vehicles in 2055 if the proposed standards are successful would drop to 1962 levels. If, however, HOLC fuel with 20% to 30% ethanol were to replace E10 by 2055, the amount of petroleum used would drop to levels not seen since 1952. [EPA-HQ-OAR-2022-0829-0756, pp. 10-11]

Aromatic Reductions from the Use of HOLC Fuel. Reducing heavy aromatics in gasoline at the refinery level is complicated by the corresponding loss in octane. Finding a solution within the refinery using compounds made from petroleum will be expensive and do nothing to reduce overall fossil fuel use. On the other hand, as shown in Figure 1, adding ethanol to an existing blend stock both increases the octane rating of the resulting fuel but also decreases the concentration of all the other petroleum compounds, including aromatics and benzene. In addition, by replacing a portion of the blend stock portion of the fuel with a low carbon alternative, overall CO2 emissions will also be reduced. Finally, if the HOLC fuel is made using existing blend stocks, then expensive capital investment in refineries will be unnecessary. [EPA-HQ-OAR-2022-0829-0756, pp. 11-12]

In 2020, the Defour Group evaluated the aromatic standards being considered for use in the Next Generation Fuels Act (NGFA). These standards (shown in Table 4), in conjunction with octane and carbon intensity standards, would require the production and sale of mid-level ethanol blend {MLEB} high octane low carbon fuels beginning in the year 2028. [EPA-HQ-OAR-2022-0829-0756, pp. 12-13]

[See original attachment for "Table 4. Standards Included in Next Generation Fuel Act"] [EPA-HQ-OAR-2022-0829-0756, pp. 12-13]

This study was based on data regarding fuel propertites found in the 2016 EPA Fuels Trend Report.11 This report contained values for the average and 95% (2 standard deviation for a normal distribution) for both summer and winter reformulated and conventional gasolines. [EPA-HQ-OAR-2022-0829-0756, pp. 12-13]

11 Fuel Trends Report: Gasoline 2006 - 2016 Office of Transportation and Air Quality U.S. Environmental Protection Agency EPA-420-R-17-005 October 2017

The Aromatic Average. As proposed in the NGFA, the aromatic standard in retail gasoline for 2027 and beyond will be 17.5%. In its Fuel Trends Report, EPA reported that the average concentration of aromatics in all grades of fuels during the five-year period from 2012 - 2016 ranged from 18.8% to 19.6% and average ethanol concentration in gasoline was only 9.57%. MathPro estimated the average aromatic concentrations for all grades of fuel was 19.0%.12 For modeling purposes, Defour Group assumed an average aromatic concentration of 18.5% and an average ethanol concentration of 9.8%. The aromatic concentration was then apportioned to regular grade gasoline (17.52%) and premium grade gasoline (24.57%).[EPA-HQ-OAR-2022-0829-0756, pp. 12-13]

12 David S. Hirshfeld et al, "Refining Economics of U.S. Gasoline: Octane Ratings and Ethanol Content," Journal of Environmental Science and Technology, August 21, 2014

Under the NGFA: [EPA-HQ-OAR-2022-0829-0756, pp. 12-13]

-A new NGFA fuel will be introduced into the market prior to January 1, 2027. If this fuel is an E20 fuel (20% ethanol) combined with regular grade E10 gasoline blend stock, its average Research Octane Number (RON) is estimated to be 96.2 RON and the aromatic average is estimated to be 15.6%. [EPA-HQ-OAR-2022-0829-0756, pp. 12-13]

-New vehicles model year 2028 and later are required to use the new HOLC fuel. About 30% of these vehicles (approximately 5 million vehicles) are expected to be sold in the 2027 calendar year. [EPA-HQ-OAR-2022-0829-0756, pp. 12-13]

-Some of these new vehicles operating on NGFA fuel in 2027 will be replacing legacy vehicles that operate on E10 premium. [EPA-HQ-OAR-2022-0829-0756, pp. 12-13]

-All flex-fuel vehicles (approximately 5 million vehicles) can use the new HOCL fuel or E85 (with an estimated aromatic concentration of 4.7%). [EPA-HQ-OAR-2022-0829-0756, pp. 12-13]

-All vehicles 2001 and newer can use E15, with an estimated aromatic concentration of 16.5% (regular) and 23.2% (premium). [EPA-HQ-OAR-2022-0829-0756, pp. 12-13]

With all these sources of low aromatic gasoline in the marketplace in 2027, multiple scenarios can be developed that would assure compliance with the 17.5% average aromatic concentration standard. Furthermore, compliance with the average standard in subsequent years will become easier as more new vehicles using NGFA fuel enter the market. The aromatic average will continue to decline over time, and by 2055, the average aromatic concentration is estimated to be about 14%. [EPA-HQ-OAR-2022-0829-0756, pp. 12-13]

Aromatic Cap. As proposed in the NGFA, the aromatic standard in retail gasoline for 2028 and beyond will be 30% for years 2027 – 2031 and 25% for 2032 and thereafter. Since there is no uniform standard across the country for octane, premium gasolines range from 90 AKI to 93 AKI.13 The highest-octane premium grade gasoline is 93 AKI with an average aromatic concentration of 29.8%. An E15 version of 93 AKI premium, however, would have an aromatic concentration of 28.1%. [EPA-HQ-OAR-2022-0829-0756, p. 13]

13 There are even high-octane specialty premium fuels on the market primarily used for racing. Since these are already uniquely blended boutique fuels, it is assumed that these fuels could be made with no more than 30% aromatics.

Two options could be employed to meet the aromatic cap in 2027. The first option would be to replace E10 with E15 in areas that have 93 AKI premium. 14 The second option would be to replace 93 AKI premium with 91 AKI premium. This second option has the additional advantage of making the octane standard for legacy premium more consistent across the country. Either option (or a combination of the two) would enable compliance with the 30% cap for 2027 2031. [EPA-HQ-OAR-2022-0829-0756, p. 13]

14 Anti-Knock Index, which is the average of a fuel’s Research Octane Number (RON) and Motor Octane Number (MON).

In 2032, the cap drops to 25% under the NGFA. At this point, fuel retailers would need to limit their premium grade option to E15 with an octane rating no higher than 91 AKI to be in compliance. By this time, however, nearly half of the fleet will be vehicles designed to run on high octane NGFA fuel. [EPA-HQ-OAR-2022-0829-0756, p. 13]

In the past. EPA stated their opinion that, while they had the authority to make significant changes to vehicle fuel, it would only be possible after all other alternatives have been exhausted. As established, there is only one realistic technological alternative that can effectively reduce gasoline consumption by 50%, but that alternative has many issues yet to be resolved and requires sweeping changes that are not likely to occur in less than nine years. [EPA-HQ-OAR-2022-0829-0756, pp. 14-15]

A second alternatitve has been under development for a decade that could assist automakers in complying with the standards: a new high octane low carbon fuel made with ethanol. It seems reasonable that any future rulemaking establishing fuel standards would include regulatory changes to assist in implementing this new fuel. Such changes include, but are not limited to, the following: [EPA-HQ-OAR-2022-0829-0756, pp. 14-15]

-Specifications for E20 and E25 -E30 certification fuels.

-Octane standards for legacy fuels that would, at a minimum, limit the octane of premium

gasoline nationwide to 91 AKI.

-Octane standards for E20 fuel of 95 RON and for E25 and E30 fuels of 98 RON.

-Permanently extend the RVP waiver for E10 to any gasoline-ethanol blend fuel.

-Aromatic standards for all gasoline that would address both average and maximum levels of aromatic compounds in gasoline.

-Any other standards or regulations that the Agency believes would facilitate the transition into a high-octane low carbon fuel as outlined in the 2019 Co-Optima report entitled "Top Ten Blendstocks For Turbocharged Gasoline Engines: Bioblendstocks With Potential to Deliver the for Highest Engine Efficiency." [EPA-HQ-OAR-2022-0829-0756, pp. 14-15]

Organization: Marathon Petroleum Corporation (MPC)

EPA is seeking comment on promulgating future gasoline fuel property standards aimed at further reducing Particulate Matter ("PM") emissions specifically within the existing light duty transportation fleet. MPC data and testing show that the use of analytical methods as support for restrictions on the back end, or tail, distillation point of gasoline is misplaced. [EPA-HQ-OAR-2022-0829-0593, pp. 4-5]

1. Simulated Distillation does not provide data that reliably predicts PMI.

EPA states that the basis of its discussion and request for comments relies on the theory that high boiling point compounds in gasoline increase PM emissions and, further, that the high boiling point tail of gasoline contains a high proportion of multi-ring aromatics. Particulate Matter Index ("PMI") is a method to analytically predict the tailpipe PM-forming potential of one fuel compared to another. However, other factors including vehicle hardware design, calibration, and ethanol content also impact vehicle tailpipe PM emissions. As the agency correctly points out, the method to calculate PMI using a Detailed Hydrocarbon Analysis ("DHA") via ASTM 6370 is time- consuming and expensive. As a proxy for DHA, EPA proposes using a final boiling point ("FBP") via Simulated Distillation ("SimDis") as an indicator of PMI since, theoretically, the majority of the multi-ring aromatics occur in the T90 portion of the distillation curve. The Agency believes that use of SimDis could be an accurate and cost-effective means of measuring PMI. MPC has already tested this approach to determine if using SimDis is an accurate way of predicting PMI. [EPA-HQ-OAR-2022-0829-0593, pp. 4-5]

MPC completed an analysis on sixty (60) gasoline samples before ethanol blending from all of its refineries. All samples were tested using the SimDis method ASTM D2887, with twenty (20) of these samples also tested by SimDis ASTM D7096. Results showed that C10+ aromatic content varied greatly among the fuel types and grades at a given distillation point. Consequently, MPC's correlation of the SimDis data showed there was no relationship between the D2887 final boiling points and C10+ aromatic content, see Figure 1. [See original comment for Figure 1 – C10+ Aromatics vs. Simulated Distillation Final Boiling Point] For the D7096 simulated distillation data – the method recommended by the EPA— correlations of T98, T95, and T90 points to PMI showed slightly stronger correlation with R2 values ranging from 0.21 to 0.36. [EPA-HQ-OAR-2022-0829-0593, pp. 4-5]

Based on MPC's analysis, there is a significant amount of uncertainty that the SimDis method can accurately predict a lower PM-forming potential fuel. Most importantly, MPC found little correlation between the PMI of a fuel and its final boiling point minus T98 or T95 values. In fact, in the analysis, fuels with the highest distillation values had the lowest C10+ aromatics and yielded the lowest PMI values (see Figure 2). [See original comment for Figure 2 – PMI Comparison to SimDis Final Boiling Point and Tail (FBP – T95)] [EPA-HQ-OAR-2022-0829-0593, pp. 4-5]

Consumers and refiners will be impacted by changes to gasoline distillation parameters.

Limiting certain portions of gasoline based on distillation properties will impact refiners and consumers due to restrictions of the gasoline pool. Each refinery is an individual operation, fine-tuned to run on particular feedstocks based on the type of equipment used at that refinery. The Haverly model used by the EPA is not reflective of actual refinery operations, and use of simulations and models, including the Haverly model, rely on generalizations and averaging, which result in flawed model outputs. [EPA-HQ-OAR-2022-0829-0593, pp. 6-7]

EPA states that to make up for lost gasoline and octane in its Haverly model, it simply "increased the reformer severity, purchased and isomerized natural gas liquids, and produced more alkylate," ignoring the reality that each one of these changes represents significant adjustments to refinery planning, operations, and expense. EPA's simplistic modeling input changes do not reflect how individual refineries would need to react to new distillation restrictions. The actual impacts for each refinery would likely be widely varying depending on each refinery's current operations and expenses. EPA modeling needs to consider hydrotreating and hydrocracking capacity, hydrogen availability, alkylation capacity to make up octane loss, and butane blending losses. Changes of these parameters and associated losses due to refining constraints would represent significant monetary impacts that are not accounted for in the current proposal. [EPA-HQ-OAR-2022-0829-0593, pp. 6-7]

Restricting back-end distillation would result in the loss of a significant amount of gasoline volume. And critically, as has been discussed, the volume that would be removed from the gasoline pool does not contribute to PM emissions. By way of example, MPC modeled a refinery's light product outputs using site-specific information to determine the impact of shifting FCC naphtha from the gasoline pool to the distillate pool. The model showed that the total gasoline production was reduced by one and one-half (1.5) barrels for each barrel of FCC naphtha that was shifted to the distillate pool. This resulted in a reduction of the refinery's daily production of gasoline by approximately 4%. Other refineries likely would be required to reduce gasoline volumes to restrict back-end distillation. These decreases in daily production could leave some markets short, translating to consumer impacts at the pump in both price and supply. [EPA-HQ-OAR-2022-0829-0593, pp. 6-7]

Additionally, if EPA implements changes that limit distillation properties of gasoline, existing blending practices that occur downstream of the refinery may be prohibited. EPA regulations currently allow the blending of transmix into fuel because the quality and performance of the final fuel is unaffected. Transmix represents a conglomeration of off-specification refined products and product interfaces that are collected and reintroduced into a final fuel, most often after the final fuel has left a refinery. The potential fuels specification being discussed could impact the amount of transmix being used within the gasoline pool, which in turn could also impact the total available gasoline volume. The alternative to blending transmix would be to reprocess the off-specification refined products at a refinery creating unnecessary criteria and GHG emissions from transporting the material to a refinery and reprocessing it. Also, the transportation of fuels occurs within fungible systems – pipelines, ships, trucks— where products share transportation assets as these products move to retail locations, often with the same types of products being commingled. As such, residual fuels present within these shared transportation assets could alter the distillation properties of any given fuel. Any effort by EPA to change or disallow these practices would serve to further restrict supplies of gasoline on top of that which would be caused by changes to distillation parameters. [EPA-HQ-OAR-2022-0829-0593, pp. 6-7]

Organization: Minnesota Corn Growers Association (MCGA)

FUEL QUALITY RULEMAKING NEEDED

The EPA proposed rulemaking requested "comment on potential future gasoline fuel property standards aimed at further reducing PM emissions, for consideration in a possible subsequent rulemaking". A major advantage of fuel property standards is that they affect emissions from all vehicles on the road today – not just new vehicles. [EPA-HQ-OAR-2022-0829-0612, pp. 6-7]

In response to EPA's request for input on fuel standards, NCGA supports EPA establishing a pathway to a higher minimum clean octane standard for fuel of at least 98 RON that enables mid-level ethanol blends to immediately and cost-effectively reduce both GHG and tailpipe emissions, supporting greater fuel efficiency and bringing lower carbon and lower cost fuels to the market. [EPA-HQ-OAR-2022-0829-0612, pp. 6-7]

Even with advancements in engine technology, automotive manufacturers are nearing a point where further improvements are difficult without a higher-octane fuel. This is because advanced downsized, down sped engines, and their associated technologies, make an engine more susceptible to knock. Due to its knock-limiting properties, a higher-octane fuel, such as a midlevel ethanol blend, enables engine designs featuring higher compression ratios, turbocharging, and down speeding and increases overall engine performance and efficiency.12 According to Department of Energy (DOE) researchers at Oak Ridge National Laboratory, "the opportunity for further downsizing and down speeding of engines to improve fuel economy is limited by the available octane rating of fuels…[which] allow higher efficiency designs of naturally aspirated and turbocharged engines dedicated to use the high octane fuel."13 Since 2016, DOE has completed extensive research through its Co-Optimization of Fuels and Engines initiative (Co-Optima) on innovating fuels and engines together and understanding the types of fuels that can improve engine performance and efficiency to reduce emissions.14[EPA-HQ-OAR-2022-0829-0612, pp. 6-7]

14 . Department of Energy, Office of Energy Efficiency and Renewable Energy, “Co-Optimization of Fuels & Engines,” https://www.energy.gov/eere/bioenergy/co-optimization-fuels-engines.

The recently concluded Co-Optima research15 validates the solution of pairing clean octane and optimized engines to deliver greater environmental and economic benefits on the pathway to a net-zero transportation future, and DOE confirms ethanol’s declining carbon intensity.16 [EPA-HQ-OAR-2022-0829-0612, pp. 6-7]

15 U.S. Department of Energy, Office of Energy Efficiency and Renewable Energy, “On the Road to a Net-Zero-Carbon Transportation Future,” https://www.energy.gov/eere/bioenergy/articles/road-net-zero-carbon-transportation-future.

16 U.S. Department of Energy, Office of Energy Efficiency and Renewable Energy, “Ethanol vs. Petroleum-Based Fuel Carbon Emissions,” https://www.energy.gov/eere/bioenergy/articles/ethanol-vs-petroleum-based-fuel-carbon-emissions.

- New fuel options can improve fuel economy by 10 percent with today’s turbocharged engines, with an additional 15 percent improvement with advanced engines.

- Domestically sourced bio-based fuels produce 60 percent fewer GHG emissions than petroleum-based fuels.

- Optimized fuel and engine combinations also cut criteria pollutant emissions. [EPA-HQ-OAR-2022-0829-0612, pp. 6-7]

As DOE explained in its GHG analysis of high-octane fuel, determining GHG impacts of high-octane fuel relative to current gasoline requires accounting for vehicle efficiency gains, refinery operation changes and GHG emissions changes from ethanol blending. DOE’s results show the largest impacts on wells-to-wheels (WTW) emissions from high-octane fuel come from efficiency gains and the level of ethanol blending. [EPA-HQ-OAR-2022-0829-0612, pp. 6-7]

DOE’s modeling compared 100 RON E25 and E40 fuels to baseline E10. When used in HOF vehicles, the E25 reduced WTW GHG emissions by a total of 8 to 9 percent (or 36-40 g CO2e/mile driven) compared to baseline E10. The vehicle efficiency gains from HOF reduced GHG emissions by 4 percentage points of that total, and the additional 4 percentage points of GHG reductions with the E25 fuel were realized from ethanol offsetting petroleum. For the E40 HOF, the ethanol content provided a 9 percent reduction in WTW GHG emissions.17 [EPA-HQ-OAR-2022-0829-0612, pp. 6-7]

17 Theiss et al., 2016.

Current fuels with higher octane, marketed as premium grades, where ethanol blends are limited to 10%, are not cost-effective for consumers, and fall short of enabling the efficiency and emissions technology changes automakers need to advance transportation decarbonization. Because ethanol results in nearly half the emissions of gasoline and is on a pathway to future net-zero emissions, producing higher-octane fuel with a midlevel ethanol blend would do more to reduce GHG emissions and support the stringency goals of the proposed rule. Optimized vehicles powered by low carbon, high-octane fuel made from a midlevel ethanol blend would have much lower GHG emissions than vehicles running on either current E10 blends or premium E10 blends. [EPA-HQ-OAR-2022-0829-0612, pp. 6-7]

Higher ethanol content, reached by removing regulatory barriers to higher blends, would boost GHG reductions and replace harmful aromatics, providing a cost-effective low carbon fuel solution for consumers, including low- income consumers, and the environment. [EPA-HQ-OAR-2022-0829-0612, pp. 6-7]

EPA should adopt rules to limit PMI of both finished fuels and the hydrocarbon blend stocks used for E10, E15, and E85. Limiting PMI of hydrocarbon blend stocks will ensure that the particulate emissions benefits of ethanol are not offset by negative changes at refineries. [EPA-HQ-OAR-2022-0829-0612, pp. 10-11]

Improved fuel property standards should be a high priority because they can achieve significantly lower particulate emissions and dramatically lower GHG emissions. California's Low Carbon Fuel Standard already recognizes the importance of fuel standards, and it has led to dramatic increases in sales of E85 and other low- carbon biofuels. High-octane low-carbon fuels are a key enabler for continued GHG emissions improvements in the millions of liquid-fueled vehicles which will be produced over the next 10+ years, as documented by the U.S. Department of Energy Co-Optimization of Fuels & Engines initiative and in numerous other studies, such as those by MIT and by automakers. A detailed proposed blueprint for future high-octane low-carbon fuels exists in the Next Generation Fuels Act, and EPA has the statutory authority to make these changes without waiting for Congress to act. [EPA-HQ-OAR-2022-0829-0612, pp. 10-11]

In summary, EPA should pursue stringent new fuel standards – not only for reduced particulate emissions but also for dramatically lower GHG emissions. Fuel standards can achieve benefits much more quickly than standards which only impact new vehicles. [EPA-HQ-OAR-2022-0829-0612, pp. 10-11]

Organization: National Association of Clean Air Agencies (NACAA)

Potential Future Gasoline Fuel Property Standards

EPA seeks comment on potential future gasoline fuel property standards aimed at further reducing PM emissions. The agency writes in the proposal that comments on this topic would inform a possible subsequent EPA rulemaking that could provide an important complement to the vehicle standards being proposed in this current action. "The emissions standards for new vehicles (MY 2027 and later) proposed in this rule would achieve significant air quality benefits. However, there is an opportunity to further reduce PM emissions from the existing vehicle fleet, the millions of vehicles that will be produced during the phase- in period [of the proposed vehicle standards], as well as millions of nonroad gasoline engines, through changes in market fuel composition. Given the current population of vehicles and nonroad equipment, we expect that tens of millions of gasoline-powered sources will remain in use well into the 2030s. Although EPA has not undertaken sufficient analysis to propose changes to fuel requirements under CAA section [EPA-HQ-OAR-2022-0829-0559, pp. 8-9]

211(c) in this rulemaking, and considers such changes beyond the scope of this rulemaking, EPA has begun to consider the possibility of such changes."29 NACAA agrees with EPA that fuel property standards to further reduce PM emissions would yield significant and necessary reductions from the existing fleet and also provide an important complement to the currently proposed emission standards. We support EPA pursuing such a program. [EPA-HQ-OAR-2022-0829-0559, pp. 8-9]

Organization: National Corn Growers Association (NCGA)

The EPA proposed rulemaking requested "comment on potential future gasoline fuel property standards aimed at further reducing PM emissions, for consideration in a possible subsequent rulemaking". A major advantage of fuel property standards is that they affect emissions from all vehicles on the road today – not just new vehicles. [EPA-HQ-OAR-2022-0829-0643, p. 5]

In response to EPA's request for input on fuel standards, NCGA supports EPA establishing a pathway to a higher minimum clean octane standard for fuel of at least 98 RON that enables mid-level ethanol blends to immediately and cost-effectively reduce both GHG and tailpipe emissions, supporting greater fuel efficiency and bringing lower carbon and lower cost fuels to the market. [EPA-HQ-OAR-2022-0829-0643, p. 5]

Even with advancements in engine technology, automotive manufacturers are nearing a point where further improvements are difficult without a higher-octane fuel. This is because advanced downsized, down sped engines, and their associated technologies, make an engine more susceptible to knock. Due to its knock-limiting properties, a higher-octane fuel, such as a midlevel ethanol blend, enables engine designs featuring higher compression ratios, turbocharging, and down speeding and increases overall engine performance and efficiency. 12 According to Department of Energy (DOE) researchers at Oak Ridge National Laboratory, "the opportunity for further downsizing and down speeding of engines to improve fuel economy is limited by the available octane rating of fuels…[which] allow higher efficiency designs of naturally aspirated and turbocharged engines dedicated to use the high octane fuel." 13 Since 2016, DOE has completed extensive research through its Co-Optimization of Fuels and Engines initiative (Co-Optima) on innovating fuels and engines together and understanding the types of fuels that can improve engine performance and efficiency to reduce emissions. 14 [EPA-HQ-OAR-2022-0829-0643, p. 5]

16 U.S. Department of Energy, Office of Energy Efficiency and Renewable Energy, "Ethanol vs. Petroleum-Based Fuel Carbon Emissions," https://www.energy.gov/eere/bioenergy/articles/ethanol-vs-petroleum-based-fuel-carbon-emissions

- New fuel options can improve fuel economy by 10 percent with today's turbocharged engines, with an additional 15 percent improvement with advanced engines.

- Domestically sourced bio-based fuels produce 60 percent fewer GHG emissions than petroleum-based fuels.

- Optimized fuel and engine combinations also cut criteria pollutant emissions. [EPA-HQ-OAR-2022-0829-0643, p. 5]

As DOE explained in its GHG analysis of high-octane fuel, determining GHG impacts of high-octane fuel relative to current gasoline requires accounting for vehicle efficiency gains, refinery operation changes and GHG emissions changes from ethanol blending. DOE's results show the largest impacts on wells-to-wheels (WTW) emissions from high-octane fuel come from efficiency gains and the level of ethanol blending. [EPA-HQ-OAR-2022-0829-0643, pp. 5-6]

DOE's modeling compared 100 RON E25 and E40 fuels to baseline E10. When used in HOF vehicles, the E25 reduced WTW GHG emissions by a total of 8 to 9 percent (or 36-40 g CO2e/mile driven) compared to baseline E10. The vehicle efficiency gains from HOF reduced GHG emissions by 4 percentage points of that total, and the additional 4 percentage points of GHG reductions with the E25 fuel were realized from ethanol offsetting petroleum. For the E40 HOF, the ethanol content provided a 9 percent reduction in WTW GHG emissions. 17 [EPA-HQ-OAR-2022-0829-0643, pp. 5-6]

17 Theiss et al., 2016.

Current fuels with higher octane, marketed as premium grades, where ethanol blends are limited to 10%, are not cost-effective for consumers, and fall short of enabling the efficiency and emissions technology changes automakers need to advance transportation decarbonization. Because ethanol results in nearly half the emissions of gasoline and is on a pathway to future net-zero emissions, producing higher-octane fuel with a midlevel ethanol blend would do more to reduce GHG emissions and support the stringency goals of the proposed rule. Optimized vehicles powered by low carbon, high-octane fuel made from a midlevel ethanol blend would have much lower GHG emissions than vehicles running on either current E10 blends or premium E10 blends. [EPA-HQ-OAR-2022-0829-0643, pp. 5-6]

Higher ethanol content, reached by removing regulatory barriers to higher blends, would boost GHG reductions and replace harmful aromatics, providing a cost-effective low carbon fuel solution for consumers, including low-income consumers, and the environment. [EPA-HQ-OAR-2022-0829-0643, pp. 5-6]

Bringing high octane fuel to market in the form of midlevel ethanol blends will be significantly less capital-intensive than attempting to increase blend stock octane with hydrocarbon components at refineries. It will also be incredibly cleaner. The avoided production cost and offset emissions lower end-costs to consumers, reducing both economic costs and social costs related to health and environment, key considerations in advancing environmental justice and avoiding adverse impacts from oil refineries on communities that have historically borne them. [EPA-HQ-OAR-2022-0829-0643, p. 7]As explained in EPA's Fuel Trends Report: Gasoline 2006-2016, "Ethanol's high-octane value has also allowed refiners to significantly reduce the aromatic content of the gasoline, a trend borne out in the data." EPA's data shows that aromatics' share of gasoline volume dropped from nearly 25 percent to 19.3 percent, and benzene volume dropped from 0.99 percent to 0.58 percent between 2000 and 2016, the same time as ethanol blending increased from 1 percent to at least 10 percent. [EPA-HQ-OAR-2022-0829-0643, p. 8]

EPA's data demonstrates the air quality and human health benefits of increased ethanol blending in gasoline by replacing harmful aromatics with clean octane from ethanol. Limiting the aromatics content of gasoline and using higher ethanol blends in high octane fuel would further reduce risks from SOA formation and exposure to PM 2.5, which causes serious respiratory, cardiovascular, and other health harm, including premature death, according to the American Lung Association. The same GDI engine advancements that help lower GHG emissions have the unfortunate side effect of increasing particulate emissions, which could be reduced by use of midlevel ethanol blends. [EPA-HQ-OAR-2022-0829-0643, p. 8]

Petroleum-based aerosol particles represent a significant source of pollution, especially in population-dense urban areas. Health issues related to PM and other emission-based pollutants can be reduced by lowering the volume of petroleum in the domestic gasoline pool, which can be accomplished by increasing octane with higher ethanol blends and replacing more hydrocarbon aromatics with ethanol. [EPA-HQ-OAR-2022-0829-0643, p. 8]

It is well known that particulate emissions are a strong function of aromatic fuel components with a high double bond equivalent and low vapor pressure, and the particulate forming potential is well represented by the "PMI" metric developed by Honda. 27 The value of the PMI metric has been validated in many other studies including the joint auto-oil Coordinating Research Council 28 and the EPA. 29 PMI and particulate emissions can be reduced by altering refinery processes to reduce heavy aromatic content of the fuel, and, as noted, ethanol can replace those aromatics. [EPA-HQ-OAR-2022-0829-0643, p. 8]

VI. Fuel Effects on Particulate Emissions

EPA's proposal requests "comment on potential future gasoline fuel property standards aimed at further reducing PM emissions, for consideration in a possible subsequent rulemaking." [EPA-HQ-OAR-2022-0829-0581, p. 14]

88 Fed. Reg. at 29,197. A major advantage of supporting biofuels is that their use reduces emissions from all vehicles on the road today – not just new vehicles. Therefore, emissions benefits are achieved quickly on a larger scale. [EPA-HQ-OAR-2022-0829-0581, p. 14]

Particulate emissions are a strong function of aromatic fuel components with a high double bond equivalent and low vapor pressure. The particulate forming potential is well represented by the "PMI" metric developed by Honda.33 The value of the PMI metric has been used and validated by others including the Coordinating Research Council34 and EPA.35 [EPA-HQ-OAR-2022-0829-0581, p. 14]

33 See Koichiro Aikawa, et al., Development of a Predictive Model for Gasoline Vehicle Particulate Matter Emissions, SAE paper 2010-01-2115 (2010), available at https://doi.org/10.4271/2010-01-2115.

34 See Coordinating Research Council, Evaluation and Investigation of Fuel Effects on Gaseous and Particulate Emissions on SIDI In-Use Vehicles, Report No. E-94-2, March 2017, available at http://crcsite.wpengine.com/wp- content/uploads/2019/05/CRC_2017-3-21_03-20955_E94-2FinalReport-Rev1b.pdf.

35 See EPA, Exhaust Emission Impacts of Replacing Heavy Aromatic Hydrocarbons in Gasoline with Alternate Octane Sources, EPA-420-R-23-008 (April 2023), available at https://www.epa.gov/system/files/documents/2023- 05/420r23008.pdf.

PMI and particulate emissions can be reduced by altering refinery processes to reduce heavy aromatic content of the fuel. This may require other refinery changes in order to achieve fuel octane requirements, and the changes generally increase cost. A more cost-effective option for octane is higher blends of ethanol, and higher blends of ethanol have been shown to reduce particulate matter emissions.36 But the petroleum gasoline with which ethanol may be blended can impact the benefits of ethanol. As such, EPA should adopt rules to limit PMI of both finished fuels and the hydrocarbon blendstocks used for ethanol blends, including ensuring the ability to use mid-level ethanol blends. Limiting PMI of hydrocarbon blendstocks will ensure that the particulate emissions benefits of ethanol are not offset by negative changes at refineries. Such rules can also incentivize improved pipeline practices, to minimize contamination of gasoline with diesel and jet fuel. [EPA-HQ-OAR-2022-0829-0581, p. 14]

36 See, e.g., Tianbo Tang, et al., Expanding the ethanol blend wall in California: Emissions comparison between E10 and E15, Fuel Vol. 350 (2023), available at https://doi.org/10.1016/j.fuel.2023.128836.

Organization: Northeast States for Coordinated Air Use Management (NESCAUM) and the Ozone Transport Commission (OTC)

C. Potential Future Gasoline Fuel Property Standards

EPA also seeks comment on a potential future rulemaking to establish gasoline fuel property standards aimed at further reducing PM emissions. NESCAUM and the OTC believe that, while the proposed emissions standards for MYs 2027 and later would achieve significant air quality benefits, cleaner fuel standards would provide an important complement to the standards for new vehicles proposed in the NPRM. It is critical to address emissions from the existing vehicle fleet, as well as the millions of vehicles that will be produced during the phase-in and operative periods of the proposed standards. Accordingly, NESCAUM and the OTC support EPA exercising its authority under CAA 211(c) to develop gasoline property standards in a future rulemaking. [EPA-HQ-OAR-2022-0829-0584, p. 11]

Organization: Oryxe International Inc.

3. EPA Should Ensure that the Approach Applied to Any Future Gasoline Fuel Property Standards Harnesses the Full Benefit that Low Emission Fuel Additives Can Provide.

In the event EPA moves forward with promulgating new gasoline fuel property standards aimed at achieving additional particulate matter emission reductions, Oryxe urges EPA to establish waivers under which states desiring to mandate gasoline with lower emission properties are able to do so. Oryxe also urges EPA to provide credit to original equipment manufacturers achieving lower emission gasoline through the use of fuel additives. [EPA-HQ-OAR-2022-0829-0752, p. 4]

Additionally, Oryxe encourages EPA to move forward with a program that would base the carbon intensity of fuels on emissions performance. By setting greenhouse gas intensity standards for lifecycle emissions per unit of transport fuel energy supplied in a specific market, EPA would encourage innovation and make additional progress toward the Administration's goal of reducing emissions in the transportation sector. Emissions intensity standards are important tools for decarbonizing transport fuels that should be pursued. [EPA-HQ-OAR-2022-0829-0752, p. 4]

Organization: Pearson Fuels

During the period of harmonized CAFE and GHG crediting, the U.S. FFV fleet grew rapidly. Now, at a critical time for climate change mitigation, the U.S. FFV fleet is in dramatic decline.

On April 22, 2021, President Biden announced a “nationally determined contribution” pledge under the 2015 Paris climate agreement to cut U.S. GHG emissions in half by 2030 at a virtual climate summit attended by dozens of world leaders. In his remarks about the pledge from the White House, the President stated, “These steps will set America on a path of net zero emissions economy by no later than 2050.” Thus the President has re-established aggressive GHG reduction as a priority policy of the federal government and set a goal of carbon neutrality by 2050. While there has been a significant expansion of BEVs, internal combustion engines continue to dominate the market and roads of America and are anticipated to maintain this dominant role for the next decade and potentially longer. The following illustrative graphics were developed by the Alliance for Automotive Innovation. [EPA-HQ-OAR-2022-0829-0577, pp. 5-6]

During the period of harmonized GHG crediting, when both the GHG and CAFE programs utilized the 0.15 divisor, there was a substantial expansion of the FFV fleet peaking with the manufacture of 2.8 million total light-duty vehicles in MY 2014. The total registered fleet of FFVs in the U.S. continued to grow incrementally until 2020, but from 2015-2020 automakers sharply reduced the number of vehicle offerings. The attached Exhibit 1 developed by the Renewable Fuels Association details vehicle offerings by model and engine type and shows the massive reduction of models that occurred due to the near total elimination of light-duty GHG program crediting. During the peak period of manufacturing, Chrysler, Ford and General Motors manufactured 76 different models of FFVs. This scale of manufacturing has since been decimated with only 8 FFV models offered in 2023 with 5 of these being limited to fleet models. [EPA-HQ-OAR-2022-0829-0577, pp. 5-6]

II. EPA SHOULD TAKE THE OPPORTUNITY IN THIS RULEMAKING TO RECOGNIZE THE TRUE GHG POLICY VALUE OF FFVS BY RESTORING MEANINGFUL GHG CREDITING FOR FFVs

We encourage the Agency to re-affirm the policy value of FFVs and American ethanol production and use by restoring meaningful GHG crediting for the manufacture of FFVs by modifying the methodology for determining GHG crediting for FFVs beginning MY 2027. EPA has authority to better harmonize crediting between the GHG and CAFE standards and thereby expand FFV manufacturing through two alternative means both of which are supported by Pearson Fuels. [EPA-HQ-OAR-2022-0829-0577, p. 16]

a. EPA should re-integrate the methodology that continues to exist in the CAFE program by re-establishing its use of the 0.15 multiplier in the EPA’s GHG Standards, or,

b. EPA should establish a new GHG Emissions Factor for the GHG Standards that recognizes the lifecycle emissions reductions of E85 as compared with conventional gasoline. [EPA-HQ-OAR-2022-0829-0577, p. 16]

Crediting based on lifecycle GHG emissions reductions can be accomplished simply by establishing a GHG Emissions Factor that is based on the average GHG emissions reduction provided by ethanol as compared to petroleum gasoline on a lifecycle basis. This GHG Emissions Factor would be subject to adjustment based on a determination by Argonne National Laboratory regarding the average lifecycle emissions of U.S. used as a transportation fuel as compared to the average lifecycle emissions of the U.S. gasoline used as a transportation fuel. [EPA-HQ-OAR-2022-0829-0577, p. 16]

Organization: POET, LLC

Finally, POET strongly supports EPA's proposal to set gasoline fuel property standards to reduce particulate matter ("PM") emissions from gasoline-fueled LDVs and medium-duty vehicles.11 Bioethanol must play a major role in any future regulatory proposal. Bioethanol has been shown to significantly reduce PM and other toxic air emissions relative to alternative aromatics and other blending compounds. It will also boost octane levels in gasoline to make up for any loss in octane from standards requiring removal of certain high-boiling, heavy aromatics. Bioethanol also has the added benefit of significantly reducing lifecycle GHG emissions unlike other, carbon-intensive alternatives. EPA should propose standards that tackle two problems at once, by promoting increased bioethanol blends, such as E15, that both reduce PM emissions and help combat climate change. [EPA-HQ-OAR-2022-0829-0609, pp. 6-7]

11 See Proposed Rule at Section IX, 88 Fed. Reg. at 29397-29404.

VIII. POET Strongly Supports EPA's Suggestion in Section IX of the Proposed Rule to Institute a Future Regulatory Action to Further Limit PM Emissions from Vehicles and Nonroad Equipment.

POET strongly supports EPA's consideration of a possible future rulemaking aimed at further PM emissions reductions for vehicles and nonroad equipment.134 POET agrees with the EPA's assessment that reducing certain high-boiling compounds in gasoline could further reduce vehicle PM emissions.135 However, removing those heavy aromatic compounds will lower gasoline octane levels. To most effectively reduce tailpipe PM emissions while retaining high-octane gasoline, POET urges EPA to support a future rule that would limit the use of high-boiling compounds while encouraging those compounds to be replaced with higher bioethanol blends, such as E15. Bioethanol boosts octane while decreasing PM emissions. Bioethanol also significantly reduces lifecycle GHG emissions compared to more carbon-intensive alternative octane-boosting compounds, such as heavy aromatics.136 Bioethanol should be EPA's preferred solution because it both reduces toxic air pollutants and helps combat climate change. [EPA-HQ-OAR-2022-0829-0609, pp. 29-31]

134 88 Fed. Reg. at 29397.

135 Id. at 29398.

136 See generally Attachment 3.

In support of POET's position, POET retained Environmental Health & Engineering, Inc. ("EH&E"), who prepared a report on the potential changes to EPA gasoline fuel property and GHG standards for light- and medium-duty vehicles in the Proposed Rule, attached hereto as Attachment 3. EH&E's report confirms that heavy aromatics have significant negative impacts on PM emissions.137 The report assesses EPA's position that high boiling compounds are associated with increased tailpipe emissions, reviews the impact of removing high boiling compounds on gasoline and refineries, analyzes the suitability of EPA's Haverly model, studies the importance of octane for gasoline, and evaluates increased ethanol blending as an alternative for octane contributions in gasoline. [EPA-HQ-OAR-2022-0829-0609, pp. 29-31]

137 88 Fed. Reg. at 29398.

EH&E's report uses the particulate matter index, or "PMI," to predict the propensity of PM in various gasoline compounds. PMI values are correlated with emissions of PM: the higher a compound's PMI value, the higher the tailpipe PM emissions for gasoline containing that compound.138 Studies have found that high-boiling compounds—and particularly heavy aromatics—have significantly higher PMI values than other, lower-boiling compounds in gasoline blends.139 And while heavy aromatics are only a small portion of the compounds making up gasoline, about 2.4% of gasoline by volume, they contribute disproportionately to the PMI of gasoline, making up about 38 percent of gasoline's PMI value.140 In comparison, ethanol has proven to be the most favorable component in gasoline in terms of PMI contribution: it represents 10% of gasoline volume but contributes less than 1% to PMI.141 Because the PMI value of ethanol is so low, the PM emissions associated with gasoline blended with higher levels of ethanol are significantly lower than gasoline containing heavy aromatics.142 [EPA-HQ-OAR-2022-0829-0609, pp. 29-31]

138 Attachment 3 at 3.

139 Id. at 1, 3.

140 Id. at 6.

141 Id.

142 Id. at 3-8.

Despite the negative air quality impacts of heavy aromatics, they do serve to increase octane in gasoline. Sufficiently high octane levels are necessary for the efficient operation of vehicles with internal combustion engines.143 Specifically, octane supports high compression ratios, turbocharging, and advanced spark and valve timing and downsizing.144 If EPA moves forward with a rulemaking to limit heavy aromatics in gasoline, EPA should also identify an alternative to maintain octane levels and develop its standards with that alternative in mind. [EPA-HQ-OAR-2022-0829-0609, pp. 29-31]

143 Id. at 10-11.

144 Id. at 11.

EPA requested comment on several potential alternatives to maintain octane levels, including increasing alkylation operations, increasing isomerization production, or increasing reliance on ethanol blending.145 But increased alkylation and/or isomerization are not workable solutions. Refiners already produce alkylate and isomerized natural gas liquids at near capacity, so additional infrastructure would be required to meaningfully increase production.146 And it is unlikely that refiners will make any significant investments into alkylation/isomerization infrastructure, as the gasoline market is facing long-term decline as alternative fuel vehicles become more popular.147 [EPA-HQ-OAR-2022-0829-0609, pp. 31-32]

145 88 Fed. Reg. at 29401-02.

146 Attachment 3 at 2-3, 9.

147 Id. at 9.

POET strongly supports EPA's third proposed alternative: increasing ethanol blending, specifically bioethanol. Increasing bioethanol blending is feasible. The bioethanol industry continues to grow significantly, and trends indicate that this growth will continue. Unlike the infrastructure that supports alkylation and isomerization capacity, bioethanol production infrastructure continues to expand, providing sufficient capacity for a possible increased reliance on bioethanol to lower vehicle PM emissions. Bioethanol is also cost-effective. Edgeworth Economics assessed economic data provided by POET to compare the costs of using gasoline additives other than ethanol and determined that those alternatives would cost between $0.10 to $0.24 cents more per gallon based on prices from January 2021 through January 2022.148 Adding alkylate, for instance, costs $0.19 more per gallon than ethanol.149 [EPA-HQ-OAR-2022-0829-0609, pp. 31-32]

148 EPA Docket No. EPA-HQ-OAR-2021-0427, comment submitted by POET LLC at 22.

149 Id.

As we have discussed above, bioethanol has a significantly lower PMI value than heavy aromatics. Bioethanol also contributes significantly to octane in gasoline. Increasing ethanol blending from E10 to E15 would more than make up for the octane loss related to reducing heavy aromatics in gasoline.150 Using bioethanol blending as a replacement would significantly reduce the PMI beyond the reductions that would be realized simply by imposing the potential PM emissions standards.151[EPA-HQ-OAR-2022-0829-0609, pp. 31-32]

150 Attachment 3 at 10.

2. Aromatics

a. Aromatics are hydrocarbons built around one or more benzene rings. Often referred to by the acronym BTEX, they include not just benzene itself, a known carcinogen, but also toluene, ethylbenzene, xylenes, and other compounds similar to benzene in their behavior in the environment. People are exposed to BTEX primarily through emissions from motor vehicles and cigarette smoke. [EPA-HQ-OAR-2022-0829-0570, pp. 7-8]

c. The BTEX chemicals are characterized as hazardous air pollutants “known or suspected to cause cancer or other serious health or environmental effects.” They are identified as mobile source air toxics and formed in four ways, of which the first two are most pertinent. According to EPA: [EPA-HQ-OAR-2022-0829-0570, pp. 8-9]

21 U.S. Environmental Protection Agency, “What are Hazardous Air Pollutants?”, online fact sheet: https://www.epa.gov/haps/what-are-hazardous-air-pollutants (accessed Aug. 29, 2021).

22 U.S. Environmental Protection Agency, “Control of Emissions of Hazardous Air Pollutants from Mobile Sources; Final Rule,” Federal Register (2001): 66(61): pp. 17235-39: https://www.govinfo.gov/content/pkg/FR-2001-03-29/pdf/01-37.pdf (accessed Feb. 24, 2021).

i. “First, some air toxics are present in fuel and are emitted to the air when it evaporates or passes through the engine as unburned fuel. Benzene, for example, is a component of gasoline. Cars emit small quantities of benzene in unburned fuel, or as vapor when gasoline evaporates. [EPA-HQ-OAR-2022-0829-0570, pp. 8-9]

ii. “Second, mobile source air toxics are formed through engine combustion processes. A significant amount of automotive benzene comes from the incomplete combustion of compounds in gasoline such as toluene and xylene that are chemically very similar to benzene.” (emphasis added) [EPA-HQ-OAR-2022-0829-0570, pp. 8-9]

d. According to a review of the literature by a Health Effects Institute panel, “It is estimated that about 50% of the benzene produced in the exhaust is the result of decomposition of aromatic hydrocarbons in the fuel. … [Two] studies showed that lowering aromatic levels in gasoline significantly reduces toxic benzene emissions from vehicle exhausts.” [EPA-HQ-OAR-2022-0829-0570, pp. 8-9]

23 Health Effects Institute, Panel on the Health Effects of Traffic-Related Air Pollution, “Traffic-Related Air Pollution: A Critical Review of the Literature on Emissions, Exposure, and Health Effects” (Special Report 17): Chapter 2, “Emissions from Motor Vehicles,” Appendix B: “Fuel Composition Changes Related To Emission Controls” (2010): pp. 3-4: https://www.healtheffects.org/system/files/SR17TrafficReviewChapter2AppendixB.pdf (accessed Aug. 24, 2021).

e. Gasoline-powered vehicles accounted for 69% of all U.S. emissions of single-ring aromatic hydrocarbons, based on source-specific speciation in the 2005 National Emissions Inventory. [EPA-HQ-OAR-2022-0829-0570, pp. 8-9]

6. EPA's modeling – Part 1

a. EPA has long acknowledged its modeling shortcomings in this area. Noting that "SOA continues to be a significant topic of research and investigation," it said in 2005: "Despite significant progress that has been made in understanding the origins and properties of SOA, it remains the least understood component of PM2.5." [EPA-HQ-OAR-2022-0829-0570, pp. 21-22]

106 U.S. Environmental Protection Agency, "Proposed Rule To Implement the Fine Particle National Ambient Air Quality Standards," Federal Register (2005): 70(210): p. 65997: https://www.govinfo.gov/content/pkg/FR-2005-11-01/pdf/05-20455.pdf (accessed Feb. 24, 2021).

i. Atmospheric models have been found to underestimate SOA emissions by an order of magnitude or more when applied in and downwind of urban areas/polluted regions. (emphasis added) [EPA-HQ-OAR-2022-0829-0570, pp. 21-22]

107 Q. Zhang et al., "Ubiquity and dominance of oxygenated species in organic aerosols in anthropogenically?influenced Northern Hemisphere midlatitudes," Geophysical Research Letters (2007): 34(13), L13801: https://agupubs.onlinelibrary.wiley.com/doi/full/10.1029/2007GL029979 (accessed Feb. 24, 2021).

108 Allen H. Goldstein and Ian E. Galbally, "Known and Unexplored Organic Constituents in the Earth's Atmosphere," Environmental Science & Technology (2007): 41(5): pp. 1515-21: https://pubs.acs.org/doi/10.1021/es072476p (accessed Feb. 24, 2021).

b. EPA's summary of a 2015 workshop on UFPs contained this admission, based on the PNNL research described above, unpacking the implications of its knowledge gap: [EPA-HQ-OAR-2022-0829-0570, pp. 21-22]

i. "[SOA] particles play an important role in air quality but for many years available atmospheric models were not able to predict SOA formation. The main issue was the fact that: all models relied on the assumptions that SOA particles were well-mixed low viscosity solutions and maintained equilibrium with the gas-phase by rapid mixing in the condensed phase with evaporation and condensation. Recent studies using the multidimensional characterization approach demonstrated that these assumptions were wrong and that SOA particles must be viscous semi-solid. These studies showed also that there is a synergetic effect between PAHs and SOA since PAHs trapped inside the SOA particles slow down SOA evaporation and increase SOA yield and lifetime. This can explain the long-range transport of toxic compounds like PAHs and other persistent pollutants. In conclusion, a new SOA paradigm has been developed." (emphasis added) [EPA-HQ-OAR-2022-0829-0570, pp. 21-22]

109 Richard W. Baldauf et al., "Ultrafine Particle Metrics and Research Considerations: Review of the 2015 UFP Workshop," International Journal of Environmental Research and Public Health (2016): 13(11):

p. 13: https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5129264/pdf/ijerph-13-01054.pdf (accessed Feb. 24, 2021).

- Note: The modeling that EPA has used to assess and regulate SOA emissions was thus based on erroneous assumptions and completely missed the scale of the problem. The significance of this failure is heightened by the finding in the 2011 National Air Toxics Assessment that secondary formation is the largest contributor of all sources to cancer risks nationwide, accounting for 47% of the risk. [EPA-HQ-OAR-2022-0829-0570, pp. 21-22]

XI. Potential Fuel Property Controls to Address Particulate Matter Emissions

EPA’s proposed rule requests comment on “potential future gasoline fuel property standards aimed at further reducing PM emissions, for consideration in a possible subsequent rulemaking.” A major advantage of fuel property standards is that they can reduce emissions from all vehicles on the road today – not just new vehicles. Therefore, emissions benefits can be achieved much more quickly than with standards that only apply to new vehicles. [EPA-HQ-OAR-2022-0829-0602, pp. 21-22]

It is well established that particulate (PM) emissions are a strong function of aromatic fuel components with a high double bond equivalent value and low vapor pressure, and the particulate forming potential is accurately represented by the “PMI” metric developed by Honda.44 The PMI metric has been validated in many other studies, including from the joint auto-oil Coordinating Research Council45 and the EPA.46 [EPA-HQ-OAR-2022-0829-0602, pp. 21-22]

44 Aikawa, Sakurai, and Jetter, "Development of a Predictive Model for Gasoline Vehicle Particulate Matter Emissions", SAE paper 2010-01-2115, 2010; https://doi.org/10.4271/2010-01-2115.

45 Coordinating Research Council, "Evaluation and Investigation of Fuel Effects on Gaseous and Particulate Emissions on SIDI In-Use Vehicles," Report No. E-94-2, March 2016; http://crcsite.wpengine.com/wp- content/uploads/2019/05/CRC_2017-3-21_03-20955_E94-2FinalReport-Rev1b.pdf

46 US Environmental Protection Agency, "Exhaust Emission Impacts of Replacing Heavy Aromatic Hydrocarbons in Gasoline with Alternate Octane Sources", report EPA-420-R-23-008, April 2023.

PMI and particulate emissions can be decreased by altering refinery processes to reduce the heavy aromatic content of the fuel. As EPA recognizes, reducing heavy aromatics typically requires other refinery changes in order to achieve fuel octane requirements, and those changes generally increase cost and the energy intensity of refining. As an alternative, larger volumes of ethanol can be added to the fuel, which simultaneously reduces PMI and increases octane. [EPA-HQ-OAR-2022-0829-0602, pp. 21-22]

Emissions studies that use “splash blends” (i.e., a constant hydrocarbon base fuel blended with varying levels of ethanol), invariably show lower PM emissions with higher ethanol content. Studies which use “match blends” sometimes show higher PM emissions with higher ethanol content, because the hydrocarbon portion of the fuel was modified in an attempt to hold other properties (such as distillation curve) constant.47 Perhaps the most credible and comprehensive study on this topic was recently published by the University of California Center for Environmental Research and Technology,48 showing statistically significant 16-54% reductions in PM emissions for E15 (15% ethanol) compared to E10 (10% ethanol). [EPA-HQ-OAR-2022-0829-0602, pp. 21-22]

47 Anderson, Wallington, Stein, and Studzinski, "Issues with T50 and T90 as Match Criteria for Ethanol-Gasoline Blends", SAE paper 2014-01-9080, 2014, https://doi.org/10.4271/2014-01-9080

48 Tang et al., "Expanding the ethanol blend wall in California: Emissions comparison between E10 and E15", Fuel, June 2023; https://doi.org/10.1016/j.fuel.2023.128836

Via a future rulemaking, EPA should adopt standards to limit PMI of both finished fuels and the hydrocarbon blendstocks used for E10, E15, and other ethanol blends. Limiting PMI of hydrocarbon blendstocks will ensure that the particulate emissions benefits of ethanol are not offset by negative changes at refineries. The standards should also be designed to incentivize improved pipeline practices to minimize contamination of gasoline with diesel and jet fuel. Alternatively, EPA could consider instituting a volumetric cap (per gallon of gasoline) on the allowable content of the heavy aromatics most closely linked to PM formation. [EPA-HQ-OAR-2022-0829-0602, pp. 21-22]

Improved fuel property standards should be a high priority because they can achieve significantly lower particulate emissions and dramatically lower GHG emissions. As EPA considers undertaking future rulemaking to address fuel properties, RFA strongly encourages the Agency to include a higher minimum octane standard (e.g., 95-98 RON) as part of the discussion. [EPA-HQ-OAR-2022-0829-0602, pp. 21-22]

High-octane low-carbon fuels are a key enabler for continued GHG emissions improvements in the tens of millions of liquid-fueled vehicles that will be produced in the decades ahead, as documented by the U.S. Department of Energy Co-Optimization of Fuels & Engines initiative49 and in numerous other studies, e.g. by MIT50 and by automakers.51 A detailed blueprint for a future high-octane low-carbon fuel program exists in the Next Generation Fuels Act, and EPA has the statutory authority to make these changes without waiting for Congress to act. [EPA-HQ-OAR-2022-0829-0602, pp. 21-22]

Organization: Satya Consultores

As EPA notes in the rule preamble, the International Agency for Research on Cancer has recently concluded that diesel exhaust is “carcinogenic to humans.” 88 Fed. Reg. at 29216. [EPA-HQ-OAR-2022-0829-0687, pp. 1-2]

Accordingly, EPA also should evaluate the feasibility of further PM2.5 and NOX reductions from new diesel fuel standards in a future fuel-controls rulemaking. [EPA-HQ-OAR-2022-0829-0687, pp. 1-2]

Below we share information about Satya's Dispersive Energy Process ("DEP"), which can achieve further significant emissions reductions of PM2.5 and NOX when used to modify ultra-low sulfur diesel fuel, bypassing the trade-off that usually exists when controlling for these two pollutants. The emissions reductions can be accomplished at a reasonable cost, without compromising the calorific value of the improved, less-polluting diesel fuel. [EPA-HQ-OAR-2022-0829-0687, pp. 1-2]

Satya began its DEP work with the goal of solving the tradeoff between reducing diesel soot and NOX emissions. At higher temperatures, diesel engines achieve more complete combustion, and emit less soot and other fine particulate matter as a result. However, under these conditions NOX emissions increase. In turn, lower engine temperatures result in lower NOX emissions but cause soot emissions to increase. This tradeoff is well known among fuel scientists.1 Both pollutants have significant adverse environmental impacts and health effects. [EPA-HQ-OAR-2022-0829-0687, pp. 2-3]

Satya's DEP resolves this conundrum. We call the resulting fuel "Next Diesel." [EPA-HQ-OAR-2022-0829-0687, pp. 2-3]

1 See, e.g., Narayan et al., Combustion Monitoring in Engines Using Accelerometer Signals, J. VIBROENGINEERING, Sep. 2019, at 4; Tie Li & Hideyuki Ogawa, Analysis of the Trade-Off between Soot and Nitrogen Oxides in Diesel- Like Combustion by Chemical Kinetic Calculation.

In DEP, two proprietary additives are mixed into the diesel fuel. The first additive ("A1") is an ethoxylated fatty acid ester, made with a mixture of stearic and palmitic acid esters of sorbitol and its mono- and dianhydrides. The second additive ("A2") is a complex water-based blend of aromatic solvents with methyl radicals mixed with ethoxylated phenol-derived surfactants. [EPA-HQ-OAR-2022-0829-0687, pp. 2-3]

Diesel fuel flows from a tank at the end of the refining process in a continuous stream through piping to a Shock Wave Power Reactor. En route, A1 is metered into the diesel fuel stream via a Progressive Cavity Injection Pump, and the combination is blended using a static mixer. Once the fuel/A1 mixture is homogenous, A2 is metered in, and that combination is blended in a second static mixer. The resulting diesel fuel/A1/A2 mixture then flows into the Shock Wave Power Reactor where it is subjected to controlled cavitation, a process which creates vapor bubbles in the fuel mixture. As a liquid passes through the SPR it is subjected to "controlled cavitation." The heart of the reactor is a specially designed rotor. The spinning action generates hydrodynamic cavitation in the rotor cavities away from the rotor to prevent damage to metal surfaces. As microscopic cavitation bubbles are produced and collapse, shockwaves are given off into the liquid which can heat and/or mix.2 [EPA-HQ-OAR-2022-0829-0687, pp. 2-3]

2 Hydro Dynamics, Inc. (n.d.). Retrieved from Harnessing the Power of Cavitation: https://www.hydrodynamics.com/cavitation-technology/.

The resulting diesel fuel exhibits improved properties, including significantly improved ignition characteristics. Its electrical conductivity is more than 1,000 times greater than regular diesel fuel, and the lubricity value is more than 100 times greater. These and other upgraded properties of Next Diesel enable more complete fuel combustion, which in turn results in less soot production and also reduces NOX emissions. The corresponding loss of fuel power, if any, is negligible. [EPA-HQ-OAR-2022-0829-0687, pp. 2-3]

As EPA notes in Section IX of the preamble, fuel controls would address a large category of air pollutants that the current proposal would not touch: emissions from the existing vehicle fleet. 88 Fed. Reg. at 29397. The preamble discussion considers potential standards that would limit the amounts of heavy aromatics in gasoline by reducing T90 [4] temperatures and limiting the production of gasoline with a PM Index ("PMI")5 greater than 2. Diesel fuel controls would be just as important and impactful to achieve further reductions in soot emissions. Importantly, Next Diesel can significantly reduce soot emissions and lower the PMI of diesel fuel without modifying the distillation curve or lowering T90 values. EPA proposed a lower primary annual PM2.5 ambient air quality standard in January 2023. See 88 Fed. Reg. 5558 (January 27, 2023). [EPA-HQ-OAR-2022-0829-0687, p. 6]

4 88 Fed. Reg. at 29398 ("The T90 parameter refers to the temperature at which 90 volume percent of the gasoline sample has been distilled.").

5 Id. ("The PM Index (PMI) parameter, first described in a 2010 publication, combines detailed fuel composition data (from ASTM D6730) with volatility and structural characteristics for all compounds identified in the fuel to predict its relative propensity to form PM.").

Further, the air quality benefits of diesel fuel controls would extend beyond highway vehicles to the many existing non-road diesel engines, including locomotives. See 88 Fed. Reg. at 29210 (nonroad diesel engines are generally older technology and more polluting). The PM in diesel exhaust consists principally of particles less than 2.5 micrograms, mostly soot, which are most damaging to human health. 88 Fed. Reg. at 29210. As EPA notes in the preamble, "[t]hese particles have a large surface area which makes them an excellent medium for adsorbing organics and their small size makes them highly respirable." Id. In other words, the particles themselves are dangerous, and they transport mutagenic and carcinogenic organics from diesel into the body as well. [EPA-HQ-OAR-2022-0829-0687, pp. 6-7]

Diesel engine emissions, especially emissions from existing vehicles, medium- and heavy-duty vehicles, and nonroad engines, can be effectively addressed with DEP and Next Diesel. Satya continues to develop the technology and to look for opportunities to demonstrate its effectiveness in reducing diesel soot and NOX emissions on a large scale [EPA-HQ-OAR-2022-0829-0687, pp. 6-7]

Organization: Southern Environmental Law Center (SELC)

EPA is also proposing that BEVs and fuel cell electric vehicles (FCEVs)—i.e., vehicles with no internal combustion—retain a zero gram per mile (g/mi) compliance value and not be required to account for upstream emissions under the GHG standards.69 This aligns with the standards' treatment of other, fossil fuel-powered vehicles. Even though this regulatory regime deals specifically with tailpipe emissions, EPA should not lose sight of the upstream GHG or other emissions associated with light- and medium-duty vehicles—ZEVs or otherwise. We therefore support EPA's consideration of future gasoline fuel property standards that could provide additional meaningful reductions in PM emissions.70 However, even more could be done. Some states, for example, are leading the way by implementing low carbon fuel standards that consider lifecycle GHG emissions from energy used for fuel.71 [EPA-HQ-OAR-2022-0829-0591, p. 9]

69 Id.

70 See id. at 29197.

71 See, e.g., KELSI BRACMORT, CONG. RSCH. SERV., R46835, A LOW CARBON FUEL STANDARD: IN BRIEF 2 (2021), https://sgp.fas.org/crs/misc/R46835.pdf.

Organization: Valero Energy Corporation

VI. EPA should not limit heavy aromatics in gasoline.

EPA has requested comments on a possible future rulemaking aimed at further particulate matter (PM) emission reductions from the current population of vehicles and nonroad equipment via the introduction of gasoline fuel property standards aimed at reducing heavy aromatics. [EPA-HQ-OAR-2022-0829-0707, pp. 92-94]

As EPA stated, "[i]f heavy aromatics were to be removed from gasoline, then not only their volume, but their octane would have to be replaced."371 The high- octane properties of heavy aromatics make them an excellent gasoline blending component as they improve engine performance and fuel economy. Using heavy aromatics in gasoline blending is superior to their likely alternate disposition in the diesel pool. The low cetane properties of heavy aromatics make them detrimental to diesel engine efficiency and therefore a poor diesel fuel component. [EPA-HQ-OAR-2022-0829-0707, pp. 92-94]

371 88 Fed. Reg. 29404, 29401 (May 5, 2023).

Thus, introducing a rule that limits heavy aromatics in gasoline may have the unintended consequence of increasing diesel engine PM emissions due to less efficient combustion of lower cetane fuel. Replacing the volume and octane loss from the removal of heavy aromatics from gasoline would require capital projects and operational changes that would increase emissions from refinery stationary sources and would increase emissions from the transportation of components between refineries. Because this potential rulemaking would not reduce emissions when viewed holistically, EPA should refrain from proposing limits on heavy aromatics in gasoline. [EPA-HQ-OAR-2022-0829-0707, pp. 92-94]

Furthermore, EPA's discussion of a potential future rulemaking is entirely premised on "the ability to use high boiling point as a surrogate for heavy aromatic content."372 Although we agree there is some degree of correlation, with some high boiling point components containing heavy aromatics, that is not always the case. Using high boiling point as a surrogate would require removal of high boiling point components indiscriminately, including removal of clean-burning components that do not contribute to tailpipe PM emissions. We therefore disagree with the use of high boiling point as a surrogate for heavy aromatics. If a limit is proposed, it should be proposed on heavy aromatics specifically (i.e., C10+ polycyclic aromatics). [EPA-HQ-OAR-2022-0829-0707, pp. 92-94]

372 Id. at 29398.

Before EPA proposes any new gasoline standard aimed at reducing heavy aromatics, however, CAA § 211(c) requires EPA to consider technologically and economically feasible alternatives. Further, significant additional analysis is needed to understand the impacts of such a rule on refineries, gasoline and diesel fuel properties, gasoline and diesel engine exhaust emissions, fuel supply market dynamics, consumer impacts, and other emissions impacts, including potential increases in stationary source emissions and emissions from transportation of components between refineries. EPA presented oversimplified options for volume and octane replacement that are unrealistic. In reality, such a limit may require significant capital investments at some refineries, significantly impact refinery operations, lead to closure of disadvantaged refineries, exacerbate supply disruptions, increase costs to consumers, and may even increase emissions in the aggregate. [EPA-HQ-OAR-2022-0829-0707, pp. 92-94]

A. At a Minimum, CAA Section 211(c) Requires that EPA Consider Other Technologically or Economically Feasible Means of Achieving Emissions Standards.

We agree that “EPA has not undertaken sufficient analysis to propose changes to fuel requirements under CAA section 211(c) in this rulemaking.”373 We also agree that CAA section 211(c) requires EPA “to consider other technologically or economically feasible means of achieving emissions standards under section 202” before introducing a new fuel standard.374 However, we do not agree that limiting the heavy aromatic content of gasoline is the only “practical means of significantly reducing PM emissions from the existing fleet.”375 EPA must consider other options as required by CAA Section 211(c). [EPA-HQ-OAR-2022-0829-0707, pp. 92-94]

373 Id. at 29397.

374 Id. at 29402.

375 Id.

Just a few examples of additional options for PM reductions that warrant review before proposing a limit on heavy aromatics in gasoline include vehicle hardware options (potential retrofits to existing gasoline vehicles and non-road engines such as modern fuel injection and combustion management); reducing PM emissions from brake, tire, and road wear (improvements here would be especially impactful for electric vehicle emission control376); fuel additives to improve combustion; and other ways to improve fuel economy which would result in lower PM emissions, such as a 95 RON octane standard. The results of a cost-benefit analysis of technologically or economically feasible options should inform any future rulemaking. [EPA-HQ-OAR-2022-0829-0707, pp. 92-94]

376 EVs tend to be heavier than internal combustion engine vehicles (ICEVs) due to battery weight. Heavier EVs yield higher PM emissions from increased brake, tire, and road wear. Roadway dust emissions which include particles from tire wear are correlated with vehicle weight, so increases in vehicle weight would be expected to increase roadway dust PM2.5 emissions. EPA, Emissions Factor Documentation for AP-42 (Dec. 31, 2003) available at https://www3.epa.gov/ttn/chief/old/ap42/ch13/s021/final/c13s0201.pdf.

B. If a Limit Aimed at Reducing Heavy Aromatics in Gasoline is Proposed, it Should be on Heavy Aromatics Directly (not on High Boiling Point as a Surrogate and not on Total Aromatics).

1. Limiting High Boiling Point Would Cut Out Clean-Burning Gasoline Components for No Environmental Benefit.

High boiling point is not always correlated with heavy aromatic content; limiting it without consideration to actual aromatic content would lead to gasoline volume and octane loss and higher prices to consumers with limited corresponding environmental benefit. There would be no environmental benefit from the removal of gasoline blend components such as iso-octene, iso-octane, and alkylate made from heavier olefins, as these components have high boiling points but contain no aromatics. Alkylation units typically have a debutanizer make a low Reid Vapor Pressure (RVP) gasoline blending component, but they seldom have subsequent fractionation that could split out the heavy portion of the alkylate. To do so would require significant capital investment, for no environmental benefit – to the contrary, stationary source emissions would increase due to additional processing and fractionation. Establishing limits solely on end point and not considering heavy aromatic levels would prevent refineries from using heavy, clean-burning, high octane alkylate as a gasoline blend component. The extent of the impact depends on what specific limit EPA may propose on high boiling point. [EPA-HQ-OAR-2022-0829-0707, pp. 94-95]

If EPA proposes a limit based on high boiling point, at a minimum, there should be an alternative compliance option based on heavy aromatics to allow refineries to continue to blend clean-burning high boiling point components into gasoline. Such an approach would be similar to flexibilities provided for jet fuel PM and aromatics defined in ASTM D1655 – Standard Specification for Aviation Turbine Fuels and to flexibilities provided for diesel fuel cetane index and aromatics in ASTM D975 – Standard Specification for Diesel Fuel. [EPA-HQ-OAR-2022-0829-0707, pp. 94-95]

2. Limiting Total Aromatics Would Limit Production of Premium Gasoline for Minimal Environmental Benefit.

If a rule aimed at reducing heavy aromatics is proposed, it should only limit heavy aromatics, not total aromatics. A total aromatic limit may limit production of premium gasoline with minimal benefits in terms of emissions reduction and air quality improvement. Premium gasolines often require higher aromatic content to meet high octane requirements. This is especially true during summer months when high octane/high RVP blendstock components like butane and isobutane must be used in lower concentrations due to stringent RVP limitations. Aromatics provide high octane/low RVP material for blending. [EPA-HQ-OAR-2022-0829-0707, pp. 94-95]

If a limit is proposed, EPA may want to consider specifically limiting C10+ heavy aromatics such as naphthalenes, which are more likely to result in tailpipe PM emissions. Lighter, monocyclic aromatics such as toluene and xylene provide significant octane (100+) while remaining below 2 psi RVP. These compounds contribute less to tailpipe PM emissions in comparison with heavier polycyclic compounds such as naphthalenes and its derivatives. Limiting only heavy aromatics (e.g., naphthalenes) would still allow blending of lighter monocyclic aromatics (xylene/toluene) which would assist in curtailing major production decreases and price increases for premium gasolines. [EPA-HQ-OAR-2022-0829-0707, pp. 94-95]

C. The Gasoline Pool is the Ideal Location for High Boiling Point Aromatics when Compared to the Environmental Impacts of Shifting them to the Diesel Pool.

A new limit on heavy aromatics in gasoline would likely result in shifting heavy aromatics out of the gasoline pool and into the diesel pool. Diesel engine performance improves with increases in diesel fuel cetane. However, heavy aromatics are low in cetane. Such a shift would therefore result in increased PM emissions from less efficient combustion of low cetane heavy aromatics in diesel engines. These aromatics would not be shifted into jet fuel due to smoke test requirements. Overall, heavy aromatics are a misfit for their alternate dispositions in diesel and jet engines. [EPA-HQ-OAR-2022-0829-0707, pp. 94-95]

1. A Limit Aimed at Reducing Heavy Aromatics in Gasoline would Shift Heavy Aromatics into Diesel Fuel.

EPA's analysis must consider the alternate disposition of the molecules being discussed. There are three main sources for aromatics in gasoline: fluid catalytic cracking (FCC) gasolines, reformate, and hydrocracker naphtha. As discussed below, adjustments to each of these streams that would likely be made in response to a rulemaking aimed at limiting heavy aromatics in gasoline would shift heavy aromatics out of gasoline into diesel fuel. [EPA-HQ-OAR-2022-0829-0707, pp. 95-96]

The aromatics in the swing heavy FCC gasoline are an inherent result of cracking gas oil. The swing cut is either hydrotreated for sulfur and blended into gasoline or it is routed into a distillate hydrotreater. Typical distillate hydrotreaters do very little aromatics saturation. Thus, swinging the endpoint of FCC gasoline to keep heavy aromatics out of gasoline simply shifts aromatics into diesel, to the extent permitted while continuing to comply with diesel fuel aromatics specifications (total and/or on polycyclic aromatics, depending on market). [EPA-HQ-OAR-2022-0829-0707, pp. 95-96]

To reduce the high boiling point aromatics in reformate, refiners would reduce the endpoint of heavy naphtha feeding the reformer in the upstream crude unit, coker, and/or hydrocracker fractionators. These heavy naphtha swing cuts are a mix of paraffins, naphthenes, and aromatics. Straight run naphtha from light crude may be 40% naphthene and aromatic (N+A). Coker and hydrocracker naphtha streams are typically even higher in N+A content. The net result is shifting naphthenes and aromatics from gasoline into diesel. [EPA-HQ-OAR-2022-0829-0707, pp. 95-96]

Some refiners further reform hydrocracker naphtha. Many refiners currently blend hydrocracker naphtha with high aromatics directly into gasoline. Such refiners would reduce the cutpoint of the hydrocracker naphtha stream to address a high boiling point aromatics limit, shifting those aromatics into the diesel pool. [EPA-HQ-OAR-2022-0829-0707, pp. 95-96]

Jet fuel is not a suitable alternate disposition for heavy aromatics due to the requirement to pass a smoke test. [EPA-HQ-OAR-2022-0829-0707, pp. 95-96]

2. Shifting Heavy Aromatics into Diesel Fuel Would Increase PM Emissions from Diesel Engines.

Given the likely result of shifting heavy aromatics out of the gasoline pool into the distillate pool described above, EPA should consider what impacts this possible future rulemaking would have on diesel engine tailpipe PM. Limiting the heavy aromatic content of gasoline may actually increase PM emissions overall when considering the impact to the distillate pool. Spark ignition gasoline engines provide more efficient combustion of aromatics than a diesel combustion cycle. Heavy aromatics are low cetane; swinging them into diesel will directionally diminish the effectiveness of the PM controls on diesel engines. [EPA-HQ-OAR-2022-0829-0707, pp. 95-96]

The potential future rulemaking under discussion may result in an increase in diesel engine tailpipe PM emissions, greater than the reduction achievable by limiting heavy aromatics in gasoline fuel, which would be contrary to the purpose of the rule. As such, EPA should refrain from proposing limits aimed at reducing heavy aromatics in gasoline. [EPA-HQ-OAR-2022-0829-0707, pp. 95-96]

D. EPA's Analysis of Impacts to the U.S. Gasoline Market and Refiners' Ability to Replace Volume and Octane is Oversimplified and Unrealistic.

The refining industry has notably less capacity to simply replace octane barrels and shift more production to the export market than EPA's broad statements suggest. Some of the mechanisms identified by EPA that may help with octane replacement are not feasible, or may only be feasible at certain refineries, or may only be feasible with significant capital investments, higher energy consumption, and increased emissions from sources other than the vehicle tailpipes targeted by this potential rulemaking. Refiners' ability to replace octane and export more products that are no longer appropriate for the U.S. market vary by refinery, with inland refineries generally at a disadvantage as they are typically configured to be in balance with little or no intermediate purchases or sales. The cost to make up gasoline volume and octane while continuing to comply with gasoline RVP limits could result in significant increases in prices consumers pay at the pump and could potentially result in refinery shutdowns and exacerbate supply disruptions. [EPA-HQ-OAR-2022-0829-0707, pp. 96-98]

1. EPA's Predictions of How Refinery Production Will Shift with Shifting

U.S. Market Demand Miss the Mark.

EPA has predicted that a new limit aimed at reducing heavy aromatics in gasoline will cause the gasoline-to-distillate ratio (GDR) to continue to shift downwards over the coming decades.377 Because a decreasing GDR is associated with a decrease in the T90 level of gasoline, EPA has predicted that "[t]o the extent that U.S. refinery production shifts along with U.S. market demand, then the T90 level of gasoline would be expected to continue to decline in the future as well."378 EPA has also noted a relationship of these changes with the export market, and assumed refiners will "maintain or expand export markets as much as possible."379 [EPA-HQ-OAR-2022-0829-0707, pp. 96-98]

377 88 Fed. Reg. 29404, 29400 (May 5, 2023).

378 Id.

379 Id.

These predictions rely on the false assumption that these barrels can simply be shifted from the gasoline pool to the distillate pool with little consequence, and that any excess distillate barrels can simply be exported. In reality, for some refineries, market size is fixed (e.g., for land-locked refineries), as the capacity to move barrels into and out of a region is limited. Any notable shift in products for a refinery with limited to no ability to export products could mean notable investment to find a new home for additional distillate and could create a short supply for gasoline. Furthermore, in some cases, the distillate pool cannot absorb these barrels and continue to meet fuel specifications such as flash, cetane, aromatics, and jet smoke. In other cases, refineries are running against physical and permitting limits that prevent them from further shifting to the distillate pool today; significant capital investments would be needed to shift these molecules through diesel hydrotreating units. [EPA-HQ-OAR-2022-0829-0707, pp. 96-98]

Refinery shutdowns and exacerbated supply disruptions are a more likely outcome of a new gasoline standard aimed at removing heavy aromatics from gasoline than EPA's prediction that the industry will simply seeing a decreasing GDR and a decline in the T90 of gasoline over time. [EPA-HQ-OAR-2022-0829-0707, pp. 96-98]

2. Low RVP Replacement Costs Must be Considered.

We agree that "[i]f heavy aromatics were to be removed from gasoline, then not only their volume, but their octane would have to be replaced."380 Additionally, their low RVP must be replaced. The RVP of high boiling point aromatics in reformate and FCC gasoline are in the 1-2 psi range; their removal therefore displaces low cost butane from gasoline, resulting in lower gasoline supply volumes and higher gasoline production costs. [EPA-HQ-OAR-2022-0829-0707, pp. 96-98]

380 Id. at 29401.

3. Many Refiners Do Not Have Spare Reformer Throughput Capacity or the Ability to Increase Reformer Severity for Octane Replacement.

As EPA noted, "[o]ne source for additional octane is via increased reformer severity or throughput to generate additional light aromatics."381 However, many refineries do not have spare reformer throughput capacity or the ability to increase reformer severity. [EPA-HQ-OAR-2022-0829-0707, pp. 96-98]

381 Id.

Throughput and severity may be physically limited and/or limited by refinery permits. Increasing either throughput or severity would result increased stationary source emissions; both are typically limited by refinery permits. Physical limitations on existing furnace capacity also limit a refiners' ability to increase the severity of reacting conditions (temperature). [EPA-HQ-OAR-2022-0829-0707, pp. 96-98]

Reformer severity may actually have to be reduced at refineries with limited ability to shift aromatics to the distillate pool. Reducing reformer severity will lower their gasoline pool octane, requiring them such refineries to import components that are high octane and low heavy aromatics. It will also cause a reduction in hydrogen production which could have a negative impact on gasoline sulfur. Hydrogen is used in hydroprocessing units dedicated to meeting low sulfur requirements. Reformer hydrogen is often the only source of hydrogen for many refiners [EPA-HQ-OAR-2022-0829-0707, pp. 96-98]

Refinery configurations are tailored to match the range of crude oils they process and the demand for products in the markets they serve. For example, light sweet crude refineries typically have little to no spare reforming throughput capacity or the ability to increase reformer severity. [EPA-HQ-OAR-2022-0829-0707, pp. 96-98]

4. Refiners Do Not Have Spare Alkylation Capacity for Octane Replacement and Isomerization Provides Very Little Octane Benefit.

EPA's suggestion that "[a] refinery may also be able to increase high-octane isoparaffin production through additional alkylation and/or isomerization operations" is not a feasible method of octane replacement without significant capital investment. Refinery alkylation units are already highly utilized, with little or no spare capacity available to make additional octane barrels. If an alkylation unit is not operating at its capacity, it is likely maximized to the capacity of upstream fractionation on the FCC unit producing olefin feedstocks. With significant capital investment, the industry could expand FCC capacity to allow increased utilization of alkylation units. However, expanding FCC capacity to increase alkylation rates would also cause an increase in FCC naphtha production. In many instances, FCC naphtha has a higher production yield compared to C3-C5 olefin production, so any increases in low aromatic alkylation feedstocks would be accompanied and overshadowed by increased volumes of high aromatic FCC naphtha blendstocks, which may ultimately raise the overall aromatic content of the gasoline blending pool. Additionally, these projects would likewise result in their own stationary source emission increases. [EPA-HQ-OAR-2022-0829-0707, pp. 98-99]

Light straight run (LSR) isomerization provides very little octane benefit relative to reforming of heavy naphtha. Isomerization also increases the RVP of the stream, backing low cost, high octane butane out of the gasoline pool. [EPA-HQ-OAR-2022-0829-0707, pp. 98-99]

5. Cost and Impacts on Refining Will Vary Greatly for Individual Refineries and Are Not Accurately Reflected by EPA's Simplified Application of the Haverly LP Refining Model.

EPA requested comment on their use of the Haverly linear programming (LP) refinery model to estimate cost and impacts on refining. While LP models such as Haverly or PIMS could provide directional guidance on likely impacts in a typical refinery, these models are highly complex and should be run and interpreted by experienced refining engineers using data from actual operations and laboratory testing to ensure the modeled gasoline streams have sufficiently extensive definition to correctly balance and optimize to meet finished product specifications. Furthermore, likely impacts to a "typical" refinery may not sufficiently predict impacts to the actual U.S. refining industry. [EPA-HQ-OAR-2022-0829-0707, pp. 98-99]

For example, to simulate the effects of removing high boiling point components from the gasoline pool, EPA "used the Haverly LP refinery model to reduce the average T90 of U.S. gasoline by 15°F in 5°F steps."382 However, it cannot be assumed that the entire industry would make a similar shift. Distillation properties of gasoline vary by refinery. For example, refineries making California grade gasoline are likely making lower end point reformate and may not have to change anything (other than possibly building a splitter to cut the tail off of their zero aromatics alkylate). Refineries with large jet fuel markets are likely operating with lower heavy naphtha (and therefore reformate); jet fuel has a lower flash specification than diesel and allows them to operate as such. Refineries with some combination of no jet market, running light sweet crude, filling a large FCC with purchased vacuum gas oil (VGO) and/or selling low boiling point components like LSR will have a gasoline pool with higher endpoint and T90. A refinery with a configuration producing higher baseline endpoint gasoline would be making a larger cutpoint change. The cost is likely not linear with the number of degrees that the cutpoint is changed. [EPA-HQ-OAR-2022-0829-0707, pp. 98-99]

382 Id. at 29403.

EPA's cost estimates need to consider different refinery configurations and costs related to production and logistics, including the potential need for capital expenditures. The cost impact will be different for every refinery depending on its required cutpoint change, its product markets, and its location (relative to the alternate disposition for displaced butane and additional diesel to be marketed and to the supply of gasoline to replace lost volume). Any notable swing in the formulation of gasoline will likely require significant capital investments to produce the new fuel specification and for logistics to move excess barrels to their new disposition and to replace the supply of displaced gasoline barrels. [EPA-HQ-OAR-2022-0829-0707, pp. 98-99]

E. Comments on the Structure of the Standard will Depend on the Stringency of any Standard that May be Proposed in the Future; Advance Notice and Engagement with the Refining Industry is Essential Ahead of Rulemaking.

We appreciate that EPA "understand[s] that it may be difficult to comment on the various structures for a standard without having some idea of what the stringency of the standard might be."383 Given this limitation, and our view that high boiling point is not an appropriate surrogate for heavy aromatics in gasoline to begin with, we have provided limited general comments in this area at this time. [EPA-HQ-OAR-2022-0829-0707, pp. 99-102]

383 Id.

Before proposing a rule, EPA should provide the refining industry with a specific limit or narrow range of potential limits and enough time to fully evaluate the feasibility of such a standard given unique refinery configurations, supply constraints, and demand balances across the nation. Refiners will need enough time to determine if the proposed limits are feasible, and if so, time to identify what capital investments and/or operational changes would be needed. The implementation timeline included in any proposed rule should reflect the time industry would need to implement such changes, including time for any required federal and regional permitting, project construction, etc. [EPA-HQ-OAR-2022-0829-0707, pp. 99-102]

EPA has presented many options for consideration, including a "per-gallon cap, a national annual average standard implemented along with an averaging, banking, and trading program (ABT), a facility maximum annual average standard, or some combination of these."384 [EPA-HQ-OAR-2022-0829-0707, pp. 99-102]

384 Id. at 29402.

1. If EPA Proceeds With a Rulemaking, a Company-Wide Annual Average Standard Would Likely be the Best Approach, Depending on the Stringency of the Standard.

Although we agree with EPA's statements about the regulatory burdens associated with managing a company-wide annual average standard385, we would prefer to manage these regulatory burdens over the burdens associated with producing a fuel that must meet a per-gallon standard or a facility maximum annual average standard. A company-wide average standard would allow some degree of flexibility for refiners to respond to issues with gasoline production, reduce supply disruptions, and minimize costs to consumers. [EPA-HQ-OAR-2022-0829-0707, pp. 99-102]

385 Id.

Depending on what limit may be proposed, an ABT system may be necessary for certain sites or companies to maintain compliance. While not preferred, providing banking flexibility is better than causing supply disruptions and increasing costs to consumers. [EPA-HQ-OAR-2022-0829-0707, pp. 99-102]

A thorough review of potential implications of a company-wide annual average standard is needed before proposing such a standard, and will depend on the stringency of the standard proposed. [EPA-HQ-OAR-2022-0829-0707, pp. 99-102]

2. Per-Gallon Caps and Facility Maximum Annual Average Standards are Untenably Inflexible and May Lead to Increased Emissions from Transportation of Components Between Refineries Among Other Issues.

We strongly agree with the downsides of a per-gallon cap identified by EPA.386 A per-gallon standard is simply not feasible if refiners are to have flexibility to respond to gasoline production issues and to reduce supply disruptions and prices at the pump. A per-gallon standard would have additional downsides beyond those already identified by EPA, and we have similar concerns with a facility maximum annual average standard. [EPA-HQ-OAR-2022-0829-0707, pp. 99-102]

386 Id.

Such a standard may lead to an increase in emissions associated with the transportation of components between refineries that are needed for an individual refinery to comply. For example, refineries without an FCC generally do not produce alkylate and rely heavily on reformer aromatics for octane replacement. Such refineries may have to ship light naphtha and reformate to a third party and backhaul low aromatics alkylate. Shipping barrels around to meet per-gallon standards, or even to meet annual facility-specific average targets, is inefficient and may result in increased emissions associated with the transportation of said intermediates. In addition, compliance may not be possible during necessary refinery turnarounds/planned maintenance events or during unplanned unit shutdowns. [EPA-HQ-OAR-2022-0829-0707, pp. 99-102]

If EPA has health risk concerns for particular areas of the country, they should only target those areas, and not penalize areas with low PM emissions. Regional variables such as altitude, humidity, and air temperature have considerable impacts on engine performance and tailpipe emissions. EPA should consider regional limits for geographies with PM NAAQS non-attainment issues rather than requiring all refineries across the nation to comply with a facility maximum annual average or per-gallon limits. For example, this may be similar to local/regional reformulated gasoline (RFG) requirements. [EPA-HQ-OAR-2022-0829-0707, pp. 99-102]

A thorough review of potential implications of a per-gallon standard or a facility maximum annual average standard is needed before proposing such a standard, and will depend on the stringency of the standard proposed. [EPA-HQ-OAR-2022-0829-0707, pp. 99-102]

3. Seasonal Limits May or May Not Be Appropriate Depending on the Stringency of Any Standard if Proposed.

Gasoline produced and introduced into the market between May 1 and September 15 must meet summer RVP standards defined in Title 40 of the Code of Federal Regulations (40 C.F.R.)

Part 1090 – Regulation of Fuels, Fuel Additives, and Regulated Blendstocks. These standards require RVP suppression during summer months due to elevated ambient temperatures. Refiners typically achieve these more stringent summer standards by reducing the volume of lighter blendstocks in the blend pool such as butanes and pentanes, while also increasing the use of heavier endpoint blendstocks. Many refineries may not have the ability to purchase isomerate (as noted in EPA's Haverly study) due to logistical constraints and may not have the ability to increase reformer severity or produce more alkylate. Individual refineries may be further constrained by the lack of disposition of high RVP blendstocks which need to be removed from summer blends. The geography and interconnectivity of a given refinery to other customers or sources of blendstocks or LPG caverns will determine their flexibility to meet these standards. Additionally, introducing season average limits could reduce flexibility during maintenance outages, which will result in lower production and/or higher market prices. [EPA-HQ-OAR-2022-0829-0707, pp. 99-102]

A thorough review of potential implications of a seasonal standard is needed before proposing such a standard, and will depend on the stringency of the standard proposed. [EPA-HQ-OAR-2022-0829-0707, pp. 99-102]

F. Test Methods.

Although we do not believe high boiling point is an appropriate surrogate for heavy aromatics in gasoline, we offer the following comments on test methods EPA presented as possible candidates for demonstrating compliance with a high boiling point limit. If EPA moves forward with a limit on distillation as a surrogate for heavy aromatics, EPA should propose ASTM D86 – Standard Test Method for Distillation of Petroleum Products and Liquid Fuels at Atmospheric Pressure, the current industry standard, as the default test method. However, we also provide comments regarding test methods for direct measurement of heavy aromatics, which we think would be a more appropriate than distillation, as described previously. ASTM D8071 - Standard Test Method for Determination of Hydrocarbon Group Types and Select Hydrocarbon and Oxygenate Compounds in Automotive Spark- Ignition Engine Fuel Using Gas Chromatography with Vacuum Ultraviolet Absorption Spectroscopy Detection (GC-VUV) would be an appropriate test method to propose for refiners to demonstrate compliance with such standards if proposed in the future. [EPA-HQ-OAR-2022-0829-0707, pp. 102-104]

1. ASTM D86 is the Industry Standard for Distillation Evaluation and is the Best Test Method if EPA Proposes a Limit on High Boiling Point as a Surrogate for Heavy Aromatics in Gasoline.

ASTM D86 is the industry standard for distillation evaluation for distillate and lighter streams. It is the only distillation test method referenced in 40 C.F.R. Part 1090 – Regulation of Fuels, Fuel Additives, and Regulated Blendstocks. It is also one of only two methods approved by ASTM D4814 – Standard Specification for Automotive Spark-Ignition Engine Fuel. The only other distillation test method approved for use by ASTM D4814 is ASTM D7345 – Standard Test Method for Distillation of Petroleum Products and Liquid Fuels at Atmospheric Pressure (Micro Distillation Method). ASTM D86 is the referee of the two methods approved under ASTM D4814. [EPA-HQ-OAR-2022-0829-0707, pp. 102-104]

ASTM D86 is efficient (refineries already have the equipment), more accurate than simulated distillation estimates, and provides more precise results (lower published reproducibility) compared to other methods. ASTM D86 T90 is preferred over T95 or final boiling point (FBP) because there is more established data for T90, which was previously reported to EPA under 40 C.F.R. Part 80 – Regulation of Fuels and Fuel Additives, and because distillation curves have lower published reproducibility and repeatability at T90 than at T95 or FBP. As EPA noted, the ASTM D86 distillation parameter with the best correlation to the PM Index (PMI) parameter is T90387; as such, if a distillation limit is proposed, it should be based on T90 by ASTM D86. [EPA-HQ-OAR-2022-0829-0707, pp. 102-104]

387 Id.

2. The Downsides of ASTM D7096 Outweigh the Potential Benefits.

EPA identified ASTM D7096, a simulated distillation (SimDis) method, as "[t]he most promising alternative" test method.388 However, the downsides of employing ASTM D7096 for measuring simulated distillation outweigh the potential benefits identified by EPA. [EPA-HQ-OAR-2022-0829-0707, pp. 102-104]

388 Id.

ASTM D7096 is not currently referenced or approved by 40 C.F.R. Part 1090 – Regulation of Fuels, Fuel Additives, and Regulated Blendstocks. It is also not approved by ASTM D4814 – Standard Specification for Automotive Spark- Ignition Engine Fuel for gasoline certification. There are no established correlation equations between ASTM D86 and ASTM D7096. If EPA were to require ASTM D7096 testing, all gasoline certified in the U.S. would need to be tested redundantly by both ASTM D86 and ASTM D7096 for distillation. Gasoline meeting the ASTM D4814 Final Boiling Point maximum standard of 437°F using ASTM D86 could produce a value above 437°F if tested using D7096. [EPA-HQ-OAR-2022-0829-0707, pp. 102-104]

Labs certifying gasoline intended for U.S. consumption may not have trained personnel or equipment to perform D7096. D7096 is a gas chromatography (GC) method which requires significant capital and expensive standards to operate. Third party laboratories generally charge approximately three times more for ASTM D7096 testing than for ASTM D86 testing. [EPA-HQ-OAR-2022-0829-0707, pp. 102-104]

Flaws with ASTM D7096 distillation prediction cause the method to be less accurate towards the end of the boiling range because it tends to estimate a longer distillation tail which can manifest more significantly for heavier gasolines. This is because D7096 estimates distillation based on molecular composition. Estimates are not always accurate due to abnormalities and non-linearities when mixing compounds. A similar phenomenon can be seen with RVP. When pure ethanol (RVP = 2 psi) is mixed with summer gasoline (RVP = 9 psi) in a 10:90 ratio (i.e., E10 gasoline), the expected result would be to have a mixture under 9 psi RVP based on the blending components. However, the RVP of the mixture is actually higher than the individual sources, resulting in a mixture of approximately 10 psi RVP. Similarly, ASTM D7096 expects a mixture to have a higher FBP based on the presence of high end point molecules, but in practice, the mixture physically boils away at a temperature lower than the predicted ASTM D7096 value. [EPA-HQ-OAR-2022-0829-0707, pp. 102-104]

Flaws with ASTM D7096 distillation prediction cause the method to have lower precision when compared to ASTM D86. For comparison, ASTM D7096-19 has a published FBP reproducibility of 18.5°F, while ASTM D86-23 has a published FBP reproducibility of 7.1°F.

ASTM D86 results will have 2.5 times higher precision than ASTM D7096 results when tested and compared to a quality control sample with an established Accepted Reference Value (ARV). [EPA-HQ-OAR-2022-0829-0707, pp. 102-104]

3. ASTM D8071 is the Best Test Method if EPA Proposes a Limit Directly on Heavy Aromatics (i.e., C10+ Aromatics) in Gasoline.

ASTM D8071 - Standard Test Method for Determination of Hydrocarbon Group Types and Select Hydrocarbon and Oxygenate Compounds in Automotive Spark-Ignition Engine Fuel Using Gas Chromatography with Vacuum Ultraviolet Absorption Spectroscopy Detection (GC-VUV) would be an appropriate test method to propose for refiners to demonstrate compliance with heavy aromatic standards. Any aromatic standards should be limited to heavy aromatics (i.e., polycyclic C10+ aromatics such as naphthalenes). [EPA-HQ-OAR-2022-0829-0707, pp. 102-104]

Vacuum Ultra-Violet (VUV) methods such as ASTM D8071 are preferred over traditional gas chromatography (GC) methods, such as D5769 – Standard Test Method for Determination of Benzene, Toluene, and Total Aromatics in Finished Gasolines by Gas Chromatography/Mass Spectrometry. VUV solves a known drawback of traditional GC technology with the coelution of molecules at the same retention time resulting in chromatograph peaks which cannot be properly separated or integrated. VUV has the ability to provide deconvolution to coeluting peaks by identifying unique spectral fingerprints through first-order molecular absorption. Traditional GCs would require increased runtime to resolve peak coelution, and even with additional runtime, many peaks still could not be separated based on molecular similarities. VUV resolved coelution through algorithms and run times are much quicker than traditional GCs. [EPA-HQ-OAR-2022-0829-0707, pp. 102-104]

As such, VUV is superior to GC and to Detailed Hydrocarbon Analysis (DHA) methods such as ASTM D6729 – Standard Test Method for Determination of Individual Components in Spark Ignition Engine Fuels by 100 Metre Capillary High Resolution Gas Chromatography and ASTM D6730 – Standard Test Method for Determination of Individual Components in Spark Ignition Engine Fuels by 100- Metre Capillary (with Precolumn) High-Resolution Gas Chromatography. [EPA-HQ-OAR-2022-0829-0707, pp. 102-104]

G. Additional Considerations

1. EPA Should Consider Impacts to Gasoline Benzene and Sulfur.

Displacing aromatics from gasoline shrinks the gasoline pool, thereby concentrating benzene and possibly sulfur. This could result trigger a need for additional benzene and sulfur removal, which would further raise costs for the consumer, and may result in other emissions impacts. [EPA-HQ-OAR-2022-0829-0707, pp. 104-105]

Also, aromatics production is desirable as its production in reformer units results in production of an essential source of hydrogen that is then used in hydroprocessing units to help refiners meet low sulfur limits. To meet a new aromatics limit, some refineries may have to decrease reformer severity, resulting in decreased hydrogen production and related impacts to gasoline sulfur. [EPA-HQ-OAR-2022-0829-0707, pp. 104-105]

2. Historical Decreases in Gasoline-to-Distillate Ratio were Not Related to the Tier 2 Sulfur Program.

We agree that "[a] common thread across the market shifts in T90 has been a decreasing gasoline-to-distillate ratio (GDR) in the product slates produced by refineries" and that this shift was largely attributable to "the influx of ethanol into gasoline."389 However, we disagree that lower T90 values can also be attributed to the Tier 2 program.390 As a whole, the refining industry built Gasoline Desulfurization Units (GDUs) to respond to Tier 2 sulfur limits; the T90 shifts seen in this time period were more related to market pricing impacts. [EPA-HQ-OAR-2022-0829-0707, pp. 104-105]

389 Id. at 29400.

390 Id.

3. Scope and Applicability of a Potential Future Rulemaking.

If EPA proposes a rule that aims to decrease heavy aromatics in the gasoline pool, EPA should clarify the scope of the rule and how it interacts with various state programs and for imports. For example, EPA should clarify if CARB gasoline will be granted the same exemption criteria it is offered today under § 1090.625. Regarding imports, there may be special considerations for import by truck similar to those in § 1090.1610. [EPA-HQ-OAR-2022-0829-0707, pp. 104-105]

Organization: Wisconsin Department of Natural Resources

7. Updating fuel property standards. EPA is requesting comment on if it should, in a separate rule, update fuel property standards to reduce PM tailpipe emissions from legacy light and medium-duty vehicles. Since updated fuel standards would ensure additional PM emissions reductions occur in the near term, which would both protect public health and help states attain and maintain any upcoming revisions to the PM NAAQS, the WDNR recommends that EPA pursue such a rulemaking. [EPA-HQ-OAR-2022-0829-0507, p. 3]

EPA Summary and Response

Summary:

Commenters representing petroleum suppliers and refiners generally opposed new standards aimed at limiting heavy aromatics or other high-boiling components of gasoline. They suggested that EPA overestimates the amount of heavy aromatics currently in gasoline, noting that it has declined over time. They also suggest that EPA overstates the benefits of reducing gasoline heavy aromatics, and underestimates the cost and other negative impacts on refining. They raise concerns about the suitability of ASTM D7096 SimDis test method as a compliance parameter, and question whether EPA has the statutory authority to put in place market fuel standards aimed at a pollutant (PM) that will be greatly reduced under the proposed vehicle emission standards.

Commenters representing ethanol producers and related companies support a limit on heavy aromatics, and suggest that the limit should apply to the petroleum blendstocks prior to ethanol blending so that higher-ethanol blends will result in further reductions via dilution. They also advocated for a high-octane/low-carbon fuel standard to reduce both PM and GHGs.

Commenters from the auto industry support a limit on heavy aromatics and/or other high boiling gasoline components, suggesting this will reduce emissions from existing vehicles regardless of future vehicle standards. An industry trade group cited an emission study recently published by EPA and several partners showing the impacts of heavy aromatics reductions on emissions from a range of recent model-year vehicles. They also advocated for other fuel improvements including a lower sulfur cap (currently 80ppm) and reduction of fuel components that act as precursors for air toxics. Another commenter voiced support for surrogate compliance methods (such as ASTM D7096 SimDis) if they can provide equivalent performance to a heavy aromatics or PM Index standard.

Response:

We are not finalizing fuel standards at this time. We thank the commenters for their statements and will continue to assess options for limiting the heavy aromatic content of gasoline.
