As noted throughout these comments, the projected increases in vehicle electrification will deliver the bulk of the pollutant reductions being sought by EPA. The majority of the benefits achieved will be from the phasedown of ICE vehicles. Enrichment may appear to provide a narrow pathway for incremental gains, but as Auto Innovators has outlined above, these potential gains may disrupt other holistic gains from downsized engines overall. Benefits would likely be very small relative to the disruption this could pose in the phasedown of ICE powertrains. [EPA-HQ-OAR-2022-0829-0701, pp. 185-186]

Auto Innovators recommends that EPA leverage the existing AECD process to continue the dialogue with OEMs on concerns with enrichment. The AECD process already includes agency review of the need for controls such as commanded power and thermal protection enrichment. We recommend that EPA continue to use the existing AECD process to review strategies with OEMs and that EPA not finalize the elimination of enrichment as proposed in the NPRM. In order for enrichment to be managed through the AECD process, the proposed CO standards will also require adjustment as they also serve as a de facto enrichment ban. [EPA-HQ-OAR-2022-0829-0701, pp. 185-186]

To the extent that additional data could be helpful in informing EPA it of enrichment in the future, we recommend EPA convene a stakeholder group to review options that could be used to gather data. Data on a broad range of vehicles could be used to better understand the actual real-world impact of enrichment on emissions, including the frequency of AECD commanded fuel enrichment. This process, conducted over a range of driving conditions and engine types, could serve as a basis for a future proposal. Once the data is collected and analyzed, then EPA could better determine if there is a need (or not) to address enrichment in a future regulatory rulemaking. Without such data, it is difficult to understand the opportunity for reduction that can then be weighed against the implementation challenges. [EPA-HQ-OAR-2022-0829-0701, pp. 185-186]

Auto Innovators wants to ensure that while the transition to electric vehicles is ongoing, customers of ICE vehicles continue to experience the benefits of high specific power engines and not be forced to reconsider their purchase decisions should future options no longer meet their utility needs. [EPA-HQ-OAR-2022-0829-0701, pp. 185-186]

3. Recommendations on the Definition of “Normal Operation”

Auto Innovators has significant reservations about EPA’s proposal to generally prohibit enrichment. However, if EPA does finalize such provisions, it should revise the definition of “normal operation” to be workable. [EPA-HQ-OAR-2022-0829-0701, pp. 185-186]

The text at the proposed 40 C.F.R. § 86.1809-12(d)(1) defines “normal operation” to include all operating conditions of a vehicle such as trailer tow, altitude and ambient conditions. Also, the proposal requires similar effectiveness in emission control compared to the levels demonstrated in the test cycles (or that the vehicle design does not incorporate strategies that unnecessarily reduce emission control effectiveness exhibited during the certification test procedures). This is not feasible because the demonstrated test cycle conditions operate at different mass flow and temperatures which affects the space velocity or residence time of the species in the converter which in turn affects the conversion efficiency or effectiveness of the emission control system. Hence, maintaining similar effectiveness under all operating conditions is not practical from an emissions control perspective. [EPA-HQ-OAR-2022-0829-0701, pp. 185-186]

We recommend that EPA modify the proposed 40 C.F.R. § 86.1809-12(d)(1) text as follows:

The manufacturer must show to EPA’s satisfaction that the vehicle design does not incorporate strategies that unnecessarily reduce emission control effectiveness exhibited during the certification test procedures specified in this subpart, the fuel economy test procedures in 40 CFR part 600, or the air conditioning efficiency test in 40 CFR 1066.845, when the vehicle is operated under conditions that may reasonably be expected to be encountered in normal operation and use, unless allowed as an AECD. During normal operation, operating at stoichiometry or near stoichiometric conditions should not be considered as reducing the effectiveness of the emissions control system. [EPA-HQ-OAR-2022-0829-0701, pp. 186-187]

Organization: American Honda Motor Co., Inc.

Further, there appears to be a disconnect between the agency's position on PM stringency and commanded enrichment. GPF regeneration will be necessary to avoid damage to the engine and exhaust system. While passive regeneration can occur under certain high load conditions, in many cases it will not occur under lighter load operation. The agency itself acknowledges that no significant passive regeneration would occur during -7°C FTP and 25°C FTP cycles, and that a US06 test cycle would be required to reach the necessary 600°C temperature needed for passive regeneration.23 Consumers who generally operate their vehicles under lighter load conditions would likely need some degree of active regeneration. Unfortunately, by proposing to disallow commanded enrichment for the purpose of engine and aftertreatment protection, the agency has effectively prohibited active regeneration. Other potential strategies such as spark retard and air fuel ratio modulation have been examined as potential solutions, but the technical effectiveness of those approaches remains inadequate.24 [EPA-HQ-OAR-2022-0829-0652, pp. 14-15]

23 88 Fed. Reg. 29267 (May 5, 2023)

24 Van Nieuwstadt, et al., 2019. Regeneration Strategies for Gasoline Particulate Filters. SAE 2019-01-0969.

D. Enrichment

One of the more surprising elements included in the NPRM is the agency's proposed elimination of commanded enrichment for ICE-powered vehicles for power and component protection. By our read, three high-level arguments are posited by the agency in support of this position:

1. "Technologies exist that can prevent thermal damage of engine and/or exhaust system components without the use of enrichment during normal operation and use" [EPA-HQ-OAR-2022-0829-0652, pp. 19-20]

2. "The use of enrichment only has the potential to incrementally increase power" [EPA-HQ-OAR-2022-0829-0652, pp. 19-20]

3. "Modern vehicles have sufficient power without the use of enrichment"37 [EPA-HQ-OAR-2022-0829-0652, pp. 19-20]

37 88 Fed. Reg. 29277 (May 5, 2023).

While Honda respects the agency's desire to minimize excess criteria emissions, we believe the arguments put forth by the agency on this topic are not sufficiently supported. As such, we believe the enrichment-related aspect of the proposal should be omitted from the Final Rule and reconsidered at a future date pending additional supporting evidence. [EPA-HQ-OAR-2022-0829-0652, pp. 19-20]

Argument #1. Technologies exist that prevent the need for such enrichment [EPA-HQ-OAR-2022-0829-0652, p. 20]

EPA addresses this point in the Draft RIA:

Technologies exist today which can prevent thermal damage of exhaust system components without the use of commanded enrichment during normal operation and use, and modern vehicles have sufficient power without the use of commanded enrichment. The use of commanded enrichment only has the potential to increase power by approximately 5 percent on a naturally aspirated engine but significantly reduces the effectiveness of three-way catalytic converter systems, resulting in increases of NMOG, CO and air toxics, in some cases by orders of magnitude.38 [EPA-HQ-OAR-2022-0829-0652, p. 20]

38 EPA, 2023. Draft RIA, p. 3-46. Available online at https://nepis.epa.gov/Exe/ZyPDF.cgi?Dockey=P10175J2.pdf

The agency's subsequent elaboration on these technologies, however, simply points to "modern engine technologies" and cites examples such as VVT and cylinder deactivation as providing sufficient control "to limit or avoid operation in areas that require enrichment for any normal vehicle operation"39: [EPA-HQ-OAR-2022-0829-0652, p. 20]

39 EPA, 2023. Draft RIA, p. 3-45. Available online at https://nepis.epa.gov/Exe/ZyPDF.cgi?Dockey=P10175J2.pdf

Modern engines have also added technologies such as VVT, cylinder deactivation, turbo boost control and other technologies that effectively allow the manufacturer designed controls, when used in conjunction with electronic throttle and transmission control to operate the engine in nearly any manner they determine to be optimal for the customer and manufacturer drivability expectations and durability goals. [EPA-HQ-OAR-2022-0829-0652, p. 20]

The agency believes that these same technologies, only available in recent years, could also be used for limiting operation in areas described previously as requiring enrichment that result in substantial increases in emission levels in normal operation including high acceleration rates, high loads. The reasons for the original allowances for enrichment discussed in the SFTP FRM can easily be addressed in modern engine and transmissions by utilizing existing controls to limit or avoid operation in areas that require enrichment for any normal vehicle operation. Vehicles can "drive" through these areas but quickly exit by changing the engine airflow control, ignition timing, valvetrain settings, speed, or other parameters that would avoid this unnecessary increase in emissions.40 [EPA-HQ-OAR-2022-0829-0652, p. 20]

40 EPA, 2023. Draft RIA, p. 3-45. Available online at https://nepis.epa.gov/Exe/ZyPDF.cgi?Dockey=P10175J2.pdf

The agency provides no technical research or real-world examples to support the position that customer and manufacturer drivability expectations and durability goals can be maintained while "driving through" problematic areas of the engine map. Automakers have spent years refining and finessing internal combustion engine performance to deliver today's drivers a satisfying and compelling product; the insinuation that automakers have willfully been eschewing potential emissions reductions and fuel savings is illogical and wholly inconsistent with our commitment to the customer. [EPA-HQ-OAR-2022-0829-0652, pp. 20-21]

As an example, Honda's cylinder deactivation systems can only activate in conditions with reduced engine output demand, due to having fewer firing cylinders. Enrichment during high load is used during conditions when the vehicle requests higher engine output demand. It is therefore impossible to use cylinder deactivation to operate in the same conditions as when enrichment is demanded. [EPA-HQ-OAR-2022-0829-0652, pp. 20-21]

Additionally, Honda's cylinder deactivation may or may not reduce the catalytic converter temperatures, depending on the engine operating conditions. It is therefore not a robust method to control exhaust temperatures. [EPA-HQ-OAR-2022-0829-0652, pp. 20-21]

Argument #2. The use of enrichment only has the potential to incrementally increase power [EPA-HQ-OAR-2022-0829-0652, p. 21]

The agency claims that "the use of commanded enrichment only has the potential to increase power by approximately 5 percent on a naturally aspirated engine,"41 citing, as proof, an analysis conducted for the recently finalized 2027 and later heavy-duty vehicle and engine standards. As we understand it, that analysis utilized a single 6.4L heavy duty engine, hardly representative of today's passenger car and light duty truck fleet as a whole. To our knowledge, EPA did not examine the peak power loss that would occur in smaller naturally aspirated and/or downsized turbocharged designs that are more reflective of today's passenger car and light truck market. As noted in comments submitted to this Docket by our trade association, today's engines could lose roughly 30-50% of peak power as a result of enrichment elimination. While results would of course vary, the range provided by Auto Innovators is generally consistent with our engineering understanding. [EPA-HQ-OAR-2022-0829-0652, p. 21]

41 EPA, 2023. Draft RIA, p. 3-45. Available online at https://nepis.epa.gov/Exe/ZyPDF.cgi?Dockey=P10175J2.pdf

Argument #3. Modern vehicles have sufficient power without the use of enrichment [EPA-HQ-OAR-2022-0829-0652, pp. 21-22]

The definition of "sufficient" is highly subjective and, as such, is difficult to either prove or disprove. In our view, the agency's rationale supporting Argument #3 is lacking. Although commanded enrichment for the purpose of power and component protection occurs relatively infrequently on Honda products, it does occur and therefore reflects a genuine need for at least a portion of our customers – be it power for towing, a temporary need for urgent acceleration, or other customer applications. Honda has taken great care in right-sizing our powertrains to provide the best balance of efficiency, customer drivability expectations/requirements and regulatory compliance. [EPA-HQ-OAR-2022-0829-0652, pp. 21-22]

Should commanded enrichment be eliminated as proposed, a paradoxical but logical outcome of that decision could be that – to ensure continued performance associated with those customers' needs – application of a larger, less efficient internal combustion engine is deemed warranted. The agency's proposed handling of enrichment is unnecessarily disruptive and, as such, we recommend that EPA maintain the current AECD process to ensure emissions system effectiveness, durability and fundamental vehicle utility. [EPA-HQ-OAR-2022-0829-0652, pp. 21-22]

Recommendation: Omit proposed changes regarding commanded enrichment from the Final Rule and reconsider them at a future date pending additional supporting evidence. Maintain the current AECD process to ensure emissions system durability and fundamental vehicle utility. [EPA-HQ-OAR-2022-0829-0652, p. 22]

Organization: Aston Martin Lagonda (AML)

3. COMMANDED ENRICHMENT AECD

EPA is proposing to eliminate the use of commanded enrichment as an AECD on engines used in light-duty vehicles for either power or component protection during normal operation and use. Normal operation is defined at 40 CFR 86.1803-01 to include vehicle speeds and grades of public roads, and vehicle loading and towing within manufacturer recommendations, even if the operation occurs infrequently. [EPA-HQ-OAR-2022-0829-0566, pp. 10-11]

EPA requests comment on the proposed prohibition of commanded enrichment including benefits and costs, and additional exceptions where brief rich operation should be allowed. [EPA-HQ-OAR-2022-0829-0566, pp. 10-11]

- Commanded enrichment should continue to be permitted for SVMs in high performance engines We urge EPA to continue to allow commanded enrichment in high performance SVM engines beyond the limited, brief permissible circumstances permitted in the NPRM based on the following considerations: [EPA-HQ-OAR-2022-0829-0566, pp. 10-11]

- Aston Martin high performance engines use enrichment as a failure avoidance strategy and it is therefore employed only in extreme circumstances, accounting for as little as 3% of all normal driving. Aston Martin can provide its EU findings on the subject of enrichment to EPA, if required. [EPA-HQ-OAR-2022-0829-0566, pp. 10-11]

- At present, there are no viable technical solutions for alternatives to enrichment for high performance engines (i.e., alternatives that are reasonable in cost and timeframe). [EPA-HQ-OAR-2022-0829-0566, pp. 10-11]

- Enrichment allows high-performance engines to be downsized and thereby made more efficient. [EPA-HQ-OAR-2022-0829-0566, pp. 10-11]

- To conclude, as regards Commanded Enrichment EPA should: [EPA-HQ-OAR-2022-0829-0566, pp. 10-11]

- At a minimum, allow commanded enrichment on SVM vehicles meeting both of the following two criteria: [EPA-HQ-OAR-2022-0829-0566, pp. 10-11]

- having a power-to-weight (mass) ratio clearly indicative of high-performance (e.g.,> 200 kW/tonne (based on curb weight),3 and also [EPA-HQ-OAR-2022-0829-0566, pp. 10-11]

- using high-power output engines (e.g., engines> 100 hp per liter or> 600 hp).4 [EPA-HQ-OAR-2022-0829-0566, pp. 10-11]

3 Determine a vehicle's power-to-weight ratio by dividing the engine's rated power by the vehicle's GVWR (in hp/pound). If a test group includes multiple configurations, use the vehicle with the highest power-to-weight ratio to characterize the test group

4 We also note that CARB does not have commanded enrichment rules like those proposed in the NPRM

[See original attachment for table of engine descriptions] [EPA-HQ-OAR-2022-0829-0566, pp. 10-11]

Organization: California Air Resources Board (CARB) (Part 1 of 5)

Criteria Air Pollutant Standards

CARB supports U.S. EPA's proposal to tighten criteria air pollutant emission standards, particularly given the continued role that internal combustion engine vehicles will play in the national fleet over the regulatory timeframe and beyond. Reducing exposure to harmful air pollution is a key element of the proposed standards, and the proposals to tighten criteria air pollutant emissions are needed to protect public health, especially in communities with disproportionate exposure to air pollution. Because U.S. EPA's proposal does not require ZEV sales, as California's rules do, the tightening of criteria air pollutant emission standards is even more critical to ensure that the internal combustion engine vehicles that will continue to be sold are becoming cleaner. [EPA-HQ-OAR-2022-0829-0780, pp. 26-27]

As part of its ACC II rulemaking, CARB adopted its fourth iteration of its Low Emission Vehicle (LEV) standards, referred to as LEV IV. CARB finds that U.S. EPA's proposals are appropriate and largely consistent with the LEV IV standards. CARB has documented our analysis and recommends strengthening the proposal to realize the greatest degree of emission reductions achievable, considering cost and technology availability, to further protect public health. As described further below, CARB recommends that U.S. EPA adopt its proposed NMOG+NOx and PM standards, adopt elements of CARB's evaporative emission standards program, and eliminate the use of commanded enrichment as proposed while collecting additional information on the use of auxiliary emissions control devices to further improve emission standards in the future. [EPA-HQ-OAR-2022-0829-0780, pp. 26-27]

Commanded Enrichment

U.S. EPA requested comment on eliminating commanded enrichment for vehicles with engines for power and component protection. Commanded enrichment involves control of the fuel system to achieve a richer air fuel ratio mixture during combustion and in the exhaust stream for various desired outcomes that may include increased engine output power, decreased exhaust temperature, or a different composition of unburned fuel or oxygen in the exhaust stream. Most current vehicles incorporate auxiliary emission control devices (AECD) that utilize enrichment for the purpose of protecting components in the exhaust system from thermal damage during specific driving and ambient conditions that can occur in some routinely encountered in-use conditions. Some vehicles incorporate similar strategies for the purpose of increasing the power output of the engine under specific driving conditions. Such strategies significantly reduce the effectiveness of the aftertreatment system during their operation and cause significantly increased tailpipe emissions. [EPA-HQ-OAR-2022-0829-0780, pp. 37-38]

CARB agrees with U.S. EPA's findings that the need for enrichment to temporarily boost engine power levels is no longer necessary given the state of electronic controls and advanced powertrains such as turbocharged engines, variable valve timing and lift systems, and advanced multi-speed transmissions that have allowed manufacturers to introduce vehicles with higher power levels and performance than ever before. CARB also agrees the elimination of enrichment for engine component protection would better ensure that manufacturers, despite U.S. EPA and CARB prohibitions, are not using such strategies to protect frail designs in lieu of using more robust components that can better withstand the temperatures and exhaust environment. Even with full disclosure by manufacturers at the time of certification, AECDs that result in enrichment can utilize a complex set of enabling criteria that make it difficult to review and assess the likely frequency and duration of activation during in-use vehicle operation. [EPA-HQ-OAR-2022-0829-0780, pp. 37-38]

CARB supports U.S. EPA's proposal to eliminate the allowance of the use of commanded enrichment as an AECD on spark ignition engines used in light- and medium-duty vehicles for either power or component protection during normal operation and use. CARB also agrees with U.S. EPA that the use of frequent or prolonged enrichment can significantly increase tailpipe emissions to levels far above the emission standards and the current approach of relying on U.S. EPA (and CARB) staff review to identify strategies that are being used in lieu of appropriate robust emission controls is insufficient to catch all of the inappropriate implementations. Because of this issue, CARB recommends that U.S. EPA require standardized data to be stored onboard vehicles to track AECD activation that adversely impacts emissions so that the agency will be better informed as to the frequency, duration, and cumulative emission impact of such strategies even beyond those that trigger enrichment for component protection. Manufacturer-required collection and reporting of such data to the agency could also better ensure that all manufacturers are being held to a more consistent implementation and enable U.S. EPA to consider alternative regulatory approaches in the future such as setting maximum allowable activation limits for AECDs of concern. [EPA-HQ-OAR-2022-0829-0780, pp. 37-38]

Organization: Ferrari N.V. and Ferrari North America, Inc.

FERRARI POSITION

Among the new requirements introduced in EPA's proposal, Ferrari identified the following main challenges. [EPA-HQ-OAR-2022-0829-0572, pp. 4-5]

Fuel Enrichment Ban

EPA proposes to eliminate commanded enrichment for ICE-powered vehicles for component protection or power increase in any driving condition, considering it unnecessary for modern vehicles. However, Ferrari is deeply concerned by this statement, especially given the wide range of operation that EPA proposes to define as "normal". [EPA-HQ-OAR-2022-0829-0572, pp. 4-5]

The necessity of the enrichment strategy is strictly dependent on the driver power demand (e.g. towing conditions, rapid acceleration for safety purpose), aggressiveness of the driver (e.g. aggressive acceleration) and vehicle capabilities. Moreover, to address stricter GHG and CAFE Regulations, there has been a trend over the years to downsize and boost engines to reduce pumping losses. These improvements are achieved by operating an engine at very high specific output, relying on enrichment to control exhaust temperatures and protect engine and exhaust system components from damage. [EPA-HQ-OAR-2022-0829-0572, pp. 4-5]

This is even more true for high-performance vehicles with track capabilities. Our vehicles are designed to reach clients racetrack expectations to preserve Ferrari DNA, resulting in a very limited use well beyond the restrictions of the US Highway Code. Under these circumstances, the proposed ban of enrichment as protection strategy would inevitably lead to increased exhaust gas temperatures that would severely damage and compromise the engine and related emission control system. [EPA-HQ-OAR-2022-0829-0572, pp. 4-5]

Therefore, Ferrari suggests maintaining the current Auxiliary Emission Control Device (AECD) approach that leaves room for discussion on the need for enrichment as protection strategy. [EPA-HQ-OAR-2022-0829-0572, pp. 4-5]

Organization: Ford Motor Company

Second, to ensure the final rule does not go too far and too fast, especially in 2027 – 2029, the EPA should adjust two aspects of the proposal regarding criteria emissions: fuel enrichment and particulate matter testing obligations. Although fuel enrichment can lead to higher emissions during brief and infrequent conditions which are disclosed to the EPA, fuel enrichment has been critical for overall emissions reductions. The practice enables automakers to downsize engines while also meeting consumer needs for some of the toughest jobs, without compromising powertrain durability. Removing fuel enrichment, as EPA has proposed, will directly impact customers' acceptance of new products, especially trucks, and they may keep their existing vehicle longer or opt for a larger (i.e., higher emitting) vehicle to be sure they can get the job done. Major powertrain redesigns would be needed to recover this lost utility, and these are not possible within the timeframe defined by the enrichment phase-out proposed by EPA. Next, although Ford supports aspects of EPA's proposed particulate matter (PM) standards which will necessitate the use of gasoline particulate filters, the proposed PM standard will challenge current laboratory equipment and procedures. Ford requests that the EPA eliminate the need to measure PM on the -7°C FTP for vehicles that are equipped with gasoline particulate filters. [EPA-HQ-OAR-2022-0829-0605, p. 3]

Light- and Medium-Duty Fuel Enrichment [EPA-HQ-OAR-2022-0829-0605, pp. 12-13]

EPA is proposing to eliminate commanded enrichment for ICE-powered vehicles for power and component protection. Fuel enrichment protects engine components during infrequent and/or short duration high-power demand events, such as freeway on-ramps or towing on steep grades. The ability to employ limited commanded enrichment has allowed downsized engines to meet customer performance demands across a broad range of real-world driving condition, resulting in considerable CO2 savings. If left unmitigated, the elimination of commanded enrichment would result in performance degradations that would be unacceptable to most customers, forcing many to retain older models or to upgrade to larger, more capable vehicle classes. Either result would run counter to EPA's intention to reduce on-road emissions. [EPA-HQ-OAR-2022-0829-0605, pp. 12-13]

In order to meet customer needs without enrichment, Ford will need to implement expensive, long-lead time engine development actions, such as increasing component sizes (turbos and heat exchangers) and adding more expensive engine and manifold materials. Under the EPA proposal, this would need to be accomplished and during a timeframe when we are already stretching our capital and engineering resources to their limits in order to transition to electrification. The proposal would also not provide the lead-time needed to undertake such engine redesign programs. For these reasons, Ford does not consider the proposed phase-in for the enrichment prohibition to be feasible. For recommends that EPA shift the phase-in requirements to at least 2029MY for vehicles below 6,000lb GVWR. [EPA-HQ-OAR-2022-0829-0605, pp. 12-13]

[See original comment for Table 2: Ford Recommended Enrichment Phase-in] [EPA-HQ-OAR-2022-0829-0605, pp. 12-13]

Regarding EPA's proposed enrichment exception allowances under 40 CFR 86.1811-17(d)(2), Ford requests that EPA include the following additional conditions to account for sporadic pre- ignition and other potential future technologies that may be deemed acceptable for agency approval through the AECD review process: [EPA-HQ-OAR-2022-0829-0605, pp. 12-13]

- Temporary and infrequent enrichment following sporadic pre-ignition events (used to prevent follow-on events which are prone to causing engine damage), [EPA-HQ-OAR-2022-0829-0605, pp. 12-13]

- Enrichment conditions substantially demonstrated during emissions testing, or [EPA-HQ-OAR-2022-0829-0605, pp. 12-13]

- Enrichment conditions otherwise approved by the EPA. [EPA-HQ-OAR-2022-0829-0605, pp. 12-13]

Organization: Hyundai America Technical Center, Inc. (HATCI)

HMG opposes removal of commanded enrichment as an AECD [EPA-HQ-OAR-2022-0829-0554, p. 3]

EPA is proposing to eliminate the allowance of commanded enrichment as an AECD on spark ignition engines used in light-duty vehicles (LDV) and medium-duty vehicles (MDV) for either power or component protection during normal operation and use. Normal operation is defined at 40 CFR § 86.1803-01 to include vehicle speeds and grades of public roads and vehicle loading and towing within manufacturer recommendations, even if the operation occurs infrequently. Commanded enrichment includes lean best torque enrichment. EPA requested comment on the proposed prohibition of commanded enrichment as an AECD, including analyses of benefits and costs, and additional exceptions where brief rich operation should be allowed. [EPA-HQ-OAR-2022-0829-0554, p. 3]

HMG supports AFAI's public comment position to oppose enrichment prohibitions in the Proposed Rule. HMG appreciates the current Tier 3 enrichment exceptions allowed by the EPA and asks that all be included in the final rule. HMG believes EPA's proposed enrichment prohibitions will require the diversion of resources and time that would be better invested in the long-term goal of deploying 100% ZEVs in exchange for little short-term gain [EPA-HQ-OAR-2022-0829-0554, p. 3]

HMG believes exceptions for enrichment are needed for consumer-requested performance and vehicle component protection because excessive exhaust temperatures quickly damage the after-treatment system. The catalyst and sensors are critical for maintaining effective emission control shift conditions , pre ignition conditions, and excessive ignition timing retarding due to fuel condition. The shift conditions mentioned earlier refer to specific safety and performance conditions, including terrain, snow, towing, and climbing grades. During shifting and engine torque reduction, there is a concern about a rapid increase in exhaust temperature by retarding the ignition timing. Accordingly, HMG recommends the following specific exceptions: [EPA-HQ-OAR-2022-0829-0554, p. 3]

For the shift conditions, engine torque should be adjusted to reduce shift shock. In this case, ignition timing is retarded/adjusted to around 20-25 degrees for a fast response. The exhaust temperature rises by this control, and in order to prevent this, there is more fuel injected when the ignition timing is over delayed. [EPA-HQ-OAR-2022-0829-0554, p. 3]

Pre-ignition can damage an engine very quickly. When the knock sensor detects vibrations caused by pre ignition, additional fuel is injected as a countermeasure. This enrichment lowers temperature in the combustion chamber and stops the pre-ignition. [EPA-HQ-OAR-2022-0829-0554, p. 3]

The vehicle monitors for low-quality and low-octane fuel because it can easily cause knocking across the engine operating range. To prevent this, the timing is retarded, which increases exhaust temperature. [EPA-HQ-OAR-2022-0829-0554, p. 3]

Enrichment is used to counteract the rising temperature [EPA-HQ-OAR-2022-0829-0554, p. 3]

The EU has several upcoming regulations with enrichment provisions to be passed within the next few years, including Euro-6e (2024) and Euro 7 (2025). Euro-6e limits enrichment but allows for several exceptions including towing, uphill, and at very high speeds. Euro-7 eliminates enrichment completely with no exceptions, which more closely aligns with Tier-4. HMG is currently focused on meeting Euro- 6e. Further, compliance with EU regulations cannot be directly compared to Tier 4 given the difference between the EU and U.S. markets . R&D efforts and cost spent to meet Euro-6e or 7 cannot be used to justify Tier 4's elimination of enrichment because the Euro-6e engines being developed more closely align with Tier 3 requirements for enrichment, and thus would not be compliant with Tier 4. The Euro-7 engines to be developed will also not be transferable as the European market does not have the larger engines demanded by the U.S. market. [EPA-HQ-OAR-2022-0829-0554, pp. 3-4]

The Tier 4 proposed elimination of enrichment would also require a large amount of R&D, specific to the U.S. market and ICE vehicles. These added costs and resources will only result in potential short-term gain given the overall drive to ZEV development, and deployment and will undoubtedly impact the funding and resources available for ZEV development. HMG's goal is to prioritize ZEV development, but the proposed Tier 4 requirements will require sharing resources and funding between ICE and ZEVs, which will slow the ability to develop the long-term technologies necessary to fully transition to ZEVs. [EPA-HQ-OAR-2022-0829-0554, pp. 3-4]

Additionally, if the enrichment prohibitions are finalized, Tier 4's proposed durability requirements will be difficult to meet because enrichment is an important part of component protection. The Tier 4 proposed durability requirements for electric powertrain components and major emission control components is 8 years/100,000 miles. Component protection is needed to maintain integrity of after treatment hardware. Indeed, this is one of the main benefits of enrichment. Without additional enrichment exceptions, there are certain situations that will damage the catalyst, making it difficult for the vehicle to reach 100,000 miles before there are unnecessary costs associated with repairs and warranty claims. [EPA-HQ-OAR-2022-0829-0554, p. 4]

HMG supports AFAl's public comment position to oppose new enrichment prohibitions. HMG believes the proposed enrichment prohibitions would necessitate a large manufacturing investment, completely re-organizing new engine development, and result in rising costs that are not beneficial to our customers or the ultimate goal of 100% ZEV deployment. HMG also supports AFAl's recommendation to maintain the current AECD process to ensure emissions system durability, safe vehicle operation, and fundamental vehicle utility demanded by customers . HMG agrees with AFAl's recommendation that EPA gather data across a broad range of vehicles covered by this regulation to better understand the actual real-world impact on emissions and purported benefits, including the frequency of AECD commanded fuel enrichment. In addition, HMG believes it is necessary to set clear criteria for detailed test conditions about enrichment restriction. [EPA-HQ-OAR-2022-0829-0554, p. 4]

Organization: Kia Corporation

- Kia supports EPA continuing to allow Auxiliary Emission Control Devices (AECDs) for enrichment to satisfy our customers' requirements and maintain vehicle utility.4 Kia does not support EPA's proposal to eliminate commanded enrichment for ICE-powered vehicles for power and component protection. Elimination of enrichment will require a large amount of research and development specific to ICE vehicles in the U.S. market. [EPA-HQ-OAR-2022-0829-0555, p. 3]

4 88 Fed. Reg. 29,258.

Kia Supports Continuing to Allow Auxiliary Emission Control Devices

Kia does not support EPA's proposal to eliminate commanded enrichment for ICE-powered vehicles for power and component protection. Elimination of enrichment will require a large amount of research and development specific to ICE vehicles in the U.S. market. EPA must allow automakers to focus resources on the transition to EVs, not incremental emissions improvement to ICE vehicles. Kia proposes that the EPA continue to allow Auxiliary Emission Control Devices (AECDs) for enrichment to satisfy our customers' requirements and maintain vehicle utility.20 [EPA-HQ-OAR-2022-0829-0555, p. 12]

20 88 Fed. Reg. 29,258.

There are specific driving circumstances that enrichment is still needed for component protection such as challenging terrain or snow mode operation. automakers use enrichment only as needed and it is always reported as an AECD during certification. The conflicting need for higher efficiency and lower emissions comes as consumer demand for towing remains unchanged. [EPA-HQ-OAR-2022-0829-0555, p. 12]

Kia is concerned that derating the engine's performance in high load operations will prolong the use of older, less efficient, and higher emitting GHG and criteria emissions vehicles. Further, EPA's proposed prohibition on enrichment would encourage automakers to build larger displacement engines that could provide the capability needed by the vehicle, or the customer could just opt for a larger engine. This would be counterproductive as it could increase GHG and criteria emissions just to prevent minimal NMOG+NOx emission increases in limited circumstances. [EPA-HQ-OAR-2022-0829-0555, p. 12]

Organization: Mazda North American Operations

Criteria

Mazda anticipated some changes to EPA's light duty vehicle criteria emissions (i.e., NMOG, CO, NOx, PM) requirements, particularly to align with the new changes in the California Air Resources Board's (CARB) recent Advanced Clean Cars II regulation. However, we did not expect two of the new requirements included in the proposal: the reduction of the PM standard to 0.5 mg/mile, and the ban of enrichment during normal engine operation. [EPA-HQ-OAR-2022-0829-0595, p. 3]

Reducing the PM standard to 0.5 mg/mile is excessive. There was already considerable difficulty and effort put into meeting CARB's planned 1mg/mile PM standard, and there is still uncertainty that the 0.5 mg/mile standard will be measurable using current laboratory technology. It will also make it necessary to have all vehicles equipped with Gasoline Particulate Filters (GPF) and the resulting cost and development resources that come with new hardware. CARB evaluated the PM standards in its ACC II regulation and only reduced them to 1 mg/mile for the US06 cycle. While GPFs are required in some other markets, CARB set the standards with the intention that they would only be necessary for some limited cases. [EPA-HQ-OAR-2022-0829-0595, p. 3]

The enrichment ban will significantly impact the power and robustness of current internal combustion engines and Mazda strongly opposes it. This could force manufacturers such as Mazda to develop new engine designs, or to eliminate certain powertrain or vehicle designs entirely, making it even more difficult to remain profitable at a time when exceptional investment is needed to fuel the transition to EVs and to satisfy consumer needs. Controlling unnecessary or excessive enrichment is already sufficiently covered by EPA's existing AECD certification processes. [EPA-HQ-OAR-2022-0829-0595, p. 3]

Organization: Mclaren Automotive, McLaren Group

Enrichment

EPA is proposing to eliminate the use of commanded enrichment as an AECD on engines used in light-duty vehicles for either power or component protection during normal operation and use. [EPA-HQ-OAR-2022-0829-0748, pp. 4-5]

We appreciated the EPA requesting comment on the proposed prohibition of commanded enrichment including benefits and costs, and additional exceptions where brief rich operation should be allowed. As we have already outlined, our vehicles have exceptionally low mileage and that mileage is often not driven on public roads. Use cases of our vehicles compared to mass market is very different, given the high-performance nature of our cars that are often driven on private racetracks where they are driven outside of 'normal operation'. Enrichment in McLaren vehicles for power or component protection is a rare/exceptional occurrence which we do not expect to occur in normal driving conditions. Enrichment is essential in to protecting our high-performance engines in the exceptional limited circumstances in normal operation. [EPA-HQ-OAR-2022-0829-0748, pp. 4-5]

It should also be noted that supercars typically have a relatively small difference between curb weight and maximum gross weight, given that they are usually two-seaters, with very limited luggage capacity. As such, McLaren vehicles do not exhibit any significant difference in emissions control when in fully laden weight condition. [EPA-HQ-OAR-2022-0829-0748, pp. 4-5]

In addition, at present there are no viable technical alternatives to enrichment for deployment in lightweight high-performance supercars. Enrichment has enabled high-performance supercar engines to be downsized making them more efficient and emitting lower CO2. We believe that command enrichment should be allowed in high-performance supercars. [EPA-HQ-OAR-2022-0829-0748, p. 5]

We understand the concerns of the EPA and would therefore recommend that enrichment should be allowed in the following:

- having a power-to-weight (mass) ratio clearly indicative of high-performance (e.g., >## 250 bhp/ ton (based on curb weight) 2 [EPA-HQ-OAR-2022-0829-0748, p. 5]

2 Determine a vehicle's power-to-weight ratio by dividing the engine's rated power by the vehicle's GVWR (in hp/pound). If a test group includes multiple configurations, use the vehicle with the highest power-to-weight ratio to characterize the test group

Organization: MCS Referral & Resources (MCSRR)

At III.C.8, EPA "requests comment on the proposed prohibition of commanded enrichment as an AECD, including analyses of benefits and costs, and additional exceptions where brief rich operation should be allowed." [EPA-HQ-OAR-2022-0829-0615, p. 3]

EPA says it is "proposing to eliminate the allowance of the use of commanded enrichment as an AECD on SI engines used in light-duty vehicles and MDV for either power or component protection during normal operation and use. Normal operation is defined at 40 CFR 86.1803–01 to include vehicle speeds and grades of public roads, and vehicle loading and towing within manufacturer recommendations, even if the operation occurs infrequently." [EPA-HQ-OAR-2022-0829-0615, p. 3]

Regardless of whether EPA lowers the limits for CO emissions, the proposed prohibition of command enrichment as an AECD for power or component protection is appropriate and should be adopted. [EPA-HQ-OAR-2022-0829-0615, p. 3]

When AECDs are used during routine accelerations, they typically allow vehicles to release 10s to 100s of times more CO than when not in use. These CO emissions pose little risk to vehicle occupants, but in urban traffic, pedestrians, bicyclists, and motorcyclists may be repeatedly exposed to CO concentrations coming from the tailpipes of accelerating vehicles in the range of 100 to 1000 ppm, which is much higher than considered safe by the US EPA (9 ppm), US NIOSH (35 ppm), US OSHA (50 ppm), and US CPSC (70 ppm). [EPA-HQ-OAR-2022-0829-0615, p. 3]

Since "normal operation" is not actually defined at 40 CFR 86.1803-01, WE recommend that EPA define normal operation in this rule to include cold starts. Cold starts are expected, predictable, and common since they occur at least once every day that a non-EV vehicle is started. [EPA-HQ-OAR-2022-0829-0615, p. 3]

CO data from cold starts published by 3DATX in 2022 from a PEMS study of various makes of light-duty petrol and diesel vehicles tested in Sweden show several manufacturers are already making at least one model that achieves low CO emissions–under 500 ppm—throughout the entire cold start phase. These data are online at https://3datx.com/wp-content/uploads/3DATX_Enhanced-PTI-Pilot_Opus-Sweden_TimeSeries_221014.pdf. There is thus no technical need for EPA to exempt cold starts from CO emission limits. [EPA-HQ-OAR-2022-0829-0615, p. 3]

Organization: MECA Clean Mobility

Commanded enrichment should be phased-out for all MDVs. [EPA-HQ-OAR-2022-0829-0564, pp. 25-26]

MECA supports the elimination of commanded enrichment for all MDVs under the phased schedule proposed by EPA. Heavier medium-duty and heavy-duty gasoline vehicles can operate at higher loads and exhaust temperatures (i.e., due to towing) which can impact catalyst durability. Moving the catalytic converter closer to the exhaust manifold to improve cold start performance can result in increasing the time it is exposed to higher temperatures under higher load conditions. Manufacturers may use fuel enrichment modes to ensure cylinder head, exhaust manifold and catalyst temperatures are maintained below design durability thresholds. Using fuel enrichment to control catalyst temperature while effective, can cause significant increases in both criteria pollutant emissions and fuel consumption. [EPA-HQ-OAR-2022-0829-0564, pp. 25-26]

Catalyst manufacturers have continued to improve the thermal stability of supporting catalyst washcoats and performance of precious metal catalysts under higher exhaust temperatures that occur when converters are close coupled to reduce the need to employ fuel enrichment modes. Modern gasoline engines also have several design, calibration and advanced technologies that could be used to reduce the occurrence of higher exhaust temperatures by modifying combustion or load characteristics. Examples of engine-based technologies include exhaust gas recirculation (EGR), modified valve timing, electronic throttle airflow, cylinder heads with improved cooling and exhaust manifolds which are partially integrated into the cylinder head, and cooled exhaust manifolds. [EPA-HQ-OAR-2022-0829-0564, pp. 25-26]

In addition, engine down-speeding or governing of the engine operating range can reduce exhaust temperatures and the need to employ enrichment for thermal protection. This strategy will allow the emission controls to remain in stoichiometric air-fuel control (i.e. closed loop) where the catalysts can maintain peak emissions reduction efficiency for a broader range of operation. [EPA-HQ-OAR-2022-0829-0564, pp. 25-26]

Finally, it is possible to replace a close-coupled catalyst with an electrically heated three-way catalyst (EHC) or electric heater located in front of a three-way catalyst in a downstream location farther from the engine in order to protect it from thermal exposure during times of high engine load. These commercially-available technologies employ electrically generated heat to improve catalyst light-off, especially at cold start and times of low exhaust temperature. This configuration is further enabled by 48-volt system architectures described in more detail above. [EPA-HQ-OAR-2022-0829-0564, pp. 25-26]

In 2005, MECA applied some of the above-mentioned strategies to two full-sized 2004 pick-up trucks equipped with a 5.4L and 6.0L engine.35 The aftertreatment systems were packaged with dual-wall insulated exhaust systems and fully aged to represent 120,000 miles of real-world operation. Even with 15-year-old engine technology and limited engine calibration on one of the vehicles, both vehicles achieved FTP NMHC+NOx emissions of 60-70 mg/mile. Although the cast-iron exhaust manifolds on these vehicles were retained, an OEM likely would take advantage of such cost effective passive thermal management strategies, including dual-wall insulated exhaust or integrated exhaust manifolds, to further reduce cold-start emissions. [EPA-HQ-OAR-2022-0829-0564, pp. 25-26]

35 J. W. Anthony and J. E. Kubsh, SAE 2007-01-1261, 2007.

MECA would like to note that although the technology (described above) is ready, we support a phase-in of this requirement as many engine applications require component modifications that take time to industrialize and apply to market, including full consideration of durability and emission development. Therefore, retention of a phased approach consistent with the phase-in of other new requirements is appropriate. [EPA-HQ-OAR-2022-0829-0564, pp. 25-26]

Organization: Mercedes-Benz AG

EPA is proposing “to eliminate the allowance of the use of commanded enrichment as an AECD [Auxiliary Emissions Control Device] on SI [Spark Ignition] engines used in light-duty vehicles and MDV [Medium-Duty Vehicles] for either power or component protection during normal operation and use.”3 The EPA states that current vehicles use enrichment for component protection and to increase engine power, and that enrichment is no longer needed, because “[t]echnologies exist that can prevent thermal damage of engine and/or exhaust system components without the use of enrichment during normal operation and use (see DRIA Chapter 3 for technology discussion). Modern vehicles have sufficient power without the use of enrichment.”4 While today’s engines have made vast improvements, these assertions overstate the situation, and at the same time, lack important detail to ensure a level-playing field if this provision is finalized. [EPA-HQ-OAR-2022-0829-0623, pp. 6-7]

3 NPRM at 29197.

4 NPRM at 29277.

The EPA is proposing to allow enrichment only in a few select circumstances, namely:

1) engine start, [EPA-HQ-OAR-2022-0829-0623, pp. 6-7]

2) lambda dithering or slight lambda biasing to achieve optimal three-way catalyst (TWC) conversion efficiency of criteria emissions, [EPA-HQ-OAR-2022-0829-0623, pp. 6-7]

3) catalyst re-wetting after deceleration fuel cut off (DFCO), [EPA-HQ-OAR-2022-0829-0623, pp. 6-7]

4) brief lambda excursions during engine transients, [EPA-HQ-OAR-2022-0829-0623, pp. 6-7]

5) intrusive OBD monitoring of aftertreatment, evaporative canister purge valve, etc., and[EPA-HQ-OAR-2022-0829-0623, pp. 6-7]

6) in vehicle “limp-home” operation where the malfunction indicator light (MIL, commonly known as the “check engine light”) or other warning systems are triggered. [EPA-HQ-OAR-2022-0829-0623, pp. 6-7]

The agency should clarify these intended exceptions and also expand the list of allowable circumstances for the use of enrichment to include: [EPA-HQ-OAR-2022-0829-0623, pp. 6-7]

7) Confirm that lambda biasing in general is allowed for optimum emissions control, particularly before the catalyst has reached 400 deg F, and for engine operation at cold ambient temperatures below -15 deg F for stable combustion [EPA-HQ-OAR-2022-0829-0623, pp. 6-7]

8) Confirm that OBD-related enrichment is allowed, for example to account for the parallel diagnostic which checks for proper catalyst function and oxygen storage levels by running rich and lean briefly. [EPA-HQ-OAR-2022-0829-0623, pp. 6-7]

9) Extend allowable enrichment circumstances to allow for prevention of continued low speed pre-ignition that leads to severe knocking conditions that will result in catastrophic engine failures [EPA-HQ-OAR-2022-0829-0623, pp. 6-7]

These confirmations and additional allowance would permit calibrations for optimal emissions controls and component protection. They also ensure that allowable uses are more clearly defined and therefore provide more certainty when designing new engines to meet this provision; it is unlikely that current engines can or will meet this requirement without redesign. [EPA-HQ-OAR-2022-0829-0623, pp. 6-7]

Under EPA’s proposed enrichment restrictions, many engines will need to reduce power as soon as the temperature in the exhaust system is too high. Certification of power is currently voluntary in the United States. As a result, the question arises: how should net power be measured in the future? [EPA-HQ-OAR-2022-0829-0623, pp. 7-8]

A uniform measurement method is critical for net power determination:

- Ensures comparability for the customer [EPA-HQ-OAR-2022-0829-0623, pp. 7-8]

- Power of the engine influences pricing [EPA-HQ-OAR-2022-0829-0623, pp. 7-8]

- Provides a level-playing for automakers [EPA-HQ-OAR-2022-0829-0623, pp. 7-8]

European regulations currently require testing to the UN-R 85 6 steady-state test to determine the net engine power. There is a similar procedure, SAE J1349 7, which could provide the same level-playing field in the US. [EPA-HQ-OAR-2022-0829-0623, pp. 7-8]

SAE J1349 steady-state testing requires torque, speed and temperatures to be held substantially constant at multiple, different levels for at least one minute each. The diagram below depicts an example of how the test operates. [EPA-HQ-OAR-2022-0829-0623, pp. 7-8]

6 https://op.europa.eu/en/publication-detail/-/publication/44471446-bc46-44f0-bc97-0de997b18106/language- en.

7 https://www.sae.org/standards/content/j1349_201109/.

[See original for diagram on how the test operates] [EPA-HQ-OAR-2022-0829-0623, pp. 7-8]

If EPA adopts its proposal to eliminate enrichment, the agency should also add a requirement to test all internal combustion engine vehicles to SAE J1349 steady-state for declaration of net engine power. Any such requirement would, of course, add to testing burden across the entire industry and therefore be appropriately considered in any updated costs associated with this rulemaking. [EPA-HQ-OAR-2022-0829-0623, pp. 7-8]

§ 86.1809-12 Prohibition of Defeat Devices

As mentioned in the Enrichment section, EPA proposes to allow commanded engine enrichment in limp-home operation mode when the check engine light is on. This language forces a 1-trip failure, while OBD typically uses 2-trip Malfunction Indicator Light ("MILs"). [EPA-HQ-OAR-2022-0829-0623, p. 12]

Mercedes-Benz requests that EPA align their language with CARB OBD and change the requirement from "when check engine light is on" to "when OBD failure is present". This change will align with the OBD standard of a 2-trip MIL. [EPA-HQ-OAR-2022-0829-0623, p. 12]

Organization: Mitsubishi Motors North America, Inc. (MMNA)

6. Tier-4 criteria Pollutant Emissions

Mitsubishi echoes Auto Innovators' support for EPA's adoption of the California ACC II (i.e., LEV-IV) criteria test procedures and standards. [EPA-HQ-OAR-2022-0829-0682, p. 9]

Mitsubishi supports cost-effective reductions in criterial pollutant emission from Internal Combustion Engines (ICE). However, some of EPA's proposed changes to the criteria emission standards - like the more stringent Particulate Mass (PM) and NMOG+NOx requirements and the enrichment prohibition - go above and beyond those adopted by CARB in ACC II standards. If finalized as proposed, these changes would require OEMs to divert large resources in time and capital (resources that could otherwise be directed to accelerate EV technology deployment) towards further ICE technology development and additional testing facilities. Mitsubishi believes that allowing OEMs to focus their finite R&D investments on developing EV technologies, rather than having to continue to invest in technology that is being phased out, is the most effective way to reach our shared goal to transition to electrification. [EPA-HQ-OAR-2022-0829-0682, p. 9]

Organization: National Association of Clean Air Agencies (NACAA)

Criteria Pollutant Emission Standards and Related Issues

For reasons cited above, NACAA strongly supports EPA's proposal of more protective emission standards for non-methane organic gas (NMOG)+NOx and for PM. [EPA-HQ-OAR-2022-0829-0559, pp. 6-7]

The proposed 12-milligrams-per-mile (mg/mi) NMOG+NOx fleet average standard for LDVs, to be phased in by MY 2032, will reduce emissions by 60 percent relative to the existing 30-mg/mi (Tier 3) MY 2025 standard set in 2014. The proposed 60-mg/mi NMOG+NOx fleet average standard for MDVs, also to be phased in by MY 2032, will reduce emissions by 66 to 76 percent from the Tier 3 standards of 178 mg/mi for Class 2b vehicles and 247 mg/mi for Class 3 vehicles. EPA's proposed cold temperature (-7°C) NMOG+NOx standards will ensure that emissions are controlled over a wide range of operating conditions. [EPA-HQ-OAR-2022-0829-0559, pp. 6-7]

With respect to PM, EPA proposes a standard of 0.5 mg/mi for LDVs and MDVs, with a requirement that this standard be met across three duty cycles, including a cold-temperature (-7°C) cycle. Such a standard will appropriately drive the use of gasoline particulate filters, which are readily available. EPA projects that making these revisions to the standards set by the agency in the 2014 Tier 3 rule would reduce PM emissions from ICE vehicles by more than 95 percent and also yield reductions in toxic air pollutants. [EPA-HQ-OAR-2022-0829-0559, pp. 6-7]

NACAA also supports EPA's proposal to eliminate commanded enrichment as an auxiliary emission control device on ICE engines used in LDVs and MDVs. Commanded enrichment is an engine operation that overrides the engine management feedback control system by applying extra fuel in order to provide additional power or protect engine or exhaust system components, thereby producing very high levels of excess emissions. This strategy is deployed during normal operation and use (e.g., vehicle speeds, grades of public roads and vehicle loading and towing within manufacturer recommendations, even if the operation occurs infrequently). However, as EPA explains in the proposal," Technologies exist that can prevent thermal damage of engine and/or exhaust system components without the use of enrichment during normal operation and use Modern vehicles have sufficient power without the use of enrichment. [EPA-HQ-OAR-2022-0829-0559, pp. 6-7]

The use of enrichment only has the potential to incrementally increase power but significantly reduces the effectiveness of the catalytic aftertreatment system, resulting in a ten-fold or greater increase of CO and HC emissions."27 NACAA recommends that in addition to eliminating commanded enrichment EPA require that vehicle data related to enrichment be collected and analyzed. [EPA-HQ-OAR-2022-0829-0559, pp. 6-7]

Organization: Nissan North America, Inc.

Eliminating the commanded enrichment allowance for component protection will require new engine development without sufficient lead time. Automakers already understand the importance of minimizing the use of such commanded enrichment strategies and report the use of these strategies as part of their certification documentation. While the need for such strategies may be narrower, there are still legitimate circumstances in which enrichment is needed for component protection, particularly to maintain safe operation during high capacity use. To avoid significant engine de-rating without such strategies, a larger capacity engine would be needed. As a result, eliminating the narrow use of commanded enrichment for component protection could indirectly result in GHG and criteria pollutant emissions increases as larger engines would be needed to compensate. EPA should continue to allow manufacturers to use commanded enrichment for narrow component protection purposes so long as such use is disclosed in corresponding certification documentation, which is subject to EPA review. Nissan requests that EPA align with California's LEV IV exhaust and evaporative emission standards, allowing the industry to work towards a cohesive set of standards. Nissan also requests that EPA consider prioritization of the ultimate goal of electrification of the US fleet, allowing manufacturers to focus their resources on developing and rolling out safe, reliable, and affordable EVs. [EPA-HQ-OAR-2022-0829-0594, p. 7]

Organization: North American Subaru, Inc.

The NPRM also proposes to "eliminate commanded enrichment for ICE-powered vehicles for power and component protection." Enrichment is an infrequently occurring engine strategy to help improve engine performance at critical times when demanded by the driver and protects the engine from emission control degradation and/or component damage. The Proposed Rule suggests that enrichment is unnecessary and vehicles already have the capabilities to overcome the need for commanded enrichment. As noted In Auto Innovators comments, this is incorrect. Modern light-duty engines would require significant investment and development time to achieve EPA's proposal. Considering the transition away from ICE through heavy investment in EV production, this proposal is counter to the Administration intended, long-term goals. [EPA-HQ-OAR-2022-0829-0576, p. 2]

Organization: Porsche Cars North America (PCNA)

5. Porsche recommends continuity for current enrichment strategies.

Porsche recommends that EPA not adopt the proposal to broadly eliminate enrichment for Tier-4 vehicles. Porsche maintains the current approach used by industry and the agency to consider enrichment strategies within current certification processes should continue to be sufficient to provide the opportunity to review the appropriateness of commanded enrichment. Porsche, like many manufacturers, has evolved its powertrain offerings in response to greenhouse gas and fuel economy goals to adopt a range of highly charged, downsized engines that provide increased efficiency and customer demanded power. These highly charged, downsized motors continue to utilize enrichment to limit the potential for thermal damage from elevated exhaust temperatures. In addition, customers continue to demand increasing levels of performance and enrichment can enable customers to have their needs met with an efficient downsized engine rather than otherwise having to revert to larger, less efficient engines. [EPA-HQ-OAR-2022-0829-0637, pp. 11-12]

Porsche supports comments from the AFAI specific to this topic and provides additional information, found in Appendix- A (section marked confidential). This data illustrates that the potential opportunity for overall emissions reductions from eliminating enrichment may be very narrow given that the cumulative operation of sample vehicles driving under real- world conditions in which enrichment may be triggered is infrequent. Porsche recognizes that the data set is limited in the range of models and total trips and that the vehicles that were instrumented reflect European driving conditions. However, Porsche contends that the variation in overall driving conditions is not that significant, and that this data provides a reasonable proxy for expected US conditions. [EPA-HQ-OAR-2022-0829-0637, pp. 11-12]

Porsche recommends that EPA convene a test program to instrument vehicles in the US to gather similar data across a wider range of vehicle types, powertrains, and driving environments. The benefits of this broad data program would be to provide estimates on the overall opportunity for emissions reductions and to weigh this against the impacts of eliminating enrichment. Porsche contends that without such US specific data, it is unclear what the potential benefits may be against the potential negative side effects of increased cost, reduced power, and possible consumer backsliding on the adoption of downsized engines. [EPA-HQ-OAR-2022-0829-0637, pp. 11-12]

Porsche supports the position outlined in the AFAI comments regarding EPA’s arbitrary declaration that “Modern vehicles have sufficient power without the use of enrichment”. Most Porsche models marketed in the US are made available with an assortment of engines spanning a wide range of power options that customers can choose from. Porsche has been successful in the past several years in expanding the offering of high power, downsized engine options for our customers. These downsized engines are becoming increasingly prevalent within the overall sales mix as customers have responded positively to the balance of power and improved fuel economy. This trend has also been positive in contributing to improved greenhouse gas emissions and aligns with previous agency analysis that projected the benefits of highly charged downsized engines. [EPA-HQ-OAR-2022-0829-0637, pp. 11-12]

Porsche, like many manufacturers, is in the midst of a broad shift towards electrification. Developing new engineering solutions to achieve the goal of this proposal from EPA would be difficult to implement and not deliver significant emissions reductions relative to the cost and complexity. Porsche is concerned that consumers who continue to seek out combustion vehicles would reduce their consideration of downsized engine options if those engines are unable to meet the customers desired power level. The elimination of enrichment and the infrequent emissions benefits may outweigh the daily benefits of reduced GHG emissions and improved fuel economy from downsized engines if customers end up shifting back into larger displacement options. [EPA-HQ-OAR-2022-0829-0637, pp. 11-12]

6. Porsche seeks to clarify the intended scope of the proposed definition for ”Normal Operation” to reflect expected operation on US public roads.

Within the NPRM, EPA proposes to add the definition of “Normal Operation” to 86.1803-01. Porsche seeks to clarify the intended scope of this definition with respect to the conditions expected to be seen in US operation on public roads. In the preamble for the NPRM,3 EPA describes their intent to eliminate the use of commanded enrichment “during normal operation and use”. EPA then describes normal operation “…to include vehicle speeds and grades of public roads, and vehicle loading and towing within manufacturer recommendations, even if the operation occurs infrequently”. [EPA-HQ-OAR-2022-0829-0637, pp. 12-13]

3 88 FR 29277

Given the focus on enrichment, Porsche understands the reasoning from EPA to define more clearly the term “Normal Operation”. Porsche supports the term reflecting operation that can reasonably be expected on public roadways in the United States as described in the preamble. Specific to acceleration, Porsche recognizes that certain models may have acceleration capabilities that very quickly will approach speed limits for most US roadways. Porsche also recognizes that the maximum vehicle velocity for many models far exceeds the legal limits on most US highways. Many of the high acceleration and high-speed operation may only be used by customers on closed tracks or off-highway events. [EPA-HQ-OAR-2022-0829-0637, pp. 12-13]

Porsche seeks to clarify that the definition proposed for “Normal Operation” in 86.1803-01 is intended to reflect “vehicle speeds and grades of public roads”, meaning that the range of speeds and grades of US roadways would generally define boundary conditions on the new definition. The purpose for this clarification is related to the DRIA which seems to indicate a more expansive view than what is expressed by EPA in the preamble. In the DRIA, EPA states that the agency “…considers normal operation and use to include … driving at sustained high speeds, maximum acceleration at wide open throttle”. For example, Porsche would view the term “sustained high speeds” as referenced in the DRIA as indicating sustained high speeds on US roadways, not for example extreme speeds far in excess of legal limits that would likely only ever be seen on closed racing tracks. [EPA-HQ-OAR-2022-0829-0637, pp. 12-13]

To help with clarity, Porsche recommends that EPA modify the proposed definition for Normal Operation in 86.1811- 03 to include the following amendment to (3). [EPA-HQ-OAR-2022-0829-0637, pp. 12-13]

Normal operation means any vehicle operating modes meeting all the following conditions:

(3) Any ambient conditions during any season for operation at allowable vehicle speeds and grades commonly found on public roads in the United States [EPA-HQ-OAR-2022-0829-0637, pp. 12-13]

Organization: Stellantis

EPA Should Not Ban Enrichment or Set CO Standards Resulting in a Ban on Enrichment Thermal enrichment is a necessary strategy to maintain the utility and safe operation of nearly all ICE vehicles currently being sold today. This critical control strategy has also enabled the proliferation of more efficient (lower emitting) down-sized turbocharged engines in applications that have typically been dominated by large displacement powertrains – a technology transition EPA itself has driven and supports. An enrichment strategy enables as much as a 50% increase in engine output, enabling a much lower displacement engine with much greater efficiency to meet the needs of a vehicle typically equipped with a large displacement, lower efficiency V8. This strategy allows for significant emissions savings during every-day driving where the down-sized engine can meet driving demands easily, relying on enrichment only for the infrequent times significantly more capability is needed by the customer. [EPA-HQ-OAR-2022-0829-0678, p. 15]

Similarly, EPA proposes an infeasible US06 CO standard which is effectively a secondary ban on enrichment, as this CO standard can likely only be met at stoichiometric operation. [EPA-HQ-OAR-2022-0829-0678, p. 15]

By banning enrichment outright (and setting an overly stringent US06 CO standard), EPA is eliminating the feasibility of using highly efficient down-sized turbocharged engines in these larger, more capable vehicle applications and markets. This forces OEMs to either invent new technology or revert back to larger displacement, less efficient engines that cannot use enrichment for peak output. Due to GHG requirements, reverting to larger displacement naturally aspirated engines is not possible. EPA should continue to allow enrichment enabled by the existing and robust AECD process and collect data to better understand if and where further emissions benefits could be gained by constraining (vs. banning) enrichment without compromising the progress industry has made, with any future changes being phased in over an adequate lead time to industry. We agree with Auto Innovators that the proposed prohibition on commanded enrichment is inappropriate. [EPA-HQ-OAR-2022-0829-0678, p. 15]

EPA Should Adopt Stringent CARB ACCII LEV IV Criteria Emissions Standards

Stellantis fully supports AAI's comments and the recommendation to align to CARB ACC II LEV IV criteria emissions requirements. EPA should either adopt or align with California's stringent ACCII LEV IV criteria requirements, avoiding the unnecessary development of all new technology to apply to a shrinking ICE fleet (distracting from EV focus). As highlighted in the examples above, the California standards still provide significant improvements over EPA's Tier 3 standards. EPA must also continue to allow enrichment for component protection which is critically needed for continued use of highly efficient downsized turbocharged powertrains and avoid PM requirements that mandate development of all-new GPF systems and/or extraneous new testing. [EPA-HQ-OAR-2022-0829-0678, pp. 16-17]

Avoid a wholesale prohibition on enrichment – whether by design requirement or unrealistic CO threshold – and continue to allow infrequent enrichment that enables proliferation of highly efficient down-sized engines to displace larger and much less efficient powertrains (a GHG and emission reduction strategy endorsed by the EPA) [EPA-HQ-OAR-2022-0829-0678, pp. 24-25]

Organization: Volkswagen Group of America, Inc.

Enrichment (Section III.C.8)

Normal Operation Definition: “normal operation” in 40 CFR §86.1803-01 [EPA-HQ-OAR-2022-0829-0669, pp. 6-8]

It is Volkswagen’s concern that the NPRM recognizes an implied definition for normal vehicle operation. The NPRM states that normal operation is defined in 40 CFR 86.1803-01 and is further described to include vehicle speeds and grades of public roads, and vehicle loading and towing within manufacturer recommendations, even if the operation occurs infrequently. [EPA-HQ-OAR-2022-0829-0669, pp. 6-8]

EPA’s proposed definition of “normal” operation drastically changes the calibration and engine design requirements for manufacturers. As shown in the 4-cylinder Small Compact, Compact and Midsize SUV engine maps, the vehicles already use their maximum potential in terms of power output to meet customer demands and GHG requirements at the same time. Broadening the definition of “normal” to include infrequent operation with elimination of fuel enrichment will result in engine power loss and loss of vehicle utility to the customer. As noted in the AFAI comments, this could potentially require larger engine displacements, which is counterproductive to the goal of reduced emissions and GHG. Based on recent measurements on Portable Emission Measurement Systems (PEMS) including test routes in LA (city, highway, and hard effort Mount Baldy), the graphs below represent the findings and use of enrichment on production vehicles. [EPA-HQ-OAR-2022-0829-0669, pp. 6-8]

Small Compact SUV

Compact SUV

SEE ORIGINAL COMMENT FOR Cumulative run duration to total duration (%)

Mid-Size SUV

SEE ORIGINAL COMMENT FOR Cumulative run duration to total duration (%) [EPA-HQ-OAR-2022-0829-0669, pp. 6-8]

As referenced by the EPA DRIA, a light-heavy duty gasoline spark-ignited (SI) engine operating over the Supplemental Engine Test had shown only a 4% reduction in power when enrichment was disabled. This is not the same when compared to a light-duty downsized turbocharged vehicle. Light-duty vehicle utility will be greatly affected and may realize up to a 20% power reduction in some cases. [EPA-HQ-OAR-2022-0829-0669, pp. 6-8]

The popularity of SUVs as all-purpose family vehicles, which are typically used for daily commuting, results in infrequent heavy-load towing operational use. Most families do not have the resources to own a specialized vehicle for occasional heavy-load towing. Decreased engine power on smaller displacement engine vehicles would decrease vehicle utility (e.g., trailer towing) in a way that customers would either keep driving their old cars as long as possible or upgrade to a larger, but less fuel efficient, displacement engine. Neither option benefits the environment. [EPA-HQ-OAR-2022-0829-0669, pp. 6-8]

Enrichment for Smaller-Volume Vehicles

Volkswagen consists of iconic brands, which span from our popular utility "People's Car" to the exotic supercars featured by brands Audi, Lamborghini, Bentley and Bugatti. These supercars are fully compliant to the requirements for on-road use; however, the enthusiast customer base may utilize these vehicles in a track environment. Datasets show that while catalyst protection and power enrichment is not demonstrated on regulated cycles and normal driving, extreme off-road/track usage results in significant need to protect the catalysts for compliance when re- entering the roadways. The removal of the enrichment zones for these vehicles would require technologies, which have yet to be demonstrated for production use and may require more adjustable parameters (e.g., water injection) than currently productionized. [EPA-HQ-OAR-2022-0829-0669, pp. 6-8]

Organization: Volvo Car Corporation (VCC)

Enrichment

VCC supports the EPA proposal to prohibit fuel enrichment for any type of performance increase or component protection. This prohibition will eliminate any unnecessary pollution where the catalyst will be unable to operate at its best due to unnecessary rich air/fuel ratio. And, there is available technology to achieve the EPA proposed enrichment requirements. [EPA-HQ-OAR-2022-0829-0624, p. 2]

EPA Summary and Response

Summary:

EPA received many comments regarding the proposed elimination of command enrichment. Most vehicle manufacturers commented in opposition to the proposal and noted the significant impact that the elimination of enrichment might have on the designs of their existing powertrains. CARB, NACAA, and MECA all commented in support of the proposed elimination of enrichment.

Vehicle manufacturers commented that enrichment is used judiciously and within the bounds of the current AECD provisions. They also commented that there are no alternatives to enrichment in many current powertrain designs. Manufacturers also noted that one alternative to enrichment would be to increase engine displacement which could potentially increase CO2 emissions. Honda commented that EPA's proposal would create a conflict between our proposed PM standards and the elimination of enrichment, noting that enrichment would be required under some circumstances to regenerate gasoline particulate filters. Several manufacturers also commented on EPA's definition of "normal operation" and provided recommendations regarding how normal operation should be defined.

One vehicle manufacturer, Volvo Car Corporation, supported EPA's proposal to eliminate command enrichment and noted, "This prohibition will eliminate any unnecessary pollution where the catalyst will be unable to operate at its best due to unnecessary rich air/fuel ratio. And, there is available technology to achieve the EPA proposed enrichment requirements."

Comments from Mercedes-Benz AG noted, "While today's engines have made vast improvements, these assertions overstate the situation, and at the same time, lack important detail to ensure a level-playing field if this provision is finalized." Mercedes included comments regarding the specific conditions for when rich operation might be allowed, even within a broader prohibition and made recommendations on how a level playing field might be achieved within the industry.

CARB commented in support of the elimination of command enrichment and supported EPA's conclusion that control technologies do exist that would eliminate the need for enrichment as a means of protecting powertrain components. CARB also noted that vehicle manufacturers could make different design decisions when developing powertrains: "CARB also agrees the elimination of enrichment for engine component protection would better ensure that manufacturers, despite U.S. EPA and CARB prohibitions, are not using such strategies to protect frail designs in lieu of using more robust components that can better withstand the temperatures and exhaust environment." CARB also agreed with EPA that enrichment does result in significantly higher emissions and "can occur in some routinely encountered in-use conditions." CARB recommended that "… U.S. EPA require standardized data to be stored onboard vehicles to track AECD activation that adversely impacts emissions so that the agency will be better informed as to the frequency, duration, and cumulative emission impact of such strategies even beyond those that trigger enrichment for component protection."

NACAA commented similarly to CARB in its support for the elimination of command enrichment. They stated, "The use of enrichment only has the potential to incrementally increase power but significantly reduces the effectiveness of the catalytic aftertreatment system, resulting in a ten-fold or greater increase of CO and HC emissions. NACAA recommends that in addition to eliminating commanded enrichment EPA require that vehicle data related to enrichment be collected and analyzed."

MECA also commented in support of the elimination of enrichment and confirmed EPA's conclusions that "Examples of engine-based technologies include exhaust gas recirculation (EGR), modified valve timing, electronic throttle airflow, cylinder heads with improved cooling and exhaust manifolds which are partially integrated into the cylinder head, and cooled exhaust manifolds."

<u>Response:</u>

EPA thanks all the commenters that provided their relative positions in support of and in opposition to the proposed restrictions on command enrichment. EPA recognizes both the potential substantial environmental benefits of reducing or eliminating enrichment as well as the substantial level of effort that would be required by vehicle manufacturers to eliminate enrichment in many of their current powertrain designs. While EPA stands by its initial assessment that there are many more options available to vehicle manufacturers other than enrichment to protect powertrain components, we also recognize that these control alternatives could potentially result in a reduction in available engine power and/or a deterioration in vehicle drivability in certain current vehicle designs. In their efforts to reduce CO_2 emissions, vehicle manufacturers have made design decisions in their ICE powertrains that have resulted in the need for command enrichment for component protection, with CARB noting that vehicle manufacturers have adopted designs that require “strategies to protect frail designs in lieu of using more robust components that can better withstand the temperatures and exhaust environment.” Comments from MECA and Volvo also confirm EPA’s initial assessment. The comments from Mercedes further show that enrichment can be reduced or even eliminated with additional collaboration between vehicle manufacturers and EPA. Despite the potential for significant emission reductions as the result of eliminating enrichment, EPA has decided not to finalize any new provisions for the control of enrichment as part of this final rule. At this time the agency will continue to rely on existing requirements for Auxiliary Emission Control Devices (AECD) to ensure that vehicle manufacturers use AECD in a manner dictated by the existing AECD process.

EPA plans to revisit this issue, potentially in a future rulemaking, as outlined in Preamble III.D.8. EPA recognizes the value of tracking AECD usage, as recommended by both CARB and NACAA, and will consider a monitoring provision as we consider potential future controls on enrichment.

4.1.7 - Averaging, banking, and trading provisions

Comments by Organizations

Organization: American Fuel & Petrochemical Manufacturers

And even for criteria pollutants emitted from ICEVs, the Clean Air Act says nothing about averaging across fleets or banking and trading credits across different model years, different vehicle classes, and OEMs. While EPA previously adopted fleetwide averaging, it has also acknowledged that “Congress did not specifically contemplate an averaging program when it enacted the Clean Air Act.”91 And “[j]ust as the statute does not explicitly address EPA’s authority to allow averaging, it does not address the Agency’s authority to permit banking and trading.”92 By definition, then, the Act does not address—let alone clearly authorize—the use of averaging, banking, and trading in a manner that mandates electrification of the national vehicle fleet of motor vehicles and motor vehicle engines. Instead, as EPA acknowledges, even if its authority to use averaging, banking, and trading could be inferred, such programs are limited to compliance flexibilities rather than setting the standards with which vehicles must comply or phasing out ICEVs on a national scale.93 [EPA-HQ-OAR-2022-0829-0733, p. 23]

91 48 Fed. Reg. 33,456, 33,458 (July 21, 1983)

92 54 Fed. Reg. 22,652, 22,665 (May 25, 1989); see 55 Fed. Reg. 30,584, 30,593 (July 26, 1990) (same).

93 Proposed Rule at 29,196-97 (describing averaging, banking, and trading provisions as “help[ing] manufacturers to employ a wide range of compliance paths”).

Organization: Valero Energy Corporation

a) The statutory structure confirms EPA lacks statutory authority to use fleetwide averaging to mandate ZEVs.

EPA’s proposal would require electrification by setting average emission standards for manufacturers' nationwide fleets and "averaging" in more and more zeros to represent the electric vehicles it wants to see in future years. Manufacturers that exceed the standards may bank credits and trade them to other manufacturers that fall short. [EPA-HQ-OAR-2022-0829-0707, pp. 78-80]

EPA relies on NRDC v. Thomas, 805 F.2d 410 (D.C. Cir. 1986), for the proposition that it is authorized to average vehicles. That case found EPA could average a manufacturer’s different engine families. Id. at 425. It did so, however, with some caveats. First, its reasoning was based on a deference to EPA’s interpretation of the statute “in the absence of clear evidence Congress meant to prohibit averaging.” This standard, of course, is directly contrary to the standard applicable in this case in which EPA is proposing regulations that affect a major question—clear Congressional authority to permit averaging to mandate electric vehicles. Second, the parties failed to raise a textual argument against averaging. Id. at n.24 (“Although it was not raised by any party before the agency, and accordingly cannot be dispositive here … there is an additional argument against emissions averaging. The Act’s testing and certification provision, 42 U.S.C. § 7525 [Link: https://1.next.westlaw.com/Link/Document/FullText?findType=L&pubNum=1000546&cite=42USCAS7525&originatingDoc=I80714eef94d311d9a707f4371c9c34f0&refType=LQ&originationContext=document&transitionType=DocumentItem&ppcid=0591cc222593448083058c4608d3c583&contextData=(sc.UserEnteredCitation)], speaks of ‘any,’ ‘a,’ or ‘such’ motor vehicle or engine being tested and certified. With averaging, some vehicles or engines would not be required to comply with the standards and would not be subject to NCPs for failing to so comply. This practice appears inconsistent with the requirement that ‘any,’ ‘a,’ or ‘such’ vehicle or engine be tested and required to comply with emissions standards.”). [EPA-HQ-OAR-2022-0829-0707, pp. 78-80]

On the other hand, EPA has previously acknowledged that the Act is silent on the mechanisms of averaging, banking, and trading (ABT). When EPA first adopted fleetwide averaging, it recognized that "Congress did not specifically contemplate an averaging program when it enacted the Clean Air Act." 48 Fed. Reg. 33,456, 33,458 (July 21, 1983). And "[j]ust as the statute does not explicitly address EPA's authority to allow averaging, it does not address the Agency's authority to permit banking and trading." 54 Fed. Reg. 22,652, 22,665 (May 25, 1989); see 55 Fed. Reg. 30,584, 30,593 (July 26, 1990) (same). By definition, then, the Act does not address—let alone clearly authorize—the use of averaging, banking, and trading to electrify the Nation's vehicle fleet. [EPA-HQ-OAR-2022-0829-0707, pp. 78-80]

That should be the end of the analysis. Section 202 of the Clean Air Act does not itself "direct [conventional vehicles] to effectively cease to exist." West Virginia, 142 S. Ct. at 2612 n.3. EPA has instead relied on mechanisms that are not themselves spelled out in the statute and that have never before been used to mandate LD and MD electric vehicles. Just as in West Virginia, EPA has nothing "close to the sort of clear authorization" necessary for such a transformational policy shift. 142 S. Ct. at 2614. [EPA-HQ-OAR-2022-0829-0707, pp. 78-80]

But in truth, the problem is far worse for EPA than that. As explained below, the Act unambiguously precludes fleetwide-average emission standards under Section 202(a). And even if the statute permitted some fleetwide averaging, it does not allow EPA to take the additional step of incorporating non-emitting vehicles into emission averages and thus forcing the market toward electric vehicles. The proposal is not merely stretching vague statutory language. It is defying clear statutory text. [EPA-HQ-OAR-2022-0829-0707, pp. 78-80]

The text and structure of Section 202, and of Title II more broadly, unambiguously require that emission standards under Section 202(a) apply to individual vehicles, not manufacturers' fleets on average. EPA claims to find authority for fleetwide averaging in Section 202(a), which authorizes EPA to issue "standards applicable to the emission of any air pollutant from any class or classes of new motor vehicles ... which in [its] judgment cause, or contribute to, air pollution which may reasonably be anticipated to endanger public health or welfare." 42 U.S.C. § 7521(a). [EPA-HQ-OAR-2022-0829-0707, pp. 78-80]

On its face, that provision authorizes EPA to set standards for vehicles that emit harmful air pollutants. It says nothing about averaging across fleets. As noted, when EPA first adopted fleetwide averaging, it acknowledged that "Congress did not specifically contemplate an averaging program when it enacted the Clean Air Act." 48 Fed. Reg. at 33,458. EPA claimed to have the authority because the Act "does not explicitly preclude standards" based on averaging. 54 Fed. Reg. at 22,666 (emphasis added). EPA was wrong. "[T]he broader context of the statute as a whole," Robinson v. Shell Oil Co., 519 U.S. 337, 341 (1997), makes clear that Section 202(a) does not permit fleetwide averaging. And, even if EPA could somehow show that the statute tacitly or implicitly allows (or does not expressly preclude) averaging, that would still be insufficient to meet the necessary clear congressional authority to use fleetwide averaging as a means to force a transition from internal-combustion engines to ZEVs. [EPA-HQ-OAR-2022-0829-0707, pp. 78-80]

a. Other provisions in Section 202 demonstrate that emission standards may not be based on averaging.

Title II is replete with provisions that necessarily apply to vehicles individually, not to fleets on average. That is evident first in the emission standards prescribed by Section 202 itself. For example, in Section 202(b), the Act sets forth specific light-duty vehicle emission standards that EPA must promulgate in "regulations under" Section 202(a). 42 U.S.C. § 7521(b). For vehicles in model years 1977 to 1979, the standards must provide that "emissions from such vehicles and engines may not exceed 1.5 grams per vehicle mile of hydrocarbons and 15.0 grams per vehicle mile of carbon monoxide." Id. § 7521(b)(l)(A). [EPA-HQ-OAR-2022-0829-0707, pp. 80-81]

Those provisions require that the "regulations under [Section 202(a)]" apply to "vehicles and engines," not "vehicles and engines on an average basis across a fleet." Construing those provisions to allow averaging would, in effect, add words to the statute that change its meaning. Neither courts nor agencies may "supply words ... that have been omitted." Antonin Scalia & Bryan Garner, Reading Law: The Interpretation of Legal Texts 93 (2012); accord Rotkiske.v. Klemm, 140 S. Ct. 355, 360-361 (2019). And supplying the extra words "on average" would have a significant substantive effect: "roller coaster riders must be 48 inches tall" means something very different from "roller coaster riders must be 48 inches tall on average." [EPA-HQ-OAR-2022-0829-0707, pp. 80-81]

The testing requirements accompanying the Section 202(b) standards confirm that those standards apply to all vehicles. In particular, EPA must "test any emission control system incorporated in a motor vehicle or motor vehicle engine ... to determine whether such system enables such vehicle or engine to conform to the standards required to be prescribed under

[Section 202(b) of the Act]." 42 U.S.C. § 7525(a)(2). If the system complies, EPA must issue a "verification of compliance with emission standards for such system." Id. Those requirements plainly contemplate standards that apply to individual vehicles and their emission-control systems. Not only does the statutory text frame the inquiry as whether an individual "vehicle" or "engine" conforms to the emission standards, but the provision's foundational premise-that an emission-control system can enable a vehicle to meet emission standards depends on individually applied standards. [EPA-HQ-OAR-2022-0829-0707, pp. 80-81]

Other parts of Section 202 further demonstrate that emission standards under Section 202(a) cannot rely on averaging. Section 202(b)(3), for example, authorizes EPA to grant waivers from certain nitrogen-oxide emission standards—which, again, are standards "under" Section 202(a), see 42 U.S.C. § 7521(b)(l)(B)—for no "more than 5 percent of [a] manufacturer's production or more than fifty thousand vehicles or engines, whichever is greater." Id. § 7521(b)(3). This provision would be nonsensical under a fleetwide-averaging regime. It contemplates a default under which every vehicle meets a standard, then gives manufacturers a waiver from that default for up to 5% of the fleet. But under fleetwide averaging, no waiver is needed. Instead, a vast proportion of a manufacturer's fleet—perhaps 50% or more— effectively has a "waiver" so long as a sufficient number of vehicles outperform the standard. Likewise, Section 202(g), which specifies an increasing "percentage of each manufacturer's sales volume" of each model year's vehicles that must comply with specified emission standards, is fundamentally incompatible with averaging. Id. § 7521(g)(l). [EPA-HQ-OAR-2022-0829-0707, pp. 80-81]

Similarly, under Section 202(m), EPA must require manufacturers to install on "all" new light-duty vehicles and trucks "diagnostic systems" capable of identifying malfunctions that "could cause or result in failure of the vehicles to comply with emission standards established under this section." Id. § 7521(m)(l). As this requirement makes clear, individual vehicles must "comply with emissions standards established under [Section 202]." Id. Otherwise, requiring diagnostic equipment on "all" vehicles makes no sense. In a fleetwide-averaging regime, this requirement would be pointless, as the deterioration or malfunction of an individual vehicle's emission-related systems would provide virtually no information about whether the fleet as a whole is compliant. [EPA-HQ-OAR-2022-0829-0707, pp. 80-81]

b. Title II's compliance and enforcement provisions for emission standards confirm that EPA cannot use fleetwide averaging.

Fleetwide averaging also clashes with "the design and structure of [Title II] as a whole." Utility Air, 573 U.S. at 321 (citation omitted). Title II sets forth a comprehensive, interlocking scheme for enforcing emission standards through testing, certification, warranties, remediation, and penalties. Fleetwide-average standards are incompatible with these provisions, which are "designed to apply to" individual vehicles and "cannot rationally be extended" to fleets. Id. at 322. [EPA-HQ-OAR-2022-0829-0707, pp. 81-82]

Testing and Certification. Under Title II, EPA must "test, or require to be tested in such manner as [it] deems appropriate, any new motor vehicle or new motor vehicle engine submitted by a manufacturer to determine whether such vehicle or engine conforms with the regulations prescribed under [Section 202]." 42 U.S.C. § 7525(a)(l). If the "vehicle or engine conforms to such regulations," EPA must issue the manufacturer a "certificate of conformity." Id. EPA may later test a manufacturer's vehicles and engines, and if "such vehicle or engine does not conform with such regulations and requirements, [EPA] may suspend or revoke such certificate insofar as it applies to such vehicle or engine." Id. § 7525(b)(2)(A)(ii). A manufacturer may not sell a vehicle or engine not "covered by a certificate of conformity." Id. § 7522(a)(l). [EPA-HQ-OAR-2022-0829-0707, pp. 81-82]

Fleetwide averaging is incompatible with these requirements in at least two respects. First, by using the singular terms "vehicle" and "engine," along with "any" and "such," the statute contemplates that individual vehicles may be tested, determined to "not conform" with the standards, and have their certificates of conformity suspended or revoked. In a fleetwide-averaging regime, testing an individual vehicle or engine does not enable EPA to determine whether it "conforms with the regulations prescribed under [Section 202]," 42 U.S.C. § 7525(a)(l), because conformity turns not on an individual vehicle's emissions but on the fleet's average performance overall. Second, fleetwide averaging also makes it impossible to determine compliance with applicable emission standards before a vehicle is sold, as required to obtain the certificate of conformity needed for a sale. See 42 U.S.C. § 7522(a)(l). Under fleetwide-average standards, a vehicle's "conform[ity] with the regulations prescribed under [Section 202]" cannot be determined until the manufacturer calculates its production-weighted average at "the end of each model year," when the manufacturer knows the quantity and model of "vehicles produced and delivered for sale." 40 C.F.R. §§ 86.1818-12(c)(2)(2), 86.1865-12(i)(l), (j)(3). [EPA-HQ-OAR-2022-0829-0707, pp. 81-82]

For similar reasons, fleetwide averaging is inconsistent with the statutory definition of an "emission standard," which "limits the quantity, rate, or concentration of emissions of air pollutants on a continuous basis." 42 U.S.C. § 7602(k). It is impossible to know on a "continuous basis" whether a manufacturer's fleet complies with EPA's proposed average standards, because a manufacturer cannot calculate its production-weighted average until the end of the year. Simply put, an after-the-fact compliance regime is incompatible with the Act's testing and certification scheme. [EPA-HQ-OAR-2022-0829-0707, pp. 81-82]

c. The broader text and history of Title II confirm that the rule exceeds EPA’s authority through fleetwide averaging.

Other indicia of statutory meaning demonstrate that the proposed rule exceeds EPA's statutory authority under Section 202(a). Elsewhere in Title II, Congress showed that it knew how to legislate with respect to "average annual aggregate emissions." 42 U.S.C. § 7545(k)(l)(B)(v)(II) (directing EPA to take certain actions if "the reduction of the average annual aggregate emissions of toxic air pollutants in a [designated district] fails to meet" certain standards). [EPA-HQ-OAR-2022-0829-0707, pp. 83-84]

Thus, "if Congress had wanted to adopt an [averaging] approach" for motor vehicle standards under Section 202(a), "it knew how to do so." SAS Inst., Inc. v. Iancu, 138 S. Ct. 1348, 1351 (2018); see Rotkiske, 140 S. Ct. at 360-361 ("Atextual judicial supplementation is particularly inappropriate when, as here, Congress has shown that it knows how to adopt the omitted language or provision."). It did not choose that approach in Section 202(a). [EPA-HQ-OAR-2022-0829-0707, pp. 83-84]

The Energy Policy Conservation Act, enacted just two years before the 1977 Clean Air Act amendments, reinforces that conclusion. There, Congress directed the Secretary of Transportation to issue regulations setting "average fuel economy standards for automobiles manufactured by a manufacturer" in a given model year. 49 U.S.C. § 32902(a). That Congress has not used similar language in Section 202(a) of the Clean Air Act is a "telling clue" that the Act does not permit fleetwide averaging. Epic Sys. Corp. v. Lewis, 138 S. Ct. 1612, 1626 (2018). [EPA-HQ-OAR-2022-0829-0707, pp. 83-84]

The Clean Air Act's history also reflects Congress's understanding that emission standards would apply to all vehicles individually. Congress was so focused on reducing emissions at the level of the individual vehicle that, in the 1970 amendments, Congress permitted EPA to test any individual vehicle as it comes off the assembly line. See Pub. L. No. 91-601, § 8, 84 Stat. 1676, 1694-1696. Such a vehicle-by-vehicle test was meant to supplement the pre-1970 testing of prototypes. Congress explained that while testing of prototypes "will continue," "tests should require each prototype rather than the average of prototypes to comply with regulations establishing emission standards." H.R. Rep. No. 91-1146, at 6 (1970). And if Congress forbade averaging across prototypes, it certainly did not permit averaging across entire fleets. [EPA-HQ-OAR-2022-0829-0707, pp. 83-84]

d. Related provisions confirm that Section 202(a) does not authorize averaging of non-emitting electric vehicles.

Other provisions of the Clean Air Act drive home the lack of statutory authorization to mandate electrification as well. In the Clean Air Act Amendments of 1990, Congress spoke directly to the phase-in of electric vehicles on America's roads. Congress instructed EPA to establish standards for "clean-fuel vehicles" operating on "clean alternative fuel," including "electricity." Pub. L. No. 101-549, § 229, 104 Stat. 2399, 2513 (codified at 42 U.S.C. §§ 7581(2), (7), 7582(a)). Congress required that certain areas of the country with the worst pollution would have to "phase-in" a "specified percentage" of "clean-fuel vehicles" using "clean alternative fuels" (defined to include "electricity") in certain fleets. 42 U.S.C. § 7586; see id. § 758l(a). The 1990 amendments highlight that Congress knows how to clearly establish standards that apply to electric vehicles, and to directly require that such vehicles be phased into a particular fleet. But Congress chose to do so only on a targeted, regional basis. The contrast between the 1990 amendments and Section 202(a) highlights the absence of any statutory authority for EPA's rule. [EPA-HQ-OAR-2022-0829-0707, p. 84]

Other related statutes also suggest the same. In the Energy Policy Act of 1992, Congress directed NHTSA to set fuel-economy standards based on averages, but prohibited NHTSA from setting fuel-economy standards that average in the fuel economy of electric vehicles. See Pub. L. No. 102-486 §§ 302, 403, 106 Stat. 2776, 2870-2871, 2876 (later codified at 49 U.S.C. § 32902(h)). This prohibition bars NHTSA from doing exactly what EPA is doing here: misusing its regulatory authority to force a transition from conventional vehicles to electric vehicles by artificially tightening the "average" standard a fleet must meet. Of course, when Congress finalized the language of Section 202(a)(l) in 1977, it had no need to explicitly block EPA from considering electric vehicles, because it did not contemplate that EPA would set emission standards using averaging in the first place (or that EPA would be setting standards for greenhouse gases). The prohibition on NHTSA nevertheless underscores just how far EPA is reaching here: it is straining statutory language to seize a power that Congress expressly denied to a sister agency that actually has authority to promulgate fleetwide-average standards. [EPA-HQ-OAR-2022-0829-0707, p. 84]

e. EPA’s lack of authority for a credit-trading scheme further confirms its lack of authority to set fleetwide averages.

The proposal’s credit banking and trading program is critical to EPA's electrification mandate. But the agency also lacks authority under Title II to establish a credit scheme as part of its emission standards under Section 202(a). [EPA-HQ-OAR-2022-0829-0707, pp. 84-86]

As with fleetwide averaging, EPA has previously acknowledged that Title II says nothing about banking and trading credits in connection with motor-vehicle emission standards. See 54 Fed. Reg. at 22,665. What EPA has ignored, however, is that Title II is not silent regarding banking and trading in other contexts. Indeed, in multiple other provisions under Title II, Congress expressly authorized the use of bankable and tradable credits. See, e.g., 42 U.S.C. § 7545(k)(7) (reformulated gasoline credits); § 7545(o)(2)(A)(ii)(II)(cc), (5)(A)(i) (renewable fuel credits); id. § 7545(o)(2)(A)(ii)(II)(cc), (5)(A)(ii) (biodiesel credits); id. § 7545(o)(2)(A)(ii)(II)(cc), (5)(A)(iii) (small refineries credits); id. § 7586(f) (clean- fuel fleet-operator credits); id. § 7589(d) (California pilot test program's clean-fuel vehicle manufacturer credit). [EPA-HQ-OAR-2022-0829-0707, pp. 84-86]

Under EPA's proposed approach, those provisions would all be superfluous, because EPA already had the discretion to adopt a credit-trading regime for any program. If Congress had wanted to permit credits in connection with emission standards under Section 202(a), it knew how to and would have done so expressly. See SAS Inst., 138 S. Ct. at 1351. [EPA-HQ-OAR-2022-0829-0707, pp. 84-86]

For all these reasons, courts have cast substantial doubt on EPA's authority to set fleetwide-average emission standards. As the D.C. Circuit Court of Appeals explained in NRDC v. Thomas, 805 F.2d 410 (D.C. Cir. 1986), the "engine specific thrust" of Title II's "testing and compliance provisions" is evident both in Congress's choice to "spea[k] of 'any,' 'a,' or 'such' motor vehicle or engine" in the text of the statute and in the "troubling" legislative history recounted above. Id. at 425 n.24. The arguments were not dispositive in Thomas only because the parties there had failed to present them. Id. But the Court nevertheless recognized that the arguments were relevant to "future proceedings." Id.. [EPA-HQ-OAR-2022-0829-0707, pp. 84-86]

f. At a minimum, EPA may not use fleetwide averaging to require electrification.

Despite the absence of statutory authorization for fleetwide averaging, EPA has long employed that mechanism without significant industry pushback. That is likely because fleetwide averaging has generally been offered as an accommodation to regulated parties, allowing them flexibility that the statute does not in fact permit. In its current proposal, however, EPA is not offering an extrastatutory accommodation. It is taking an additional step away from the statutory text by using fleetwide averaging to mandate electrification. [EPA-HQ-OAR-2022-0829-0707, pp. 84-86]

To be clear, in prior rules EPA set an average emission standard and allowed manufacturers to make some vehicles that emitted more and some that emitted less. Here, EPA has set tailpipe emission standards at a level so stringent that manufacturers must incorporate an increasing percentage of LD and MD electric vehicles—which EPA treats as zero-emission vehicles—into their averages in order to comply with the "standards." See p. 13, supra. Put differently, the agency is proposing an emission standard that is artificially low because it incorporates electric vehicles, which EPA treats as emitting zero pollutants for averaging purposes. [EPA-HQ-OAR-2022-0829-0707, pp. 84-86]

Whatever the permissibility of fleetwide averaging, the text and structure of Title II make plain that EPA cannot manipulate averaging as a means to force production of an increasing market share of electric vehicles. Section 202 does not grant EPA the power to make the internal-combustion engine go the way of the horse and carriage. At the very least, Section 202 is hardly clear in granting that awesome power—which is what matters under West Virginia. For automobiles as for power plants, EPA has purported to discover in the Clean Air Act the authority to "forc[e]" manufacturers to "cease making" a particular type of energy "altogether." 142 S. Ct. at 2612. We have seen that play recently before, and it should end the same way. [EPA-HQ-OAR-2022-0829-0707, pp. 84-86]

Penalties. Finally, EPA' s fleetwide-averaging regime is inconsistent with the statute's penalty provision. Under Section 205, any violation "shall constitute a separate offense with respect to each motor vehicle or motor vehicle engine," with each offense subject to its own civil penalty of up to $25,000. 42 U.S.C. § 7524(a) (emphasis added). Under EPA's approach, however, no individual vehicle or engine violates the applicable standard, only the fleet as a whole. The statute provides no method for calculating penalties when a fleet fails to meet its fleetwide-average standard-because it does not authorize fleetwide-average standards. [EPA-HQ-OAR-2022-0829-0707, p. 83]

EPA Summary and Response

Summary:

EPA received a number of comments regarding EPA's authority to adopt standards with averaging, banking and trading (ABT) from stakeholders including the American Fuel and Petrochemical Manufacturers (AFPM) and Valero Energy Corporation.

Response:

For EPA's complete response on EPA's authority to adopt standards with ABT, refer to Section 2 of this document.

4.1.8 - MDV criteria emissions certification requirements

Comments by Organizations

Organization: California Air Resources Board (CARB) (Part 1 of 5)

Feasibility of Proposed Medium-duty Vehicle Emission Levels

Based on U.S. EPA's analysis, medium-duty vehicles under 22,000 lbs. GCWR consist mainly of vans and gasoline trucks, and U.S. EPA certification data shows that 75 percent of 2022 and 2023 MY gasoline vehicles were already below 120 mg/mi. For CARB's ACC II regulations, as part of the Initial Statement of Reasons, Appendix H, ACC II LEV Technology Appendix, CARB had shown FTP NMOG+NOx certification data for the 2021 MY medium-duty vehicles in both classes. 43 CARB's assessment is similar to U.S. EPA's analysis, which shows many gasoline medium-duty vans have emission levels under 120 mg/mi. Because many gasoline medium-duty vehicles are already at levels close to meeting both standards and many light-duty vehicles, some of which use similar or the same engines, are also at or below these levels, it is clear that the technology exists for manufacturers to clean up their higher emitting vehicles and bring their emission levels closer to the lower emitting vehicles. Additionally, as the fleet average emission standard declines over time, it will likely allow manufacturers to introduce improvements across their conventional fleet concurrent with scheduled redesigns or updates to their models in a resource-efficient manner. [EPA-HQ-OAR-2022-0829-0780, p. 32]

43 CARB. ACC II ISOR. Appendix H: ACC II LEV Technology Appendix, p. H-44. Available at: https://ww2.arb.ca.gov/sites/default/files/barcu/regact/2022/accii/apph.pdf.

Conclusion

While CARB's LEV IV fleet average standard and U.S. EPA's proposed standards are structured differently, precluding side-by-side comparisons, CARB has determined based on the above analysis that the proposed standards are similar in stringency for the same category of conventional vehicles. Because these vehicles are required to meet similar emission levels in both programs, manufacturers would be able to use the same technologies to meet both standards. Additionally, many gasoline medium-duty vehicle test groups are close to or already emitting under 120 mg/mi, which allows manufacturers to make minimal changes to their gasoline fleets while focusing on increasing deployment of zero-emission technology in their fleets to meet both CARB and U.S. EPA requirements. As discussed previously, CARB also notes that the requirements under CARB's ACT and ACF regulations are promoting technological advancement of medium-duty ZEVs, providing a strong foundation for U.S. EPA's ZEV projections. CARB supports U.S. EPA's proposed standard, which will ensure conventional medium-duty vehicles continue to make modest improvements to their emission control systems and rely on ZEVs in combination with their cleaner conventional medium-duty vehicles to meet the proposed fleet average standard. [EPA-HQ-OAR-2022-0829-0780, pp. 32-33]

Organization: Cummins Inc.

Tier 3 credits from high GCWR MDV should carry over into the HD engine program

In contrast to the proposals for averaging, banking, and trading (ABT) for light-duty vehicles and low GCWR MDV, EPA has not proposed any opportunities for transferring non-methane organic gases (NMOG) + NOx credits (or debits) from the Tier 3 program into the HD engine program for high GCWR MDV vehicles. Manufacturers already certifying in the HD engine program likely have developed their engine compliance strategies, including use of ABT, for MY 2027 and later HD engines without knowledge of EPA's proposal to move high GCWR MDV into the same program. With no mechanism to carry pre-existing Tier 3 credits rightfully earned by high GCWR MDV into the engine program, and no mechanism to earn early credits on engine-dynamometer certified high GWCR MDV, manufacturers looking to smooth the transition to new standards may be forced to use engine credits already earmarked for other HD engines. There is also a level playing field concern where manufacturers with a broader product line which includes both high and low GCWR MDV would still get the benefit of using their Tier 3 high GCWR MDV credits for Tier 4 early compliance of their low GCWR MDV, but for manufacturers whose product line consists of only high GCWR MDV, those Tier 3 credits would be forfeited. [EPA-HQ-OAR-2022-0829-0645, pp. 8-9]

There are precedents in past regulations which could inform the conversion of Tier 3 credits into credits for the HD engine program, such as converting non-methane hydrocarbons (NMHC) + NOx credits to NOx credits via a discount factor and adjusting for different emissions useful life periods. EPA should consider this history and create a pathway for Tier 3 credits from high GCWR MDV to transfer into the HD engine program. [EPA-HQ-OAR-2022-0829-0645, pp. 8-9]

Cummins supports fungibility of high GCWR MDV NOx credits in the appropriate HD engine averaging set.

If EPA finalizes the requirement for high GCWR MDV to certify criteria pollutant emissions in the HD engine program, Cummins supports allowing those engines to participate in the 40 CFR Part 1036 ABT program within the appropriate averaging set with other HD engines. [EPA-HQ-OAR-2022-0829-0645, pp. 8-9]

VIII. Stronger GHG and Criteria Pollutant Standards for Medium-Duty Vehicles Are Feasible.

We now turn to EPA's proposed emission standards for medium-duty vehicles. Below, we examine the combustion vehicle and zero-emission technologies that can further reduce GHG emissions from the medium-duty fleet, comment on EPA's modeling, address economic considerations, and make suggestions on certain aspects of EPA's regulatory program. We also offer recommendations for the Tier 4 NMOG+NOx standards and PM requirements. As detailed below, strong GHG and criteria pollutant emission standards for MDVs are feasible and cost-reasonable. [EPA-HQ-OAR-2022-0829-0759, p. 64]

3.EPA's proposed change to criteria pollution requirements for MDVs with a gross combined weight rating of more than 22,000 pounds is likely appropriate, but should be monitored for manipulation and efficacy. [EPA-HQ-OAR-2022-0829-0759, p. 77]

EPA is proposing to require that vehicles with a GCWR greater than 22,000 pounds be certified to the heavy-duty engine standards, rather than to the proposed MDV standards.212 EPA's logic here is sound: these vehicles' powertrains are often more powerful than the Class 4 and Class 5 vehicles in which related engines may be deployed, and they have a GCWR comparable to vehicles currently covered by the heavy-duty engine rules. [EPA-HQ-OAR-2022-0829-0759, p. 77]

212 88 Fed. Reg. at 29257.

Table VIII.B-1. Market share of MDVs above and below the 22,000-pound gross combined weight rating213[EPA-HQ-OAR-2022-0829-0759, p. 77]

[See original attachment for Table VIII.B-1.].

213 Taken from EPA OMEGA2 modeling inputs: vehicles_mdv_20230208.csv (MY 2020 MDV fleet).

MY 2020 data indicates that this change could require more than half of the MDV fleet to certify to the heavy-duty engine standards (Table VIII.B-1).214 Based on the emissions and warranty requirements for such engines, certifying the engines in these MDVs to such standards will likely yield emissions reductions at least as strong as if they were instead required to meet the proposed MDV standards. However, these standards apply solely to combustion engines and are not influenced by the share of deployed ZEVs. [EPA-HQ-OAR-2022-0829-0759, p. 78]

214 In the Proposal, EPA notes: "Based on an analysis of the MY 2022 and MY 2023 emissions certification data, most MDV complete and incomplete diesel pickup trucks would be required to switch to engine dynamometer certification; MY 2022 vans would not be required to use engine dynamometer certification; and only a small number of gasoline pickup trucks would be required to switch to engine certification." 88 Fed. Reg. at 29270. However, the data are not provided.

In contrast, ZEV deployment affects the required emissions reductions for medium-duty combustion vehicles with a GCWR less than or equal to 22,000 pounds, as illustrated above in Section VIII.B.1. It is possible that manufacturers could try to shift more of their sales to vehicles with a GCWR over 22,000 pounds in order to reduce the required improvements to their remaining combustion fleet. If this change is finalized, the Agency should monitor future data from the MDV and heavy-duty engine in-use testing program to assess the nature of any difference between the emissions performance of MDVs above and below the 22,000-pound GCWR, and should commit to releasing a report on its findings. [EPA-HQ-OAR-2022-0829-0759, p. 78]

Organization: MECA Clean Mobility (MECA)

Commercially Available Technologies Support Tighter Medium Duty Standards

Both gasoline and diesel engines feature prominently amongst medium duty vehicles which often share many attributes and powertrain platforms also certified as light- duty trucks or medium duty passenger vehicles. MECA would highlight that the proposed MDV Class 2b and Class 3 NMOG+NOx fleet averages of SULEV150 (Class 2b: 8500 to 10,000lbs) and SULEV175 (Class 3: 10,000 to 14,000lbs) still reflect fleet averages of 5 to almost 6 times higher than that proposed for light duty trucks and SUVs <8500lbs, as well as medium duty passenger vehicles. This despite the fact that Class 2b and 3 vehicles have gross vehicle weights that are equivalent to no more than 18% to 65% heavier. [EPA-HQ-OAR-2022-0829-0564, pp. 12-24]

Regarding Class 2b and 3 gasoline-fueled vehicles, MECA's review of available EPA FTP NMOG+NOx certification data,17 shown in Table 2, [See original comment for Table 2. EPA Certified Levels of Class 2b and 3 Medium-Duty Vehicles] indicates ranges in certification level value (corresponding to the actual test results combined with the deterioration factors) of 9 to 192 mg/mile (average ca. 92 mg/mile) for Class 2b and 74 to 120 mg/mile (average ca. 102 mg/mile) for Class 3. [EPA-HQ-OAR-2022-0829-0564, pp. 12-24]

17 US EPA Light-Duty Vehicle Certification Database, https://www.epa.gov/compliance-and-fuel-economy- data/annual-certification-data-vehicles-engines-and-equipment

Our review of available EPA FTP certification data for Class 2b and 3 diesel-fueled vehicles finds current reported ranges in certification level value (corresponding to the actual test results combined with the deterioration factors) of 113 to 180 mg/mile (average ca. 147 mg/mile) for Class 2b and 136 to 190 mg/mile (average ca. 163 mg/mile) for Class 3 vehicles. [EPA-HQ-OAR-2022-0829-0564, pp. 12-24]

Given the proportional vehicle weights, reported NMOG+NOx certification values of best-in-class performers, as well as the need to provide further air quality benefits, MECA believes gasoline and diesel fueled medium-duty vehicles are capable of complying with the lower NMOG+NOx standards proposed by EPA. Furthermore, the removal of the highest certification bins (i.e., >160 mg/mile NMOG+NOx) will provide significant emission benefits by removing the highest emitting vehicles from the fleet. [EPA-HQ-OAR-2022-0829-0564, pp. 12-24]

With respect to proposed PM standards for medium-duty vehicles, MECA supports EPA's proposed limits that match light-duty vehicles. The combination of advanced fuel injection and gasoline particulate filters on medium-duty gasoline vehicles can enable compliance with proposed standards. Based on over 15 years of experience with diesel emission controls, medium-duty diesel vehicles that implement DPFs will be able to meet the stringent PM requirements proposed in this rule. [EPA-HQ-OAR-2022-0829-0564, pp. 12-24]

Medium-duty vehicles with Gasoline Engines

Historically, spark-ignition engine FTP tests have shown that the majority of NMHC, CO, and NOx emissions occur during the cold start phase; however, emissions during warmed-up and hot operation, specifically during high-load operation, can also significantly contribute to emissions, especially with heavier MD and HD vehicles. There are a variety of measures that can be utilized on spark-ignition gasoline engines to further reduce emissions. [EPA-HQ-OAR-2022-0829-0564, pp. 12-24]

Engine Mapping and Calibration

In order to comply with lower NMOG+NOX and PM emissions standards over certification cycles such as the FTP, US06, SC03, and LA92, manufacturers will employ improved engine maps and calibration strategies of existing engines and emission control related systems. Other design changes to system architecture can be deployed to manage engine-out emissions and exhaust flows, reduce catalyst light-off times, increase exhaust temperatures during periods of low-load or idle and reduce excessive warmed-up and hot running emissions to protect engine and emission control components which are susceptible to deterioration from extended exposure to severe exhaust temperatures. [EPA-HQ-OAR-2022-0829-0564, pp. 12-24]

Exhaust Emission Control Technologies

Several emission control choices can be made to improve and optimize emission control performance. For gasoline engines, the technology base of advanced three-way catalysts deposited on high cell density (as high as 1200 cells/in2), thin-walled substrates (approaching 0.05mm) have evolved dramatically for light- and medium-duty chassis certified vehicles to comply with Tier 3/LEV 3 standards. Recent advances have yielded high porosity, low thermal mass substrates with narrow pore size distributions, which enable high emission reduction efficiency with less precious metal loading.18,19 Catalyst manufacturers have also developed coating techniques based on layered or zoned architectures to strategically deposit precious metals in ways that optimizes their performance and cost. These advanced catalysts are then packaged using specially designed matting materials and passive thermal management strategies which can be used to allow chassis certified medium-duty trucks to meet the stringent Tier 3 emission fleet average limit of 30 mg/mile or approximately 100 mg/bhp-hr. [EPA-HQ-OAR-2022-0829-0564, pp. 12-24]

18 T. Asako, D. Saito, T. Hirao and E. Popp, SAE 2022-01-0543.

19 J. Warkins, T. Tao, M. Shen and S. Lyu, SAE 2020-01-0652.

Reducing Cold Start Emissions

Close-coupled catalyst exhaust architectures (with or without a secondary underfloor converter) have been used on light-duty vehicles starting with Tier 2 LDV standards and are an effective strategy for addressing cold-start or low-load operation. [EPA-HQ-OAR-2022-0829-0564, pp. 12-24]

Secondary air injection can also be used to accelerate catalyst activation under cold-start conditions in spark ignition engines. Using a richer air/fuel ratio via intake air throttling, retarding fuel injection, or post combustion in-cylinder fuel additions during the exhaust stroke while injecting air directly into the exhaust port of the engine, results in excess fuel combustion within the exhaust manifold, creating additional heat that results in increasing catalyst temperatures to achieve faster catalyst light-off. These strategies can also be coupled with exhaust gas recirculation. [EPA-HQ-OAR-2022-0829-0564, pp. 12-24]

Spark-ignition engines that employ a richer cold start calibration used in combination with a secondary air injection system experience improved combustion stability. In addition, the richer calibration is less sensitive to variations in fuel volatility since less volatile fuels may lead to poor start and idle performance on engines calibrated to run lean during cold operation20,21 (Serrano, et al., 2009) (Lee & Heywood, 2010). [EPA-HQ-OAR-2022-0829-0564, pp. 12-24]

20 Serrano, D., Lavy, J., Kleeman, A., Zinola, S., Dumas, J., Le Mirronet, S., & Heitz, D., SAE 2009-01-2706.

21 Lee, D., & Heywood, J., SAE 2010-01-2124.

In support of the Tier 3 light-duty regulation,22 EPA tested a 2011 LDT4 pick-up truck with a 5.3L V8 engine that included a MECA supplied aftertreatment system. The aftertreatment package consisted of advanced catalyst coating on 900 cpsi substrates in the close-coupled location as well as underfloor catalysts and was aged to 150,000 miles. The system was combined with cylinder deactivation and achieved an FTP NMHC+NOx level of 18 mg/mile. We believe that these same technology approaches can be deployed on medium-duty gasoline engines to meet more stringent emission levels than those being currently proposed. [EPA-HQ-OAR-2022-0829-0564, pp. 12-24]

22 https://www.epa.gov/regulations-emissions-vehicles-and-engines/proposed-rule-and-related-materials-control-air-pollution

Medium-duty Vehicles with Diesel Engines

With regards to diesel engine emissions, MECA members have been developing and commercializing a full suite of technologies to help medium and heavy-duty engine manufacturers to comply with the MY 2027 heavy-duty engine standards and these technologies can be readily applied to medium-duty chassis certified vehicles as well. Exhaust and emission control technologies include next generation close coupled and under chassis selective catalytic reduction (SCR), oxidation and diesel soot ignition catalysts with high porosity, low thermal mass substrates with heated catalyst and urea dosing strategies. These can be combined with engine thermal management strategies such as cylinder deactivation and advanced forms of turbocharging and EGR. These technologies already exist on some passenger car applications in Europe where real driving emission test procedures demand them. We further elaborate on these technologies below. [EPA-HQ-OAR-2022-0829-0564, pp. 12-24]

Cylinder Deactivation and Variable Valve Actuation

Cylinder deactivation (CDA) is an established technology on light-duty gasoline vehicles, with the primary objective of reducing fuel consumption and CO_2 emissions. This technology combines hardware and software computing power to, in effect, “shut down” some of an engine’s cylinders, based on the power demand, and keep the effective cylinder load in an efficient portion of the engine map without burning more fuel. Based on decades of experience with CDA on gasoline passenger cars and trucks, CDA is now being adapted for diesel engines. On a diesel engine, CDA is programmed to operate differently than on gasoline engines, with the goal of the diesel engine running hotter in low-load situations by having the pistons that are firing do more work. This programming is particularly important for vehicles that spend a lot of time in creep and idle operation modes. During low-load operation, CDA has resulted in exhaust temperatures increasing by 50°C to 100°C when it is most needed to maintain effective conversion of NOx in the selective catalytic reduction (SCR) catalyst bed. In some demonstrations, CDA has been combined with a 48V mild hybrid motor with launch and sailing capability to extend the range of CDA operation over the engine, and this may deliver multiplicative CO_2 reductions from these synergistic technologies.23 [EPA-HQ-OAR-2022-0829-0564, pp. 12-24]

23 https://www.meca.org/wp-content/uploads/resources/MECA_2027_Low_NOx_White_Paper_FINAL.pdf

The use of variable valve actuation (VVA) is another approach for active thermal management. VVA approaches include: early exhaust valve opening (EEVO), early intake valve closing (EIVC) or late intake valve closing (LIVC), all considered active thermal management strategies. Both EIVC and LIVC reduce the amount of air trapped at valve closing. Both methods reduce the effective compression ratio and volumetric efficiency, resulting in lower NOx emissions and reduced air-fuel ratio, and in turn, hotter exhaust temperature. EEVO results in hotter exhaust gas to heat-up aftertreatment; however, more fueling is needed to maintain brake power output. This results in a CO_2 emissions penalty that must be accounted for in calibrating for better fuel economy and higher engine-out NOx during hot operation when the SCR can be used to remediate NOx emissions. VVA offers some potential cost savings and is therefore used in some medium- duty applications as a fast heat-up strategy. OEMs will have multiple pathways at varying costs to achieve their thermal management objectives and achieve ultra-low NOx emissions in low-load and low-speed operation. [EPA-HQ-OAR-2022-0829-0564, pp. 12-24]

Modern Turbochargers

Modern turbochargers have a variety of available design options enabling lower CO_2 emissions by improving thermal management capability, such as: i) state of the art aerodynamics, ii) electrically-actuated wastegates that allow exhaust gases to by-pass the turbocharger to increase the temperature in the aftertreatment, and iii) advanced ball bearings to improve transient boost response. These and other technologies are available to support further reductions in CO_2 and other emissions. More advanced turbochargers are designed with a variable nozzle that adjusts with exhaust flow to provide more control of intake pressure and optimization of the air-to-fuel ratio for improved performance (e.g., improved torque at lower speeds) and fuel economy. These variable geometry turbochargers (VGT), also known as variable nozzle turbines (VNT) and variable turbine geometry (VTG), also enable lower CO_2 emissions through improved thermal management capability to enhance aftertreatment light-off. Finally, modern turbochargers have enabled engine and vehicle manufacturers the ability to downsize engines, resulting in fuel savings without sacrificing power and/or performance. The latest high-efficiency turbochargers are one of the more effective tools demonstrated in the DOE SuperTruck program.24 In addition to affecting the power density of the engine, turbochargers play a significant role in NOx and CO2 regulations compliance. Continuous improvement in turbocharger technology is making it possible to run very lean combustion (high air/fuel ratios), which increases efficiency. This improvement allows for very low particulate generation and even lower engine-out NOx. [EPA-HQ-OAR-2022-0829-0564, pp. 12-24]

Turbo-compounding

Turbo-compounding is a variant of turbocharger technology that allows for the energy from the exhaust gas to be extracted, converted to mechanical or electrical energy and either mechanically added to the engine crankshaft through a transmission or stored electrically for opportunistic use in other driving conditions. Mechanical turbo- compounding has been employed on some commercial diesel engines, and EPA estimated penetration to reach 10% in the U.S. by the time the Phase 2 GHG Regulation is fully implemented in 2027.25 An early 2014 version of a turbo-compound-equipped engine was used during the first stage of testing at SwRI under the HD Low NOx Test Program, and the results from this engine with advanced aftertreatment have been summarized in several SAE technical papers.26,27,28 While turbo-compounding has the potential to reduce fuel consumption, it can result in lower exhaust temperatures that can challenge aftertreatment performance. Therefore, it is important to consider turbo-compound designs that incorporate bypass systems during cold start and low load operation or electrically driven turbo-compounding systems where the unit can be placed after the aftertreatment system. [EPA-HQ-OAR-2022-0829-0564, pp. 12-24]

Driven Turbochargers

Driven turbochargers can be used to control the speed of the turbomachinery independently of the engine's exhaust flow and vary the relative ratio between engine speed and turbo speed. Driven turbochargers may be utilized for several reasons, including performance, efficiency, and emissions. Considered an 'on-demand' air device, a driven turbocharger also receives transient power from its turbine. During transient operation, a driven turbocharger will behave like a supercharger and consume mechanical or electrical energy to accelerate the turbomachinery for improved engine response. At high-speed operation, the driven turbocharger will return mechanical or electrical power to the engine in the form of turbo-compounding, which recovers excess exhaust power to improve efficiency. This cumulative effect lets a driven turbocharger perform all the functions of a supercharger, turbocharger, and turbo-compounder. NOx emission control uniquely benefits from the application of driven turbochargers in several ways, including the ability to decouple EGR from boost pressure, reduce transient engine-out NOx, and improve aftertreatment temperatures during cold start and low load operation. Bypassing a driven turbine can provide quick temperature rises for the aftertreatment while still delivering the necessary boost pressure to the engine through supercharging, which also increases the gross load on the engine to help increase exhaust temperature.29 Testing has shown that routing engine exhaust to the aftertreatment by bypassing a turbocharger is one of the most effective methods to heat up the aftertreatment.30 [EPA-HQ-OAR-2022-0829-0564, pp. 12-24]

Hybridization

Mild Hybridization

48-volt mild hybrid electrical systems and components are expected to make their way onto commercial diesel vehicles in the near future. These 48-volt systems can be found on many light-duty vehicle models (primarily in Europe) from Mercedes, Audi, VW, Renault and PSA. In the U.S., Stellantis is offering a 48-volt system on the RAM 1500 pick- up and the Jeep Wrangler under the eTorque trademark. Because the safe voltage threshold is 60 volts, which is especially important when technicians perform maintenance on the electrical system, 48-volt systems are advantageous from an implementation standpoint. From a cost perspective, 48-volt systems include smaller starter and wire gauge requirements, offering cost savings from a high voltage architecture of a full hybrid. The U.S. Department of Energy's SuperTruck II program teams employed 48-volt technologies on their vehicles to demonstrate trucks with greater than 55% brake thermal efficiency. A recent study demonstrated through model-based simulations that a 48-volt technology package combined with advanced aftertreatment can achieve a composite FTP emission level of 0.015 g/bhp-hr.31 [EPA-HQ-OAR-2022-0829-0564, pp. 12-24]

31 F. Dhanraj, M. Dahodwala, S. Joshi, E. Koehler, M. Franke and D. Tomazic, 2022-01-0555.

Similar to the passenger car fleet, truck OEMs are considering replacing traditionally mechanically-driven components with electric versions to gain efficiency. Running accessories off 48-volt electricity rather than 12-volts is more efficient due to reduced electrical losses and because components that draw more power, such as pumps and fans, have increased efficiency when operating at higher voltages. The types of components that may be electrified include, electric turbos, electronic EGR pumps, AC compressors, electrically heated catalysts, electric cooling fans, oil pumps and coolant pumps, among others. Another technology that 48-volt systems could enable is electric power take-offs rather than using an engine powered auxiliary power unit or idling the main engine during hoteling while the driver rests. MECA members supplying commercial 48V components for commercial vehicles believe that the technology may be feasible to apply to a limited number of engine families by 2024, and it is likely to see greater penetration by 2027, especially on Class 8 line-haul where full hybridization is less practical. [EPA-HQ-OAR-2022-0829-0564, pp. 12-24]

Mild hybridization covers a range of configurations, but a promising one includes an electric motor/generator, regenerative braking, electric boost and advanced batteries. Stop/start deployment also provides a thermal management benefit to the aftertreatment by preventing cooling airflow through the aftertreatment during hot idle conditions. In this way, 48-volt mild hybridization is complementary technology to CDA and start-stop capability, allowing the combination of multiple technologies on a vehicle to yield synergistic benefits and justify the cost. By shutting off the engine at idle or motoring using start/stop, micro hybrid technology can help to maintain aftertreatment temperature by avoiding the pumping of cold air through the exhaust. Capturing braking energy and storing it in a small battery for running auxiliary components when the engine is off offers another CO2 reducing strategy for OEMs to deploy. [EPA-HQ-OAR-2022-0829-0564, pp. 12-24]

In lighter medium-duty applications, advanced start-stop systems have been developed that use an induction motor in a 48-volt belt-driven starter-generator (BSG). When the engine is running, the motor, acting as a generator, will charge a separate battery. When the engine needs to be started, the motor then applies its torque via the accessory belt and cranks the engine instead of using the starter motor. The separate battery can also be recharged via a regenerative braking system. In addition to the start- stop function, a BSG system can enhance fuel economy even during highway driving by cutting off the fuel supply when cruising or decelerating. Such systems can also be designed to deliver a short power boost to the drivetrain. This boost is typically 10 to 20 kW and is limited by the capacity of the 48V battery and accessory belt linking the motor to the crankshaft. New designs are linking the BSG directly to the crankshaft and allowing additional power boost of up to 30kW to be delivered, giving greater benefits to light and medium commercial vehicles.32 [EPA-HQ-OAR-2022-0829-0564, pp. 12-24]

32 https://www.meca.org/wp-content/uploads/resources/MECA_2027_Low_NOx_White_Paper_FINAL.pdf

Full hybridization and plug-in hybrids

Full hybrid configurations are currently found on several models of light-duty passenger cars and light trucks in the U.S. and a limited number of medium-duty trucks. These include PHEV models that can also be plugged-in to enable all-electric operation over a defined all-electric range (AER). A full hybrid can enable electrification of many of the components described above for mild hybrid vehicles, but the higher voltages allow for more parts to be electrified and to a larger degree of efficiency. Full hybrids implementing larger electric motors and batteries, can also support greater acceleration capability and regenerative braking power. Full hybrid vehicles have made the highest penetration into parcel delivery, beverage delivery and food distribution vehicles because they can take advantage of regenerative braking in urban driving.33 We expect to see some application of full hybrids combined with low NOx engines to reduce CO2 emissions in several vocational and local delivery applications. Integrated electric drivetrain systems, consisting of a fully qualified transmission, motor and power electronics controller, are now commercially available. With power levels of over 160kW and the ability to meet high torque requirements, these systems enable electrification of medium-duty commercial vehicles. There is also an increasing number of electric drivetrain solutions up to 300kW that are suitable for medium and heavy-duty vehicles that can be used with either battery or fuel cell power sources.30 [EPA-HQ-OAR-2022-0829-0564, pp. 12-24]

33 CARB, "Draft Technology Assessment: Heavy-Duty Hybrid Vehicles," 2015.

30 Navistar, "Final Scientific/Technical Report for SuperTruck Project: Development and Demonstration of a Fuel-Efficient, Class 8 Tractor & Trailer Engine System," 2016.

Plug-in hybrids (PHEVs) can be practical for light and medium- duty trucks (e.g., Class1 through 3) that do not travel long distances or operate for long periods of time without returning to a central location. In addition, serial plug-in hybrids which employ an engine operating only as a generator to charge the traction battery to extend range, offer operational flexibility for commercial vehicles while full electric vehicles and their needed infrastructure are established. It is worth noting that both HEVs and PHEVs are able to achieve significant GHG benefits compared to their conventional vehicle counterparts by employing relatively low-capacity batteries. Further discussion on efficient use of battery critical materials is presented below and displayed in Table 1. [EPA-HQ-OAR-2022-0829-0564, pp. 12-24]

Organization: Mercedes-Benz AG (M-B)

Diesel-Powered MDVs Are Not Considered in EPA's NPRM PM Feasibility Analysis [EPA-HQ-OAR-2022-0829-0623, p. 17]

Decarbonization of the Medium Duty segment is not an easy path and requires huge investments in development, manufacturing, supply chains, and infrastructure – for customers, the public, and for industry. The adjustment proposed to the emission limits should remain feasible and obtainable for diesel-powered vehicles to avoid negative economic impacts to the MDV segment. [EPA-HQ-OAR-2022-0829-0623, p. 17]

Today's Mercedes-Benz diesel-powered Sprinters form the benchmark for CO2 emissions when compared to other MDVs. A diesel Sprinter van has between a 23%-27% MPG advantage when compared to a competitor vehicle in terms of fuel economy, and CO2 emissions can be up to 20% lower based on the efficiency of a diesel powertrain: [EPA-HQ-OAR-2022-0829-0623, p. 17]

[See original for graph on CO2 Comparison Between MDVs in Class 2b Segment (g/mi)] [EPA-HQ-OAR-2022-0829-0623, p. 17]

These benefits, however, must be balanced with other portions of EPA's proposal for criteria emissions. Regarding EPA's proposed PM standards, existing ACCII standards have formed the basis of development work and internal goals since the beginning of CARB engagement in 2020. Significant work and investment is already underway to design to CARB's LEV IV PM standards for MDVs. In stark contrast to the already finalized CARB LEV IV standards, EPA's proposed PM standards are 16-20x more stringent than EPA's current MDV PM standards. [EPA-HQ-OAR-2022-0829-0623, p. 17]

In proposing these aggressive PM standards, EPA's rationale is focused on MDV gasoline engines, with the potential to match the capabilities of light-duty vehicle emissions levels once GPFs are applied. This logic is problematic, but our main concern is that EPA has not considered diesel specifications or technical limits as part of its analysis, leaving out a notable technology pathway in this segment. The chart below depicts the significantly higher reduction burden EPA proposes to apply to MDV, when compared to the proposed reduction in the light-duty segment. Also illustrated below is the discrepancy in stringency between the NPRM proposed PM standard and the PM standard adopted by EPA in December of 2022 in their Heavy-Duty Engine Rule. The proposed PM limit of 0.5mg/mi is from 8 to 18 times more stringent than EPA's rule promulgated just last year, after conversion from mg/bhp-hr standards to mg/mi across a typical Class 2b/3 MDV vehicle. [EPA-HQ-OAR-2022-0829-0623, pp. 17-18]

[See original for graph on Existing PM vs New PM Stringency Comparison (mg/mi)] [EPA-HQ-OAR-2022-0829-0623, pp. 17-18]

EPA's proposed jump in PM stringency in the MDV segment will pose a challenge for MDVs, including diesel powertrains. Cutting edge technology and the best-known methodology is already in use, in diesel-powered MDVs on the road today. [EPA-HQ-OAR-2022-0829-0623, pp. 17-18]

Additional MDV Criteria Emissions Considerations

Mercedes-Benz is also concerned with the overall Tier 4 criteria emissions requirements for MDVs. As such, our primary recommendation is that EPA align to CARB's ACCII LEV IV requirements for MDVs, including but not limited to additional emissions bins, decoupling BEV from the fleet average, and application of US06 testing. The emissions bins are necessary to assist with reduction of burden and complications from the two differing approaches. They are also useful for providing flexibility while Mercedes begins electrifying MDVs. [EPA-HQ-OAR-2022-0829-0623, p. 19]

Decoupling BEVs from the NMOG+NOx fleet average simplifies compliance planning, but if EPA does not apply this approach then the fleet average standards need to be adjusted (or at least adjustable) to account for potential changes in BEV projections during the time this rule is in effect. [EPA-HQ-OAR-2022-0829-0623, p. 19]

Organization: North Dakota Farmers Union (NDFU)

Criteria Emissions

Further tightening criteria emissions standards on new vehicles may not be effective at improving air quality, and it also discourages technologies that can help meet GHG emissions reductions goals – and meet them today. For example, flexible fuel vehicles allow use of greater ethanol blends, which provide increasing GHG emissions reductions. However, overly restrictive criteria emissions standards make it more difficult to design engines, cold start strategies, and catalytic aftertreatment which can handle the wide range of fuel properties required for flex-fuel vehicles. Moreover, higher ethanol blends would reduce air toxic emissions that may be more important to focus on with respect to light-duty and medium-duty vehicles that will continue to use gasoline well into the future. [EPA-HQ-OAR-2022-0829-0586, p. 6]

<u>EPA Summary and Response</u>

<u>Summary:</u>

CARB, MECA, and EPHO were generally supportive of our proposed MDV criteria pollutant emissions standards. CARB referenced their analysis of certification emissions data which was consistent with EPA's certification emissions data for MDV. The LEV IV fleet average standards and U.S. EPA's proposed standards, while structured differently, were determined to be of similar stringency for the same category of conventional ICE MDV, and because the vehicles are required to meet similar emission levels in both programs, manufacturers would be able to use the same technologies to meet both federal and California standards. EPHO characterized the proposed MDV criteria pollutant standards as "…feasible and cost-reasonable." EPHO characterized the proposed requirement for engine-certification of high-GCWR MDV as

"...likely appropriate, but should be monitored for manipulation and efficacy." EPHO also asked the Agency to monitor future data from MDV and from the heavy-duty engine in-use testing program in order to assess emissions differences between high-GCWR MDVs and other MDVs, and requested that the Agency commit to releasing a report any pertinent findings.

MECA provided a significant level of detail regarding specific technologies that are already commercially available for reducing NMOG+NOx emissions. These included a description of technologies similar to those currently used for light-duty truck applications, including both passive (system design) and active (engine controls) thermal management of exhaust catalyst systems; new, more advanced three-way catalyst coatings and substrate designs; and close-coupling and use of secondary air injection for cold-start emissions control. MECA referenced a report submitted to the docket for this rule detailing an integrated approach to criteria pollutant emissions control applied to a gasoline/spark-ignition pickup truck. With respect to diesel criteria pollutant and GHG emissions control, MECA referenced work from the U.S. DOE Supertruck II program, in particular achieving FTP NOx emissions of 0.015 g/bhp-hr. MECA commented that based on over 15 years of experience with diesel emission controls, medium-duty diesel vehicles that implement DPFs will be able to meet the stringent PM requirements proposed in this rule.

Cummins submitted comments regarding the lack of program to carry Tier 3 MDV NMOG+NOX credit into the new program for certifying engines installed in high-GCWR engines under part 1036. Cummins also supported fungibility of engine-certified high GCWR MDV NOX credits within the heavy-duty ABT program.

M-B expressed concern that the Agency's assessment of the feasibility of the proposed MDV PM standards was focused solely on spark-ignition gasoline engines equipped with GPF. M-B asserted that the EPA "…has not considered diesel specifications or technical limits as part of its analysis…" for the proposed rule. Similar to comments received with respect to our light-duty criteria pollutant standards, M-B requested alignment with California ACCII LEV IV standards including the decoupling of BEVs from NMOG+NOX fleet average standards, the approach to US06 testing and standards, and additional emissions certification bins.

NDFU expressed a concern that tightening criteria emissions standards on new vehicles may not improve air quality and that such standards would discourage technologies, such as flexible fuel vehicles, that help meet GHG emissions reductions goals. In particular, they were concerned that more stringent emissions standards would make it more difficult to design engines, cold start strategies, and catalytic aftertreatment for flex-fuel vehicles. NDFU also asserted that reducing air toxic emission by using higher ethanol blends may be more important for medium-duty vehicles than reducing criteria pollutant emissions.

Response:

EPA agrees with CARB that LEV IV fleet average standards[366] and U.S. EPA's final standards, while structured differently, are of similar stringency for the same category of conventional ICE MDVs. The emissions standards applicable to MDV are of comparable levels of stringency in California programs and under the Federal program, and manufacturers would thus be able to use the same MDV technologies to meet both Federal and California standards.

[366] EPA has not at this time approved the waiver that would allow California to follow the ACC II program, including the LEV IV requirements.

With respect to EPHO's comments regarding high-GCWR MDV, EPA has not finalized a requirement for engine dynamometer certification. Instead, EPA has finalized in-use standards for high-GCWR MDV comparable to the California ACC II in-use standards for MDV with GCWR above 14,000 pounds. Please refer to § III.D.5 "Requirements for Medium-Duty Vehicles With High GCWR" within the preamble to this rule. With respect to EPHO's concern that EPA monitor MDV and LHDE emissions, it should be noted EPA regularly conducts confirmatory testing and other compliance testing, including surveillance testing, to ensure manufacturer's full compliance with Federal emissions standards. The Agency also periodically issues progress reports on vehicle and engine compliance activities. The latest report covering the 2014-2017 model years was issued in April of 2019 (https://www.epa.gov/ve-certification/compliance-activity-reports-vehicles-and-engines).

We greatly appreciate the level of detail provided by MECA regarding criteria pollutant emissions control technologies for both spark-ignition and compression-ignition MDV. MECA's detailed comments on MDV criteria pollutant emissions control technologies is broadly consistent with EPA's analysis of MDV criteria pollutant emissions, emissions controls and feasibility within Chapter 3.2 of the RIA.

Regarding Cummins comments about Tier 3 NMOG+NO_X credit carry over, the Agency did not finalize a requirement for high GCWR MDV engine certification, although engine certification is still available as an option for high GCWR MDV (see Preamble § III.D.5 and Response to Comments § 6.4). Chassis-certified high GCWR MDV may optionally choose early compliance with the MDV criteria pollutant standards. Manufacturers choosing early compliance may carry over Tier 3 Class 2b and Class 3 NMOG+NO_X credits subject to the limits for carrying forward NMOG+NO_X credit within the Tier 3 program. With respect to Cummins comments regarding averaging, banking and trading and fungibility of engine-certified MDV NO_X credit within the HD program, manufacturers opting to engine-certify high GCWR MDV to LHD engine criteria pollutant standards under 40 CFR part 1036 would be fully eligible to participate in averaging, banking and trading, including fully exchanging credits with other engine families certified under 40 CFR part 1036, subject to the various credit provisions that apply under 40 CFR part 1036, subpart H. Credits earned under 40 CFR part 86, subpart S, before model year 2027 are not available for certifying engines under 40 CFR part 1036 for the same reasons that 40 CFR part 1036 restricts the transfer of banked engine credits for certifying model year 2027 and later engines. For example, engines installed in vehicles certified under 40 CFR part 1036, subpart S, have not been designed to control emissions for towing heavy payloads, for low-load operation, or for other off-cycle operation. As such, allowing the suggested use of credits would overstate the value of credits earned under 40 CFR part 86, subpart S, and accordingly reduce the environmental benefits associated with the standards adopted under 40 CFR part 1036.

In response to M-B comments regarding the feasibility of the proposed diesel PM standards, EPA conducted a statistical analysis of composite FTP test results from 32 distinct MY 2022 through MY 2024 MDV test groups certifying to Federal Tier 3 emissions standards. Composite FTP PM test results are shown using a box plot within the figure below. The horizontal line represents the median MDV PM emissions test results (approximately 0.35 mg/mi). The "x" within the box represents mean MDV PM emissions test results (approximately 0.5 mg/mi). The upper and lower bounds of the box represent the first through third quartile of MDV PM emissions test results. The "whiskers" above and below the box represent 1.5 times the interquartile range (IQR). Of the test groups above 1 mg/mi, 4 were MY 2022 M-B Class 2b and Class 3 test groups and one was a MY 2024 GM test group. All of the MY 2022 M-B test groups had PM emissions test results above the median and mean for all MDV and ranged from 0.6 to 1.1 mg/mi. It is notable, however, that the M-B test results for MY 2023 and MY 2024 were considerably lower, with all test groups having PM test results at or below the mean and 4 of the 5 test groups having PM test results lower than the median for all MDV test groups. M-B introduced both engine changes and exhaust aftertreatment changes for MY 2023 that likely resulted in the considerable PM emissions reductions observed within FTP certification test results.

In following with the analysis outlined below, the agency believes that the final PM standard for diesel MDVs of 0.5 mg/mi is feasible. The analysis of recent model year MDV diesel PM emissions shows that the average manufacturer reported PM emissions for this segment is already at the 0.5 mg/mi standard, and the median PM emissions is 0.35 mg/mi, which is below the final standard. In other words, half of the reported values are below the final MDV PM standard with a compliance margin. However, EPA recognizes that vehicles within this regulatory class may not undergo redesigns as often as light-duty vehicles and the powertrains with which they are equipped may have an equally long design life. As such, the agency has decided to provide an additional year of lead-time relative to the proposal, for both the default and early compliance. However, this additional lead-time is not reflective of the agencies assessment of the feasibility of the 0.5 mg/mi standard for diesel MDVs, but rather the recognition of the requisite redesign cycles for this regulatory class. In light of the above, including this leadtime consideration, as well as our consideration of the statutory and other relevant factors as described in sections III and V of the preamble, we find that the MDV PM standard reflects “the greatest degree of emission reduction achievable through the application of technology which the Administrator determines will be available for the model year to which such standards apply.” CAA section 202(a)(3)(A)(i).

-

Howe

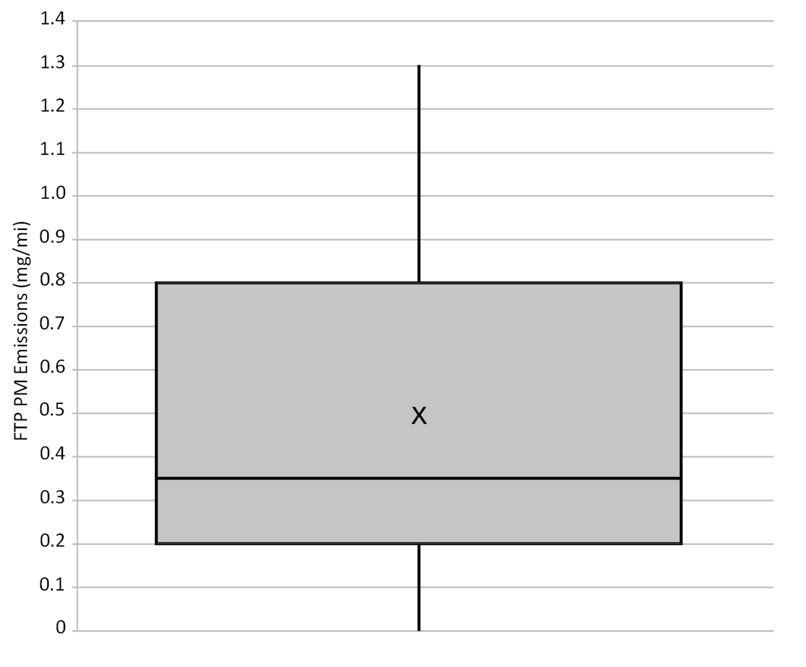

Figure 1: Box plot of FTP composite PM emissions test results for 32 MY 2022 through MY 2024 MDV test groups.

EPA also notes MECA's comment that based on over 15 years of experience with diesel emission controls, medium-duty diesel vehicles that implement DPFs will be able to meet the stringent PM requirements proposed in this rule.

M-B's comment requesting decoupling MDV BEVs from the MDV NMOG+NOx fleet average and adoption of California ACC II LEV IV MDV criteria pollutant standards is similar to comments received by the Agency with respect to light-duty criteria pollutant emissions standards. EPA is not finalizing a wholesale adoption of the California ACC II LEV IV program. The ACC II program includes synergistic elements for both greenhouse gas and criteria pollutant emissions, with the foundation of the ACC II program being a ZEV sales requirement. M-B did not recommend adopting the ZEV standards provisions of ACC II and instead recommended that EPA only adopt the criteria pollutant elements of ACC II. This ala carte approach to emissions standards fails to consider the synergistic nature of California's ACC II program. The treatment of ICE-based vehicles under ACC II is premised on an increasing penetration of ZEVs and their associated emission reductions. EPA's 2027 and later MDV program, being performance-based for both GHG and criteria pollutant emissions, relies on increasingly stringent performance-based standards to achieve substantial emissions reductions nationwide. EPA is, however, finalizing additional provisions in the FRM which are responsive to requests for greater alignment with ACC II. These include:

- Alignment with all ACC II MDV NMOG+NOx emissions bins at or below Bin 170
- Adoption of in-use standards for high-GCWR MDV comparable to California ACC II in-use standards for MDV above 14,000 pounds GCWR
- Alignment with California MDV OBD

4.1.9 - Small volume manufacturer alternative criteria standards

EPA addresses comments related to small volume manufacturers for both GHG and criteria emissions in Section 3.1.7 of this document.

4.1.10 – CARB's ACC II supplemental NMOG+NOx standards

Comments by Organizations

Organization: Alliance for Automotive Innovation

4. Mid-Temperature Intermediate Soak Standard

In the NPRM, EPA describes that manufacturers are required to submit data for three separate standards: 9–11 minutes for the 10-minute requirement, 39–41 minutes for the 40-minute requirement, and 5–7 hours for the 3–12 hour requirement.263 Conversely, CARB's ACC II regulations allow for manufacturers to use attestation to meet the respective requirement.264 Therefore, we request that EPA align with California's approach and allow attestation to meet the mid-temperature intermediate soak requirement. Laboratory test burden will be significantly reduced by omitting the requirement for manufacturers to provide test data at three different soak times. [EPA-HQ-OAR-2022-0829-0701, pp. 148-149]

263 NPRM at 29276.

264 13 C.C.R. § 1961.4(d)(2)(B).

5. Early Drive-Away

a) Early Drive-Away Attestation

We request that EPA allow attestation to meet the quick drive-away requirement. [EPA-HQ-OAR-2022-0829-0701, p. 149]

b) Early Drive-Away Speed Tolerance specification [EPA-HQ-OAR-2022-0829-0701, p. 149]

Due to the sensitivity of the early drive-away standard to variation and transients during the initial part of the test cycle, Auto Innovators recommends a tighter speed trace tolerance for the first seven seconds of the test to ensure the vehicle is fully stopped while the transmission is placed in drive mode. A 0.3 mile per hour tolerance was proposed to CARB during the ACC2 rulemaking, but CARB did not incorporate the change due to lack of precedence for tolerance variation in the other test cycles. Auto Innovators encourages EPA to fully evaluate the necessity of a 0.3 mile per hour speed tolerance, and to adopt this change for the first seven seconds of the cycle to address the unique nature and stringency of this requirement. [EPA-HQ-OAR-2022-0829-0701, p. 149]

6.PHEV High-Power Cold Start Standard

EPA is proposing to implement the CARB LEV IV high-power cold start (HPCS) standard for light- and medium-duty vehicles. "EPA requests comment on Step 2 of the PHEV HPCS standard, Specifically whether the Step 2 standard should 1) be finalized as proposed, 2) have a start date later than MY 2029, 3) have an alternative stringency, either for all light-duty vehicles or just for LDT3 and LDT4, or 4) should be removed, leaving Step 1 to apply indefinitely."265 Auto Innovators believes that for larger vehicles, especially those needing large towing capacity, Step 1 of the PHEV HPCS standard should be extended through the end of the Tier 4 rule period. [EPA-HQ-OAR-2022-0829-0701, pp. 149-150]

265 NPRM at 29276.

PHEVs will be an especially important technology for use cases in which charging or hydrogen refueling infrastructure isn't readily available, in particular for larger body-on-frame vehicles that are designed for towing large loads. Due to the nature of these vehicles, the amount of battery needed to meet the Step 2 provisions is difficult to achieve for the foreseeable future. In addition, larger vehicles such as P/U and large SUVs tend to have a longer model life, making it very expensive to modify if it needs to be done mid-model life. [EPA-HQ-OAR-2022-0829-0701, pp. 149-150]

Therefore, we believe that for GVWR > 6,000 lbs, extending the Step 1 provision through MY 2032 is important to allow those vehicles time for market development. EPA should extend Step 1 HPCS provision for GVWR > 6,000 lbs through 2032MY. [EPA-HQ-OAR-2022-0829-0701, pp. 149-150]

Finally, we recommend EPA allow OEMs to certify to this standard using attestation. The vehicles would meet the standards, and be held to the standard, this would simply reduce the upfront certification test. [EPA-HQ-OAR-2022-0829-0701, pp. 149-150]

Organization: Ford Motor Company

Adoption of CARB ACC2 NMOG+NOx Provisions

The EPA has proposed adoption of three NMOG+NOx provisions for light-duty vehicles aligned with the CARB ACC2 program (PHEV High Power Cold Starts, Early Driveaway and Intermediate Soak Mid-Temperature Starts). [EPA-HQ-OAR-2022-0829-0605, p. 14]

Ford supports EPA adopting these requirements using the existing CARB ACC2 bin-specific standards. EPA's proposed alterations to the California requirements, including applying a different bin structure, are unnecessary and add unwarranted complexity. In addition, Ford seeks confirmation that the PHEV High Power Cold Starts mileage exemption requirement is tied to the unadjusted all-electric range on the cold-start US06 driving cycle. [EPA-HQ-OAR-2022-0829-0605, p. 14]

Organization: International Council on Clean Transportation (ICCT)

ICCT supports EPA's inclusion of the new provisions on vehicles' operating conditions for light- duty vehicles that align with the CARB ACC II program. The additional operating conditions include high power cold starts in plug-in hybrid vehicles, SFTP early drive-away, and SFTP intermediate soak mid-temperature starts (called partial soak standard in ACC II). The bin-specific standards are mostly congruent with those in the ACC II program with some slight difference. Instead of having Bin 125, 25 or 15, the proposal includes Bin 10 which has more stringent NMOG + NOx standards compared to CARB's. [EPA-HQ-OAR-2022-0829-0569, pp. 44-45]

Organization: Kia Corporation

Kia Urges EPA's NMOG+NOx Emissions Standards Align with ACC II

EPA proposes adoption of a NMOG+NOx standard of 12 mg/mi by 2032 over four operating conditions. These three conditions are not currently captured in test procedures and could result in significant criteria pollutant emissions: high power cold starts in plug-in hybrid vehicles (HPCS), cold FTP, and mid-temperature intermediate soak starts. The proposal represents a 60 percent reduction for light-duty vehicles that include a fleet average that declines from MYs 2027 - 2032, the elimination of higher certification bins, and a requirement for the same fleet average emissions standard to be met across four test cycles (FTP, HFET, US06, SC03). However, EPA proposes to keep all ZEV and non-ZEV vehicles in the fleet average. [EPA-HQ-OAR-2022-0829-0555, p. 11]

Kia urges EPA to align its criteria pollutant regulation with the California ACC II program. Kia supports EPA's proposal of requiring automakers to attest to meeting the three specific CARB- defined test procedures: HPCS, cold FTP, and mid-temperature intermediate soak starts. However, because California's ACC II NMOG+NOx fleet averaging standard applies to a non-ZEV fleet average (in a phasing out ZEVs in the average), Kia does not support keeping all ZEVs and non-ZEVs in one fleet average. [EPA-HQ-OAR-2022-0829-0555, p. 11]

Organization: MECA Clean Mobility

EPA should align with CARB's ACC II requirements for PHEV high power cold starts, early drive-away, and mid-temperature engine starts. Similar to CARB, EPA should allow PHEVs with all electric range greater than or equal to 40 miles to be exempt from the high-power cold start requirement. [EPA-HQ-OAR-2022-0829-0564, pp. 26-29]

MECA supports EPA's proposed alignment with CARB ACC II provisions to address emissions from operation previously not considered by certification testing, including high power cold starts of plug-in hybrid electric vehicles, shortened idle and early drive-away after start-up, and short to intermediate soak times in between engine starts. MECA believes that emissions after engines are restarted after intermediate soak time, between three and eight hours, can be readily addressed with engine calibration revisions without the need for additional technology, and this is a cost-effective way to reduce these off- cycle emissions that are found during real world operation. [EPA-HQ-OAR-2022-0829-0564, pp. 26-29]

Regarding drive-away emissions, we believe that faster system warm-up can be achieved through improvements in calibration as well as the use of commercially available engine technologies, such as turbochargers, exhaust gas recirculation (EGR), and cylinder deactivation (CDA). Extensive engine calibration and combustion strategies, such as the use of variable valve timing (VVT), have been developed to enable faster exhaust heat-up in order to increase catalyst performance. Higher voltage hybrid architectures ranging from 48V mild to full hybrids also create opportunities to incorporate electrically-heated catalysts (EHCs) to address these shorter cold-start idle times. Additional aftertreatment efficiency gains have been and continue to be developed through improvements in catalyst materials to enable higher performance at lower exhaust temperatures. Furthermore, new system architectures, more robust thermal management controls and advanced thermal insulation materials facilitate faster heat-up and heat retention during real world operation. [EPA-HQ-OAR-2022-0829-0564, pp. 26-29]

MECA acknowledges the need to better control PHEV high power demand engine cold start emissions. In particular, MECA is aware of published work highlighting the use of engine and exhaust emission control strategies to address high power starting emissions used in other electrified hybrid powertrains.36 Several of the technologies and strategies listed above to address "quick drive-away" emissions can also be employed to address emissions from off-cycle high power starts. MECA believes that the proposed PHEV minimum requirements in CARB ACC II address the shortcomings of some earlier generation PHEVs. To that end, EPA should be finalized as proposed to harmonize with CARB ACC II on the Step 2 PHEV high power cold start standard that exempts PHEVs with a cold start US06 all electric range of at least 40 miles. [EPA-HQ-OAR-2022-0829-0564, pp. 26-29]

Organization: Mercedes-Benz AG

Intermediate Soak Mid-Temperature Starts

EPA's proposal states that manufacturers are required to submit data for three separate standards:

1. 9–11 minutes for the 10-minute requirement [EPA-HQ-OAR-2022-0829-0623, p. 15]
2. 39–41 minutes for the 40-minute requirement, and [EPA-HQ-OAR-2022-0829-0623, p. 15]
3. 5–7 hours for the 3–12 hour requirement [EPA-HQ-OAR-2022-0829-0623, p. 15]

Testing at three different points triples the amount of testing required for each vehicle group. [EPA-HQ-OAR-2022-0829-0623, p. 15]

In contrast, CARB's ACCII LEV IV regulation allows for manufacturer attestations under Section 1961.4(d)(2)(B). This attestation provides testing relief and reduces the cost of implementation, without any impact on emissions. [EPA-HQ-OAR-2022-0829-0623, p. 15]

Mercedes-Benz requests that EPA align with CARB ACC II LEV IV and allow attestation to meet this requirement. Lab test burden and certification time will be significantly reduced by omitting the requirement for manufacturers to provide test data at three different soak times. [EPA-HQ-OAR-2022-0829-0623, p. 15]

EPA Summary and Response

Summary

EPA received comments on the proposed light-duty vehicle standards aligned with the CARB ACC II program that range from supportive to those recommending changes to specific parts of the program. Comments and EPA's responses for each of the three provisions are provided below.

1) PHEV High Power Cold Starts

ICCT and MECA supported the high power cold starts (HPCS) provision. MECA noted that emissions from HPCS were not previously considered by certification testing and describes commercially available technologies that can be employed to address these emissions, including technologies described in published work. MECA recommends that EPA finalize the HPCS provision, including exempting PHEVs with a cold start US06 all electric range of at least 40 miles in Step 2 of the program. Ford requested confirmation that the all-electric range exemption is tied to the unadjusted all-electric range on the cold-start US06 driving cycle.

Ford commented that it supports EPA adopting the light-duty provisions aligned with the ACC II program using CARB's ACC II bin structure, not the different structure proposed by EPA, to avoid unnecessary complexity. Manufacturers requested that EPA should finalize more bins to provide additional resolution in certifying test groups. AAI and Kia recommended that manufacturers be allowed to attest to the standard to reduce test burden.

AAI commented that for larger vehicles, especially those needing large towing capacity, Step 1 of the PHEV HPCS standard should be extended through the end of the Tier 4 rule period and Step 2 should not be adopted. A major manufacturer also requested that EPA not adopt Step 2 for vehicles above 6000 lb GVWR.

2) Early Driveaway

ICCT and MECA submitted supportive comments for the early driveaway provision. MECA noted that emissions from early driveaway were not previously considered by certification testing and describes calibration strategies and several commercially available technologies that can reduce early driveaway emissions.

Ford supported EPA adopting the early driveaway standard using CARB's ACC II bin structure, not the different structure proposed by EPA, to avoid unnecessary complexity. Manufacturers commented that EPA should finalize more bins to provide additional resolution in certifying test groups. AAI and Kia recommended that manufacturers be allowed to attest to the standard to reduce test burden.

AAI recommended a tighter speed tolerance for the first seven seconds of the early driveaway test to ensure a test driver does not drive off much before 8 seconds.

3) Intermediate Soak Mid-Temperature Starts

ICCT and MECA submitted supportive comments for the intermediate soak mid-temperature start provision. MECA identified that emissions from intermediate soak times were not previously covered by certification testing and comments that elevated emissions from intermediate soak times can be readily addressed with engine calibration revisions without the need for additional technology.

Ford commented that to avoid unnecessary complexity, EPA should adopt CARB's ACC II bin structure for the intermediate soak mid-temperature start provision. Manufacturers commented that EPA should finalize more bins to provide additional resolution in certifying test groups. AAI, Kia and Mercedes-Benz requested that manufacturers be allowed to attest to the standard to reduce laboratory test burden.

<u>Response</u>

1) PHEV High Power Cold Starts

After considering the comments on HPCS, EPA is finalizing Step 1 and Step 2 of the HPCS standard and is requiring manufacturers to provide data demonstrating compliance (instead of entirely relying on attestation) because according to EPA's modeling of the future fleet and input from AAI and manufacturers, PHEVs may play a significant role in the future vehicle fleet and that would make PHEV HPCS an significant operating mode.

EPA agrees with MECA that technologies can be employed to meet the HPCS standards but also recognizes that manufacturers need time to implement these design changes, especially on some models. To address that concern, the Agency is providing manufacturers with an extra year to comply with Step 1 and Step 2, relative to the CARB program, to give manufacturers more time to comply. The criteria pollutant phase in schedules described in preamble Section III.D.1.i also provide additional lead time. EPA is finalizing the exemptions to Step 1 and Step 2 of the standard as proposed.

In response to requests from Ford and other manufacturers for EPA to not adopt a bin structure different from CARB's ACC II bin structure and to add more bins for additional resolution, EPA is finalizing a bin structure that includes all CARB ACC II bins except Bin 125 and includes bins from 0 to 70 in increments of 5. EPA is not finalizing Bin 125 because EPA is eliminating this bin from the list of bins available to light-duty vehicles (Preamble Section III.D.2.i). The inclusion of bins from 0 to 70 is to provide manufacturers with additional resolution in certifying test groups to meet the standard.

As noted in CARB's ACC II requirements, PHEVs with a minimum US06 all-electric range value greater than 40 miles are exempt from the High Power Cold Start Standards for Plug-in Hybrid Electric Vehicles. PHEVs achieving this minimum all electric range on a charge-depleting cold start US06 test qualify for the exemption. The California regulations do not specify applying any adjustments to the charge depleting US06 result when determining the all-electric US06 range value. As EPA is adopting the California exemption from the High Power Cold Start requirements for PHEVs with a minimum US06 all-electric range, EPA will also use the unadjusted cold start US06 all-electric range for this determination.

2) Early Driveaway

EPA considered the submitted comments on early driveaway and is finalizing an early driveaway standard with several changes from what was proposed. EPA is finalizing an early driveaway standard and is requiring manufacturers to provide data (instead of relying on attestation) demonstrating compliance. Field data indicates that there is a propensity of drivers to drive off sooner than the delay represented in the FTP, making early driveaway a significant operating mode. In addition, there are commercially available technologies that can reduce early driveaway emissions and vehicle manufacturers have demonstrated that they are able to reduce the emissions associated with this event.

EPA is finalizing a bin structure that includes all CARB ACC II bins except Bin 125 and includes bins from 0 to 70 in increments of 5. EPA is not finalizing Bin 125 because EPA is eliminating this bin from the list of bins available to light-duty vehicles (preamble Section III.D.2.i). The inclusion of bins from 0 to 70 is to provide manufacturers with additional resolution in certifying test groups to meet the standard.

In response to AAI's request for a tighter speed tolerance for the first seven seconds of the early driveaway test, EPA is finalizing an early driveaway test in which vehicle speed may not exceed 0.0 mph until 7.0 seconds and vehicle speed between 7.0 and 7.9 seconds may not exceed

2.0 mph. This reduces the possibility of a test driver driving off significantly earlier than 8 seconds without setting unrealistic requirements on the test driver and doesn't significantly skew the trace to drive-off times larger than 8 seconds. Details are provided in Preamble Section III.D.7.ii.

3) Intermediate Soak Mid-Temperature Starts

EPA is finalizing an intermediate soak mid-temperature starts standard similar to what was proposed but with several changes. EPA is finalizing an intermediate soak mid-temperature starts standard because many current vehicles emit at elevated levels after an intermediate soak start, intermediate soak starts occur frequently, and the issue can be readily addressed with engine calibration revisions without the need for additional technology.

In response to comments from Ford and other manufacturers, EPA is finalizing a bin structure that includes all CARB ACC II bins except Bin 125 and includes bins from 0 to 70 in increments of 5. EPA is not finalizing Bin 125 because EPA is eliminating this bin from the list of bins available to light-duty vehicles (preamble Section III.D.2.i). The inclusion of bins from 0 to 70 is to provide manufacturers with additional resolution in certifying test groups to meet the standard.

EPA proposed that manufacturers provide certification test data at three intermediate soak times and attest to meeting the standard at all other times between 10 minutes and 12 hours. The purpose of manufacturers supplying test data is to ensure compliance with the standard. EPA considered requests from AAI, Kia and Mercedes-Benz to allow attestation to the standard at all soak times and appreciates that intermediate soak testing takes time. To achieve a balance between high confidence in compliance and minimizing test burden, EPA is finalizing that manufacturers submit certification test data at a minimum of one intermediate soak time (between 39 and 41 minutes) and attest to meeting the standard at other times between 10 minutes and 12 hours.

5 - On board diagnostics (OBD)

Comments by Organizations

Organization: Alliance for Automotive Innovation

IX. OBD

A. Gasoline Particulate Filter (GPF) § 86.1806-27 Onboard diagnostics. Section (h)

1. PM Filter Threshold

EPA proposes adding monitoring requirements for GPFs installed on vehicles with spark-ignition engines in §86.186-27(h). These are new requirements for GPFs that do not exist in either California's OBD II regulations (see 13 CCR §1968.2) or EPA's regulations. The proposed regulation requires the OBD system to detect a malfunction before any of the following thresholds are exceeded (§86.1806-27(h)(2): [EPA-HQ-OAR-2022-0829-0701, p. 249]

- (i) Filtering decreases to the point that PM exceeds 10 mg/mile. If no malfunction of the GPF can cause emissions to exceed 10 mg/mile, the OBD system must detect when free flow through the filter such that 30% of less of the normal filtration is occurring. [EPA-HQ-OAR-2022-0829-0701, p. 249]

- (ii) When excessive GPF regeneration frequency would cause HC, CO, or NOx to exceed 1.5x the applicable FTP standard. If no malfunction could cause emissions to exceed 1.5x the applicable standard, the OBD system must detect when PM filter regeneration exceeds the design limits for allowable regeneration. [EPA-HQ-OAR-2022-0829-0701, p. 249]

- (iii) When regeneration does not restore the GPF when regeneration is designed to occur. [EPA-HQ-OAR-2022-0829-0701, p. 249]

With respect to the 10 mg/mile standard, we note the California OBD threshold for diesel particulate filters is 17.5 mg/mile though MY28, and while the California diesel PM threshold drops to 10 mg/mile starting in MY29, no vehicles have currently certified to a 10 mg/mile threshold. [EPA-HQ-OAR-2022-0829-0701, p. 249]

We would also like to work with EPA to clarify whether EPA intends to apply the 10 mg/mi standard to every emission correlated major monitor, or only for GPF monitoring. We recommend a GPF monitoring threshold of 10 mg/mi or higher and harmonizing all other monitors with CARB OBD requirements of 17.5 mg/mi. See Section VIII.C. (Figures 83-85) below. [EPA-HQ-OAR-2022-0829-0701, p. 249]

3. GPF Monitoring Requirements

a) Detection Requirements

When developing a GPF monitor, manufacturers often target six-sigma separation between worst performing acceptable (WPA or “good parts”) and best performing unacceptable (BPU or “bad parts”). To achieve this separation, there needs to be enough separation in systems that meet the emission standard and those that should turn on the MIL for the OBD threshold. As the emission standards decrease, the OBD threshold multiplier needs to increase to provide necessary separation for a robust monitor. [EPA-HQ-OAR-2022-0829-0701, pp. 250-251]

We propose to revise the language found in (§ 86.1806–27 (h)(2)(i), to read:

If there is no failure or deterioration of the PM filter that could cause a vehicle to exceed the specified PM emission level, [Strikethrough: the system must detect a malfunction if the PM filter allows free flow of exhaust through the PM filter assembly where 30 percent or less of the normal filtration is occurring] [In Red: [Underline: the OBD II system shall detect a malfunction when no detectable amount of PM filtering occurs . . .]] [EPA-HQ-OAR-2022-0829-0701, pp. 250-251]

This revision aligns with CARB’s long-standing precedent for detection requirements and this revision is the only option that is feasible with today’s commercially available sensing technology. Figure 81 below shows delta pressure curves as a function of exhaust flow from a completely intact substrate and completely missing substrate. For a robust diagnostic, manufacturers require at least six-sigma separation between these curves. At low exhaust flows (of the Worldwide Harmonized Light Vehicles Test Procedure (WLTP) or FTP drive cycle), there is practically no separation between a fully intact substrate and a missing substrate. There is more separation at higher exhaust flows, as shown, but most of the higher exhaust flows are off cycle (i.e., higher exhaust flow than a US06). [EPA-HQ-OAR-2022-0829-0701, pp. 250-251]

The below example data with a delta pressure sensor shows the lack separation between an intact and missing substrate. Requiring detection of a filter flowing 30% of normal would further reduce the limited separation between "intact substrate" and "missing substrate". Therefore, robust detection with this sensing technology is not possible for any partial failure modes of the GPF. [EPA-HQ-OAR-2022-0829-0701, pp. 250-251]

As demonstrated in the graph below, the delta pressure versus exhaust flow curves also illustrates the challenge for meeting In-Use Monitor Performance Ratio (IUMPR) minimum ratios for missing substrate detection. One way to address this could be by defining a special denominator for this monitor. Following previous and current examples from both CARB and European Union (EU) regulations regarding monitoring of Diesel Particulate Filter (DPF), the following special denominator criteria are needed to ensure that the IUMPR requirements can be met. We recommend that EPA add the following GPF special denominator criteria: [EPA-HQ-OAR-2022-0829-0701, pp. 250-251]

- Minimum of 500 miles [EPA-HQ-OAR-2022-0829-0701, pp. 250-251]

- High enough exhaust flow rate is achieved for a specified amount of time, and [EPA-HQ-OAR-2022-0829-0701, pp. 250-251]

- Alternate or additional denominator criteria, with Administrator approval. [EPA-HQ-OAR-2022-0829-0701, pp. 250-251]

[See original for graph. "Figure 81: Delta Pressure vs Exhaust Flow Rate"] [EPA-HQ-OAR-2022-0829-0701, pp. 250-251]

b) Thresholds for Detection

Additionally, we request that EPA harmonize with CARB as it pertains to (h)(2)(ii). EPA and CARB should harmonize on GPF monitoring requirements to allow manufacturers to have one OBD system for all 50 states. For the 1.5x multiplier for the regeneration frequency requirement (§ 86.1806–27 (h)(2)(ii)), EPA should harmonize with CARB's OBD II Gasoline Thresholds, which allow higher multipliers of the vehicles certifying to lower emission standards. For example, as noted below in Figure 83, the SULEV30 OBD multiplier is 2.5x rather than 1.5x. Industry and CARB agreed to these higher multipliers at lower standards to allow for robust detection (i.e., no false passing or false failing) while still achieving the required In-Use Monitor Performance Ratio minimums. [EPA-HQ-OAR-2022-0829-0701, pp. 251-252]

Auto Innovators agrees with EPA's proposal which harmonizes with CARB's gasoline three-way catalyst requirements that allow partial volume monitoring such that the rear brick is unmonitored. For systems that employ a catalyzed rear GPF, harmonization with CARB OBD II requirements would only require PM emission correlation (not NMHC, NOx, and CO). Auto Innovators' understanding of the proposal in (h)(2)(i) aligns with this recommended harmonization, but we would like to confirm EPA's intention. [EPA-HQ-OAR-2022-0829-0701, pp. 251-252]

B. Incorporation by Reference

Section 86.1806-27 (a) references CARB's OBD-II regulation (13 CCR 1968.2) dated November 22, 2022. However, 86.1(d)(2) Incorporation by Reference (d)(2) refers to 13 CCR 1968.2 dated November 30, 2002. Auto Innovators recommends revising the 86.1806-27 (a) to reference the November 30, 2022 version of the regulation, as that version incorporates revisions specific to LEV IV. Auto Innovators recommends revising the language as follows: [EPA-HQ-OAR-2022-0829-0701, pp. 253-254]

(a) Vehicles must comply with the 2022 OBD requirements adopted for California as described in this paragraph (a). California's 2022 OBD–II requirements are part of Title 13, section 1968.2 of the California Code of Regulations, approved on November 3022, 2022 (incorporated by reference, see § 86.1). We may approve your request to certify an OBD system meeting a later version of California's OBD requirements if you demonstrate that it complies with the intent of this section. The following clarifications and exceptions apply for vehicles certified under this subpart: [EPA-HQ-OAR-2022-0829-0701, pp. 253-254]

C. OBD Monitor Thresholds

Auto Innovators recommends EPA harmonize with CARB on OBD Gasoline and Diesel monitor thresholds as written in 13 CCR 1968.2. OEMs and CARB worked together to develop OBD emission thresholds that will allow robust detection while allowing IUMPR requirements to be met. OBD systems require separation between WPA and BPU systems for robustness. False MILs are a burden to all stakeholders, from the government agency to the customer and auto repair shops. Therefore, separation between WPA and BPU is needed. [EPA-HQ-OAR-2022-0829-0701, pp. 254-258]

86.1806-27 (a)(8) says "for Tier 4 standards that have no corresponding bin standards from the California LEV III program, use the next highest LEV III bin." Applying the SULEV15 multipliers to Bin 10 would require manufacturers to detect faults when NMOG+NOx exceeds 0.033 grams/mile which is much more stringent than what is required for LEV IV. Manufacturers do not have experience with certifying vehicles at this emission standard and have not demonstrated capability of detecting malfunctions robustly at this malfunction threshold. Auto Innovators recommends that EPA adopt the same strategy CARB used for SULEV20 and SULEV15 for the Tier 4 Bin 10 category. Due to uncertainty about how the lower standards will affect OBD monitoring capability, this strategy includes interim OBD threshold multipliers for the first 3 model years that SULEV20 and SULEV15 vehicles are introduced by manufacturers (no later than 2030 model year). [EPA-HQ-OAR-2022-0829-0701, pp. 254-258]

SULEV20 and SULEV15 interim threshold multipliers are defined to correspond to detection of malfunctions before emissions exceed 0.065 g/mi NMOG+NOx. Final thresholds are defined at 0.050 g/mi NMOG+NOx. We recommend EPA adopt this same strategy and define an interim NMOG+NOx monitor threshold multiplier for Tier 4 Bin 10 of 6.50 (for first three model years a vehicle is certified to Bin 10, no later than 2030MY) and a final multiplier of 5.00. Figures 83 and 86below show the recommended thresholds. [EPA-HQ-OAR-2022-0829-0701, pp. 254-258]

CARB has provisions in 13 CCR 1968.2 (e)(17.1.6)(B)(i) and (f)((17.1.8)(B)(i) that define alternate malfunction criteria for engine cooling system thermostat monitor for LEV IV vehicles. Therefore, we recommend that EPA allow the same alternative malfunction criteria for Tier 4 Bin 10 as is applied to the LEV IV SULEV15 category. [EPA-HQ-OAR-2022-0829-0701, pp. 254-258]

Similarly, CARB has provisions in 13 CCR 1968.2 (e)(17.1.6)(C)(i) and (f)((17.1.8)(C)(i) that define alternate test-out criteria for LEV IV vehicles. Auto Innovators recommends that EPA allow the same test-out provisions for Tier 4 Bin 10 as is applied to the LEV IV SULEV15 category. [EPA-HQ-OAR-2022-0829-0701, pp. 254-258]

[See original for table, “Figure 83: Recommended Thresholds Passenger Cars and Light-Duty Trucks”] [EPA-HQ-OAR-2022-0829-0701, pp. 254-258]

[See original for table, “Figure 84: Gasoline Chassis-certified MDVs with GVWR ≤ 10,000 lbs”] [EPA-HQ-OAR-2022-0829-0701, pp. 254-258]

[See original for table, “Figure 85: Gasoline Chassis-certified MDVs with GVWR between 10,000 lbs and 14,000 lbs”] [EPA-HQ-OAR-2022-0829-0701, pp. 254-258]

[See original for table, Figure 86: Diesel Passenger Cars, Light-duty Trucks, and Chassis-certified MDPV's] [EPA-HQ-OAR-2022-0829-0701, pp. 254-258]

D. Vehicle Compliance

In the NPRM, § 86.1806-27 Onboard diagnostics it states that, “Vehicles may optionally comply with the requirements of this section instead of the requirements of § 86.1806-17 before model year 2027.” Auto Innovators proposes EPA amend the language to harmonize with 1036.110 by adding the words “any or all” to the above language. Reference 1036.110, “You may optionally comply with any or all of the requirements of this section instead of 40 CFR 86.010–18 in earlier model years.” [EPA-HQ-OAR-2022-0829-0701, pp. 258-259]

The resulting language in 86.1806-27 would be written, “Vehicles may optionally comply with any or all the requirements of this section instead of the requirements of § 86.1806-17 before model year 2027.” [EPA-HQ-OAR-2022-0829-0701, pp. 258-259]

Organization: Alliance for Vehicle Efficiency (AVE)

AVE is also asking EPA to provide more clarity to its Proposed On-Board Diagnostics (OBD) Program. Current OBD sensors can determine if a GPF has been removed from a vehicle and we support this requirement. AVE also supports requiring OBD systems that can detect emissions above 10mg/mi or a limit that is found measurable by current PM sensor technology. [EPA-HQ-OAR-2022-0829-0631, p. 8]

Organization: California Air Resources Board (CARB) (Part 1 of 5)

Onboard Diagnostics

CARB’s current onboard diagnostic requirements ensure that emerging emission control technologies such as PM filters must be monitored and to date, a few manufacturers have already certified vehicles so equipped for sale in California. U.S. EPA’s proposed monitoring requirements are consistent with the type of failure modes CARB already requires to be monitored and CARB expects manufacturers would readily be able to meet CARB’s requirements with diagnostics developed to meet the proposed requirements. [EPA-HQ-OAR-2022-0829-0780, p. 34]

Further, due to the likely widespread use of PM filters across industry to comply with EPA's proposed PM standards, CARB agrees that onboard diagnostic requirements should be amended to explicitly address this technology. However, CARB suggests some modifications to the proposed regulatory requirements. Specifically, in 40 CFR section 86.1806-27(h)(2)(ii), CARB recommends replacing the phrase "HC, CO, or NOx emissions" with "NMOG+NOx or CO emission" to align with how the applicable FTP standards are defined. Additionally, in this same section, CARB recommends adding the PM emission criterion as "PM emissions exceed 2.0 times the applicable FTP standard" as PM emissions will increase if PM filter regeneration frequency increases and a multiplier of 2.0 is consistent with the monitoring thresholds for PM emissions within the onboard diagnostics program. [EPA-HQ-OAR-2022-0829-0780, p. 34]

In 40 CFR section 86.1806-27(h)(2)(iii), CARB recommends replacing the phrase "if regeneration does not properly restore the PM filter when regeneration is designed to occur based on the manufacturer's specified conditions" with "when the PM filter does not properly regenerate under manufacturer-defined conditions where regeneration is designed to occur." The phrase "regeneration does not properly restore the PM filter" lacks clarity unless "properly restore the PM filter" is also separately defined. [EPA-HQ-OAR-2022-0829-0780, pp. 34-35]

Lastly, in 40 CFR section 86.1806-27(h)(3), CARB recommends two clarifications. First, CARB recommends replacing the phrase, "The required minimum ratio for gasoline particulate filters is 0.150" with, "The required minimum ratio for PM filter filtering performance monitors (section (h)(2)(i)) is 0.150." This will clarify the in-use monitoring performance ratio requirement applies to the filtering performance monitors of the PM filter. Second, CARB recommends replacing the sentence, "Manufacturers must track and report the in-use performance of PM filter monitors in accordance with 13 CCR 1968.2(d)(3.2.2)" with, "Manufacturers must track and report the in-use performance of PM filter monitors under paragraph (h)(2)(i) and (ii) in accordance with 13 CCR 1968.2(d)(3.2.2)." This will more explicitly identify that the tracking and reporting requirements apply to filtering performance and frequent regeneration monitors of the PM filter. [EPA-HQ-OAR-2022-0829-0780, p. 35]

Serviceability

Vehicle serviceability is the ability for a driver to be able to repair their vehicle at any repair shop of their choosing and is key to sustaining driver use and maintaining emission benefits from ZEVs. If consumers cannot find suitable repair shops for their ZEVs, there is a risk that they will revert to conventional vehicles, limiting the emission benefits. To service vehicles, repair shops need access to on-board vehicle data and service information defining how to diagnose, repair, and maintain the vehicle, which not only requires some data standardization but also a way to access the data on the vehicle through a standardized means, such as the SAE J1962 compliant diagnostic connector. With the ACC II regulations, CARB added ZEVs to its service information regulation 56 to require the same access and disclosure of repair information and tooling, as well as the requirement that each vehicle be equipped with a standardized data set and equipped with a SAE J1962 diagnostic connector. 57 This regulation requires manufacturers to provide the same information to independent repair shops as they provide to their dealerships as is done for internal combustion engine vehicles today. 58 CARB strongly recommends that U.S. EPA include serviceability requirements for ZEVs in its proposal and, at minimum, a way to access that data through a standardized SAE J1962 compliant diagnostic connector. [EPA-HQ-OAR-2022-0829-0780, p. 42]

57 Cal. Code Regs., title 13, section 1962.5.

58 For additional background on CARB's inclusion of ZEVs in the service information regulation as part of ACC II, see ACC II Final Statement of Reasons for Rulemaking (FSOR), Including Summary of Comments and Agency Response Appendix D Summary of Comments to ZEV Assurance Measures and Agency Response, pp. 59 – 65 https://ww2.arb.ca.gov/sites/default/files/barcu/regact/2022/accii/fsorappd.pdf and ACC II ISOR, Appendix F-7, pp. 1, 10-13, 16.

Organization: Cummins Inc.

VII. Onboard Diagnostics

9. Cummins suggests revisions to the proposed LD and MDV onboard diagnostics requirements for consistency with the HD OBD requirements in 40 CFR Part 1036

Cummins requests the following revisions to the proposed onboard diagnostics regulatory language in 40 CFR 86.1806-27: [EPA-HQ-OAR-2022-0829-0645, pp. 10-11]

- Cummins requests to revise the last sentence of the opening paragraph as follows: "Vehicles may optionally comply with any or all of the requirements of this section instead of the requirements of § 86.1806-17 before model year 2027." The addition of "any or all" would align OBD for LD and MDV with the same flexibility given to manufacturers in 40 CFR 1036.110 to optionally pull ahead EPA 2027 HD OBD requirements before MY 2027. [EPA-HQ-OAR-2022-0829-0645, pp. 10-11]

- To facilitate 50-state certification and avoid the potential for doubling the OBD demonstration testing for manufacturers (i.e., demonstration to engine OBD thresholds for EPA plus demonstration to chassis OBD thresholds for CARB), Cummins requests to add a new paragraph (a)(10) similar to 40 CFR 1036.110(b)(11) and (i)-(iii), plus the underlined text: "If you have an approved Executive order from the California Air Resources Board for a given engine family, we may rely on that Executive order to evaluate whether you meet federal OBD requirements for that same engine family or an equivalent engine family. Engine families are equivalent if they are identical in all aspects material to emission characteristics; for example, we would consider different inducement strategies, different OBD demonstration test procedures/cycles, and different warranties not to be material to emission characteristics relevant to these OBD testing requirements…" This addition would confirm that EPA would accept CARB OBD certification for an equivalent family, including with different OBD demonstration test cycles. [EPA-HQ-OAR-2022-0829-0645, pp. 10-11]

- Cummins requests to add a new paragraph (a)(11), aligned with EPA 2027 HD OBD requirements in 40 CFR 1036.110(b)(6) to remove the in-use compliance/production vehicle evaluation (PVE) requirements as applicable. Note the new paragraph (a)(10) described above would align with the EPA 2027 HD OBD requirement for manufacturers to submit to EPA any PVE test results executed on an equivalent CARB family. [EPA-HQ-OAR-2022-0829-0645, pp. 10-11]

Organization: Ferrari N.V. and Ferrari North America, Inc.

On-Board Diagnostic Requirements

EPA is requiring new monitoring requirements for Gasoline Particulate Filters (GPFs) assuming that CARB OBD II Regulation does not have a requirement for GPF diagnostic. However, according to CCR §1968.2 (d) (7.2), CARB is already requiring GPFs to meet malfunction requirements of sections (f) (9) (i.e. diesel PM filter) and (e) (1.2.1) (B) (i.e. catalyst partial volume monitoring), which includes filtering performance, frequent regeneration, Incomplete regeneration and catalyst function. [EPA-HQ-OAR-2022-0829-0572, pp. 6-7]

We already implemented all the GPF diagnostics required by CCR 1968.2 to obtain CARB approval back in 2019, when we integrated GPF technology on US vehicles, gaining the leadership among other manufacturers. In support of our commitment to CARB monitoring requirements, the best technologies compatible with our applications have already been implemented (e.g. pressure sensors). [EPA-HQ-OAR-2022-0829-0572, pp. 6-7]

Moreover, as stated in §86.1806-27 (h) (2) (i), EPA is proposing a different GPF monitoring approach compared to CARB OBD II regulation. On the counter side, California requires OBD systems to detect a malfunction only when no detectable amount of PM filtering occurs. In this regards, the only technology commercially available for GPF monitoring consists in a couple of pressure sensors, which sensing capabilities do not allow to fulfill EPA's proposal requirements. [EPA-HQ-OAR-2022-0829-0572, pp. 6-7]

Therefore, Ferrari suggests that EPA align with CARB's OBD II requirements for GPF monitoring to avoid different OBD system architectures across the United States. [EPA-HQ-OAR-2022-0829-0572, pp. 6-7]

Organization: Hyundai America Technical Center, Inc. (HATCI)

HMG further recognizes there will be an additional cost of OBD-II diagnostic development, implementation , calibration, and validation required to meet the proposed the PM standard. Moreover, new engine hardware development would be required to meet the PM target without GPF. For example, engines would require increased tumble, central mount injector, and high-pressure fuel systems. [EPA-HQ-OAR-2022-0829-0554, p. 5]

HMG has a number of additional comments. Regarding the 10mg/mi OBD emission limit, there might be real-world driving maneuvers that generate higher PM at the diagnostic threshold; further research is needed to ascertain their prevalence and impact. However, HMG suggests that EPA conduct comprehensive studies to understand the prevalence and significance of these driving maneuvers which would contribute to a more robust and well-informed decision-making process. [EPA-HQ-OAR-2022-0829-0554, pp. 9-10]

HATCI further believes the EPA's assumption that every manufacturer will utilize a pressure sensor and be capable of monitoring the 30% functional threshold is inappropriate. Temperature sensors are an effective method for satisfying emission and diagnostic requirements in Europe and China. They can only be effective at detecting failures such as missing, cracked, or tampered with GPFs. Even with switching to a pressure sensor, conditions such as ash buildup can make diagnosing 30% GPF efficiency infeasible due to a high risk of false-fail or false-pass outcomes.

Fault threshold requirements for GPF would ensure consistency and avoid unnecessary complexity in the regulatory framework. HMG suggests that instead of 30% efficiency EPA use the CARB wording for diagnostics where no malfunction exceeds the OBD emission threshold, i.e. set a GPF malfunction when the system has no detectable amount of PM filtering capability. Linking the threshold to the sensing capability of the system will reduce false-failure. It is essential to consider these practical challenges and explore alternative approaches to ensure accurate and reliable diagnostics. Collaborative efforts between manufacturers and regulatory bodies can help identify innovative solutions that address the limitations associated with pressure sensors and improve the overall effectiveness of OBD diagnostics. [EPA-HQ-OAR-2022-0829-0554, pp. 9-10]

Like other diagnostics, TIJMPR performance depends on customer driving styles, necessitating further evaluation. Conducting thorough data analysis, including studying customer driving styles and their impact on the TIJMPR, would provide valuable insights into the feasibility of this proposal. Including additional denominator conditions to the ratio, with approval, for minimum exhaust flow or vehicle soak time can help to reduce concerns with feasibility. Delta pressure diagnostics usually struggle with robust monitoring at exhaust flow levels found on the FTP. [EPA-HQ-OAR-2022-0829-0554, pp. 9-10]

HMG also shares industry concerns regarding uncertainty surrounding the impact of the Proposed Rule on the OBD approval process. It remains unclear whether OEMs must obtain separate CARB OBD approval before undergoing another OBD review by the EPA for GPF alone . Clear and unambiguous guidelines regarding the impact to the OBD approval process and the interplay between CARB and EPA requirements would eliminate confusion and ensure a smoother certification process for manufacturers. [EPA-HQ-OAR-2022-0829-0554, pp. 9-10]

Finally, HMG shares concerns with industry regarding the proposed IUMPR value, which mirrors the one set for Diesel Particulate Filter (DPF) in the existing CARB OBD diesel regulation. Meeting this value has proven challenging for manufacturers in the past, underscoring the need for a thorough assessment and potential adjustments to the Proposed Rule . Conducting a comprehensive assessment of the feasibility and impact of the proposed IUMPR value for GPF, accounting for the challenges faced by manufacturers in meeting the IUMPR value, would help determine an appropriate and realistic parameter for GPF. [EPA-HQ-OAR-2022-0829-0554, pp. 9-10]

Organization: Kia Corporation

Kia does not support a more stringent PM standard of 0.5 mg/mi that must be met across three test cycles (25 °C Federal Test Procedure (FTP), US06, -7 °C FTP) and is required to be met as a per-vehicle cap, not a fleet average.17 EPA's proposal of 0.5 mg/mi per-vehicle cap will require a gasoline particulate filter (GPF) on every vehicle. Because GPF technology will be necessary for meeting the proposed PM standard, OBD monitoring of the GPF system will be required to detect GPF malfunctions, store trouble codes, and alert operators.18 [EPA-HQ-OAR-2022-0829-0555, pp. 10-11]

17 88 Fed. Reg. 29,264.

18 88 Fed. Reg. 29,269.

Kia is concerned about the feasibility and repeatability of the measurement accuracy of the proposed 0.5 mg/mi standard. Because of these challenges there will also be challenges and additional cost of OBD-II diagnostic development, implementation, and calibration for meeting the standards. Consequently, Kia recommends considering laboratory PM measurement variability and allowing re-test for exceedances during certification, confirmatory or in-use testing, especially for vehicles equipped with Diesel or GPFs. We urge EPA to finalize reasonable PM standards to allow automakers to focus new capital investments on the transition to vehicle electrification. [EPA-HQ-OAR-2022-0829-0555, pp. 10-11]

Kia Supports Harmonized On-Board Diagnostics Requirements with California

EPA proposes to adopt California's OBD-II standards CARB approved in November 2022 and proposes to put in a few more requirements that are not included in the 2022 CARB regulation. EPA will add a new monitoring requirement for GPFs.27 [EPA-HQ-OAR-2022-0829-0555, p. 15]

27 88 Fed. Reg. 29,293.

Kia urges EPA to adopt CARB's criteria emission standards under the ACC II (i.e., LEV IV) and, similarly, to fully harmonize its OBD-II requirements with CARB's OBD-II requirements. It is critical that the criteria emissions regulatory framework is streamlined. Again, since EPA is requiring a 10-fold increase in EV sales, EPA needs to harmonize and streamline its criteria pollutants standards as much as possible. Resources should not be diverted away from the ultimate goal – transitioning successfully to electrification. [EPA-HQ-OAR-2022-0829-0555, p. 15]

EPA's proposed 10 mg/mi OBD emission limit seems reasonable for PM and NMOG+NOx, but further research is needed on stringent PM emissions scenarios.28 Kia also recommends EPA clarify in the final rule the OBD approval process and differing mission thresholds between CARB and EPA. [EPA-HQ-OAR-2022-0829-0555, p. 15]

28 88 Fed. Reg. 29,417.

Organization: MECA Clean Mobility

MECA supports technologically feasible OBD requirements that enable monitoring of technologies for achieving EPA's proposed PM standard. [EPA-HQ-OAR-2022-0829-0564, pp. 11-12]

MECA supports EPA's on-board diagnostic (OBD) concepts, with some suggested changes, related to GPF monitoring in response to the likely increase in implementation of PM emission control technologies to meet the more stringent proposed PM standards. OBD is an essential part of emission standards and provides vital information to drivers when repairs are needed in order to maintain vehicle emission performance. [EPA-HQ-OAR-2022-0829-0564, pp. 11-12]

EPA has proposed that for vehicles with engine-out emissions that never exceed 10 mg/mile and which use a GPF, the OBD system must monitor and alert if filtration performance drops below 30% of "normal" filtration. MECA requests that EPA define the term "normal" for these purposes and conduct testing with currently available PM sensors, including those that employ pressure drop, resistive and electrostatic mechanisms for sensing, to set a level to be monitored.

At a minimum, the OBD system should detect if a filter has been removed from the vehicle, which is possible to monitor via currently available sensors. [EPA-HQ-OAR-2022-0829-0564, pp. 11-12]

EPA has proposed that for vehicles with engine out emissions that exceed 10 mg/mile and use a GPF, the OBD system must monitor and alert if emissions exceed 10 mg/mile on the FTP. We support this requirement and believe that advanced electrostatic PM sensors being commercialized are able to meet these requirements. Furthermore, we support EPA working with CARB to continually review the OBD monitoring requirements and determine where thresholds may be lowered as sensor technology develops. [EPA-HQ-OAR-2022-0829-0564, pp. 11-12]

Sensor technology commercialization has a long cycle, including testing, design and real-world deployment across many vehicles in the field to make sure sensors are reliable and durable. This cycle is why stringent and predictable standards are an important signal to industry to make investments today for technologies that will be needed in the future. Subsequently reversing adopted standards leaves technology and investments stranded and creates a level of uncertainty in the need for technology innovation. MECA members are engaged in developing a portfolio of sensor options that can be installed on a vehicle to monitor emission performance. [EPA-HQ-OAR-2022-0829-0564, pp. 11-12]

Specifically related to this proposal on GPF monitoring, several advancements in PM sensor technology have been demonstrated in the past few years. Some of this work was completed (unpublished data) as part of the ongoing Particle Sensor Performance and Durability Consortium (https://www.swri.org/consortia/particle-sensor-performance- durability-pspd-consortium) managed by Southwest Research Institute. In addition, a 2020 study.12 highlights the potential of PM sensors to yield more data and greater sensitivity measurement as low as 1 mg/m^3. These advanced sensors have ben designed to help OEMs comply with the current IUMPR and thresholds adopted by CARB. We encourage EPA and CARB to periodically review the OBD monitoring requirements as PM sensor technologies evolve. [EPA-HQ-OAR-2022-0829-0564, pp. 11-12]

12 SAE 2020-01-0385

Organization: MEMA, The Vehicle Suppliers Associated

Gasoline Particulate Filter (GPF) and On-Board Diagnostics (OBD)

In the proposed rule, the agency calls for the diagnostic requirement to monitor for a removed, missing, or damaged GPF causing the PM value to go above 10 mg/mi over the Federal Test Procedure (FTP). Based on industry experience, even with a removed, non- existent or a strongly damaged GPF, the gasoline vehicle PM-emissions are below 10 mg/mi. [EPA-HQ-OAR-2022-0829-0644, pp. 10-11]

Considering the proposal for filtration efficiency monitoring below <30% efficiency, the current available technology (based on a differential pressure [AP] sensor) is not sufficiently accurate to detect the set threshold for filtration efficiency. Therefore, correctly identifying parts a with filtration efficiency of < 30 % would lead to identifying components which still having a significantly higher filtration efficiency as "Bad" (False Fail). [EPA-HQ-OAR-2022-0829-0644, pp. 10-11]

The proposal puts a restriction on "frequent regeneration" of the GPF. However, the specific tolerance for regeneration frequency is not mentioned. The limit for allowable regeneration frequency is not adequately defined and is expected to be sensitive to the application. [EPA-HQ-OAR-2022-0829-0644, pp. 10-11]

Monitoring incomplete regeneration of the GPF would be very difficult due to part/part-dispersion in a fresh state and increasing GPF differential pressure owing to ash loading over lifetime as well as other related issues. [EPA-HQ-OAR-2022-0829-0644, pp. 10-11]

MEMA urges:

• EPA to align with the CARB On Board Diagnostic (OBD) Il requirements according to current regulation 13CCR1968.2 listed below and as announced by CARB during the SAE OBD Symposia during March 14th to 16th this year in Prague, Czech Republic: [EPA-HQ-OAR-2022-0829-0644, pp. 10-11]

• Filtering Performance: "the OBD II system shall detect a malfunction when no detectable amount of PM filtering occurs".[EPA-HQ-OAR-2022-0829-0644, pp. 10-11]

• Regeneration: Limitation of any regeneration monitoring requirement to active regenerations, while passive regenerations do not need any monitoring. [EPA-HQ-OAR-2022-0829-0644, pp. 10-11]

• Infrequent Regeneration: Required to be monitored only for sensor-based regenerations, but not for soot-load model-based regenerations. [EPA-HQ-OAR-2022-0829-0644, pp. 10-11]

• Incomplete Regeneration: Postpone requirement until enough data is collected to clarify details of active regeneration, including frequency of active regenerations which is expected to be low. [EPA-HQ-OAR-2022-0829-0644, pp. 10-11]

Organization: Mercedes-Benz AG

Mercedes-Benz is requesting EPA align with CARB’s ACCII approach; EPA should harmonize its OBD emissions threshold criteria with CARB’s. [EPA-HQ-OAR-2022-0829-0623, p. 11]

In regard to the Regeneration (“regen”) Frequency OBD Requirements, current OBD emission threshold criteria evaluates NMOG and NOx as a combined threshold (i.e., NMOG+NOx). However, EPA’s NPRM is proposing to include individual multipliers for HC, NOx and CO. Since the OBD threshold multipliers are designed to work in concert with emissions standards themselves, it is important to harmonize threshold multipliers to emissions standard constituents (i.e., NMOG+NOx, CO, PM, etc.). [EPA-HQ-OAR-2022-0829-0623, p. 11]

In addition, an OBD emissions threshold is proposed to detect a malfunction when emissions exceed

1.5 times the applicable FTP standard for all emission Bins. CARB OBD regulations have allowed higher multipliers as the emission standards become more stringent. Mercedes proposes EPA adopt a similar approach for Regen Frequency OBD as other OBD monitors (e.g., provide

2.5 times multiplier for Bin30/SULEV30 instead of 1.5 times). [EPA-HQ-OAR-2022-0829-0623, p. 11]

A vehicle will regenerate, or purge, the particulate filter when the soot accumulation reaches a certain level. This regeneration process has been historically used for diesel vehicles which utilize Diesel Particulate Filters ("DPFs"). As discussed above, EPA's proposed PM standards will force the incorporation of GPFs for many gasoline vehicles. GPFs behave differently than DPFs, and the EPA should incorporate language in the final rule that provides clear direction for OBD test procedures and definitions related to GPFs. [EPA-HQ-OAR-2022-0829-0623, p. 11]

The EPA adoption of CARB OBD revealed some gaps in CARB's OBD definitions. While EPA should address these gaps in the final rule, it is equally important that EPA work with CARB, and the auto industry, to ensure CARB will also adopt the provisions as finalized [EPA-HQ-OAR-2022-0829-0623, p. 12]

Organization: Volvo Car Corporation (VCC)

Appendix- Technical comments on the OBD proposal.

1. GPF Monitoring Requirements

§ 86.1806-27, section (h)(2)(i) in the NPRM proposal requires the OBD system to "detect a malfunction if the PM filter allows free flow of exhaust through the PM filter assembly where 30 percent or less of the normal filtration is occurring" [EPA-HQ-OAR-2022-0829-0624, pp. 7-10]

OBD systems require separation between worst performing acceptable (WPA or "good parts") and best performing unacceptable (BPU or "bad parts") systems. Manufacturers often target six-sigma separation between WPA and BPU for robustness. False MILs are a burden to all stakeholders, from the government agency to the customer and workshop. Therefore, separation between WPA and BPU is needed. [EPA-HQ-OAR-2022-0829-0624, pp. 7-10]

Today, monitoring detection of a "removed GPF" (empty can or straight pipe) is challenging with existing sensor technology. See GPF test results below utilizing a delta pressure sensor. This illustrates that separation between an intact and missing substrate is challenging. The data also shows that requiring detection of a filter flowing 30% of normal would even further reduce the limited separation between a normal system and "removed GPF". Separation between an intact and a partial GPF failure is not feasible, and the data illustrates that robust detection with existing sensing technology is not possible for any partial failure modes of the GPF. [EPA-HQ-OAR-2022-0829-0624, pp. 7-10]

[See original for graph on GPF test results FTP75] [EPA-HQ-OAR-2022-0829-0624, pp. 7-10]

[See original for graph on GPF test results FTP75 – trendline] [EPA-HQ-OAR-2022-0829-0624, pp. 7-10]

[See original for graph on GPF test results FTP75+UC cycle] [EPA-HQ-OAR-2022-0829-0624, pp. 7-10]

[See original for graph on GPF test results FTP75 + UC cycle – trendline] [EPA-HQ-OAR-2022-0829-0624, pp. 7-10]

[See original for pictures on delta pressure curves as a function of exhaust flow from an intact substrate, completely missing substrate, unplugged rear surface, drilled 20mm and drilled 50mm.] [EPA-HQ-OAR-2022-0829-0624, pp. 7-10]

The pictures above show delta pressure curves as a function of exhaust flow from an intact substrate (base line 100% normal filtration), completely missing substrate, unplugged rear surface (30% of normal filtration), drilled 20mm (88% of normal filtration) and drilled 50mm (43% of normal filtration). [EPA-HQ-OAR-2022-0829-0624, pp. 7-10]

a. VCC proposes revising the language found in (§ 86.1806–27 (h)(2)(i), to only require detection "if the PM filter substrate is completely destroyed, removed, or missing, or if the PM filter assembly is replaced with a muffler or straight pipe". [EPA-HQ-OAR-2022-0829-0624, pp. 7-10]

b. Another option would be to revise the EPA language to be consistent with the CARB language for PM filtering performance. [EPA-HQ-OAR-2022-0829-0624, pp. 7-10]

"If there is no failure or deterioration of the PM filter that could cause a vehicle to exceed the specified PM emission level, the OBD II system shall detect a malfunction when no detectable amount of PM filtering occurs" [EPA-HQ-OAR-2022-0829-0624, pp. 7-10]

The CARB language is not defining a specific amount of flow and it considers the monitoring technology by referring to the minimum detectable flow the system can detect. [EPA-HQ-OAR-2022-0829-0624, pp. 7-10]

The proposed revisions a. and b. are believed to be the only options that are feasible with today's commercially available sensing technology. [EPA-HQ-OAR-2022-0829-0624, pp. 7-10]

c. The PM filtering performance monitoring is more robust at higher exhaust flow. There is more separation at higher exhaust flows, as shown, but most of the higher exhaust flows are off cycle. This would also be a challenge for meeting In-Use Monitor Performance Ratio (IUMPR) minimum ratios for PM filtering performance monitoring. To address this, VCC proposes defining a special denominator for the monitor. In addition, VCC recommends referencing the exhaust flow rate to the special denominator and only allowing it to increment if a high enough exhaust flow rate is achieved for a specified amount of time. [EPA-HQ-OAR-2022-0829-0624, pp. 7-10]

VCC respectfully requests feedback from EPA on proposal 1a.,1b and 1c. [EPA-HQ-OAR-2022-0829-0624, pp. 7-10]

2. Active regeneration requirements

§ 86.1806-27, section (h)(2)(ii) and section (h)(2)(iii) in the NPRM proposal requires the OBD system to monitor too frequent and incomplete regeneration, respectively. [EPA-HQ-OAR-2022-0829-0624, pp. 10-11]

Active regeneration is very infrequent on petrol engines and happens only during extreme conditions. For most systems it never happens on a legislative drive cycle (e.g., FTP, UC). This would make it problematic to detect too frequent or incomplete regeneration. [EPA-HQ-OAR-2022-0829-0624, pp. 10-11]

At a meeting between EPA and Volvo, EPA staff indicated that active regen would probably never be needed on a vehicle with a close coupled GPF or would only be needed very infrequently for an under floor GPF application. However, the OBD system should identify active regenerations and access if they are not working properly by the manufacturer's own specifications. In principle the vehicle should monitor the regeneration and make sure that it is happening correctly. [EPA-HQ-OAR-2022-0829-0624, pp. 10-11]

a. If a manufacturer designs their GPF system without a "periodically active regenerating system", then the manufacturer should not be subject to § 86.1806–27 (h)(2)(ii) or (iii). VCC proposes adding a definition of a "Periodically active regenerating system" which is as a system that requires active regeneration in less than 4,000 km/ 2,500 miles on a 25 deg C FTP. [EPA-HQ-OAR-2022-0829-0624, pp. 10-11]

b. VCC has a concern with requiring OEMs to monitor infrequent events. If such monitors are required by EPA, Volvo would need additional insight and clarification on how the monitors shall meet IUMPR requirements, and when to report monitor "pass" and "readiness". All this would be important for the service technician and the customer to be able to pass the I/M stations. [EPA-HQ-OAR-2022-0829-0624, pp. 10-11]

c. A third proposal would be to skip the monitoring and have active regen in the AECD description. If required, the manufacturer could provide a run time tracker (PID $8B). At the last SAE OBD Symposium in March 2023, CARB indicated similar thoughts. Currently, CARB is contemplating not requiring active regeneration monitors (only tracking through PID $8B). [EPA-HQ-OAR-2022-0829-0624, pp. 10-11]

VCC requests feedback from EPA on 2a, 2b and 2c. [EPA-HQ-OAR-2022-0829-0624, pp. 10-11]

EPA Summary and Response

EPA received OBD comments on several topics including the proposed GPF diagnostic, monitoring thresholds, suggested regulation language changes, and accepting California Executive Order chassis approval for vehicles using the same powertrains that are dyno certified for Federal use.

EPA received many comments on its GPF monitoring requirement. Some comments supported EPA's proposed GPF monitoring provisions. Other comments recommended that we remove these requirements altogether. Additional comments suggested either specific changes to regulator text and/or changes to specific requirements. Some manufacturers commented that since they had already certified GPF's with CARB using the CARB OBD regulation, they believed the CARB OBD requirement was sufficient to create a diagnostic. Commentors were also concerned that EPA's separate OBD requirement would add significant certification burden, requiring them to deal with both agencies for OBD approval. In response, EPA decided based on the comments received to not finalize a separate federal GPF requirement and instead rely on the CARB regulation for the needed GPF monitoring requirements. After working with stakeholders who have created diagnostics using CARB's OBD regulation, EPA believes the CARB provisions are sufficient to verify the integrity of the GPF system to ensure the federal emissions standards.

EPA received comments that based on the NMOG+NOx bin structure it was not clear what the correct OBD thresholds for each bin would be. Based on the comments received EPA has expanded the bins and added to the regulatory text clarifying language regarding what OBD thresholds apply.

The Alliance for Automotive Innovation commented that we had incorrect dates for the CARB OBD regulations incorporation by reference (IBR). EPA has corrected the IBR dates to match the CARB regulation releases.

The Alliance for Automotive Innovation and Cummins both requested that EPA revise the regulations to accept “any or all” of provisions of 40 CFR 86.1806-27 for vehicles certified prior to MY 2027. In response, EPA disagrees with this change since the regulations of § 86.1806-17 already allow for manufacturers to request approval of new versions of the California OBD regulations. If a manufacturer makes a request for such approval, a manufacturer must comply with the new version in its entirety. EPA does not agree that it is appropriate to mix and match different versions of the California OBD.

Cummins commented that there could be engine families that would be required to demonstrate compliance to engine-based OBD thresholds for EPA plus demonstration to chassis-based OBD thresholds for CARB, doubling the OBD demonstration work required of manufacturers. Cummins requested to add a new paragraph (a)(10) to 40 CFR 86.1806-27 similar to 40 CFR 1036.110(b)(11) and (i)-(iii) to facilitate 50-state certification and avoid the potential for doubling the OBD demonstration. EPA is not finalizing the proposal to require vehicles with GCWR greater than 22,000 lbs to comply with engine-dynamometer-based criteria pollutant emissions standards under the heavy-duty engine program. However, engine-dynamometer-based certification will be optional for such vehicles. EPA disagrees that a 50-state engine family (i.e., an engine family certified to engine dyno standards for both EPA and CARB) would be subject to engine OBD demonstration for EPA and chassis OBD demonstration for CARB.

However, EPA agrees that a 50-state engine family which fully complies with the CARB OBD requirements and has received an Executive order from CARB should not require a separate OBD demonstration for EPA certification. EPA added a reference to 40 CFR 1036.110(b)(11) in 40 CFR 86.1806-27 for the final rule to make it clear that these provisions apply to engine families intended to be installed in heavy-duty vehicles at or below 14,000 pounds GVWR.

Cummins also requested EPA align with EPA 2027 HD OBD requirements in 40 CFR 1036.110(b)(6) to remove the in-use compliance/production vehicle evaluation (PVE) requirements as applicable. EPA agrees with this comment and has added the appropriate reference to 40 CFR 1036.110(b)(6) in 40 CFR 86.1806-27.

EPA received comments from CARB’s requesting it add serviceability requirements for ZEVs similar to ACCII. EPA did not propose or solicit comment on this change, and thus it is out of scope for this rulemaking.

6 - Test procedures

6.1 – EV test procedures

Comments by Organizations

Organization: Alliance for Automotive Innovation

VIII. Certification and Compliance Procedures

A. Electric Vehicle Test Procedures

As a result of the proposed battery durability and warranty requirements referenced in section III.F.2 and section III.F.3, [323] EPA is proposing to update their BEV and PHEV testing requirements outlined in section III.F.1 of the NPRM. Based on what is outlined in this section, we have a number of concerns. [EPA-HQ-OAR-2022-0829-0701, pp. 215-216]

323 NPRM at 29286

1. BEV (SAE J1634) and PHEV (SAE J1711) Test Procedures

Our first concern relates to EPA's reference of the 2010 version of SAE J1711 for determining UBE in PHEVs, as well as the 2017 version of SAE J1634 for determining Usable Battery Energy (UBE) for class 2b and 3 BEVs. There currently are more recent versions of both standards available - SAE J1711-2023 and J1634-2021. Under EPA's most recent Heavy-Duty NPRM – "Control of Air Pollution From New Motor Vehicles: Heavy-Duty Engine and Vehicle Standards," Auto Innovators proposed to adopt the 2021 version of SAE J1634. EPA rejected this due to concerns with the SMCT and SMCT+ tests enabled by the 2021 version. We continue to encourage EPA to adopt the most recent versions of both SAE J1711 and SAE J1634. [EPA-HQ-OAR-2022-0829-0701, pp. 215-216]

Auto Innovators recently outlined our strong support for the adoption of SMCT/SMCT+ testing and harmonization with CARB under EPA's most recent heavy-duty NPRM. In those comments, we said the following:

"We request the option to allow use of the Short Multi-Cycle Test (sMCT) and the Short Multi-Cycle Test Plus Steady State (sMCT+) procedures. Allowing these procedures would also harmonize with the CARB proposed test procedures and significantly reduce laboratory test burden associated with BEV testing while providing equivalent test results. [EPA-HQ-OAR-2022-0829-0701, pp. 215-216]

EPA's current proposal prohibits manufacturers from using thermal conditioning during cold soak periods. Unlike vehicles with internal combustion engines, managing battery temperature in BEV vehicles is critical to battery durability, vehicle performance, and energy efficiency. Thermal conditioning of the BEV propulsion battery can provide real-world benefits in these areas. We would like to request for EPA to remove requirements explicitly prohibiting thermal conditioning in order to not restrict emerging technologies that could improve real-world performance and efficiency, for example under extreme cold start conditions during short trip city driving. [EPA-HQ-OAR-2022-0829-0701, pp. 215-216]

We would also request for the use of thermal conditioning to be considered as part of the 5-cycle test procedure approval process. Keeping in mind that the industry is still learning about customer behavior related to BEV thermal conditioning, and any allowance of thermal conditioning should be customer representative, either by default operation, manufacturer instruction, or demonstrated real-word usage, we urge the EPA to allow manufacturers to incorporate new technologies such as this one, when sufficient justification is provided." [EPA-HQ-OAR-2022-0829-0701, pp. 215-216]

We stand by these comments and continue to argue for the adoption of SMCT/SMCT+ testing, as well as the allowance of thermal conditioning during cold soak periods, and to be considered as a part of the 5-cycle test procedure approval process. Additionally, we would like to request additional flexibility to allow EPA to run confirmatory tests to verify accuracy of any of the three tests (MCT, SMCT, SMCT+) that it so chooses. That would eliminate any uncertainty from EPA regarding the accuracy of the new SMCT/SMCT+ testing. [EPA-HQ-OAR-2022-0829-0701, pp. 215-216]

Finally, the test procedure such as the MCT for BEVs will create extremely long test duration, especially for longer electric range vehicles, as well as other complications. [EPA-HQ-OAR-2022-0829-0701, pp. 219-220]

CREE Requirements

The Environmental Protection Agency has proposed to adopt battery durability requirements for battery electric vehicles and plug-in hybrid electric vehicles. The proposal includes measurement of usable battery energy for PHEVs during charge-depleting (CD) operation to ensure battery durability. [EPA-HQ-OAR-2022-0829-0701, p. 222]

However, EPA regulations already include a requirement for PHEVs to calculate carbon related exhaust emissions (CREE) using fleet utility factors (FUFs) based on CD range per 40 CFR Part 600.116-12. In-use CREE must be considered with the in-use vehicle's CD range. Furthermore, per 40 CFR Part 86.1823-08, PHEVs must also include a deterioration factor (DF) for CO2 or test with aged batteries to reflect the battery deterioration impact. This is in contrast to BEVs, which will have a CREE/CO2 value of 0g/mi regardless of battery deterioration and the change in UBE. The proposed UBE requirements for PHEVs would be in addition to the existing requirements for CREE and DF. We recommend that EPA remove the requirement for PHEVs to calculate CREE/CO2 based on aged batteries, and instead align with BEV requirements to ensure battery durability via the newly proposed UBE requirements. We believe that this approach would be an effective method to ensure the durability of PHEV batteries in a manner consistent with the proposed regulatory framework for BEVs. This would ensure technology neutrality and equitable treatment to PHEVs. Alternatively, if EPA decides to only require the impact of battery deterioration to be included in the CO2 values for PHEVs, we recommend that EPA remove the UBE requirement for PHEVs altogether, as battery deterioration is already accounted for via the in-use CREE requirements. [EPA-HQ-OAR-2022-0829-0701, p. 222]

6. Calculation of UBE

Under this NPRM, EPA is also proposing changes to 40 CFR § 600.116-12.331 The proposed methodology for calculating UBE as stated in 600.116-12(11)(ii) indicates the necessity to calculate the Fleet Utility Factor (FUF). However, the FUF calculation is used to calculate the ratio of Charge Depleting (CD) and Charge Sustaining (CS) driving. This ratio is unnecessary when calculating UBE because it is trying to find the DC discharge energy during charge depletion, and the ratio of CD/CS operation is unnecessary. As such we would recommend deleting 600.116-12(11)(ii). [EPA-HQ-OAR-2022-0829-0701, p. 223]

331 NPRM at 29421.

Additionally, the proposed language in 600.116-12(11)(iii) instructs to use an average of the RESS voltage during FCT, either by averaging continuous measurement or averaging the initial and final voltage measurements. This average voltage is then used in (iv) to calculate the DC discharge energy by multiplying the change in SOC per cycle to the average voltage per cycle. For PHEVs or EVs, voltage can vary during dynamic driving conditions. Voltage should be continuously integrated with current value to ensure accurate DC energy during cycle. The use of average voltage value is appropriate for HEV, but for PHEV and BEV can result in inaccurate DC energy values. Thus, as it pertains to both BEVs and PHEVs, we believe that DC energy should be measured via a continuous integration of current and voltage. If a method to calculate DC energy that allows use of average voltage in a cycle, it should be the average of a continuous voltage measurement during each cycle. [EPA-HQ-OAR-2022-0829-0701, p. 223]

Organization: BMW of North America, LLC (BMW NA)

BMW NA strongly believes that hydrogen technology will play a key role on the path to climate neutrality across all industries and has great potential, particularly for individual mobility. The pilot series of the BMW iX5 Hydrogen, which is currently being presented to the public during various events all around the globe, highlights the possibilities of hydrogen technology in this context. [EPA-HQ-OAR-2022-0829-0677, p. 3]

BMW NA would like to encourage EPA to extend the regulatory guidance for FCEVs by the means of incorporating an official test procedure (e.g., incorporation of SAE J2572). We believe that this will benefit the automotive industry to better evaluate the technology's potential compared to BEV and quantify its contribution to the overall electrification goals. [EPA-HQ-OAR-2022-0829-0677, p. 3]

Furthermore, an additional, maybe time-limited incentive through ATV multipliers - a concept which has shown its effectiveness on EVs in the past - would encourage the industry to go further down this pathway. [EPA-HQ-OAR-2022-0829-0677, p. 3]

Organization: California Air Resources Board (CARB) (Part 1 of 5)

Improved Electric Driving Range Information

Currently, the existing BEV label highlights vehicle efficiency in units of miles per gallons of gas equivalent (MPGe) based on testing across five defined drive cycles. The current label also uses this efficiency for the reported electric vehicle driving range. However, driving range based on city cycle usage or the combined cycle usage is not relevant to drivers who are primarily concerned about range for long distance travel which, by definition, is typically conducted at highway-like speeds. CARB notes that some third parties (including AAA, 75 InsideEVs, 76 and a recent SAE paper 77) have also previously assessed BEV range and noted a mismatch between label reported range and what a typical driver would likely experience in-use. [EPA-HQ-OAR-2022-0829-0780, pp. 46-47]

75 American Automobile Association, Inc. ”AAA Electric Vehicle Range Testing.” NewsRoom.AAA.com. February 2019. AAA-Electric-Vehicle-Range-Testing-Report.pdf.

76 Moloughney, T., “What's The Real World Highway Range Of Today's Electric Cars? We Test To Find Out.” InsideEVs.com. April 22, 2023. https://insideevs.com/reviews/443791/ev-range-test-results/. Accessed June 15, 2023.

77 Pannone, G. and VanderWerp, D., "Comparison of On-Road Highway Fuel Economy and All-Electric Range to Label Values: Are the Current Label Procedures Appropriate for Battery Electric Vehicles?," SAE Technical Paper 2023-01-0349, 2023, https://doi.org/10.4271/2023-01-0349.

CARB recommends that U.S. EPA require manufacturers to collect and report some higher speed highway relevant energy consumption information during ZEV certification to supplement the highway drive cycle information currently submitted. To minimize added test burden to vehicle manufacturers, this data could be collected during the constant speed cycle portion of the already required SAE J1634 certification testing procedure to capture energy consumption rates at 65 mph and perhaps 75 mph to sufficiently bracket expected usage and ensure sufficient data exists to inform a future label. [EPA-HQ-OAR-2022-0829-0780, pp. 46-47]

Additionally, based on experience to date as to information consumers are seeking, CARB recommends U.S. EPA require collection and reporting of additional data to enable calculation of range under cold and hot weather conditions. As an example, collection of both highway-speed energy consumption and total usable battery energy while carrying out required testing for the 20-degree Fahrenheit cold temperature cycle could provide sufficient information to derive a consistent cold temperature estimated driving range. Likewise, during the required supplemental test known as SC03 that represents hot weather driving with high solar load and air conditioning usage, collection of this data could provide the necessary information to allow a more meaningful future label that transparently presents range information to a consumer. Many consumers are aware of battery limitations in cold or hot weather but lack accurate information when making purchase decisions as to the likely magnitude of that impact on any particular vehicle. [EPA-HQ-OAR-2022-0829-0780, pp. 46-47]

Organization: Ford Motor Company

Battery Electric Vehicle (BEV) and Plug-In Hybrid Electric (PHEV) Battery Durability and Testing

Adoption of efficient, harmonized test methods and standards will be critical as we rapidly transition to electrified vehicles. Ford requests that EPA consider the following recommendations to streamline and clarify the ever-increasing BEV testing workload. [EPA-HQ-OAR-2022-0829-0605, pp. 15-16]

-The latest versions of SAE J1634 (2021) and J1711 (2023) should be adopted for BEV and hybrid testing across light-duty, class 2b and 3 vehicles. We are aligned on utilizing the loaded vehicle weight (LVW) with these procedures. [EPA-HQ-OAR-2022-0829-0605, pp. 15-16]

Organization: Mercedes-Benz AG

Battery Electric Vehicle (“BEV”) Testing

It currently takes about six hours of lab time to conduct a traditional ICE vehicle 5-cycle certification test sequence. In contrast, 5-cycle testing for a BEV takes more than 30 hours. While this test time will drop to 16 hours starting in 2025 Model Year (“MY”), this is still a significant increase over the time requirements for ICE testing. [EPA-HQ-OAR-2022-0829-0623, pp. 14-15]

There is a solution, a way to significantly reduce testing time and save lab resources while still providing accurate vehicle test results. In EPA's "Control of Air Pollution From New Motor Vehicles: Heavy-Duty Engine and Vehicle Standards"11 Final Rule, EPA updated from the the 2012 to the 2017 version of SAE J1634. The agency, however, chose not to adopt the most recent 2021 version of this test procedure which includes allowances for the use of the Short Multi-Cycle Test ("SMCT") and SMCT+. These two procedures both significantly reduce testing time, while providing accurate BEV testing results. [EPA-HQ-OAR-2022-0829-0623, pp. 14-15]

11 Final Rule and Related Materials for Control of Air Pollution from New Motor Vehicles: Heavy-Duty Engine and Vehicle Standards, govinfo.gov/content/pkg/FR-2023-01-24/pdf/2022-27957.pdf.

In light of the significantly increasing number of BEV tests that will need to occur under this 2027 to 2032 MY rule, Mercedes-Benz requests the agency adopt the 2022 version of SAE J1634 test procedure in this final rule, and allow for early and immediate implementation. [EPA-HQ-OAR-2022-0829-0623, pp. 14-15]

The EPA HD rule also includes an explicit prohibition of thermal conditioning. This prohibition is problematic for innovation of technological strategies that could improve battery durability and performance in cold start conditions. Mercedes-Benz requests allowance of thermal heating during certification in accordance with customer behavior [EPA-HQ-OAR-2022-0829-0623, p. 15]

Organization: Rivian Automotive, LLC

EV Test Procedures

Rivian generally supports EPA's proposed approach to EV test procedures, including the proposed use of the 2017 version of SAE J1634 for determining UBE for Class 2b-3 BEVs and testing Class 2b-3 BEVs at adjusted loaded vehicle weight ("ALVW"). Since the start of production of Rivian's Class 2b-3 electric delivery van, we have used ALVW for testing purposes as opposed to loaded vehicle weight. The EDV carries packages and the range and efficiency estimates generated by testing at ALVW are more representative of real-world driving and the use case for these vehicles. We believe similar logic applies to the full spectrum of Class 2b-3 vehicles, which are overwhelmingly used in utility applications to tow, haul, carry goods for delivery, and so on. Charge-depleting tests should be performed at ALVW across all manufacturers. [EPA-HQ-OAR-2022-0829-0653, p. 13]

EPA Summary and Response

Summary:

EPA received comments from the Alliance for Automotive Innovation, BMW NA, the California Air Resources Board, Ford Motor Company, Mercedes Benz AG, and Rivian Automotive regarding electric vehicle test procedures.

A majority of comments addressed the proposed BEV and PHEV test procedure updates for determining useable battery energy. BMW NA submitted comments encouraging the Agency to adopt test procedures for hydrogen fuel cell electric vehicles. BMW believes hydrogen FCEVs will be a key technology for achieving climate neutrality. BMW requested EPA adopt SAE technical standard J2572, Recommended Practice for Measuring Fuel Consumption and Range of Fuel Cell and Hybrid Fuel Cell Vehicles Fueled by Compressed Gaseous Hydrogen, which defines a procedure for testing FCEVs and possibly adopting a time-limited advanced technology vehicle credit multiplier for hydrogen FCEVs.

The Alliance, Ford Motor Company, Mercedes Benz AG, and Rivian Automotive all provided comments regarding SAE technical standard J1634, Battery Electric Vehicle Energy Consumption and Range Test Procedure. Rivian is supportive of the proposed use of the 2017 version of J1634 for determining useable battery energy for Class 2b and Class 3 BEVs. Rivian also commented that Class 2b and Class 3 BEVs should be tested at adjusted loaded vehicle weight which is the average of a vehicle's curb weight and the vehicle's gross vehicle weight rating.

The Alliance, Ford Motor Company and Mercedes Benz encouraged EPA to adopt the most recent version (2021) of SAE technical standard J1634 for testing BEVs. The Alliance, Ford Motor Company and Mercedes Benz requested EPA adopt the most recent version which includes two new test procedures, the shortened multicycle test (SMCT) and the shortened multicycle plus test (SMCT+), for determining useable battery energy. Both the Alliance and Mercedes Benz noted that the additional tests, the SMCT and SMCT+, reduce testing time and Mercedes Benz also noted the new tests provide accurate BEV testing results. The Alliance also noted that adopting the 2021 version of J1634 would harmonize EPA and California's BEV testing regulations as California has adopted the 2021 version of J1634. The Alliance also commented that adopting the 2021 version of J1634 would provide EPA with an opportunity to verify the accuracy of any of the test procedures, the MCT, SMCT and SMCT+, for determining useable battery energy. The Alliance and Mercedes Benz both commented that they had made similar requests to the Agency when the Agency proposed updating the reference version of J1634 from the 2012 version to the 2017 version as part of the revisions proposed with EPA's notice of proposed rulemaking – "Control of Air Pollution From New Motor Vehicles: Heavy-Duty Engine and Vehicle Standards". 87 FR 17414 (Mar. 28, 2022).

The Alliance and Mercedes Benz requested EPA adopt the 2021 version of SAE J1634 to allow for BEV battery and cabin pre-heating during testing used for generating BEV 5-cycle data used to determine the 5-cycle adjustment factor for fuel economy labeling. The Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles NPRM, 88 FR 29184 (May 5, 2023), notice of proposed rulemaking did not include any provisions to make revisions to EPA's existing BEV 5-cycle test procedures which were previously updated in the final rulemaking for Heavy-Duty Engines and Vehicle Standards. 88 FR 4296, (Jan. 24, 2023).

The Alliance and Ford Motor Company encouraged EPA to adopt the most recent (2023) version of SAE J1711, Recommended Practice for Measuring the Exhaust Emissions and Fuel Economy of Hybrid-Electric Vehicles, including Plug-In Hybrid Vehicles. The Alliance also stated that when determining the useable battery energy for a PHEV the voltage measurement should be continuously integrated with current to ensure accurate measurements of DC discharge energy during testing; and, if the Agency allows the use of average voltage in the cycle it should be the average of a continuous measurement during each cycle. The Alliance also noted the proposed regulations for determining PHEV useable battery energy required a calculation to determine the fleet utility factor. The Alliance noted the fleet utility factor is not necessary for determining PHEV useable battery energy and recommended deleting § 600.116-12(11)(ii).

The Alliance also noted that EPA currently has regulatory requirements for PHEVs requiring manufacturers to account for battery durability when determining the in-use CREE standard. The Alliance requests that EPA drop the requirement for PHEVs use aged batteries when accounting for the impact of battery deterioration on weighted CREE emissions with the adoption of the battery durability requirement. The Alliance noted that EPA should drop the PHEV battery durability requirement if EPA keeps the requirement to account for battery deterioration when estimating the weighted PHEV CREE emissions.

The California Air Resources Board recommends that U.S. EPA gather additional information during manufacturer testing of fuel economy data vehicles to supplement drive cycle information currently submitted by manufacturers to U.S. EPA. California suggests collecting data during the constant speed cycle of the multi-cycle test and capture energy consumption data at 65 mph and perhaps at 75 mph with intent of using these data to inform a future fuel economy label. California also recommends EPA collect and report additional data to enable calculation of range under cold and hot weather conditions. Collecting additional data during 20°F testing, including highway speed energy consumption and useable battery energy could also be beneficial for deriving a cold temperature driving range. California also recommends collection of similar data during the SC03 test (representative of high ambient temperature with high solar load conditions) to allow a more meaningful future fuel economy label which transparently present range information under different load and ambient conditions to consumers.

Response:

EPA has considered BMW’s comment encouraging the Agency to propose a specific test procedure for hydrogen FCEVs by adopting SAE technical standard J2572. This is beyond the scope of our proposal as the Agency did not address test procedures for fuel cell vehicles or seek comments regarding testing of fuel cell vehicles in the NPRM. We note, however, that manufacturers producing hydrogen FCEVs are eligible to propose special test procedures according to the existing provisions of 40 CFR 1065.10(c)(2). BMW and other hydrogen FCEV manufacturers are eligible to request approval to use SAE J2572 for testing. The request to use the special procedure needs to be made prior to the manufacturer beginning the test program.

Rivian Automotive’s comments addressing the use of the 2017 version of SAE J1634 for testing Class 2b and Class 3 vehicles along with performing these tests at the adjusted loaded vehicle weight are supportive of the Agency’s proposal and adopted regulations. With the issuance of the final rule, the Agency has adopted using the 2017 version of J1634 for testing Class 2b and Class 3 BEVs and performing these tests at the adjusted loaded vehicle weight.

The Alliance, Ford Motor Company and Mercedes Benz suggested that EPA adopt the 2021 version of SAE J1634 which would allow manufacturers to perform the SMCT and SMCT+ in addition to the MCT. The Alliance and Mercedes Benz both noted they had submitted similar comments in a prior rulemaking, “Control of Air Pollution From New Motor Vehicles: Heavy-Duty Engine and Vehicle Standards,” 87 FR 17414. EPA previously responded to these prior comments requesting use of the SMCT and SMCT+ in the Final Rulemaking for the Heavy-Duty Engine and Vehicle Standards, 89 FR 4296, and the Response to Comments Document, EPA-420-R-22-036, December 2022. The Agency is not prepared to adopt the 2021 version of SAE J1634. The Agency is continuing its evaluation of the new test procedures to determine if these procedures produce results equivalent to those generated using the existing single cycle tests and MCT test procedures. The Agency is aware that there continues to be minimal publicly available test data that could be used to conclude the procedures produce equivalent test results. The Alliance recommended the Agency adopt the 2021 version of SAE J1634 and use the Agency's confirmatory testing program to generate data which would be used to evaluate the newer procedures to determine their equivalence with the existing single cycle tests and MCT results. The Agency's confirmatory test program tests around 15 percent of all BEV tests submitted to the Agency for fuel economy labeling. The goal of the confirmatory test program is to randomly evaluate the test results provided by manufacturers to ensure the data being generated are representative and appropriate. The Agency does not believe it would be appropriate to adopt these procedures without sufficient data demonstrating equivalence with existing test procedures while using the Agency confirmatory test program to evaluate the equivalence of these procedures.

The Alliance and Mercedes Benz suggested that EPA adopt the 2021 version of SAE J1634 specifically to allow for the use of thermal conditioning when performing BEV 5-cycle test procedures used for determining the 5-cycle fuel economy adjustment factor for fuel economy labeling. The Alliance and Mercedes Benz both noted they had submitted similar comments in a prior rulemaking, "Control of Air Pollution From New Motor Vehicles: Heavy-Duty Engine and Vehicle Standards," 87 FR 17414. EPA previously responded to these prior comments requesting the use of thermal conditioning in the Final Rulemaking for the Heavy-Duty Engine and Vehicle Standards, 88 FR 4296, and the Response to Comments Document, EPA-420-R-22-036, December 2022. The Agency is not prepared to adopt the 2021 version of SAE J1634 to allow thermal conditioning of the battery and cabin prior to 5-cycle adjustment factor testing. EPA understands managing propulsion battery temperature is important for battery durability, vehicle performance, and energy efficiency. Current EPA regulations and the 2017 version of SAE J1634 do not allow for the use of thermal conditioning during cold soak periods of EPA test procedures. The function of the cold soak period is to stabilize the vehicle and its components at the desired test procedure ambient temperature prior to beginning the driving portion of the test. While BEVs have technology and operating modes designed to precondition the battery and cabin while the vehicle is soaking, for this technology to function the vehicle must have access to a dedicated EVSE and the operator must enable this operation. The Agency does not expect that a predominance of BEVs will have access to a dedicated EVSE while the vehicle is cold soaking prior to many cold starts and the operator will also have enabled the preconditioning mode. Therefore, the Agency is not prepared to adopt the 2021 version of SAE J1634 to allow for preconditioning of the battery and cabin during the cold soak.

The Alliance and Ford Motor Company encouraged EPA to adopt the most recent version of SAE J1711, Recommended Practice for Measuring the Exhaust Emissions and Fuel Economy of Hybrid-Electric Vehicles, Including Plug-In Hybrid Vehicles. Having reviewed the updates to the 2023 version of SAE J1711, EPA agrees with the Alliance and Ford Motor Company and is updating the reference from the 2010 to the 2023 version of SAE J1711. Updating this reference provides a couple of improvements related to determining the DC discharge energy when performing charge depletion testing on a PHEV. It updates the voltage measurement method to allow for a continuously integrated voltage measurement during each test cycle. In addition, the EPA regulations allow for manufacturers to both integrate voltage and current during each test cycle and calculate DC discharge energy during each cycle.

EPA also agrees with the Alliance's suggestion to delete 40 CFR 600.116-12(11)(ii). EPA concurs that there is no necessity for calculating the fleet utility factor when measuring the useable battery energy of a PHEV during charge depletion testing. Therefore, for the final regulations, paragraph § 600.116-12(11)(ii) from the proposed regulations has been deleted.

EPA does not agree with the recommendation by the Alliance that the Agency should not require PHEVs meet the battery durability requirement if the Agency keeps the requirement to include deterioration when determining weighted PHEV CREE emissions at certification. As noted in the comment, PHEV weighted CREE emissions are a combination of charge depleting CREE and charge sustaining CREE emissions. As the PHEV battery degrades the vehicle will spend more time in charge depletion operation with the engine running. This will lead to increases in CREE emissions which are accounted for at the time of certification either by using a CREE deterioration factor or testing with an aged battery. This increase will occur even with a battery which has degraded yet still meets the battery durability criteria. This accounting is no different than the Agency requiring manufacturers account for the deterioration in the efficiency of catalyst aftertreatment systems at the time of certification. This loss of performance is included in the determination the vehicle will meet the standard as it normally degrades. At this time the Agency believes it is appropriate to maintain the existing PHEV CREE durability requirements in addition to the battery durability requirements being adopted with this rulemaking.

The California Air Resources Board made several recommendations related to gathering additional data for informing a future update to the fuel economy labeling requirements for BEVs. As part of the NPRM, EPA did not make any proposals to revise or solicit comment on revising test procedures or update the fuel economy label values for BEVs, such that this issue is beyond the scope of the rulemaking. EPA concurs with California that the range value listed on the fuel economy label, which is a combined city/highway range value weighted to represent nominal vehicle operation under a variety of city and highway operation at varying speed and accelerations along with different ambient conditions, is not representative of sustained high-speed highway driving during either cold or hot temperature ambient conditions. EPA developed the fuel economy label regulations almost 15 years ago when few electric vehicles in the U.S. market were capable of a combined range in EPA testing approaching 100 miles. The utility of BEVs has improved significantly since the Agency developed the fuel economy label requirements for BEVs. At this time, EPA has not proposed and is not seeking to revise the BEV fuel economy label or to gather additional data or require additional tests to collect data which could be applicable to revising the label at some future date.

6.2 – Testing and certification related to battery durability program

Comments by Organizations

Organization: Alliance for Automotive Innovation

a) On-Board Measurement of Current

SAE J1634 and J1711 [324] allow voltage to be read from the vehicle on-board controller instead of instrumenting vehicles with direct voltage measurements. This allowance is used to reduce test burden by not requiring the installation of direct voltage taps and to improve safety by not exposing test personnel to high voltages. [EPA-HQ-OAR-2022-0829-0701, pp. 216-217]

324 2021 SAE J1634 and 2023 J1711.

We propose allowing the use of vehicle on-board current readings (in addition to on-board voltage readings) for laboratory testing after equivalency is demonstrated by the manufacturer. The use of on-board current data will be especially important for in-use vehicles as it allows for laboratory testing without installing intrusive current sensors. [EPA-HQ-OAR-2022-0829-0701, pp. 216-217]

In order to meet the accuracy of EPA's and CARB's requirements for battery state of health (SOH) monitoring, vehicle on-board current sensors are required to be accurate. The following plot from one manufacturer includes energy (wat-hours) calculated over 712 individual test phases. This data demonstrates that energy calculated using on-board current readings at 10Hz can correlate extremely well with Hioki current measurements integrated at >## 20Hz. [EPA-HQ-OAR-2022-0829-0701, pp. 216-217]

[See original attachment for Figure 80: DC Energy Wat-Hour Comparison] [EPA-HQ-OAR-2022-0829-0701, pp. 216-217]

b) Continuous Voltage Measurement

To calculate UBE for PHEVs, we recommend adopting the latest revision of SAE J1711 FEB 2023.325 The most recent versions of J1634 and J1711 allow the acquisition of voltage from the vehicle network (which we believe is appropriate), but on-board current measurements should also be allowed based on demonstrating equivalence between off-board (i.e. Hioki Power Meter) and on-board current measurements. This is especially important for in-use testing, where it is difficult to instrument customer vehicles to measure the voltage and current without intrusive vehicle modifications. We also recommend that the average cycle voltage be the average of continuous readings over the cycle, or calculated discharge energy by using an integrated measurement of the continuous voltage and current readings. [EPA-HQ-OAR-2022-0829-0701, pp. 216-217]

325 Id.

Additionally, there is a safety concern when breaking out wiring and measuring high voltage DC systems of these electrified vehicles. Therefore, we propose using on-board current and voltage data within our laboratories instead of external testing setups after equivalency is proven. [EPA-HQ-OAR-2022-0829-0701, pp. 216-217]

4. UBE Determination in BEVs and PHEVs

EPA is requesting comment on all aspects of the proposed battery durability standards, particularly with respect to minimum performance requirements, the testing and compliance requirements for Part A and Part B, and the possibility of adopting more stringent or less stringent battery durability standards. Outlined in Section III.F.1,330 EPA is proposing to incorporate SAE Standard J1634 and J1711 as testing methods to determine Usable Battery Energy for both BEVs and PHEVs respectively. [EPA-HQ-OAR-2022-0829-0701, pp. 221-222]

330 NPRM at 29282.

While we support the incorporation of J1634 and J1711 as testing methods to determine UBE for both BEVs and PHEVs respectively, we have major concerns over the versions referenced within the NPRM. Outlined in the NPRM, EPA references the 2017 version of J1634 regarding

BEVs and the 2010 version for PHEVs as the basis for UBE testing methods. As EPA is aware, there is a 2021 version of J1634, as well as a 2023 version of J1711. We believe it is imperative that EPA adopt the most recent versions of both. [EPA-HQ-OAR-2022-0829-0701, pp. 221-222]

When it comes to BEVs, the 2021 J1634 version utilized the most up-to-date testing methods, including the use of SMCT and SMCT+ testing methods. As we have already mentioned in our comments, we support including the alternative testing methods of SMCT/SMCT+. MCT contains a variable length drive cycle while conducting the test with two constant speed sections. This results in having the middle section to be adapted to start the constant speed section at about 20% State of Charge (SOC). With MCT, building adaptive cycles to specific vehicles is overly burdensome for both OEMs and for regulators. Testing with SMCT/SMCT+ procedures does not require the building of specific test cycles, and also reduces labor burdens associated with conducting these tests. We understand that EPA was involved in the development of the 2021 SAE J1635 version, and respectfully request that it implement the updated version. [EPA-HQ-OAR-2022-0829-0701, pp. 221-222]

Additionally, as mentioned above, we are in support of incorporating the 2023 version of J1711 as it pertains to PHEV testing to determine UBE. [EPA-HQ-OAR-2022-0829-0701, pp. 221-222]

EPA proposes to allow manufacturers to utilize any sampling technique to accurately collect data from the number of vehicles mandated in GTR No. 22. [332] For example, manufacturers may choose to physically connect to the required number of vehicles and read the SOCE values directly in lieu of a remote, telematics-based data collection. [EPA-HQ-OAR-2022-0829-0701, p. 224]

332 NPRM at 29421

We have concerns regarding the requirements proposed in this section as it pertains to test sampling criteria. As is currently written, EPA is proposing test sample requirements mandating that OEMs must test 500 vehicles annually under their IUVP program. Out of those 500 test samples, the vehicles' registration must cover at least 10 states, with no particular region making up over 20% of the test sample. While we recognize the importance of achieving a broad test sample representative of the U.S. market, the current proposed thresholds are unrealistic. There are disproportionate EV penetration rates that vary by state, which poses challenges to procure the proposed required amount of vehicles. Therefore, we propose to keep the current 500 test sample size; however, requiring that no more than 50% of vehicles be registered in the same region. This will give manufacturers needed flexibility when it comes to finding, selecting and procuring these in-use test vehicles, thus ensuring that an adequate sample size is attainable. [EPA-HQ-OAR-2022-0829-0701, p. 224]

D. BEV / PHEV Test Groups

Under Section III.F.4, [340] EPA is proposing to introduce a new set of regulations as it pertains to establishing new test group families for BEVs and PHEVs. This proposed section creates both a monitor family, as well as a battery durability family, replacing the current regulatory requirement to define BEV test and durability groups. Additionally, in order to support the proposed monitor accuracy requirement outlined in Section III.F.2, EPA is proposing that OEMs install a battery State of Health (SOH) monitor to estimate, monitor and communicate the State of Certified Energy (SOCE) at the current point in the vehicle's lifetime. Under this section, manufacturers will also be required to evaluate the accuracy of the monitor through in-use testing. [EPA-HQ-OAR-2022-0829-0701, pp. 227-228]

340 NPRM at 29287.

We understand that the use of SOCE data to monitor battery durability is an important part of EPA's approach to determining test groups for application submission under this Proposed Rule. This allows EPA to ensure that each test group is representative of a range of vehicles with similar monitoring strategies and battery durability characteristics. [EPA-HQ-OAR-2022-0829-0701, pp. 227-228]

However, Auto Innovators has serious concerns with EPA's current proposal on the determination of test groups and the incorporation of GTR-22 as a guiding document for establishing monitoring and battery durability families. After careful review, Auto Innovators has been unable to fully understand the details of the methods laid out in this proposal as it pertains to test group determination. We are concerned that these new requirements are different from the method that CARB uses to group their vehicles. Differing requirements for test group determination between EPA and CARB create a large burden for manufacturers and essentially double the work when trying to certify vehicles. In addition to the extra work associated with two requirements, the proposed EPA requirements for battery durability grouping may result in the creation of an increasing amount of test groups, with related administrative and testing burden. [EPA-HQ-OAR-2022-0829-0701, pp. 227-228]

In response to this proposal, Auto Innovators first requests that EPA be open to a meeting with CARB and Auto Innovators. We have made many attempts to meet with EPA to discuss this current proposal, to no avail. Our overall goal is to achieve a singular standard when it comes to criteria determining test groups for both BEVs and PHEVs. Meeting with all three organizations will allow us to openly discuss ideas in the interest of developing one consistent standard. In addition to a singular standard, as a general principle we support the use of vehicle platforms with similar monitoring and battery durability characteristics to serve as the basis for determining test groups. With this current proposal, as well as CARB's anticipated future CARB GHG rulemaking, we believe this is an opportune time to work together to establish a national standard for BEV and PHEV test group determination. [EPA-HQ-OAR-2022-0829-0701, pp. 227-228]

1. Monitor Families

As is stated in the current NPRM, the SOCE monitoring algorithm needs to utilize the same logic and have the same value for all calibration variables used in the algorithm.341 Additionally, the algorithm used to determine UBE needs to utilize the same sampling and integration periods and the same integration technique; the locations of the sensor(s) (i.e. at the pack, module, or battery cell level) for monitoring DC discharge energy need to be the same; and the accuracy of the sensor(s) and the tolerance of the sensor(s) accuracy used for monitoring energy and range need to be the same. [EPA-HQ-OAR-2022-0829-0701, pp. 228-229]

Based on what is presented in this NPRM, we believe that it is overly strict to define different monitor families based on different sensor positions. Therefore, if the performance at differing location (ex: pack level vs cell level) can be shown to be equivalent, then we respectfully request that manufacturers should be allowed to define them as the same monitor family. [EPA-HQ-OAR-2022-0829-0701, pp. 228-229]

2. Definitions of Durability Group, Monitor Family and Battery Durability Family

The EPA proposes in section F.4.iii. Proposed Certification, Compliance, and Enforcement Provisions; Definitions of Durability Group, Monitor Family, and Battery Durability Family; BEV and PHEV Battery Durability Family that "The following powertrain characteristics and design features would be used to determine battery durability families: Maximum specified charging power, method of battery thermal management, battery capacity, battery (cathode) chemistry, and the net power of the electrical machines."342 [EPA-HQ-OAR-2022-0829-0701, pp. 229-230]

342 NPRM at 29288.

Auto Innovators proposes the following. [EPA-HQ-OAR-2022-0829-0701, pp. 229-230]

The powertrain characteristics and design features that would be used to determine battery durability families are: method of battery thermal management, battery capacity within 20% of the highest capacity within the family, battery chemistry. [EPA-HQ-OAR-2022-0829-0701, pp. 229-230]

However, clarification is required as to what defines "battery chemistry," particularly at what level they need to be separated. Auto Innovators proposes that EPA specify that "Li-Ion" (Lithium-Ion) is a sufficient separator for a battery durability family group, and it is possible to group all Li-Ion batteries in the same battery durability family. [EPA-HQ-OAR-2022-0829-0701, pp. 229-230]

The entire concept of "grouping" for certification and compliance testing is built around efficiency: logically grouping "like" systems that can be placed together and tested instead of evaluating every single permutation of a technology for very marginal benefits. The grouping criteria suggested by the EPA, containing four criteria that could each have many variants, would potentially lead to a large amount of complexity for durability testing – OEMs would be forced to test potentially hundreds of different combinations resulting in drastically increased workload and data generation for this new regulation. This is especially important considering the rapid technological developments (and associated uncertainty) in next-generation battery chemistries, even within a single nameplate's EV's 6- to 7-year product lifecycle. [EPA-HQ-OAR-2022-0829-0701, pp. 229-230]

With this in mind, Auto Innovators recommends simplifying the battery durability grouping criteria to the following characteristics and design features: 1) method of battery thermal management, 2) battery capacity within 20% of the highest capacity within the family (analogous to ICE analytical derivation criteria), and 3) battery chemistry. And by "battery chemistry, Auto Innovators proposes that EPA specify that "Li-Ion" (Lithium-Ion) is a sufficient separator for a battery durability family group, meaning it is possible to group all Li-Ion traction batteries in the same battery durability group. Even if EPA proposes to go "one level down and specify 'high level' chemistries (currently many permutations of NMC, LFP, LMO blends, etc.), given the uncertainty of proliferation of these chemistries in future vehicles, this single criterion could potentially lead to dozens more in-use tests per nameplate. [EPA-HQ-OAR-2022-0829-0701, pp. 229-230]

In addition, the measurement of battery durability should be limited to the usable battery energy made available for propulsion; thus, this grouping should be done at the battery pack and not propulsion system level. [EPA-HQ-OAR-2022-0829-0701, pp. 229-230]

We believe that maximum specified charging power should not be a pre-defined separator of a unique battery durability family since its influence on battery durability is not significant. We also believe net power of the electrical machines should not be a pre-defined separator of a unique battery durability family since its influence on battery durability is not significant. For example, electric machine net power variations for AWD, FWD, and RWD driveline configurations are not expected to influence the inherent battery durability characteristics significantly (even though the battery usage profile may be impacted). [EPA-HQ-OAR-2022-0829-0701, pp. 229-230]

Auto Innovators instead proposes that a vehicle platform with batteries of similar capacity should be possible to place in the same battery durability family, similar to the grouping statistics of the current durability group determination according to §86.1820-01. We therefore propose "within 20% of the highest battery capacity in the family should be eligible to group into the same battery durability family." [EPA-HQ-OAR-2022-0829-0701, pp. 229-230]

Organization: Ford Motor Company

Battery Electric Vehicle (BEV) and Plug-In Hybrid Electric (PHEV) Battery Durability and Testing

-In the NPRM's redline of regulatory text for 40 CFR 86.1844-01(d)(19)(2), EPA proposes that OEMs will need certified Usable Battery Energy (UBE) for each battery durability family for certification. We request confirmation that EV data from fuel economy testing can be fulfill this data requirement in EV certification applications. In the past, Ford has not been able to generate a single dataset for EV certification and FE labels due to timing differences in the processes. Using the provisions in section 86.1829-15(f), we believe that we can submit certification applications without data and supplement the required UBE data after FE testing is complete. This is not only beneficial to test reduction, but we believe using FE data for UBE declaration is more aligned to the intent of the regulation, because the certification framework of EVs is diverting from the ICE framework. Traditionally, certification testing has been done using Emission Data Vehicles (EDVs) as selected using the requirements in section 86.1828-01 (worst-case configuration). Now that EVs will not be certified in test groups, it is apparent that the EDV selection requirements in this section do not apply. That leaves a gap in the proposed regulation of test vehicle selection within a durability family for EV certification. [EPA-HQ-OAR-2022-0829-0605, pp. 15-16]

-Ford does not believe that incorporating GTR No. 22 by reference adequately addresses battery-related requirements for EVs and PHEVs. A most stringent interpretation of GTR No.22 would significantly increase the number of certification fleets (tied to sensor location, weight, trim package, tires, performance packages, driveline configuration etc.), and potentially provide different test group definitions for vehicles certified to CARB's ACC2 standards. This would increase certification workload and potentially create customer confusion. We would like to avoid a situation where OEMs are required to negotiate EV test group definition with both EPA and CARB, which will result in level-playing field issues. EPA could avoid this situation by aligning with CARB on test group definitions and provide clear and concise parameters for EV test groupings. For example, there are already issues with OEMs receiving agency approval for grouping RWD and AWD EV configurations in a single test group (which we think is appropriate), while other OEMs are unaware that this is a possibility based on regulatory language. We strongly request the EPA to provide concise guidance on the certification groups to prevent these issues. [EPA-HQ-OAR-2022-0829-0605, pp. 15-16]

-With proposed Tier IV requirements to test additional electric vehicles in-use and during certification, Ford fully supports the Auto Innovator's proposal to adopt Analytically Derived Fuel Economy (ADFE) for hybrid and xEV products. With additional electric vehicle range/energy consumption data being produced for a variety of new models, Ford is confident that analytical methods to produce FE/Range/Energy Consumption values will meet existing accuracy requirements. [EPA-HQ-OAR-2022-0829-0605, pp. 15-16]

Organization: Mercedes-Benz AG

Geographic Constraints in IUVP Program

The EPA proposes manufacturers procure 500 vehicles annual and from across at least 10 different states with no more than 20% of the test sample coming from any particular region. This is expected to be more challenging for electric vehicle programs than it is for traditional internal combustion engine (“ICE”) programs. [EPA-HQ-OAR-2022-0829-0623, p. 14]

The current distribution of electric vehicles across the country is not uniform and is impacted by many factors, such as state EV sales incentives, the availability of charging infrastructure, and customer interest. Therefore, obtaining an even distribution of electric vehicles across all states for IUVP testing is not feasible at this time. Compliance with this requirement will become more workable as the electric vehicle rollout continues across all states in the US. In the meantime, Mercedes-Benz recommends that EPA provide criteria, at least through 2030, that allows for regional procurement or alternative strategies to procure representative vehicles (but not state-by-state) across the U.S. [EPA-HQ-OAR-2022-0829-0623, p. 14]

Organization: Rivian Automotive, LLC

Test Grouping and Durability/Monitor Families

Rivian requests clarity on proposed changes to BEV test groupings. EPA proposes that for BEVs, “the new monitor family and new battery durability family would replace the current regulatory requirement to define BEV test and durability groups.”43 However, given recent information from the agency that multiple battery chemistries and types have been allowed in the same test group, Rivian requests additional detail on the inputs used to determine the test group (for example, number and type of electric motors). This new approach to defining BEV test and durability groups could also have implications for fuel economy labeling requirements. More detail and discussion by EPA are needed. [EPA-HQ-OAR-2022-0829-0653, pp. 14-15]

43 Id. at 29,287.

Organization: Tesla, Inc.

Tesla believes the proposed minimum performance requirement (MPR) for the SOH are set at reasonable and achievable levels.171 Further, the decision not to implement a MPR for Class 2b and 3 will facilitate greater early adoption in those segments. For testing purposes, defining the battery family definition is best served by allowing manufacturers to utilize the criteria mentioned in the proposed regulation such as maximum specified charging power, method of battery thermal management, battery (cathode) chemistry and the net power of the electrical machines.172 This is far preferred over defining the families based on battery capacity which would create multiple families for the same vehicles with the same battery types and chemistry but different battery capacity. While establishing a 90 percent pass requirement for battery family monitor exceed the passage rates set in the ACC II durability provisions, Tesla agrees with the agency's flexible approach allowing manufacturer to use good engineering judgment in determining the statistically adequate and representative in-use vehicle data for testing.173 [EPA-HQ-OAR-2022-0829-0792, p. 27]

171 88 Fed. Reg. at 29285, Table 64.

172 Id., at 29288. Tesla notes EPA should provide further guidance of the definition of "net power of electrical machines."

173 See 13 CCR § 1962.4 (d).

Organization: Volkswagen Group of America, Inc.

BEV/PHEV Test Groups and Durability Families (Section III.F.4)

Volkswagen aligns and supports AFAI's comments and desire for an industry-wide common solution with respect to PHEV and BEV test groups. We agree with the AFAI comments that an industry solution and clear grouping metrics, similar as those used with ICE grouping statistics, to determine durability families should be developed using good engineering basis. [EPA-HQ-OAR-2022-0829-0669, pp. 11-12]

Based on our understanding of the battery durability group definition found within the NPRM, Volkswagen believes the number of Test Groups may drastically increase. As such, Volkswagen support the EPA's decision to allow requests for alternative groupings of monitors and batteries accompanied by appropriate technical justification. This provision would promote flexibility. [EPA-HQ-OAR-2022-0829-0669, pp. 11-12]

Volkswagen is very familiar with the UN GTR-22 provisions and would be part of the AFAI industry group in collaboration with EPA and CARB in determining an industry-wide solution for PHEV and BEV test group determination. [EPA-HQ-OAR-2022-0829-0669, pp. 11-12]

Organization: Volvo Car Corporation (VCC)

In the NPRM, EPA states that powertrain characteristics and design features be used to determine battery durability families. The NPRM lists the following characteristics: maximum specified charging power, method of battery thermal management, battery capacity, battery (cathode) chemistry, and the net power of the electrical machines. VCC believes that maximum specified charging power and net power of the electrical machines should not determine and define a unique battery durability family because their impact on battery durability is not significant. [EPA-HQ-OAR-2022-0829-0624, pp. 4-5]

VCC believes that it is logical for a vehicle platform with similar batteries and comparable battery capacity be put into the same battery durability family. This is consistent with the grouping statistics of the current durability group determination according to §86.1820-01. VCC believes that EPA should state that “within 20% of the highest battery capacity in the Family should be eligible to group into the same battery durability family”. In addition, EPA should provide guidance on battery (cathode chemistry). Specifically, VCC has questions regarding how to determine separation. For Example: Is “NMC (Nickel Manganese Cobalt)” sufficient separator for a Battery Durability Group where all NMC batteries would be possible to group within the same Battery Durability Family? [EPA-HQ-OAR-2022-0829-0624, pp. 4-5]

EPA Summary and Response

Summary:

EPA received comments from the Alliance for Automotive Innovation (AAI),Ford Motor Company, Mercedes Benz, Rivian Automotive, Tesla, Volkswagen Group of America, and Volvo Car Corporation on aspects of test and certification procedures related to battery monitoring and battery durability requirements.

AAI proposed EPA allow the use of on-board current readings for laboratory testing once equivalency is established by the manufacturer between the on-board current reading and an independent measurement of battery discharge current. The Alliance believes this is important for in-use vehicles as part of the battery monitor accuracy testing program as it will allow for laboratory testing without the need for physical current sensors which are difficult to install.

AAI and Mercedes Benz proposed revisions to the procurement criteria the Agency identified for checking the in-use state-of-certified-energy sampling requirements. The Alliance proposes to maintain the current 500 test sample size, however the Alliance proposes requiring that no more than 50 percent of vehicles be registered in the same region. Mercedes Benz indicates it is not feasible at this time to obtain an even distribution of electric vehicles across all states for gathering SOCE data. Mercedes Benz recommends EPA provide criteria, at least through 2030, that allows for regional procurement or alternative strategies to procure representative vehicles across the United States.

AAI, Rivian Automotive Volkswagen Group of America, and Volvo Car Corporation have concerns with replacing the existing BEV test and durability group definitions with the battery monitor and battery durability families. The Alliance believes it is overly strict to define different monitor families based on different sensor positions. The Alliance requests manufacturers be allowed to define them as the same monitor family if the performance of sensors at different locations can be shown to be equivalent. Rivian is concerned the new battery monitory and durability family could have implications for fuel economy labeling. Rivian requests additional detail regarding the updates to BEV battery monitor and battery durability families. Volkswagen supports the Alliance’s comments and desire for an industry-wide common solution with respect to PHEV and BEV test groups. Volkswagen supports EPA’s decision to allow alternative groupings of monitors and durability families based on appropriate technical justification. Volvo does not believe that maximum charging power and the maximum net power of the electrical machines are appropriate criteria for differentiating battery durability families since their impact on battery durability is not significant. Volvo believes EPA should allow batteries with capacities within 20 percent of the highest capacity be included in the same battery durability family. Volvo also believes EPA should provide guidance on the battery cathode chemistry and how it would differentiate durability families.

AAI proposes using the following powertrain characteristics and design features be used to determine battery durability family: method of battery thermal management, battery capacity within 20 percent of the highest capacity within the family, and battery chemistry. With respect to battery chemistry, the Alliance proposes grouping all lithium-ion batteries in the same battery durability family, independent of cathode chemistry. The Alliance does not believe maximum charging power and net power of the electrical machines should be separators for unique battery durability families as their influence on battery durability is not significant.

Ford Motor Company commented on the proposed regulations in the NPRM that require manufacturers to include BEV UBE data in the application for certification. Ford noted typically fuel economy data vehicle testing does not align with emission data vehicle testing for certification and the capturing of UBE data for different battery durability families is best aligned with fuel economy testing. Ford is also concerned about the adoption of GTR No. 22 and the disconnect between California's ACC II BEV durability program and GTR No. 22. Ford has concerns about additional testing required for the California program based on the California BEV test group definition and the new battery monitor and battery durability family definitions in GTR No. 22. Ford requests EPA provide concise guidance on certification groups to prevent significant divisions between California and Federal requirements creating possible market confusion and increasing unnecessary additional testing. Ford also supports the Alliance's proposal to develop analytically derived fuel economy (ADFE) calculations for hybrids and electrified vehicles.

Tesla believes the flexibility provided in the monitoring family definition provides assurances to manufacturers that deployment of similar monitors across different vehicle lines does not create any undue or repetitive state of certified energy testing burden and costs. Tesla comments that for testing purposes, defining the battery family definition is best served by allowing manufacturers to utilize the criteria in the proposed regulation such as maximum charging power, method of battery thermal management, battery cathode chemistry, and net power of the electrical machines. In a footnote to their comments Tesla notes that EPA should provide further guidance for the definition of "net power of electrical machines."

Response:

AAI requested allowing the use of both on-board current and on-board voltage measurements to be used to determine the useable battery energy during laboratory testing to evaluate the state of certified energy monitor. The Alliance proposed that this option be allowed once a manufacturer had demonstrated the on-board current measurement was determined to be equivalent with the independent measurement of battery discharge current.

EPA believes it is difficult to install current probes on production vehicles to independently monitor the DC discharge current during laboratory testing. SAE J1634 specifies criteria for the instrumentation and the sampling interval to ensure the DC discharge current is accurately measured. Determining equivalence during a specific test or tests does not ensure equivalence for future tests. Allowing the vehicle to report the DC discharge energy is not an independent measurement of the vehicle's performance as the vehicle is self-reporting with no independent verification of the measurement or ability to determine the measurement meets the criteria for current measurement in the 2017 version of J1634. The function of the test procedure is to evaluate the ability of the vehicle to reasonably determine the state of certified energy and to allow this determination to be made without an independent measurement of discharge current does not seem appropriate to EPA. Therefore, the Agency is not willing to allow the use of the on-board current measurement to be used for determining the state of certified energy of the vehicle as proposed by AAI.

Regarding the durability test sample of at least 500 vehicles under Part B of the EPA program, AAI and Mercedes-Benz noted that distribution of some durability groups of PEVs across the U.S. may be insufficient to support the proposed sample characteristics. AAI proposed to keep the current sample size of 500 vehicles, but require that no more than 50 percent of the vehicles in the sample be registered in the same region. EPA agrees that, particularly in the early years of the program, some durability groups may be unevenly distributed across the U.S. and is modifying the sample requirements per this suggestion.

AAI, Rivian Automotive Volkswagen Group of America, and Volvo Car Corporation have concerns with replacing the existing BEV test and durability group definitions with the battery monitor and battery durability families. As noted in preamble section III.G.2, EPA will accept manufacturer compliance with the entirety of the CARB ACC II battery durability program in lieu of the EPA battery durability program. This has led the Agency to reconsider our proposal to define BEV families solely by battery monitor family and battery durability family. The Agency has determined that all BEVs will continue to be grouped using the existing battery test group definition and if the BEV meets EPA's battery durability criteria the manufacturer will also need to define a battery monitor family and battery durability family for the vehicles within the test group. Section III.G.3 of the preamble includes additional information regarding the revisions to the test group, durability group, battery monitor family, and battery durability family for BEVs and PHEVs.

AAI is requesting the Agency allow vehicles with sensors in different monitoring locations to be included in the same monitor family with data demonstrating the performance of the monitor with the sensors in different locations is equivalent. EPA has adopted the monitor family definition based on the monitor family criteria described in GTR No. 22. As noted in the GTR and in the EPA regulations the Agency will allow manufacturers to request including vehicles with sensors in different locations to be included in the same monitor family with appropriate data and technical justification.

AAI, Ford, Mercedes Benz, Rivian, Volkswagen and Volvo all recommended removing or revising a number of battery durability family criteria listed in GTR No. 22 when defining battery durability families. At this time, the Agency does not have sufficient information to conclude the suggested revisions will ensure that all vehicles within a durability family would be expected to degrade in the same manner. As noted in GTR No. 22 and the EPA regulations, EPA is providing manufacturers with the option to include in the same durability family vehicles for which these characteristics would not otherwise allow them to be in the same battery durability family. To include vehicles with characteristics noted in GTR No. 22 that would not be allowed in the same durability family, the manufacturer needs to provide data demonstrating the vehicle differences being included in the same durability family will age similarly and will degrade in an equivalent manner. Section III.G.3.iii of the preamble (BEV and PHEV Battery Durability Family) contains additional response and outlines how the manufacturer can request specific groupings when supported by appropriate data. Specifically in response to comments that all lithium-ion chemistries regardless of sub-chemistry should be eligible to be placed within the same group, EPA clarifies that placement in the same battery durability family is not indicated when chemistry differences exist that would be expected to influence durability. Chemistry differences may include differences such as proportional metal composition of the cathode (for example, NMC811, NMC622, NMC333, etc.), composition of the anode (for example, graphite, graphite with silicon, other forms of carbon), differences in particle size or morphology of cathode or anode active materials, or any other differences that would be expected to influence durability, unless data is provided otherwise as described above.

Ford commented on the requirement for including in the certification application battery UBE test results. This requirement is similar to updating applications as the manufacturer implements a running change during the model year. Manufacturers are allowed to update their applications as needed. There is no change needed to EPA's regulations to allow this current practice to continue. Ford also noted their concern about disconnects between California's ACC II test groupings and EPA's durability test groupings based on GTR No. 22. As described in section 16 of this RTC document and in section III.G of the preamble, EPA will accept compliance with California's ACC II durability program in lieu of the EPA durability program. By this means manufacturers now have the option of developing and offering for sale nationally vehicles complying with the ACC II battery durability requirements. Regarding comments related to analytically derived fuel economy (ADFE) calculations for hybrids and electrified vehicles, at this time the Agency is not proposing to develop analytically derived fuel economy calculations for hybrids and electrified vehicles. This request is beyond the scope of the proposal.

Tesla provided comments generally supportive of the EPA battery durability program and in-use testing to demonstrate compliance with the durability requirements. These comments are addressed in RTC section 16. Tesla did provide a comment in their footnotes seeking additional guidance regarding the definition of the net power of the electrical machines. At this time EPA believes the appropriate value for the net power of the electrical machines is the combined peak power of all the electrical machines used to power the vehicle.

Responses to comments relating to other topics of battery durability and warranty are covered in section 16 this document.

6.3 - Fuel economy testing

Comments by Organizations

Organization: Alliance for Automotive Innovation

5. Test Cycle Basis

We support EPA's intent to continue using the city (Federal Test Procedure or "FTP") and highway (HFET) test cycles as the basis for measuring greenhouse gas emissions. If EPA were to modify or add test cycles, the footprint-based targets would need to be modified to account for such a change. [EPA-HQ-OAR-2022-0829-0701, p. 111]

Although other approaches (for example 5-cycle tests) may yield a result closer to on-road values, it is important to recognize that reductions based on 2-cycle testing also translate to on-road reductions. Therefore, maintaining a consistent "measuring stick" does not detract from the improvements required by the standards. [EPA-HQ-OAR-2022-0829-0701, p. 111]

G.GHG / Fuel Economy Test Fuel

EPA acknowledges that it did not finalize the 2020 proposed rule238 for Tier 3 Test Procedure Adjustment.239 We look forward to working with the agency to ensure that regulatory text properly addresses necessary changes that were proposed in 2020. We reiterate comments that we submitted on the Tier 3 Test Procedure Adjustment proposed rule in 2020.240 In addition to relevant comments on the NPRM, previously submitted comments are summarized below. [EPA-HQ-OAR-2022-0829-0701, pp. 130-132]

238 85 FR 28564, May 13, 2020

239 NPRM at 29240

240 https://www.regulations.gov/comment/EPA-HQ-OAR-2016-0604-0087

1.Do Not Adjust the Tailpipe CO2 Value for E10

We appreciate EPA's decision to incorporate the change of GHG test fuel into the GHG standards, rather than pursuing a standalone test procedure adjustment for MY2027 and beyond. However, this approach creates a never-ending cycle of adjustments to GHG standards when a lower carbon certification fuel is established (e.g., E15 cert fuel). In addition, EPA has proposed an adjustment for use of Tier 3 test fuel of 1.0166 if the fuel is used to certify before MY2027. Adjusting measured GHG emissions will disincentivize OEMs from switching to Tier 3 early and will penalize the benefits of low carbon fuels. [EPA-HQ-OAR-2022-0829-0701, pp. 130-132]

The proposed action would artificially increase the measured tailpipe CO2 emissions on Tier 3 E10 test fuel before MY2027 vehicles by 1.0166. Adding CO2 emissions that are not emitted by the vehicle for the purposes of calculating an adjusted compliance level for vehicles is counter to the goal of reducing carbon emissions from the transportation sector. We recommend that if OEMs use Tier 3 E10 test fuel before MY2027, no adjustments be applied to incentivize OEMs to switch and to recognize the benefits of lower carbon fuels. [EPA-HQ-OAR-2022-0829-0701, pp. 130-132]

2. Set R-Factor Equal to 1.0 for CAFE Performance on E10

In contrast to GHG emissions, for the purposes of Corporate Average Fuel Economy (CAFE), EPA is required by statute to use test procedures that provide comparable results to those used for MY 1975.241 Also, unlike CO2, fuel economy is a calculated quantity; it is not directly measured. However, EPA's proposed actions in the 2020 proposal fall short in making the statutorily required adjustments. [EPA-HQ-OAR-2022-0829-0701, pp. 130-132]

241 49 U.S.C. § 32904(c).

One component of the fuel economy calculation is the “R-factor.”242 In simple terms, an R-factor of 1.0 implies that the impact of the energy content of a test fuel relative to that of the 1975 baseline fuel is fully observed in the test results and adjusted for. An R-factor of less than implies that a test vehicle does not fully realize the impact of fuel energy content changes and results in a lower calculated fuel economy for fuels with lower energy content. In the NPRM, EPA proposes a new R-factor of 0.81, an increase from the prior value of 0.6. [EPA-HQ-OAR-2022-0829-0701, pp. 130-132]

242 In this NPRM, EPA proposes to replace R-factor with Ra for E10. In our comments, Auto Innovators will explain that these terms are equivalent. The use of the terms R-factor and Ra are largely interchangeable in the context of our comments.

Previous studies and theoretical principles regarding ethanol fuel combustion support a conclusion that the new R-factor should be 1.0. These studies are described in greater detail in our previously submitted comments. EPA’s proposal for an R-factor of 0.81 is based solely on its data from a January 2018 study of ten vehicles. In our comments, Auto Innovators identified a number of limitations to the EPA test program, the largest of which are inherent variability issues. Although the EPA study attempted to address emission measurement variability, it did not consider significant variability attributable to laboratory testing procedures for analyzing fuel properties, a key factor in the computation of an appropriate R-factor. Additionally, the measurement of R-factor has also been shown to be highly variable on a vehicle-to-vehicle basis; the average R-factor could have differed considerably had a slightly different mix of vehicles been tested. For example, in EPA’s test program, by replacing one vehicle that should have been excluded with a vehicle that was inappropriately excluded, the R-factor calculated based on EPA’s limited test program would rise from 0.81 to 0.90. [EPA-HQ-OAR-2022-0829-0701, pp. 130-132]

A much larger test fleet, preferably of the newest vehicles, is needed to reasonably approximate a representative “average R” applicable to the wide variety of vehicles and technologies that will be included in manufacturers’ fleets. In support of a much larger test fleet, in our comments on the Tier 3 Test Procedure Adjustment proposed rule in 2020,243 Auto Innovators prepared a large and newer vehicle dataset comparing tailpipe emission test results on E0 and E10 test fuel. The industry-paired compliance dataset supports an R-factor close to 1.0. Industry compliance data represents the variability that manufacturers have to manage, and the results of EPA’s analysis demonstrate that many vehicles will be penalized if the R-factor is adjusted based solely on EPA’s ten vehicle test program. The 2020 NPRM underestimates the care that is taken in certification testing. Manufacturers take care both to supply good data to the Agency and to be able to track laboratory and model performance. We urge EPA to utilize this new larger dataset and finalize an R-factor of 1.0. [EPA-HQ-OAR-2022-0829-0701, pp. 130-132]

243 htps://www.regulations.gov/comment/EPA-HQ-OAR-2016-0604-0087

There are additional practical reasons to set an R-factor of 1.0. This approach would obviate the need for future test programs when the test fuel is changed. With a non-unity R-factor, any future test fuel (e.g., E15) or fleet (with improved fuel economy technologies) would require additional updates to the R-factor, resulting in a need to continue updating the R-factor. The R-factor at 1.0 would eliminate the necessity to reassess the R-factor in the future. [EPA-HQ-OAR-2022-0829-0701, pp. 130-132]

3. Allow Carry-Over Throughout the Duration of the Rule

The NPRM allows a three-year phase in from MY 2027 through MY 2029, but that phase-in is too quick of a transition. Auto Innovators recommends the use of carry-over throughout the duration of the rule. Requiring new data, for a vehicle that is carryover, for MY2030 and beyond adds unnecessary testng burden. [EPA-HQ-OAR-2022-0829-0701, p. 132]

4.Address the Impact of the E10 Transition on 5-Cycle Testing and Litmus Test

The fuel economy label "litmus test" determines whether a manufacturer must test a vehicle model using the full 5-cycle test procedure, or whether it can apply a simplified calculation that only requires two test cycles. In this 2020 NPRM, EPA proposes to move all litmus testing to E10 without determining the impact of using E10 tests in an empirical system founded on E0 testing. [EPA-HQ-OAR-2022-0829-0701, pp. 132-134]

EPA analysis shows that R-factor or Ra is cycle-specific, yet no analysis was conducted for the Cold CO, SC03 or US06 test cycles, all of which are used to determine 5-cycle fuel economy values for use on the consumer-based fuel economy label and to conduct the litmus assessment. Auto Innovators believes requiring the use of E0 regressions and litmus limits for vehicles tested on E10 is inappropriate. Further, this approach can be expected to result in unwarranted litmus failures, causing additional test burden and competitive fuel economy label disadvantages for vehicles that are otherwise very similar to each other. Auto Innovators requests that EPA continue to allow automakers the option to retest on E0 for litmus assessment until the implications of the new E10 test fuel on the complex 5-cycle and litmus methodology can be fully examined and addressed. [EPA-HQ-OAR-2022-0829-0701, pp. 132-134]

5.Consider Fuel Economy and Environmental Performance Labeling Impacts

Auto Innovators believes that continued use of the existing derived fuel economy values is warranted for labeling purposes until proper E10 adjustments are developed. This reasoning does not hold for litmus test, however, since relatively small shifts in the cycle relationships can cause undue litmus failure and a lower label fuel economy for an affected vehicle model. [EPA-HQ-OAR-2022-0829-0701, pp. 132-134]

In Table 30 of the NPRM, EPA includes an adjustment for Fuel Economy and Environment Label Values. We believe that this was an error in drawing, as there should not be an adjustment for CO2 for fuel economy and environment label values. [EPA-HQ-OAR-2022-0829-0701, pp. 132-134]

SEE ORIGINAL COMMENT FOR Figure 39: NPRM Table 30: Proposed fuel-related testing and certification requirements.6.Allow Use of California LEV III Test Fuel [EPA-HQ-OAR-2022-0829-0701, pp. 132-134]

EPA should allow use of California LEV III E10 test fuel for GHG and fuel economy testing. To reduce complexity and streamline operations allow OEMs, who may choose, to use California LEV III test fuel as acceptable fuel alternative to the Tier 3 test fuel. In our 2020 comments and below, we provide carbon weight fraction and net heat of combustion calculations that will enable use of LEV III test fuel in compliance calculations. [EPA-HQ-OAR-2022-0829-0701, pp. 132-134]

7.Net Heating of Combustion (NHC) and Carbon Weight Fraction (CWF) Equations

There are equation issues found in the 2020 NPRM that still must be resolved. Those issues are reiterated below. [EPA-HQ-OAR-2022-0829-0701, pp. 134-137]

a)ASTM D240, ASTM D4809, and ASTM D5291 should not be used in the calculation of fuel economy and other ASTM test method corrections.

EPA previously requested feedback regarding analytical methods ASTM D5291 for Carbon Weight Fraction (CWF) and ASTM D4809 for Net Heat of Combustion (NHC). These test methods should not be employed for determining CWF and NHC used in the calculation of fuel economy. These test methods have a bias relative to the original test methods, which were used to establish the CWF and NHC of the 1975 baseline fuel. The biases in these test methods will introduce errors in the fuel economy results. In addition, these test methods have higher variability and will introduce unwanted variation into the calculated fuel economy results. Auto Innovators supports using ASTM D3338 and D3343 with modifications for E10 in the calculation of fuel economy. The two legacy trade associations submitted a joint letter to EPA on April 4, 2018, expressing support for using modified ASTM D3338 and D3343 test methods. The letter was included as Appendix D of Auto Innovators' submitted comments on the Tier 3 Test Procedure Adjustment proposed rule in 2020.244 [EPA-HQ-OAR-2022-0829-0701, pp. 134-137]

244 htps://www.regulations.gov/comment/EPA-HQ-OAR-2016-0604-0087

Corrections are also needed to the list of ASTM procedures adopted by reference in §600.011: modified D3338 replaces D240 and D4809 for NHC in §600.113-12(f)(1), and D5580 aromatic content of LEV III fuel should be added to §600.113-12(f)(1) and the list in §600.011. [EPA-HQ-OAR-2022-0829-0701, pp. 134-137]

Auto Innovators agrees with several of the Agency's proposed revisions to §600.113-12. The exception being that fuel sulfur content, water, and aromatic content should also be included in the calculations. For the aromatic content used to determine the NHC and CWF for use in the fuel economy equation when using LEV III fuel, a second alternative method, ASTM D5580-15, can be used as long as the result is first bias-corrected as described in D5580-15 to ASTM D5769-20 and is then bias-corrected as described in ASTM D1319. This second alternative method for bias correcting the aromatic content of LEV III should be added to §600.113–12. [EPA-HQ-OAR-2022-0829-0701, pp. 134-137]

Additional details were provided in Appendix E of Auto Innovators' submitted comments on the Tier 3 Test Procedure Adjustment proposed rule in 2020.245 [EPA-HQ-OAR-2022-0829-0701, pp. 134-137]

245 htps://www.regulations.gov/comment/EPA-HQ-OAR-2016-0604-0087

b) Implement consistent units and rounding procedures for Net Heat of Combustion and other technical amendments.

Paragraph §600.113-12(f)(1)(iii) of the previous NPRM contained inconsistencies of units and rounding instructions. To resolve the inconsistencies, changes are needed and must be made regardless of whether units are going to be retained as MJ/kg or changed to BTU/lb. We request that EPA take the approach of changing to consistent use of BTU/lb rounded to the nearest whole number for both E0 and E10 NHC. Additional details were provided in Appendix F of Auto Innovators' submitted comments on the Tier 3 Test Procedure Adjustment proposed rule in 2020.246 [EPA-HQ-OAR-2022-0829-0701, pp. 134-137]

246 htps://www.regulations.gov/comment/EPA-HQ-OAR-2016-0604-0087

There are also additional changes needed to 600.113-12(f)(1) not related to units:

- NHV and CWF are used in the E0 equation in 600.113-12(h), which is the existing paragraph that addresses computation of mpg for tests still run on E0. This paragraph says to go to 600.113-12(f)(1) to obtain "NHV" and "CWF" for the E0 test fuel. But (f)(1) terminology has been changed from NHV and CWF to NHC and CMF. While this is just a terminology change, the regulations should be clarified such that they mean the same thing with regard to what values are obtained from (f)(1) for use in the equation in (h). [EPA-HQ-OAR-2022-0829-0701, pp. 134-137]

- The term vFe needs to be defined as volume fraction of ethanol which is vPe/100. vPe is defined as volume percentage, but steps in the calculations leap directly to use of vFe without definition or explanation. [EPA-HQ-OAR-2022-0829-0701, pp. 134-137]

- The typo should be fixed where it says NHCf = net neat of combustion of test fuel = NHGH · (1 – mFe) + NHCe· mFe. NHGH should be NHCh. This was shown correctly in the "signature package" version of the NPRM and then the typo appeared in the FR version. [EPA-HQ-OAR-2022-0829-0701, pp. 134-137]

A clarification is also needed in 600.101(c) to avoid additional test burden and unnecessary confusion to customers due to fuel economy value fluctuations, which are not essential, such as measurement variations. Additionally, the paragraph refers to criteria emission standards, but we believe E10 optional tests for EDV configuration is already allowed. Therefore, this sentence should be revised to refer to fuel economy as follows. [EPA-HQ-OAR-2022-0829-0701, pp. 134-137]

600.101(c)

"… This requirement starts in model year XX for all fuel economy and certification testing in new test groups that do not use carryover data for criteria emission standards fuel economy…"[EPA-HQ-OAR-2022-0829-0701, pp. 134-137]

5.3.Do not remove sulfur corrections and water correction to modified ASTM

D3338 [EPA-HQ-OAR-2022-0829-0701, pp. 134-137]

EPA is requesting feedback regarding removing the sulfur correction from the modified D3338 method for determining Net Heat of Combustion (NHC). The sulfur adjustment in ASTM D3338 lowers the calculated NHC. Eliminating the sulfur adjustment will result in a higher calculated NHC and lower calculated CAFE resulting in an increase in stringency. While the sulfur content in Tier 3 test fuel is very low and the adjustment is small, in some cases the sulfur adjustment will cause the NHC value to round up instead of down. Sulfur is a required parameter for the Tier 3 test fuel and the sulfur value is already known for the test fuel. Eliminating the sulfur adjustment does not reduce burden. [EPA-HQ-OAR-2022-0829-0701, pp. 134-137]

EPA is also requesting feedback regarding omitting the water adjustments from the modified D3338 method for determining NHC. The water adjustment in ASTM D3338 lowers the calculated NHC. Eliminating the water adjustment will result in a higher calculated NHC and lower calculated CAFE resulting in an increase in stringency. While the water content in Tier 3 and LEV III test fuel is very low and the adjustment is small, in some cases the water adjustment will cause the NHC value to round up instead of down. Water is typically reported in Tier 3 and LEV III certification fuel analyses. Omitting the water adjustment does not reduce burden. [EPA-HQ-OAR-2022-0829-0701, pp. 134-137]

The required adjustments to include sulfur and water in the various equations follow. Include after (f) (1) (i)

- Water. Determine water using ASTM E1064. [EPA-HQ-OAR-2022-0829-0701, pp. 134-137]

- Sulfur. Determine Sulfur using ASTM D2622 or ASTM D5453. [EPA-HQ-OAR-2022-0829-0701, pp. 134-137]

Change (f) (1) (ii)(A) by including the sulfur term in the E0 CMF determination:

- CMF = 1 – 0.01 × hydrogen mass percent – 0.01 × sulfur mass percent. [EPA-HQ-OAR-2022-0829-0701, pp. 134-137]

Change (f) (1) (ii) (B) by including the water term in the Carbon Mass Fraction:

- CMFf = carbon mass fraction of test fuel = CMFh × (1 – MFH2O – mFe) + CMFe × mFe. [EPA-HQ-OAR-2022-0829-0701, pp. 134-137]

Change (f) (1) (ii) (B) by including the water term in the aromatic content of the hydrocarbon fraction:

- ?? = aromatic content of the hydrocarbon fraction = vParo,f / (1 – vFe – VFH2O) [EPA-HQ-OAR-2022-0829-0701, pp. 134-137]

Change (f) (1) (ii) (B) by including ASTM D5580 as an alternative method for determining aromatic content as long as it is corrected to ASTM D1319. [EPA-HQ-OAR-2022-0829-0701, pp. 134-137]

- vParo,f = volume percent aromatics in the test fuel as determined by ASTM D1319-15 (incorporated by reference in §600.011). An acceptable alternative method is ASTM D5769-10 (incorporated by reference in §600.011), as long as the result is bias-corrected as described in ASTM D1319. An acceptable alternative method is ASTM D5580-15 (incorporated by reference in §600.011), as long as the result is bias-corrected to ASTM D5769-10 and then bias corrected again to ASTM D1319-15. [EPA-HQ-OAR-2022-0829-0701, pp. 134-137]

Change (f) (1) (ii) (B) by including the water term in the specific gravity of the hydrocarbon fraction:

- SGh = specific gravity of the hydrocarbon fraction = (SGf – sGe × vFe – SGH2O × VFH2O) / (1 – vFe – VFH2O) [EPA-HQ-OAR-2022-0829-0701, pp. 134-137]

Change (f) (1) (iii) (B) by including the water terms in the net heat of combustion of the test fuel:

- NHCf = net heat of combustion of test fuel = NHCh × (1 – mFe – MFH2O) + NHCe × mFe –

MFH2O × NHV60, H2O

- NHV60, H2O = net heat of vaporization of water at 60F = 1059 BTU/lb [EPA-HQ-OAR-2022-0829-0701, pp. 134-137]

Change (f) (1) (iii) (B) by including the water term in the aromatic content of the hydrocarbon fraction:

- ? = aromatics content of the hydrocarbon fraction = vParo,f / (1 – vFe – VFH2O) [EPA-HQ-OAR-2022-0829-0701, pp. 134-137]

Change (f) (1) (iii) (B) by including the water term in the specific gravity of the hydrocarbon fraction:

- SGh = specific gravity of the hydrocarbon fraction = (SGf – sGe × vFe – SGH2O × VFH2O) / (1 – vFe – VFH2O) [EPA-HQ-OAR-2022-0829-0701, pp. 134-137]

Organization: American Coalition for Ethanol (ACE)

Vehicle incentives/credits are not the only area in which EPA seems to penalize technologies designed to operate efficiently on ethanol-blended fuel, indeed another inequity exists with the Agency's outdated fuel economy formula. In previous statements, EPA has acknowledged part of the fuel economy formula (the R-factor) unfairly penalizes fuel containing ethanol. Consequently, EPA is discouraging automakers from developing efficient engines that require higher octane ratings and higher ethanol content. EPA has previously said the 0.6 R-factor is erroneous and fails to achieve the statutory purpose of evaluating the fuel economy of fuels containing ethanol. The auto industry has asked EPA for an R-factor of 1.0. In response, EPA has suggested the correct value may lie "between 0.8 and 0.9." ACE supports an R-factor of 1.0. [EPA-HQ-OAR-2022-0829-0613, p. 5]

Section 202(a)(3)(A)(ii) of the Clean Air Act authorizes EPA to look beyond the basic engine to set its engine or vehicle emission standards. Specifically, the statute says "in establishing classes or categories of vehicles or engines for purposes of regulations under this paragraph, the Administrator may base such classes or categories on gross vehicle weight, horsepower, type of fuel used, or other appropriate factors (emphasis added)." To account for the "type of fuel used" EPA needs to conduct a full lifecycle GHG emissions analysis. [EPA-HQ-OAR-2022-0829-0613, p. 5]

Organization: Clean Fuels Development Coalition et al.

VI. The Proposed Rule Should Fix the Problems with Fuel-Related Testing and Certification Requirements.

The proposed rule would also implement several changes to test fuel requirements, including requiring that model year 2027 and later vehicle compliance be demonstrated on Tier 3 test fuel. 88 Fed. Reg. 29,240. EPA explains that "Tier 3 test fuel more closely represents the typical market fuel available to consumers in that it contains 10 percent ethanol" and so EPA is reproposing an adjustment factor to allow demonstration of compliance with the existing standards using Tier 3 test fuel. Id. [EPA-HQ-OAR-2022-0829-0712, p. 45]

Requiring manufacturers to test on Tier 3 fuel and use the resultant tailpipe emissions directly in compliance calculation is a good step towards regulatory realism. But EPA's proposed approach does not fix many of the problems that have been identified in previous rulemakings. Some commentors here provided a full analysis of EPA's 2020 proposal to adjust vehicle test procedures for Tier 3 test fuel in comment submitted on that rulemaking docket. These previous comments should be considered comments on the agency's renewed attempt to finalize this proposal and are thus attached in an appendix to this comment. See Appendix B. EPA states that it "will be reevaluating comments received on the 2020 proposal as well as the comments for this proposal and considering if any corrections and adjustments are required, with any appropriate modifications based on the comments received and on the changing circumstances reflected in the current proposed rule for setting new standards for MY 2027 and later vehicles." 88 Fed Reg. 29,241 (emphasis added). Commentors reiterate that all issues raised in their previous comments apply to EPA's current revival of these same issues here. That the current proposal switches the 1.0166 factor from a multiplier applied to Tier 3 to test results to a divisor applied to Indolene test results does nothing to change the applicability of those comments. [EPA-HQ-OAR-2022-0829-0712, p. 45]

There are two primary issues with the proposed test fuel changes. First, the proposed rule's adjustment factor for carbon-dioxide emissions artificially inflates the carbon-related exhaust emissions for vehicles certified on the Tier 3 E10 test fuel. As a result, the rule penalizes low-carbon fuels like E10 by eliminating their natural advantage as a lower carbon solution. The Clean Air Act does not allow EPA to adjust test procedures to artificially distort CO2 emissions from vehicles. Maintaining the 1.0166 factor for pre-model year 2027 artificially inflates the CO2 emissions of vehicles certified on Tier 3 test fuels by making their CO2 emissions appear 1.66% higher than they are. Similarly, dividing test results for Indolene by 1.0166 for MYs 2027-29 makes those vehicles' CO2 emissions appear lower than they are. And maintaining a CO2 factor at all sets up barriers to future higher ethanol blends. [EPA-HQ-OAR-2022-0829-0712, pp. 45-46]

Second, EPA's proposed R-factor of 0.81 is too low and a more accurate R-factor is closer to 1. The proposed R-factor is flawed because it is based on a test program that EPA has admitted is flawed. This test program did not use representative Tier 3 vehicles or test enough vehicles. Further EPA's analysis of the Tier 3 test program data was flawed because it systematically elected to included unreliable and unrepresentative data. Finally, EPA's conclusions are inconsistent with the results of its own prior studies. [EPA-HQ-OAR-2022-0829-0712, pp. 45-46]

A. The Clean Air Act does not allow EPA to adjust test procedures to artificially distort CO2 emissions.

While EPA has discretion under the Clean Air Act to define and execute appropriate emissions test procedures, EPA's proposed CO2 adjustment, which artificially distorts the CO2 emissions measured on vehicles certified using Tier 3 test fuel, exceeds that discretion. Section 202 directs EPA to "prescribe. . . standards applicable to the emission[s] . . . from any class or classes of new motor vehicles," including CO2 emissions. 42 U.S.C. §7521(a)(1); Massachusetts v. EPA, 549 U.S. 497, 528 (2007). To establish compliance with the prescribed emission standards, Section 206 authorizes EPA to test, or require manufacturers to test, vehicles "in such manner as [the agency] deems appropriate." 42 U.S.C. §§ 7525(a)(1), (a)(3)(B). EPA can further revise those tests "[f]rom time to time . . . as deem[ed] appropriate." 42 U.S.C. §7525(a)(4)(B). [EPA-HQ-OAR-2022-0829-0712, p. 46]

But EPA's authority to adjust emissions test procedures under Section 206 is not unbounded. Congress unequivocally indicated its desire that test procedures reflect actual vehicle emissions, directing EPA to "review and revise" test procedures "to insure that vehicles are tested under circumstances which reflect the actual current driving conditions under which motor vehicles are used, including conditions relating to fuel, temperature, acceleration, and altitude. 42 U.S.C. § 7525(h) (emphasis added); see also Energy Future Coalition v. EPA, 793 F.3d 141, 147 (D.C. Cir. 2015) ("[T]he Clean Air Act provides that EPA's test fuel regulations must 'reflect the actual current driving conditions under which motor vehicles are used, including conditions relating to fuel.'")." [EPA-HQ-OAR-2022-0829-0712, p. 46]

And Section 206 limits EPA to defining test procedures that are "appropriate... to determine whether [a vehicle] conforms with" the emissions standards set under Section 202(a). 42 U.S.C. § 7525(a)(1) (emphasis added). While the term "appropriate" may "leave[] agencies with [some] flexibility," the term still must be "[r]ead naturally in the [] context" of the statute. Michigan v. EPA, 135 S. Ct. 2699, 2707 (2015); see also City of Boerne v. Flores, 521 U.S. 507, 517 (1997) (legislation is "appropriate" if it is "adapted to carry out the objects the amendments have in view") (quoting Ex Parte Virginia, 100 U.S. 339, 345–46 (1879)). The most natural understanding of the term "appropriate" in the context of Section 206 is that test procedures should reflect accurate, actual, real-world vehicle emissions. It is not appropriate to distort measured emissions simply to maintain stringency. [EPA-HQ-OAR-2022-0829-0712, pp. 46-47]

Indeed, EPA itself has historically interpreted its authority to set test procedures as requiring test procedures that reflect actual, not scaled, tailpipe CO2 emissions. For each test fuel that EPA currently allows in certification—gasoline, diesel, methanol, natural gas, ethanol, liquified petroleum gas, and related fuel blends— EPA's procedures for determining CREE reflect the actual—not "adjusted"—vehicle CO2 emissions. See 40 C.F.R. § 600.113-12(h)–(m). EPA's proposed CO2 adjustment, which artificially adjusts CO2 emissions of vehicles by 1.66%, would be unprecedented. It would single out an individual test fuel and perversely penalize it alone for its lower carbon output. [EPA-HQ-OAR-2022-0829-0712, pp. 46-47]

Under the Clean Air Act, changes in vehicle emissions due to changes in test fuels are properly addressed by adjusting emission standards, not by changing test procedures. EPA's contrary arguments in the Tier 3 proposed rulemaking are unpersuasive. In the preamble to that proposed rule, EPA claims, without support, "that for testing for CO2 emissions compliance under the Clean Air Act, the statute allows, but does not require [CO2 emissions] adjustments back to 1975 test procedures, including for changes in test fuel properties." 85 Fed. Reg. 28,567. The relevant provisions, however, make no reference to scaling vehicle emissions test procedures to align with decades-old test procedures. Indeed, as CO2 emissions were first regulated in model year 2012, 40 C.F.R. § 86.1818-12(c), EPA's theory is a pure anachronism: There are no 1975 CO2 test procedures EPA could adjust to. [EPA-HQ-OAR-2022-0829-0712, pp. 47-48]

EPA nevertheless claimed that the CO2 adjustment is necessary "to produce the expected CO2 performance had the vehicle been tested over the same test cycles while operating on Tier 2 fuel." 85 Fed. Reg. 28,573. However, unlike EPCA, which expressly states that compliance with fuel economy standards is tied to the 1975 test fuel, 49 U.S.C. § 32904(c), the Clean Air Act nowhere suggests that the greenhouse gas vehicle emissions used for compliance purposes are tied to a particular (i.e., Tier 2) baseline. Instead, the most natural reading of Section 202's requirement that "emission[s] . . . from any . . . new motor vehicles or new motor vehicle engines" must meet prescribed standards is that actual emissions—not some scaled version of them—must meet the imposed standards. [EPA-HQ-OAR-2022-0829-0712, pp. 47-48]

Had Congress intended EPA to develop test procedures that scale emissions tailpipe measurements to align with some predetermined model year baseline, it could have said so—as it did in the EPCA. The absence of any such language in the Clean Air Act suggests that Congress meant exactly what it said: that emissions test procedures should "reflect the actual current driving conditions under which motor vehicles are used, including conditions relating to fuel," 42 U.S.C. § 7525(h) (emphasis added), meaning the procedures reflect the actual CO2 emissions generated by tested vehicles using a particular test fuel that is representative of market fuel. [EPA-HQ-OAR-2022-0829-0712, p. 48]

Furthermore, the proposed adjustment is based on a fundamental misconception of EPA's statutory role under Section 202(a). EPA asserted that its CO2 adjustment is "predicated on a view of [greenhouse gas] . . . stringency as relating to vehicle efficiency rather than tailpipe emissions in a market representative fuel mix." 85 Fed. Reg. at 28,566; id. at 28,570 (claiming the proposed CO2 adjustment is "necessary to realign test results to maintain efficiency controls at the vehicle manufacturer level."). But unlike with CAFE, the purpose of CO2 regulation is not improving vehicle "efficiency," but protecting the health and welfare of the people of the United States. As the Supreme Court observed in Massachusetts v. EPA, "EPA has been charged with protecting the public's 'health' and 'welfare,' a statutory obligation wholly independent of DOT's mandate to promote energy efficiency." 549 U.S. at 532 (citation omitted). Yet the proposed CO2 adjustment is unlawfully predicated on the notion that Section 202(a) is an energy-efficiency mandate no different from DOT's obligation to increase fuel economy, in contravention of the Supreme Court's interpretation of the Act. [EPA-HQ-OAR-2022-0829-0712, p. 48]

Finally, EPA's interpretation of the scope of Section 206 has no principled limitation. If EPA may conjure up fake carbon molecules to the emissions of E10 simply to "maintain stringency," EPA would also be able to make measured carbon molecules disappear if regulatory changes or other factual circumstances make the standards more difficult to achieve than initially planned. This kind of hocus-pocus has no basis in the statute. EPA has no discretion to bias the test procedures against a test fuel to adjust the stringency of the CO2 standards. It should abandon its novel and flawed view of the Clean Air Act and adopt test procedures that measure real CO2 emissions. [EPA-HQ-OAR-2022-0829-0712, p. 48]

B. The proposed CO2 adjustment is an arbitrary and capricious departure from the agency's policy of fuel neutrality.

EPA's proposed CO2 adjustment is also an arbitrary and capricious departure from the agency's policy of fuel neutrality. When it departs from precedent, an "agency must at least 'display awareness that it is changing position' and 'show that there are good reasons for the new policy.'" Encino Motorcars, LLC v. Navarro, 136 S. Ct. 2117, 2126 (2016) (quoting FCC, 556 U.S. at 515). [EPA-HQ-OAR-2022-0829-0712, pp. 48-49]

By singling out a single test fuel for a CO2 penalty, EPA departs from its historic approach of applying emissions standards and related test procedures in a way that is "fuel neutral," so that "vehicles certified to operate on any fuel (e.g., gasoline, diesel fuel, ethanol blends, compressed natural gas, liquefied natural gas, hydrogen, and methanol) are all subject to the same standards." Cong. Research Serv., Tier 3 Motor Vehicle Emission and Fuel Standards 4 (Apr. 28, 2014); see also Tier 3 Rule, 79 Fed. Reg. at 23,558 ("Consistent with the Tier 2 principle of vehicle and fuel neutrality, the same Tier 3 standards apply to all LDVs, LDTs, or MDPVs, regardless of the fuel they use, as proposed. That is, vehicles certified to operate on any fuel (e.g., gasoline, diesel fuel, E85, CNG, LNG, hydrogen, and methanol) are all subject to the same standards."). In doing so, it eliminates the natural advantage of low-carbon test fuels in the certification process and wipes out the incentive to develop and adopt cleaner, lower-carbon fuels and technologies, cutting-off a promising pathway for achieving lower emissions and lower cost vehicles. [EPA-HQ-OAR-2022-0829-0712, pp. 48-49]

EPA's proposed rule effectively places a thumb on the scale in favor of electrification and against clean, low-carbon fuels, ultimately harming both the environment and the consumer. Moreover, by discouraging adoption of low-carbon fuels like high-octane mid-level ethanol blends as an option to reduce CO2 emissions, EPA's approach only endangers the public health and welfare, contrary to EPA's statutory duty. 42 U.S.C. § 7521(a)(1). To advance its mandate, EPA should encourage all fuel and vehicle low-carbon solutions, not pick winners and losers by erecting barriers to particular fuels. [EPA-HQ-OAR-2022-0829-0712, pp. 48-49]

C. The proposed R-factor exceeds EPA's authority to adjust fuel economy test procedures.

Under the existing statutory framework, Congress granted exclusive authority to DOT to "prescribe by regulation average fuel economy standards for automobiles." 49 U.S.C. § 32902(a). EPA has no authority to change the stringency of standards set by DOT. Rather, EPA is limited to prescribing fuel economy test procedures that give "comparable results" to the procedures used for model year 1975. 49 U.S.C. § 32904(c). [EPA-HQ-OAR-2022-0829-0712, pp. 49-50]

There is ample evidence that EPA's proposed R-factor of 0.81 is too low and that an accurate R-factor is closer to 1. See Appendix B; see also C. Scott Sluder et al., Determination of the R-factor for Fuel Economy Calculations Using Ethanol-Blended Fuels over Two Test Cycles, SAE Tech. Paper 2014-01-1572. Imposing an R-factor that is too low yields adjusted Tier 3 fuel economy results that are too low compared to the results that would be generated under 1975 vehicle test procedures, violating the comparability requirement. Moreover, EPA's improperly low proposed R-factor makes the fuel economy standards harder to meet, effectively raising their stringency and exceeding EPA's limited authority to adjust fuel economy test procedures. See id. [EPA-HQ-OAR-2022-0829-0712, pp. 49-50]

A simple example illustrates this increase in stringency: if the accurate R-factor is 1—a value that is close to values suggested by previous studies—EPA's proposed value of 0.81 results in an adjusted Tier 3 fuel economy that is 0.52% lower than the accurate adjusted fuel economy, effectively increasing the standard that a vehicle certified with a Tier 3 test fuel must meet by the same amount. EPA undertakes no such cost-benefit analysis or consideration of alternatives in its notice of proposed rulemaking, and regardless, EPA has no authority to make any such change. Only DOT has legal authority to promulgate regulations that increase the stringency of fuel economy standards. [EPA-HQ-OAR-2022-0829-0712, p. 50]

EPA's authority in this instance is limited to promulgating an R-factor that gives "comparable results" to the test procedures used for model year 1975. 49 U.S.C.§ 32904(c). Because EPA's proposed R-factor of 0.81 is erroneous, the proposed rule changes fuel economy standards and thus it exceeds EPA's statutory authority to adjust test procedures. [EPA-HQ-OAR-2022-0829-0712, p. 50]

D. EPA's analysis of the test program data was flawed and inconsistent with previous EPA studies.

EPA's analysis of the limited data it had from the test program is also flawed. Specifically, EPA systematically includes outlier data and data from unrepresentative vehicles that lowers the determined R-factor, while needlessly excluding other vehicle data that would increase the R-factor. As documented in Appendix B, the analysis inappropriately includes unreliable, outlier results from a faulty 2013 Chevrolet Malibu test vehicle, which significantly skews EPA's calculations and leads to a proposed R-factor that is far too low. At the same time, EPA arbitrarily excluded from its analysis results from the 2016 Acura ILX test vehicle simply because they were "unexpected." By excluding the Acura results, EPA's determined R-factor was lower than it would have been had it included all Test Program vehicles in its analysis. [EPA-HQ-OAR-2022-0829-0712, pp. 50-51]

EPA's analysis is also questionable because its determined R-factor is inconsistent with the results of numerous other recent EPA studies that have determined R factors much closer to 1. Within the past decade, EPA has sponsored or participated in at least three studies that have generated the data necessary to determine the R factor for vehicles operating using gasoline-ethanol fuel blends: the DOE Immediate Ethanol Effects Study, the EPAct/V2/E-89 Study, and the DOE Catalyst Durability Study. These studies included vehicles spanning model years 1999 to 2009. C. Scott Sluder et al., Determination of the R-factor for Fuel Economy Calculations Using Ethanol-Blended Fuels over Two Test Cycles, SAE Tech. Paper 2014-01-1572. While these studies were not designed specifically to measure R factor, the data they generated is nonetheless appropriate for doing so. [EPA-HQ-OAR-2022-0829-0712, pp. 50-51]

These previous EPA studies also have a significant advantage over the Tier 3 Test Program in that they evaluated a considerably larger number of vehicles and fuel blends, allowing determination of an R-factor with much greater certainty than EPA is able to do based on the Tier 3 Test Program data.25 So, while the vehicle selection and test method varied slightly compared to the Tier 3 Test Program, the results from these studies still provide a valuable reference point for corroborating EPA's conclusions from its Tier 3 Test Program. [EPA-HQ-OAR-2022-0829-0712, p. 51]

25 The Immediate Ethanol Effects Study included measurements on sixteen vehicle models and four fuel blends; the EPAct Study included measurements on fifteen vehicle models and a set of twenty- seven fuels; and the Catalyst Durability Study included 18 matched sets of vehicle models and four test fuels that produced data appropriate for R-factor analysis. The estimated uncertainties (95% confidence) for the R-

factor determinations from these studies ranges from 0.010 to 0.075, significantly smaller than the uncertainty in EPA's analysis for the proposed rule. See Appendix B.

These three previous studies uniformly found higher average R-factors than EPA's proposed R-factor of 0.81. Analysis of the Immediate Ethanol Effects Study results yielded an R-factor ranging from 0.86 to 0.89, the EPAct Study yielded an R- factor of 0.92, and the Catalyst Durability Study yielded an R factor of 0.94 to 0.96. All these studies had significantly lower uncertainties in their determined R-factors than EPA has in its proposed R-factor: the maximum R-factor uncertainty among the three studies of ±0.087, compared to an uncertainty of ±0.39 in EPA's proposal. The R-factor derived from these studies can be compared directly to EPA's proposal, and their uniformly higher values confirm that EPA's Tier 3 Test Program analysis underestimates R. [EPA-HQ-OAR-2022-0829-0712, p. 51]

As a result, the adjustment factors calculated by EPA are arbitrary and capricious. [EPA-HQ-OAR-2022-0829-0712, p. 51]

For all the reasons detailed above, EPA should withdraw the proposed rulemaking and issue another proposed rulemaking that complies with the agency's statutory obligations. To satisfy its obligations under the Clean Air Act, EPA should reconsider its proposed Tier 3 Test Fuel adjustments and instead finalize a rule that eliminates the proposed CO_2 adjustment and that includes an R-factor of not less than 0.95. Commentors strongly urge EPA to use its Section 202 powers effectively and consider the ways in which ethanol and other renewable fuels can improve our nation's light- and medium-duty fleet. [EPA-HQ-OAR-2022-0829-0712, pp. 51-52]

Organization: Environmental. and Public Health Organizations

XIII. EPA Should Finalize the Proposed Test Fuel Change for GHG and Fuel Economy Certification But Not for Labeling Purposes, and It Should Require the Use of Adjustment Factors in Appropriate Circumstances. [EPA-HQ-OAR-2022-0829-0759, p. 96]

We support EPA's proposal to require gasoline-powered vehicles to demonstrate compliance with the MY 2027-2032 GHG standards using Tier 3 test fuel, as well as its proposal to require the use of adjustment factors in certain situations. See 88 Fed. Reg. at 29240-42 & Tbl. 30. In addition to the points made below, we urge EPA to consider the comment letter that many of the undersigned organizations submitted to EPA in August 2020 regarding its related proposal on Tier 3 test fuel (which was never finalized).230 [EPA-HQ-OAR-2022-0829-0759, p. 96]

230 Comment Letter re: EPA-HQ-OAR-2016-0604, Vehicle Test Procedure Adjustments for Tier 3 Certification Test Fuel (Aug. 14, 2020), at https://www.regulations.gov/comment/EPA-HQ-OAR-2016-0604-0081.

In the 2014 Tier 3 Rule, EPA appropriately decided to transition away from Indolene (also known as "Tier 2") test fuel, which no consumer can purchase, to a test fuel ("Tier 3," which contains 10% ethanol) that represents what consumers can actually purchase at the pump. 79 Fed. Reg. at 23525-26. As part of the Tier 3 rulemaking, EPA committed to assessing the impact of the test fuel change on the GHG emissions and fuel usage of the new vehicle fleet. Id. at 23531-32. The results of the Agency's subsequent research study were conclusive: switching from Indolene to Tier 3 test fuel reduces fuel economy and tailpipe emissions of carbon dioxide.231 As EPA rightly concludes, the "difference in GHG emissions between the two fuels is significant in the context of measuring compliance" with GHG standards. 88 Fed. Reg. at 29241. [EPA-HQ-OAR-2022-0829-0759, pp. 96-97]

231 See U.S. EPA, Tier 3 Certification Fuel Impacts Test Program, EPA-420-R-18-004 (Jan. 2018), at 2, available at https://www.regulations.gov/document/EPA-HQ-OAR-2016-0604-0003.

Because EPA has based the proposed MY 2027-2032 GHG standards on the use of Tier 3 test fuel instead of Indolene, id. at 29240-41, requiring manufacturers to use Tier 3 test fuel to demonstrate compliance in MY 2027 and beyond is appropriate. We agree that compliance testing using Tier 3 fuel in MY 2027-2032 does not require an adjustment factor. [EPA-HQ-OAR-2022-0829-0759, p. 97]

We also agree with EPA's proposal that any manufacturers that use Tier 3 test fuel to certify compliance with pre-MY 2027 GHG standards must apply an adjustment factor of 1.0166. 88 Fed. Reg. at 29241 & Tbl. 30. Since the existing (pre-MY 2027) GHG standards are based on Indolene test fuel, using this adjustment factor is necessary to avoid arbitrarily crediting vehicles tested with Indolene with artificial reductions in GHG emissions. As EPA has recognized, not applying an adjustment factor would effectively (and inappropriately) reduce the stringency of the existing GHG standards. U.S. EPA, Vehicle Test Procedure Adjustments for Tier 3 Certification Test Fuel, 85 Fed. Reg. 28564, 28566 (May 13, 2020) (proposed, never-finalized rule regarding Tier 3 test fuel change). Failing to require an adjustment factor would also impose unwarranted additional costs on consumers at the gas pump. To avoid unnecessary and harmful delays in manufacturers applying the adjustment factor to pre-MY 2027 vehicles tested on Indolene, EPA should also clarify that this provision takes effect 60 days after the rule becomes final. [EPA-HQ-OAR-2022-0829-0759, p. 97]

EPA's approach to adjusting the fuel economy and GHG certification values based on the certified fuel as outlined in Table 30 of the Proposal is appropriate. However, the Agency should begin requiring Tier 3 fuel used for certification for all non-carryover vehicles beginning with the first complete model year following finalization of the rule, in order to avoid manufacturers trying to exploit relative Indolene vs. Tier 3 performance different than the average adjustment factor. Manufacturers already certify vehicles on Tier 3 fuel and are aware of any potential discrepancies that could be used to their advantage, so the Agency should eliminate any opportunity for manipulation of certification results as soon as possible, with no phase in period. Allowing carryover is a sufficient compromise to minimize testing burden. [EPA-HQ-OAR-2022-0829-0759, p. 97]

We do not support EPA's proposal to adjust certification test fuel requirements for purposes of fuel economy and emissions labels. The use of Tier 3 fuel for certification was justified because this fuel more closely aligns with the fuel available to consumers at the pump.232 Thus, Tier 3 fuel is more representative of the fuel a consumer would use to judge their own fuel economy. In contrast, the data collected to support the latest iteration of the fuel economy label was collected in 2004-2005,233 prior to the Renewable Fuel Standard (RFS2) taking effect. Ethanol content in fuel in 2004-2005 was just 2%, on average; MTBE was the more popular oxygenate; and gasoline's oxygen content averaged just over 1%, as opposed to 2014, when Tier 3 (E10) fuel was defined to reflect the 10% ethanol content of the reformulated gasoline available to consumers and oxygen content nearly doubled.234 While Indolene has never been available at the gas pump, many of the average properties for 2004 pump fuel are directionally more similar to Indolene than to Tier 3 fuel: lower gravity, lower ethanol content, lower oxygen, and higher aromatics.235 Thus, the fuel economy labeling tests were, to first order, based on the pump fuel at the time, and now such tests should reflect the updated fuel more representative of today's current pump fuel. Therefore, rather than applying the adjustment factor to Tier 3-certified vehicles, as EPA proposes, it would be more appropriate to apply the inverse adjustment factor to Indolene-certified vehicles. While we appreciate the point made by EPA that "a comprehensive assessment of real world fuel economy is the best process to ensure that all real-world effects are reflected," 85 Fed. Reg. at 28579, such an assessment is a resource-intensive undertaking that has not been attempted in nearly 20 years, and EPA has sufficient data based on its Tier 2/Tier 3 program to account for a shift in the available pump fuel. [EPA-HQ-OAR-2022-0829-0759, pp. 97-98]

232 "E10 most appropriately reflects in-use gasoline around the country today and into the foreseeable future, and thus we are finalizing E10 for the test fuel." 79 Fed. Reg. at 23450.

Organization: Ford Motor Company

E10 Fuel Economy & GHG Testing Transition

Ford generally supports EPA's proposal to transition to E10 test fuel for GHG and fuel economy testing. Specifically, we support the ability to conduct E10 testing before 2027MY with appropriate adjustments, and the application of 1.0166 divisor to E0 testing conducted after 2026MY. [EPA-HQ-OAR-2022-0829-0605, p. 9]

Ford also recommends the following clarifications/adjustments to the proposed E10 provisions: [EPA-HQ-OAR-2022-0829-0605, p. 9]

- To ease test burden and provide greater flexibility, E0 carry-over testing should be extended through 2030MY. [EPA-HQ-OAR-2022-0829-0605, p. 9]

- Clarify that re-testing on E0 for 5-cycle litmus determination be permitted until updated derived 5-cycle regression equations are developed using regular-grade octane E10 fuel. [EPA-HQ-OAR-2022-0829-0605, p. 9]

Ford looks forward to working with EPA to help develop the provisions, test procedures and regulatory text related to this test fuel transition that are needed for the final rule. [EPA-HQ-OAR-2022-0829-0605, p. 9]

Organization: Minnesota Corn Growers Association (MCGA)

Update Fuel Related Testing and Certification Requirements

As NCGA recommended to EPA in 2020 comments on Docket EPA–HQ–OAR–2016-0604, actual tailpipe carbon emissions, regardless of the test fuel, must continue to be the only measure of vehicle emissions performance in vehicle testing. CO2 test adjustments would needlessly complicate vehicle test procedures. Relying solely on test results eliminates uncertainty, averaging and potential for inaccuracies in procedures to adjust emission test results for the fuel. [EPA-HQ-OAR-2022-0829-0612, p. 12]

Correct the fuel economy formula by updating the R-Factor to 1.0 to reflect documented operation of modern engine technology.

Correcting the R-Factor in the fuel economy formula would support automakers developing high efficiency engines that require higher octane ratings and a higher ethanol content. EPA has acknowledged that the current EPA- mandated R-Factor of 0.6, originally established in the 1980s, is outdated and fails to achieve the statutory purpose of making fuel economy testing on today's fuel equivalent to fuel economy testing in 1975. An update to 1 from 0.6 would reflect results of analysis by the Department of Energy and EPA using modern engines and fulfill previous observations and commitments from EPA to address this issue. Published studies have shown that R for modern vehicles should be around 0.93 to 0.96.31 [EPA-HQ-OAR-2022-0829-0612, p. 12]

31 Sluder, C., West, B., Butler, A., Mitcham, A. et al. 2014. Determination of the R Factor for Fuel Economy Calculations Using Ethanol-Blended Fuels over Two Test Cycles. SAE Int. J. Fuels Lubr. 7(2):2014, doi:10.4271/2014-01-1572.

Setting the R-factor to 1.0 sets fuel economy results on an energy basis. In application, the R factor equation is a "fuel response factor," adjusting for more than just energy density. An R of 1.0 essentially converts fuel economy to mile per gallon gasoline equivalent (MPGge), which is how other alternative fuels such as propane, natural gas, and electricity have been compared to their gasoline counterparts for decades. Setting R to 1.0 provides equitable treatment to renewable ethanol that other alternative fuels already receive. This change could help speed the transition to certification with Tier 3 fuel as well as encourage vehicle manufacturers to seek certification for even higher ethanol blends, such as E15 or the high octane E30 EPA suggested in its Tier 3 proposal several years ago. Manufacturers are not incentivized to build dedicated high-octane vehicles that reduce GHG emissions when those low carbon benefits are penalized by a low R factor. [EPA-HQ-OAR-2022-0829-0612, p. 12]

Lower GHG emissions from vehicles benefit consumers, our environment, and our energy security. Just as updating the test fuel from E0 to E10 reduced GHG emissions by blending cleaner, renewable ethanol with gasoline, E15 and future clean, high-octane fuels that blend more ethanol will further reduce emissions and improve fuel economy when used with optimized engines. Vehicle test procedures for Tier 3 fuel, or any future certification fuel, must not create impediments to low carbon fuels such as E15 and higher blends and the vehicle technologies that help reach our mutual goal of lower GHG emissions. Stringency of the standards is best maintained through the Administrator's authority to adjust the standards, as EPA is using in this proposal, not by adjusting emission test results. [EPA-HQ-OAR-2022-0829-0612, pp. 12-13]

Update the F-factor in the fuel economy formula to a forward-looking F-factor of at least 0.2. [EPA-HQ-OAR-2022-0829-0612, p. 13]

Organization: National Corn Growers Association (NCGA)

As NCGA recommended to EPA in 2020 comments on Docket EPA–HQ–OAR–2016-0604, actual tailpipe carbon emissions, regardless of the test fuel, must continue to be the only measure of vehicle emissions performance in vehicle testing. CO2 test adjustments would needlessly complicate vehicle test procedures. Relying solely on test results eliminates uncertainty, averaging and potential for inaccuracies in procedures to adjust emission test results for the fuel. [EPA-HQ-OAR-2022-0829-0643, p. 10]

Lower GHG emissions from vehicles benefit consumers, our environment, and our energy security. Just as updating the test fuel from E0 to E10 reduced GHG emissions by blending cleaner, renewable ethanol with gasoline, E15 and future clean, high-octane fuels that blend more ethanol will further reduce emissions and improve fuel economy when used with optimized engines. Vehicle test procedures for Tier 3 fuel, or any future certification fuel, must not create impediments to low carbon fuels such as E15 and higher blends and the vehicle technologies that help reach our mutual goal of lower GHG emissions. Stringency of the standards is best maintained through the Administrator's authority to adjust the standards, as EPA is using in this proposal, not by adjusting emission test results. Organization: POET, LLC

A. An R-factor of 1.0 Should Be Used by EPA for Fuel Economy Calculations on E10.

POET supports an R-factor equal to 1.0 for EPA's calculation fuel economy performance on E10, as broadly supported by commenters such as the Alliance for Automotive Innovation and Growth Energy. An R-factor of 1.0 implies energy content impact of a test fuel relative to that of the 1975 baseline fuel is fully observed in test results and adjusted for. An R-factor of less than 1.0 implies a test vehicle does not fully realize the impact of fuel energy content changes and results in a lower calculated fuel economy for fuels with lower energy content. In the 2020 NPRM, EPA inappropriately proposed an R-factor of 0.81. For reasons including those outlined by the Alliance for Automotive Innovation and Growth Energy, including the use of more representative data, POET supports an R-factor of 1.0 for an E10 test fuel.129 [EPA-HQ-OAR-2022-0829-0609, p. 28]

129 See Alliance for Automotive Innovation, Comments on Vehicle Test Procedure Adjustments for Tier 3 Certification Test Fuel; Notice of Proposed Rulemaking (August 14, 2020), pp. 5-6, available at https://www.regulations.gov/comment/EPA-HQ-OAR-2016-0604-0087. See also, Growth Energy, Vehicle Test Procedure Adjustments for Tier 3 Test Fuel (August 14, 2020)(supporting an R-factor of 1.0 and noting that EPA's lower proposed R-factor "fails to reflect real-world numbers or recognize the myriad of advancements in technology and the wealth of research in this area by national laboratories and others"), p.1, available at https://www.regulations.gov/comment/EPA-HQ-OAR-2016-0604-0079.

B. EPA Must Not Use a Carbon Adjustment Factor That Disincentives Using Low- Carbon Fuels.

EPA must not use a "CO2 adjustment" to GHG emission test results to arbitrarily and capriciously eliminate incentives for low carbon fuels. The Proposed Rule suggests use of a "CO2 adjustment" factor of 1.0166 for GHG standards "to demonstrate compliance with a GHG standard referenced to Indolene test fuel" and regarding "fuel economy and environment label values."130 However, the Proposed Rule also states, when determining compliance based on

Tier 3 Test Fuel, that “[t]his proposal does not include an adjustment factor for tailpipe GHG emissions but rather requires manufacturers to test on Tier 3 test fuel and use the resultant tailpipe emissions directly in their compliance calculation.”131 [EPA-HQ-OAR-2022-0829-0609, p. 29]

130 88 Fed. Reg. at 29241 (emphasis added).

131 88 Fed. Reg. at 29240.

The Alliance for Automotive Innovation noted in comments on EPA’s 2020 proposed rule that “Adding CO2 emissions that are not emitted by the vehicle for the purposes of calculating an adjusted compliance level for vehicles is counter to the goal of reducing carbon emissions from the transportation sector” and “will have the unintended consequence of undermining the large potential GHG reduction opportunities low carbon fuels.”132 Similarly, Growth Energy noted EPA’s CO2 adjustment factor in the 2020 proposal would “unnecessarily penalize automakers for the use of low carbon fuels” and the “use of low-carbon biofuels, such as ethanol, should be strongly encouraged given the benefits toward reducing greenhouse gas emissions and improving air quality.” POET agrees that no CO2 adjustment factor should be used that disincentives the use of low carbon fuels.133 [EPA-HQ-OAR-2022-0829-0609, p. 29]

EPA Summary and Response

Summary:

The Alliance commented on the following items:

1. Do Not Adjust the Tailpipe CO_2 Value for E10
2. Set R-Factor Equal to 1.0 for CAFE Performance on E10
3. Delay E10 Phase-in, Allow Optional E0 Testing and Carryover of E0 Data
4. Address the Impact of the E10 Transition on 5-Cycle Testing and Litmus Test
5. Consider Fuel Economy and Environmental Performance Labeling Impacts

Several commenters advised that adjusting CO_2 measurements from Tier 3 test fuel upward by 1.6% is improper since E10 test fuel represents market fuel. (For example, a commenter states that “It is not appropriate to distort measured emissions simply to maintain stringency.”) They also suggest that the proposed adjusted R-value of 0.81 is too low, stating that values around 0.9 or higher have been published in recent literature, and that a value of 1.0 would be optimal as it avoids penalizing ethanol blends. One commenter took issue with the choice of test vehicles retained in the dataset used to compute the updated R-factor, specifically that the 2013 Malibu was included while the Acura was excluded. Another commenter explained that the computation of the test fuel’s heating value and carbon mass fraction should be done using the original ASTM methods used in characterizing the historical reference fuel rather than updated methods we proposed, and that the values should account for sulfur and water content. It was also suggested that the PM Index and/or heavy aromatics content of Tier 3 certification test gasoline should be adjusted to better match current market gasoline, pointing to a downward shift since the original specification was set.

Some commentors mentioned that they believed EPA was penalizing technologies designed to operate efficiently on ethanol-blended fuel and discouraging automakers from developing efficient engines that require higher octane ratings and higher ethanol content. This disincentivizes the use of low carbon fuels with ethanol.

A commentor suggested that the proposed CO_2 adjustment is an arbitrary and capricious departure from the agency's policy of fuel neutrality. The commenter also stated the Clean Air Act does not allow EPA to adjust test procedures to artificially distort CO_2 emissions, or that it would unnecessarily complicate the compliance calculations.

Another commenter voiced support for the proposed adjustments to CO_2 and fuel economy measurements used for compliance, but opposed the adjustments to Tier 3 fuel results for vehicle labels on the basis that Tier 3 fuel is a reasonably good representation of market fuel.

Response:

The responses to the Alliance's list are available in Section III.C.2.iv.e of the preamble.

We are finalizing GHG standards the stringency of which accounts for E10 test fuel, therefore the 1.6% adjustment is no longer required in most situations. This would have been appropriate broadly when the standards were based on E0 test fuel since that fuel produces higher CO_2 emissions for the same vehicle and test conditions. Adjustments are reasonable when the current test fuel is different from the original test fuel for which the standards were set, but that is not the case with this rule's final GHG standards.

However, we are retaining the updated R_a-factor of 0.81 to represent equivalent fuel economy performance within the CAFE program. This factor was generated from a study carefully designed and rigorously conducted at EPA's lab. The decision to include data from the 2013 Malibu was based on its performance being within the expected range.

In addition, we want to clarify that R-factor values in the literature (e.g., in Sluder, *et al.*) are generally intended to isolate the actual sensitivity of fuel economy to fuel energy content, while the R_a factor here rolls up multiple impacts related to this specific pair of test fuels that include the energy content difference, additional charge cooling due to ethanol's heat of vaporization, and potentially some marginal impacts of the octane change. Thus, we wouldn't expect this R_a value to precisely match other R-factors found in the literature.

We have revised the fuel economy calculations to use ASTM methods D3338 and D3343 with appropriate accommodations for E10 blends and have addressed the inconsistency in heating value units. We did not incorporate water and sulfur adjustments to heating value and carbon content of test fuels. Since the updated R-factor was empirically derived from a study where the test fuels contained typical levels of water and sulfur, the results effectively incorporate impacts of those contaminates on fuel economy. Additional corrections should then be very small if applied as a deviation from our study fuels, or redundant if accounted for in full measure.

We are not adjusting the aromatics content specifications for certification test gasoline at this time, as we did not include any updated ranges in the proposal. We will consider this issue as part of our assessment of a potential heavy aromatic content standard for market gasoline.

A commentor suggested that the proposed CO_2 adjustment is an arbitrary and capricious departure from a policy of fuel neutrality and that the Clean Air Act does not allow EPA to adjust test procedures to artificially distort CO_2 emissions. Another commenter suggests that the adjustment will unnecessarily complicate the compliance calculations. EPA disagrees. The statute confers on the Administrator discretion to promulgate appropriate testing requirements. The commenters fundamentally misunderstand the purpose of the adjustment, which is not meant to artificially distort CO_2 emissions, but rather to account for the effects of different test fuels and accurately represent CO_2 emissions for purposes of compliance with the GHG standards. The adjustments are necessary to produce equivalent stringency of standards between testing that used Tier 2 versus Tier 3 fuels. Having no adjustment would effectively reduce the stringency of the earlier standards when Tier 3 fuel is used. Without this adjustment, manufacturers could reduce the CO_2 emissions of a given vehicle model by simply changing which test fuel was used during GHG certification testing. In any case, the CO_2 adjustment for Tier 3 test fuel is only required through model-year 2026 vehicles. In addition, the exact value of the adjustments are the result of a carefully executed test program using a variety of technologies with a wide cross section of vehicle types represented.

In response to comments opposing the CO_2 adjustments to Tier 3 fuel results for vehicle labels (on the basis that Tier 3 fuel is a reasonably good representation of market fuel), we assert that the adjustment is appropriate because the label calculations, being based on Tier 2 E0 fuel, already apply an adjustment to account for market fuel being E10. Therefore, using the Tier 3 test fuel value directly would effectively be double-counting for the ethanol content.

In response to the comments on penalizing technologies, the revised R-factor and CO_2 adjustments apply only to existing vehicle designs using E10 test fuel. Test fuels and procedures allowing manufacturers to certify vehicles at higher ethanol blend levels do not yet exist (with the exception of E85 fuel, which does not use these adjustment factors).

6.4 – Engine certification for high-GCWR vehicles

Comments by Organizations

Organization: Alliance for Automotive Innovation (Alliance)

E. MDV Certification (Chassis vs Engine Dynamometer)

10. Background on Chassis vs. Engine Dynamometer Certification

Today, emission testing of trucks typically happens on either a chassis dynamometer or an engine dynamometer. Class 2b and 3 complete vehicles are required to test tailpipe emissions on a chassis dynamometer, while Class 4 and above vehicles test the performance of the engine itself. The two test procedures are very different in terms of laboratory hardware and test cycles. EPA is proposing that many MDVs will retain chassis dynamometer testing for GHG emissions and have the additional, new requirements for engine dynamometer testing for criteria emissions beginning in MY 2030. [EPA-HQ-OAR-2022-0829-0701, pp. 203-205]

Engine dynamometers are useful to assess the performance of engines across a wide range of loads and engine speeds. Emissions typically vary by operating conditions, or set points, and lab measurements across a range of set points can help predict emissions performance across a wide range of engine use cases where engine speed and engine load may vary significantly. In the heavy-duty industry, one engine family may be installed in diverse applications, like school buses, bucket trucks, garbage trucks, and class 8 long haul tractors. For very large vehicles, testing the entire vehicle on a chassis dynamometer is not practical, as there would be size and safety constraints, and many vehicle applications for an engine may be produced in very low volume. Regulators and industry have settled on engine dynamometer testing and engine specific criteria emissions standards for Class 4-8 vehicles, and GHG emissions standards set at the vehicle level, with vehicle GHG performance estimated with computer simulation and representative inputs. [EPA-HQ-OAR-2022-0829-0701, pp. 203-205]

Chassis dynamometers are used to test tailpipe emissions of complete vehicles. Laboratories run vehicles along predetermined speed cycles and measure the quantity and composition of exhaust mater. Regulators and manufacturers commonly use chassis dynamometers to define standards for emissions test procedures and to measure vehicle performance against emissions standards. Chassis dynamometers are frequently used to test passenger cars, light trucks, and Class 2b and 3 complete vehicles. These vehicles are typically produced in high volume, and test cycles with vehicle speeds over time are broadly representative of real-world use of automotive products. [EPA-HQ-OAR-2022-0829-0701, pp. 203-205]

11. Proposed New Engine Dynamometer Testing and Standards

Beginning in MY 2030, EPA proposes to require manufacturers to meet engine dynamometer standards (Part 1036) to certify the criteria emissions performance of capable Class 2b and 3 vehicles. EPA proposes that vehicles with a GCWR above 22,000 pounds will be subject to the Part 1036 requirements. The Part 1036 requirements have different useful life and testing requirements than chassis dynamometer standards. [EPA-HQ-OAR-2022-0829-0701, pp. 203-205]

Requiring these Class 2b and 3 MDVs to engine certify increases testing resources and aftertreatment development as duplicate testing on vehicles. CARB (and EPA today) require certification on a chassis dynamometer, while the NPRM proposes to shift these vehicles to an engine dynamometer certification. This unnecessarily drives costs up as different engine and aftertreatment hardware and separate calibration efforts are needed to meet the disparate requirements (standards, useful life, OBD, etc.). EPA is presumably doing this is to address CO concerns on SI engines, but it is unnecessary since every area in the U.S. reached attainment for CO almost 13 years ago (September 27,2010).311 Since then, automakers have continued reducing CO emissions from SI engines. [EPA-HQ-OAR-2022-0829-0701, pp. 203-205]

311 U.S. EPA, September 21, 2022, Green Book Carbon Monoxide (1971) Area Information, retrieved from https://www.epa.gov/green-book/green-book-carbon-monoxide-1971-area-information, on June 26, 2023.

12. Recommendations on Class 2b-3 Engine Dynamometer Testing and Standards

Auto Innovators recommends that EPA continue with current MDV testing, namely, continuing to have Class 2b and Class 3 trucks chassis certify, which will provide one common hardware development, testing, and certification method for OEMs. [EPA-HQ-OAR-2022-0829-0701, pp. 203-205]

EPA requested comment on alternative for high GCWR MDV criteria pollutant emissions standards:312 [EPA-HQ-OAR-2022-0829-0701, pp. 203-205]

312 NPRM at 29271

(1) MDV above 22,000 pounds GCWR would comply with the MDV chassis dynamometer standards proposed in Section III.C with the introduction of additional engine dynamometer-based standards over the Supplemental Emissions Test as finalized within the Heavy-duty 2027 and later standards; [EPA-HQ-OAR-2022-0829-0701, pp. 203-205]

(2) MDV above 22,000 pounds GCWR would comply with the MDV chassis dynamometer standards proposed in Section III.C with additional in-use testing and standards comparable to those used within the California ACC II; [EPA-HQ-OAR-2022-0829-0701, pp. 203-205]

(3) Introduction of other test procedures for demonstration of effective criteria pollutant emissions control under the sustained high-load conditions encountered during operation above 22,000 pounds GCWR. [EPA-HQ-OAR-2022-0829-0701, pp. 203-205]

Class 2b-3 vehicles can achieve low emissions targets across a range of operating conditions beyond the chassis test cycle, including those at high load, and EPA can confirm this with test procedures adopted by California ACC II. Manufacturers recommend EPA adopt the California ACC II test procedure for in-use testing and standards (Option “2”). Procedurally, this allows manufacturers to continue chassis certification, minimizing disruptions to lab processes, and manufacturers already have hardware designed to meet stringent emissions standards, even in high load in-use requirements. The chassis certification test cycle also aligns well with common use cases for Class 2b-3 vehicles, whereas the engine dyno certification process places much higher emphasis on high load conditions, and places lower emphasis on low load performance. [EPA-HQ-OAR-2022-0829-0701, pp. 203-205]

E. Engine Dynamometer Certification

If EPA finalizes its proposal (outside of OBD requirements) to require Class 2b and 3 vehicles to certify via engine dynamometer certification, Auto Innovators proposes that EPA allow product that is certified by CARB, using chassis certification method, to meet EPA’s OBD requirements. We recommend EPA use the language below from HD OBD § 1036.110(b)(11) in § 86.1806-27: [EPA-HQ-OAR-2022-0829-0701, p. 259]

> (11) If you have an approved Executive order from the California Air Resources Board for a given engine family, we may rely on that Executive order to evaluate whether you meet federal OBD requirements for that same engine family or an equivalent engine family. Engine families are equivalent if they are identical in all aspects material to emission characteristics; for example, we would consider different inducement strategies and different warranties not to be material to emission characteristics relevant to these OBD testing requirements. EPA would count two equivalent engine families as one for the purposes of determining OBD

demonstration testing requirements. Send us the following information: [EPA-HQ-OAR-2022-0829-0701, p. 259]

(i) You must submit additional information as needed to demonstrate that you meet the requirements of this section that are not covered by the California Executive order. [EPA-HQ-OAR-2022-0829-0701, p. 259]

(ii) Send us results from any testing you performed for certifying engine families (including equivalent engine families) with the California Air Resources Board, including the results of any testing performed under 13 CCR 1971.1(l) for verification of in-use compliance and 13 CCR 1971.5(c) for manufacturer self- testing within the deadlines set out in 13 CCR 1971.1. (iii) We may require that you send us additional information if we need it to evaluate whether you meet the requirements of this Paragraph (b)(11). This may involve sending us copies of documents you send to the California Air Resources Board. [EPA-HQ-OAR-2022-0829-0701, p. 259]

Organization: California Air Resources Board (CARB)

CARB also supports U.S. EPA's proposal to change to chassis certification for medium-duty vehicles for GHG emissions, which is a more robust method of determining compliance than the existing process, which combines engine testing with other modeling. [EPA-HQ-OAR-2022-0829-0780, p. 17]

Organization: Cummins Inc.

III. High GCWR MDV Certification

1. Mandatory engine-dynamometer certification of high GCWR MDV for criteria pollutants causes regulatory misalignment, regulatory uncertainty, and increased regulatory burden [EPA-HQ-OAR-2022-0829-0645, pp. 3-4]

In the Multi-Pollutant Proposal, EPA defines a new category called medium-duty vehicles, or MDV, for vehicles with 8,501-14,000 lbs GVWR which are not Medium-Duty Passenger Vehicles (MDPV), and further divides those MDV based on their gross combined weight rating (GCWR), which is an indication of the towing capability of a vehicle. MDV with GCWR >22,000 lbs are considered high GCWR vehicles, and MDV with GCWR <22,000 lbs are considered low GCWR vehicles. EPA proposes significant changes to certification protocols for high GCWR vehicles. [EPA-HQ-OAR-2022-0829-0645, pp. 3-4]

Class 2b and 3 complete vehicles such as HD pickup trucks are currently chassis-dynamometer certified for both criteria pollutant and GHG emissions. Per EPA's proposal at 88 FR 29270, high GCWR vehicles would no longer be allowed to use chassis-dynamometer certification for criteria pollutant emissions and would instead be forced into mandatory engine-dynamometer certification and subject to EPA's recently finalized HD engine 2027 NOx standards and other new HD engine program requirements in 40 CFR Part 1036. However, for GHG emissions, high GCWR complete vehicles would remain subject to chassis-dynamometer certification to 40 CFR Part 86 standards and requirements. This would result in complete high GCWR vehicles such as HD pickup trucks certifying with different test cycles (e.g., the HD Federal Test Procedure, or FTP, vs. the LD FTP, or FTP 75) and different emissions metrics (e.g., brake- specific grams per horsepower-hour NOx standards vs. distance-specific grams/mile CO2 standards) for criteria pollutants vs. GHG emissions, respectively. [EPA-HQ-OAR-2022-0829-0645, pp. 3-4]

While EPA has optionally allowed such dual protocols for limited cases in the past, the Multi-Pollutant Proposal would force it upon some MDV but not others. EPA estimates that based on model year (MY) 2022 and 2023 certification data, "most MDV complete and incomplete diesel pickup trucks would be required to switch to engine dynamometer certification; MY 2022 vans would not be required to use engine dynamometer certification; and only a small number of gasoline pickup trucks would be required to switch to engine certification." Requiring dual certification protocols for high GCWR MDV could lead to misalignment between optimization of criteria pollutant and GHG emissions controls. With different certification cycles covering different engine operating speeds and loads, manufacturers could trade-off GHG improvements at the expense of NOx control, undermining the goals of the regulation. In contrast, using the same protocols for criteria pollutants and GHG ensures linkage across all pollutants and forces manufacturers to address each of them when optimizing engine performance and emissions. [EPA-HQ-OAR-2022-0829-0645, pp. 3-4]

Dual certification and compliance requirements also have the potential to cause lack of clarity and regulatory uncertainty for manufacturers. For example, proposed 40 CFR 85.2101 applies to vehicles subject to the standards of 40 CFR Part 86 Subpart S, which would include high GCWR MDV certified to GHG standards under 40 CFR Part 86 Subpart S, and proposed 40 CFR 85.2103(f) specifies MDV emissions warranty periods for major emission control components, many of which are used to control criteria pollutant emissions. Yet high GCWR MDV certified in the HD engine program for criteria pollutants are subject to the criteria pollutant emissions warranty periods of 40 CFR Part 1036, based upon EPA's intent described in the Preamble at 88 FR 29270. There are likely other similar examples in the proposal where EPA will need to provide better clarity for manufacturers as to which aspects of requirements apply to which pollutants for which categories of vehicles. [EPA-HQ-OAR-2022-0829-0645, pp. 3-4]

Additionally, dual certification and compliance requirements will increase regulatory burden on manufacturers. Manufacturers will need to run the variety of tests required as part of certification (not only certification cycles but deterioration factor (DF) testing, infrequent regeneration adjustment factor testing, onboard diagnostics (OBD) testing, etc.) using two different types of equipment/facilities (chassis dynamometer and engine dynamometer), on two different test articles (vehicle and engine), for certification by two different divisions at EPA (HD and LD), instead of one. For compliance, EPA may require the existing In-Use Verification Program (IUVP) for GHG, while adding the possibility of Heavy- Duty In-Use Testing (HDIUT) for criteria pollutants associated with the HD engine program. For IUVP, manufacturers would be required to procure customer vehicles at low and high mileages for chassis- dynamometer testing to demonstrate GHG compliance. For HDIUT, manufacturers would be required to procure customer vehicles, equip them with Portable Emissions Measurement Systems (PEMS), and measure emissions during customer operation of the vehicles along their normal routes to demonstrate criteria pollutant compliance. Given the different types of testing for IUVP vs. HDIUT, there is no opportunity to combine testing for GHG and criteria pollutants. [EPA-HQ-OAR-2022-0829-0645, pp. 3-4]

If EPA proceeds with finalizing mandatory engine-dynamometer certification of criteria pollutants for high GCWR MDV despite the concerns raised above, additional significant changes are needed in the proposal, as outlined below. [EPA-HQ-OAR-2022-0829-0645, pp. 3-4]

2. Engine-dynamometer certification cycles are not representative of real-world duty cycles for high GCWR MDV and should be modified [EPA-HQ-OAR-2022-0829-0645, pp. 4-7]

EPA's purpose in forcing high GCWR MDV into engine-dynamometer certification for criteria pollutants is "to ensure that criteria pollutant emissions are controlled under the sustained high load conditions that many of these vehicles encounter, particularly during heavy towing operation." See 88 FR 29270. [EPA-HQ-OAR-2022-0829-0645, pp. 4-7]

EPA considers high GCWR MDV to be work vehicles and finds it more appropriate for them to be tested as HD engines due to their capabilities and use which EPA believes is more closely aligned with Class 4 and above heavy-duty applications than with light-duty trucks. While EPA did not provide any data characterizing the duty cycles of high GCWR MDV in the Multi-Pollutant Proposal, Cummins offers the data shown in Figures 1 and 2 collected from tens of thousands of Class 2b and 3 high GCWR diesel pickups for EPA's consideration. A duty cycle monitor within the engine's electronic control module (ECM) logs 1 Hz data for engine speed and load which is downloaded during service events at the dealer. The data is plotted as percent of time spent in various bins of engine speed and percent of full load. [EPA-HQ-OAR-2022-0829-0645, pp. 4-7]

Under EPA's proposal for mandatory engine-dynamometer certification for criteria pollutants, the Supplemental Emissions Test (SET) would be one of the applicable certification cycles. The SET is a continuous cycle with ramped transitions between 13 steady-state modes of operation including 25%, 50%, 75%, and 100% engine loads at each of 3 engine speeds designated as A, B, and C speeds, plus idle. The SET non-idle speeds and loads are calculated from the engine's full load torque curve. The specified amount of time spent in each of the 13 modes determines its weighting within the overall SET cycle results. For example, the 100% load modes are weighted at 9%, 9%, and 2% respectively for A, B, and C speeds. The combined weightings of all the modes at A, B, and C speeds are 45%, 38%, and 5% respectively. [EPA-HQ-OAR-2022-0829-0645, pp. 4-7]

For Figures 1 and 2, we have roughly overlaid the calculated A, B, and C speeds, shown as red lines, and the four % load points, shown as black rectangles, for the SET on the duty cycle data. There is a significant mismatch between the SET certification cycle and the vehicles' duty cycle data, with very little time spent (typically <##2%) operating in the real world near each of the 75% and 100% engine load modes of the SET. The time spent by the real-world vehicles in operation corresponding to the 12 non-idle modes, contained within the blue boxes, does not approach the total combined 88% weighting of the A, B, and C speed points in the SET cycle. [EPA-HQ-OAR-2022-0829-0645, pp. 4-7]

Modifications will be needed to the SET cycle to better represent the real-world duty cycles of high GCWR MDV. Since the HD FTP, another engine certification cycle, also contains significant operation at high engine speeds and loads, it will need modifications as well. Per 40 CFR 1065.10(c)(1), manufacturers must notify EPA if good engineering judgment indicates the specified procedures cause unrepresentative emission measurements, and EPA will cooperate with manufacturers to establish whether and how the procedures should be changed to be more representative. EPA would generally make the changes applicable through a rulemaking process. Cummins commits to working with EPA through this Multi-Pollutant rulemaking to identify the necessary changes to the HD engine certification cycles. Possible changes could include different torque curve denormalization for the SET and/or FTP, reweighting of SET modes, recalculation of SET speed and load modes, etc. [EPA-HQ-OAR-2022-0829-0645, pp. 4-7]

[See original for table titled "Figure 1 – Duty Cycle Data for Class 2b High GCWR Diesel Pickup Trucks with SET Modes Overlaid"] [EPA-HQ-OAR-2022-0829-0645, pp. 4-7]

[See original for table titled "Figure 2 – Duty Cycle Data for Class 3 High GCWR Diesel Pickup Trucks with SET Modes Overlaid"] [EPA-HQ-OAR-2022-0829-0645, pp. 4-7]

EPA requests comment on several alternatives for high GCWR criteria pollutant emissions standards: 1) complying with EPA's proposed low GCWR MDV chassis-certification standards combined with the SET engine-certification standards recently finalized by EPA, 2) complying with EPA's proposed low GCWR MDV chassis-certification standards combined with in-use testing and standards comparable to CARB's Advanced Clean Cars II (ACC II) regulation, and 3) other test procedures for demonstrating effective criteria pollutant emissions control under sustained high load conditions above 22,000 lbs combined vehicle weight. Per EPA's Draft Regulatory Impact Assessment in Chapter 3.2.1.3, diesel-powered high GCWR MDV were not considered in setting the MDV chassis-certification standards mentioned in alternatives #1 and #2, so EPA would need to do additional work to determine proposed chassis- certification standards appropriate for high GCWR MDV. Adding SET engine-certification standards as in alternative #1 would face the same need already discussed above for modifying the cycle itself to be more representative of real-world operation. Adding CARB's ACC II in-use PEMS testing requirements based on CARB's 20 mg/hp-hr NOx standard as in alternative #2 is not recommended as EPA already determined in its recently finalized HD engine 2027 NOx rule that a 35 mg/hp-hr NOx standard provides the maximum feasible NOx reduction for MY 2027. See 88 FR 4333. Cummins raised additional concerns with CARB's ACC II in-use testing approach in our comments to CARB's rulemaking.4 Finally, Cummins supports the development of other test procedures as suggested in alternative #3, or similarly supports modifications to existing test procedures, to address criteria pollutant emissions control under sustained high load conditions but requests EPA to provide duty cycle data highlighting the operation of concern to support further investigation. [EPA-HQ-OAR-2022-0829-0645, pp. 4-7]

4 See https://www.arb.ca.gov/lists/com-attach/396-accii2022-UDMBcl0xVWsAbwNt.pdf (last accessed June 27, 2023).

3. The MDV work factor should continue to account for high towing capacity in setting CO_2 targets

Phase 1 and 2 GHG standards for HD pickup trucks and vans, the same vehicles considered as MDV for this rulemaking, use a work factor (WF) attribute to set vehicle CO_2 targets. The work factor accounts for payload, towing, and four-wheel drive equipment and is calculated as follows:

WF = 0.75 × [Payload Capacity + xwd] + 0.25 × Towing Capacity, where Payload Capacity = GVWR (lbs) - Curb Weight (lbs)

xwd = 500 lbs if equipped with 4-wheel-drive, otherwise 0 lbs Towing Capacity = GCWR (lbs) - GVWR (lbs) [EPA-HQ-OAR-2022-0829-0645, pp. 7-8]

CO_2 targets in grams/mile are then calculated as [a × WF] + b, where a and b coefficients are specified in the regulations. In the Phase 1 GHG Final Rule, EPA noted that, "Based on analysis of how CO_2 emissions and fuel consumption correlate to work factor, we believe that a straight line correlation is appropriate across the spectrum of possible HD pickups and vans…" See 76 FR 57162. EPA's 2010 analysis of vehicle CO_2 data and the correlation to work factor is available in the Phase 1 rulemaking docket.5 Cummins continues to support the work factor approach to setting standards as necessary for recognizing the work capacity of MDV to haul and tow goods and provide services. [EPA-HQ-OAR-2022-0829-0645, pp. 7-8]

5 See https://www.regulations.gov/document/EPA-HQ-OAR-2010-0162-0334 (last accessed June 27, 2023).

In this rulemaking, EPA proposes to cap the GCWR input to the work factor calculation at 22,000 lbs, citing concerns that chassis-dynamometer GHG testing does not capture GCWR-related loads directly and the higher CO_2 targets may generate windfall credits for high GCWR vehicle configurations. This proposed change by itself has the effect of increasing the stringency of the CO_2 targets. In one example case of a Class 3 diesel pickup with 42,000 lbs GCWR, the stringency of its 2027 CO_2 target would increase by 27% just due to GCWR being capped to 22,000 lbs, even though the CO_2 target coefficients themselves are not proposed to change for diesels in 2027. Additionally, the annual decrease in the "a" coefficient in the CO_2 targets after 2027 already has the effect of "flattening" the CO_2 vs. work factor relationship, lessening the recognition of towing capacity in the CO_2 targets. [EPA-HQ-OAR-2022-0829-0645, pp. 7-8]

Cummins does not agree with changing the WF by arbitrarily capping GCWR. For GHG certification, EPA's proposal would ignore the towing capacity of high GCWR vehicles, which is inconsistent with EPA's proposed criteria pollutant approach of treating high GCWR MDV as HD work vehicles due to their towing capacity. EPA's 2010 analysis found GCWR to be an important attribute in characterizing the work and CO_2 emissions of MDV and confirmed the linear nature of CO_2 vs. work factor well beyond the 5,500 lbs WF level EPA approximately associates with capping GCWR at 22,000 lbs. EPA's proposed change to work factor determination has not been accompanied by an updated analysis of current vehicles or any quantification of the expected windfall credits EPA is attempting to prevent. The MDV work factor should continue to account for high towing capacity in setting CO_2 targets. [EPA-HQ-OAR-2022-0829-0645, pp. 7-8]

Without changes to the proposed certification cycles and proposed work factor cap to better account for the real-world duty cycles and usage of high GCWR MDV, the issues highlighted above could lead to unintended outcomes. For example, if manufacturers are forced to limit ratings or towing capacity to meet the proposed standards, customers who need that towing capability to carry out their daily work may be inclined to keep older vehicles longer or to use larger trucks to do the same work, and the emissions reductions envisioned for the proposal would not be achieved. [EPA-HQ-OAR-2022-0829-0645, pp. 7-8]

IV. Emissions Useful Life and Warranty Periods

4. More representative MDV-specific emissions useful life and warranty periods are needed for criteria pollutants

Moving high GCWR MDV into the HD engine program would drastically increase the emissions useful life and emissions warranty periods for criteria pollutants compared to today's requirements. For example, for a high GCWR MDV diesel engine certified in the light heavy-duty (LHD) diesel engine primary intended service class, the emissions useful life would become 15 years / 270,000 miles / 13,000 hours (whichever occurs first) compared to 15 years / 150,000 miles today. Emissions warranty would become 10 years / 210,000 miles / 10,000 hours compared to 5 years / 50,000 miles today. Increases such as these could have significant impacts on development costs and leadtime due to longer testing associated with DF aging, OBD aging, and mechanical validation, as well as increasing component costs which manufacturers would pass on to the purchasers of these vehicles, but EPA has not provided any analysis to show the HD engine program requirements are appropriate for MDV operational life and applications. EPA should perform an analysis of MDV operational life, and if increases are justified, consider data-based MDV-specific emissions useful life and warranty periods. [EPA-HQ-OAR-2022-0829-0645, p. 8]

VI. Off-Cycle Standards and In-Use Testing

7. 2B-MAW emissions calculations need to be revised for high GCWR MDV since no engine CO2 FTP FCL will be available for GHG chassis-certification

If EPA finalizes mandatory engine-dynamometer certification of criteria pollutants for high-GCWR MDV, the engines will be subject to the off-cycle standards and in-use testing requirements of the HD engine program in 40 CFR Part 1036. HD off-cycle emissions testing uses the Two-Bin Moving Average Window (2B-MAW) protocol (or B-MAW for spark-ignition engines), which uses the engine CO2 FTP Family Certification Level (FCL) determined from engine-dynamometer GHG certification. The engine CO2 FTP FCL is used to normalize CO2 emissions for determining placement of windows into the appropriate bin and for calculating brake-specific emissions. Since high GCWR MDV will be chassis-dynamometer certified for GHG rather than engine-dynamometer certified, there will be no corresponding engine CO2 FTP FCL available to use in the 2B-MAW calculations. The 2B-MAW calculations will need to be revised for use on high GCWR MDV. As discussed next, Cummins recommends the use of engine broadcasted parameters, which EPA has separately proposed for off-cycle testing of engines using non-carbon- containing fuels, instead of determining an FCL outside of certification. [EPA-HQ-OAR-2022-0829-0645, pp. 9-10]

8. Manufacturers should be allowed to use engine broadcasted torque and speed to determine power in 2B-MAW calculations instead of using CO2 as a surrogate

In EPA's recent HD Phase 3 GHG proposal at 88 FR 26021 and in 40 CFR 1036.530(j), EPA is proposing that for off-cycle testing in the field on engines using at least one fuel that is not carbon-containing, manufacturers can use engine broadcasted speed and torque to calculate power in lieu of using CO2 as a surrogate for power. This is because for fuels other than carbon-containing fuels, there will be no fuel- related CO2 emissions to correlate to power. Cummins supports this same approach of using engine broadcasted parameters in lieu of CO2 for off-cycle testing of engines in high GCWR MDV. Although high GCWR MDV running on carbon-containing fuels would emit CO2, and a value analogous to the CO2 FTP FCL could be determined through means other than certification, Cummins shared confidential data with EPA in June 2020 showing inaccuracies between CO2 and power. CO2 does not always correlate well to power produced, such as when excess fuel is burned for thermal management, or for hybrid operation when the battery/motor assists the engine and less or no fuel is burned. Allowing the use of engine broadcasted speed and torque would eliminate the need to use the CO2 FTP FCL to normalize measured CO2 in the 2B-MAW calculations which are used for placing windows into bins and for determining the brake-specific emissions for a bin. The CO2 FTP FCL is not always representative of engine thermal efficiency on other duty cycles such as those encountered during off-cycle testing. Additionally, using the CO2 FTP FCL results in higher emissions calculated for more efficient duty cycles, which penalizes manufacturers with more efficient engines. Cummins supports the use of engine broadcasted parameters such as speed and torque to provide more accurate off-cycle emissions calculations. [EPA-HQ-OAR-2022-0829-0645, pp. 9-10]

Organization: Environmental. and Public Health Organizations (EPHO

3.EPA's proposed change to criteria pollution requirements for MDVs with a gross combined weight rating of more than 22,000 pounds is likely appropriate, but should be monitored for manipulation and efficacy. [EPA-HQ-OAR-2022-0829-0759, p. 77]

EPA is proposing to require that vehicles with a GCWR greater than 22,000 pounds be certified to the heavy-duty engine standards, rather than to the proposed MDV standards.212 EPA's logic here is sound: these vehicles' powertrains are often more powerful than the Class 4 and Class 5 vehicles in which related engines may be deployed, and they have a GCWR comparable to vehicles currently covered by the heavy-duty engine rules. [EPA-HQ-OAR-2022-0829-0759, p. 77]

212 88 Fed. Reg. at 29257.

Table VIII.B-1. Market share of MDVs above and below the 22,000-pound gross combined weight rating213[EPA-HQ-OAR-2022-0829-0759, p. 77]

[See original attachment for Table VIII.B-1.].

213 Taken from EPA OMEGA2 modeling inputs: vehicles_mdv_20230208.csv (MY 2020 MDV fleet).

MY 2020 data indicates that this change could require more than half of the MDV fleet to certify to the heavy-duty engine standards (Table VIII.B-1).214 Based on the emissions and warranty requirements for such engines, certifying the engines in these MDVs to such standards will likely yield emissions reductions at least as strong as if they were instead required to meet the proposed MDV standards. However, these standards apply solely to combustion engines and are not influenced by the share of deployed ZEVs. [EPA-HQ-OAR-2022-0829-0759, p. 78]

214 In the Proposal, EPA notes: "Based on an analysis of the MY 2022 and MY 2023 emissions certification data, most MDV complete and incomplete diesel pickup trucks would be required to switch to engine dynamometer certification; MY 2022 vans would not be required to use engine dynamometer certification; and only a small number of gasoline pickup trucks would be required to switch to engine certification." 88 Fed. Reg. at 29270. However, the data are not provided.

In contrast, ZEV deployment affects the required emissions reductions for medium-duty combustion vehicles with a GCWR less than or equal to 22,000 pounds, as illustrated above in Section VIII.B.1. It is possible that manufacturers could try to shift more of their sales to vehicles with a GCWR over 22,000 pounds in order to reduce the required improvements to their remaining combustion fleet. If this change is finalized, the Agency should monitor future data from the MDV and heavy-duty engine in-use testing program to assess the nature of any difference between the emissions performance of MDVs above and below the 22,000-pound GCWR, and should commit to releasing a report on its findings. [EPA-HQ-OAR-2022-0829-0759, p. 78]

Organization: MECA Clean Mobility

EPA should finalize provisions for all MD engines in MDVs with GCWR > 22,000 lbs to meet MY 2027 heavy-duty engine certification requirements, and compliance should be in accordance with the heavy-duty standards. [EPA-HQ-OAR-2022-0829-0564, pp. 12-24]

MECA supports EPA's proposal that medium-duty engines in chassis certified medium duty vehicles (MDVs) should be required to meet the same requirements as those EPA finalized in December 2022 for MY 2027 and later heavy-duty engines. We agree with the agency that this is a viable way to address the current disparities between chassis and engine-based standards. [EPA-HQ-OAR-2022-0829-0564, pp. 24-25]

Results from the SwRI Heavy Duty Low NOx demonstration program, included diesel exhaust emission control components that were aged to current (435,000 miles) and future (650,000/750,000 miles) heavy heavy-duty durability requirements and then tested over several field duty cycles and in-use compliance results calculated with the new two bin moving average window (3B-MAW) methodology. Given durability requirements for the light heavy-duty classes are due to increase to 270,000 miles, the results from 435,000 mile aged heavy-heavy duty parts could be used to extrapolate for MY 2027 and later medium-duty engines. [EPA-HQ-OAR-2022-0829-0564, pp. 24-25]

Even in the short time since the latest emission control system was provided to SwRI for the demonstration program, improvements have continued to substrates and catalysts. For example, a recent paper published at the 2022 SAE WCX conference describes development of high-porosity honeycomb substrates with thinner wall thickness and high cell density that can be coated with SCR catalyst. The combination of developments on this substrate enables higher surface area and lower thermal mass, which improves coating efficiency, reduces catalyst heat-up time, and reduces pressure drop. These result in performance improvements that are especially prominent at low temperature operation. At engine exhaust temperatures of 175?, the NOx conversion efficiency improved by 14% compared to earlier generation substrates34 (Ido, et al., 2022). [EPA-HQ-OAR-2022-0829-0564, pp. 24-25]

34 Ido, Y., Kinoshita, K., Goto, C., Toyoshima, H., Hirose, S., Ohara, E., et al., SAE 2022-01-0550.

Catalyst suppliers have already developed a next generation of SCR catalysts with higher NOx reduction efficiency and better durability compared to the Stage 3 parts tested in the SwRI demonstration program. Through the use of sophisticated models that incorporate the latest learnings on both thermal and chemical aging effects, it is possible to project the gains in efficiency provided by these new materials. A similar methodology was used to that discussed in the MECA 2027 white paper, incorporating exhaust information from the latest engine calibration from SwRI and an optimized dosing calibration for the new downstream SCR catalyst. The catalysts were laboratory aged both thermally and chemically using sulfur containing simulated exhaust gas to represent 435,000 miles of equivalent engine aging. The catalysts were modeled over the FTP, RMC and LLC certification cycles and demonstrated lower emissions than the Stage 3 system at SwRI. The not yet published results suggest that the latest generation SCR catalyst would provide OEMs with additional margin to a 0.02 g/bhp-hr standard. [EPA-HQ-OAR-2022-0829-0564, pp. 24-25]

This example of continual improvement and optimization is a testament to the ongoing innovative technology development occurring in the industry between suppliers and their OEM customers. Each time a test is run, new information is obtained and applied to the next iteration. This has been going on continually over the past 15 years of advanced emission controls on trucks. In fact, over the life of the SwRI program, catalyst suppliers have deployed new catalyst formulations and coating techniques to continually improve the durability and performance of the SCR system in order to build greater compliance margin relative to the program targets. Our industry has seen a tremendous amount of innovation on both engines and aftertreatment since the U.S. 2010 on-road diesel standards were implemented. This learning has been applied to improve manufacturing and reduce variability that has allowed systems to be downsized by about 60% and reducing their costs by about 30%. [EPA-HQ-OAR-2022-0829-0564, pp. 24-25]

Organization: Stellantis

Also, vehicles over 22,000 lb. GCWR will be forced to certify on an engine dyno for criteria emissions. Because this is misaligned with California's ACC II LEV IV rules, it forces dual certification efforts, different hardware and uncertain impacts on GHG performance. Stellantis believes the 22,000 lb. GCWR proposed requirement should not be implemented for determination of criteria emissions standards, nor should it be used to alter the GHG stringency. To address EPA concerns, criteria emissions standards should be aligned with CARB's ACC II LEV IV rules instead. [EPA-HQ-OAR-2022-0829-0678, p. 19]

<u>EPA Summary and Response</u>

<u>Summary:</u>

CARB, MECA, and EPHO were supportive of the proposal to move high GCWR MDV to engine-certification. CARB found engine dynamometer certification to be a more robust methodology for determining high GCWR MDV compliance. MECA agreed with the Agency's proposal that such an approach would "…address the current disparities between chassis and engine-based standards." EPHO characterized the proposed requirement for engine-certification of high-GCWR MDV as "...likely appropriate, but should be monitored for manipulation and efficacy." EPHO also asked the Agency to monitor future data from MDV and from the heavy-duty engine in-use testing program in order to assess emissions differences between high-GCWR MDVs and other MDVs, and requested that the Agency commit to releasing a report on any pertinent findings.

The Alliance, Cummins, and Stellantis were all opposed to the Agency proposal to move high GCWR MDV to engine-certification. The Alliance specifically supported high GCWR MDV Option 2 from the proposal and further requested alignment of Federal OBD requirements for OBD with California OBD requirements. Cummins specifically supported high GCWR MDV "Option 3" from the proposal and stated that EPA would "…need to do additional work to determine proposed chassis-certification standards appropriate for high GCWR MDV." Stellantis asked that Agency concerns regarding high GCWR criteria pollutant emissions be addressed via alignment with California ACC II LEV IV standards.

Response:

In response to comments received from the Alliance, Cummins, and Stellantis, the Agency did not finalize the proposed requirements for high GCWR MDV engine certification. Upon further consideration of the public comments, EPA agrees with the Alliance that our specific concerns regarding high GCWR MDV emissions at high loads would be fully addressed by finalizing high GCWR MDV Alternative 2:

- MDV above 22,000 pounds GCWR would comply with the MDV chassis dynamometer standards with additional in-use testing and standards comparable to those used within the California ACC II.

The agency has finalized in-use moving average window standards for high-GCWR MDV (see Section III.D.5 of the preamble). The agency will also allow manufacturers to engine-certify high GCWR MDV as an option. We believe that this is also partially responsive to the request from Stellantis for alignment with ACC II LEV IV standards. The Agency has received numerous comments from both light-duty and MDV manufacturers requesting wholesale adoption of California ACC II LEV IV criteria pollutant emissions standards. As stated elsewhere in Sections 3 and 4 of the RTC, EPA is not finalizing a wholesale adoption of the California ACC II LEV IV program. The ACC II program includes synergistic elements for both greenhouse gas and criteria pollutant emissions, with the foundation of the ACC II program being a ZEV mandate. Stellantis did not recommend adopting the ZEV mandate provisions of ACC II and instead seems to recommend that EPA only adopt the criteria pollutant elements of ACC II. This a la carte approach to emissions standards fails to consider the synergistic nature of California's ACC II program. The treatment of ICE-based vehicles under ACC II is premised on an increasing penetration of ZEVs and their associated emission reductions. EPA's 2027 and later MDV program, being performance-based for both GHG and criteria pollutant emissions, relies on increasingly stringent performance-based standards to achieve emissions reductions. EPA is, however, finalizing additional provisions in the FRM which are responsive to Stellantis and Cummins requests for greater alignment with ACC II. These include:

- Alignment with all ACC II MDV NMOG+NO_X emissions bins at or below Bin 170 (see Section III.D.2.i of the preamble);
- Adoption of in-use standards for high GCWR MDV comparable to California ACC II in-use standards for MDV above 14,000 pounds GCWR (see Section III.D.5 of the preamble);
- Alignment with California MDV OBD (see Section III.H of the preamble).

With respect to Cummins concerns regarding the appropriateness of the proposed chassis-certification standards high GCWR MDV, our understanding of Cummins's concern is that it refers to high GCWR MDV with compression-ignition (diesel) engines in MDV pickup trucks, since these are applications for which Cummins holds certificates of conformity. As discussed within Chapter 3.2.5 of the RIA, the final standards are feasible for high GCWR MDV, including MDV pickup trucks and other MDVs using compression ignition engines. The following factors all play a role in the Agency's determination that the $NMOG+NO_X$ and other criteria pollutant standards are feasible for high GCWR MDV with compression ignition engines:

- 75% of diesel MDV engine families are certifying to $NMOG+NO_X$ emissions below 160 mg/mi, with median $NMOG+NO_X$ emissions below 140 mg/mi.
- MDV diesels can adopt dual-SCR NO_X emission control systems, passive thermal management, and active thermal management comparable to those under development for Class 4/light-heavy-duty compression-ignition applications (see Chapter 3.2.5 of the RIA), which would result in $NMOG+NO_x$ emissions comparable to spark-ignition MDV.
- The Agency has finalized NMOG+ NO_X fleet average standards that are less stringent than originally proposed (see Section III.D.2.iv of the preamble) and that allow an additional year of lead time compared to the proposal (see Section III.D.2.ii of the preamble).
- The NMOG+ NO_X standards are fleet average performance-based standards that can be met through various control technologies, including technologies applicable to spark-ignition and compression ignition vehicles, and BEV MDV. Our analysis projects BEV MDV sales of approximately 30% in 2031 and 32% in 2032 (see Chapter 12.2.3 of the RIA).
- The Agency has finalized a regulatory schedule that includes additional lead time for compliance with MDV NMOG+ NO_X fleet average standards (see Section III.D.2.ii of the preamble).
- The Agency has finalized a flexibility to allow vehicle manufacturers to transfer credits earned on BEV MDPVs to their MDV compliance.
- The Agency has finalized optional engine-certification for high GCWR MDVs (see Section III.D.5.iv of the preamble).

With respect to Cummins's preference for Alternative 3, within the proposed rule the Agency requested comment on three alternatives to high GCWR MDV engine-certification:

1. MDV above 22,000 pounds GCWR would comply with the MDV chassis dynamometer standards with the introduction of additional engine-dynamometer-based standards over the Supplemental Emissions Test as finalized within the Heavy-duty 2027 and later standards;
2. MDV above 22,000 pounds GCWR would comply with the MDV chassis dynamometer standards with additional in-use testing and standards comparable to those used within the California ACC II;
3. Introduction of other test procedures for demonstration of effective criteria pollutant emissions control under the sustained high-load conditions encountered during operation above 22,000 pounds GCWR.

The intent of requesting comment on Alternative 3 was to provide an opportunity for stakeholders to comment on specific test procedures that could address the Agency's stated concerns regarding high levels of in-use emissions during operation that included heavy-trailer towing and other sustained high-load conditions encountered during operation above 22,000 pounds GCWR. While stating a preference for Alternative 3, Cummins did not provide any specific recommendations for test procedures and/or standards that would demonstrate effective criterial pollutant emissions control under the sustained high-load conditions encountered during operation above 22,000 pounds GCWR.

6.5 - Durability test requirements for certification

EPA addresses comments related to durability test requirements for certification in Sections 4.13 and 4.2.3 of this document.

6.6 – Test fuel for PM measurement

Comments by Organizations

Organization: Alliance for Automotive Innovation

8. Emissions Certification Fuel

U.S. emissions certification fuel was designed to represent market fuel characteristics. On this basis, there is justification to adjust the composition of certification fuel today to reduce its PM-forming tendency. [EPA-HQ-OAR-2022-0829-0701, pp. 271-273]

EPA recognizes that U.S. market fuels have slowly been improving in their tendency to form PM since the Tier 3 regulations were enacted and the Tier 3 emissions certification fuel was defined.443 [EPA-HQ-OAR-2022-0829-0701, pp. 271-273]

443 NPRM Figures 40 at 29399 and Figure 42 at 29401.

[See original for graph titled “Figure 91: PM Index distribution in U.S. gasoline in 2008-12 and 2021-22 (NPRM Figure 42)”] [EPA-HQ-OAR-2022-0829-0701, pp. 271-273]

Figure 42 of the NPRM (shown above) indicates the median PMI of U.S. gasoline was approximately 1.5-1.6 in 2021-2022, whereas EPA notes in the NPRM that Tier 3 certification fuel is expected to have a PMI of 1.6-1.7. In practice, Tier 3 regular grade certification fuels from the two major certification fuel suppliers in the U.S. generally have PMI values in the range of 1.48. to 2.58 for Tier 3 regular grade, as shown in Figure 92. [EPA-HQ-OAR-2022-0829-0701, pp. 271-273]

Figure 92: Tier 3 Regular Grade Certification Gasoline [EPA-HQ-OAR-2022-0829-0701, pp. 271-273]

Tier 3 Regular Grade Certification Gasoline

Average Min Max

Mfr A 1.90 1.48 2.26

Mfr B 2.19 2.05 2.58

Mfr C 2.10 2.10 2.10

Totals 2.03 1.48 2.58 [EPA-HQ-OAR-2022-0829-0701, pp. 271-273]

In addition, survey of U.S. market E10 gasoline in 2018/2019 found the following PMI values:444 [EPA-HQ-OAR-2022-0829-0701, pp. 271-273]

444 EPA-420-R-23-008 Figure 2.1 and 2.2

Figure 93: 2018 and 2019 Summer Market Gasoline PMI

PMI average Regular E10 Premium E10

2018 Market - Summer 1.65 1.55

2019 Market - Summer 1.44 1.51 [EPA-HQ-OAR-2022-0829-0701, pp. 271-273]

The study also showed that the aromatics in U.S. market fuels have lower C10+ content as compared to the requirements in Tier 3 certification fuels:

Figure 94: Aromatic Content of U.S. Market Fuels versus Tier 3 Certification Fuels [EPA-HQ-OAR-2022-0829-0701, pp. 271-273]

Tier 3 RUL Spec. Tier 3 PUL Spec. 2018/29

Aromatics, volume%, max Mean (Vol%)

C6 Aromatics (Benzene) 0.5-0.7 0.5-0.7 no data

C7 Aromatics (Toluene) 5.2-6.4 5.2-6.4 6.2

C8 5.2-6.4 5.2-6.4 7.4

C9 5.2-6.4 5.2-6.4 5.5

C10 4.4-5.6 4.4-5.6 2.7

C10+ 4.4-5.6 4.4-5.6 1.3 [EPA-HQ-OAR-2022-0829-0701, pp. 271-273]

Based on this, we suggest a revision of Tier 3 certification fuel specifications to reduce the C10+ aromatics content to a range of 3.2 to 4.2 vol% (from the current 4.4-5.6 vol %) to be more representative of U.S. market fuel. [EPA-HQ-OAR-2022-0829-0701, pp. 271-273]

After discussing a potential market fuel rulemaking around PM formation tendency, EPA notes that “Depending on the level of a potential limit on heavy material or PMI, the specifications for certification gasoline may or may not need to be adjusted.”445 We agree that any regulation to reduce heavy aromatics in market gasoline should be preceded by or accompanied by an updating of the specification for emissions certification gasoline that yields a lower PM-forming tendency. The rationale for lowering the PM forming tendency before the market fuel rulemaking is that the new vehicles certified with this fuel will be on the road for the next 10-20 years and will see that new market fuel over the majority of their useful life. [EPA-HQ-OAR-2022-0829-0701, pp. 271-273]

445 NPRM at 29401

As part of this NPRM, EPA should adjust Tier 3 certification fuel specifications to align with current market fuel composition and enable fuel suppliers to target a PMI value in the range of 1.5-1.6. This can be accomplished by reducing the C10 and higher aromatics specification. We would be happy to work with EPA to determine a set of specifications for Tier 3 certification fuel that is consistent with market fuel composition, certification fuel supplier blending practices, and EPA's intentions prior to issuing a final rule. [EPA-HQ-OAR-2022-0829-0701, pp. 271-273]

EPA Summary and Response

Summary:

Comments from the Alliance for Automotive Innovation describe a mismatch between the PM Index values of market fuel and Tier 3 test (or cert) fuel and provide data on the ranges found in recent market fuel and cert fuel samples. They suggest EPA should adjust the heavy aromatics specifications for cert fuel to better align with market fuel (which has shifted since the specs for Tier 3 cert fuel were originally set).

Response:

We appreciate presentation of the fuel property data and recognize that the average PM Index of market fuel has shifted downward since the Tier 3 rulemaking was finalized. However, we believe that a test fuel with market-representative PM Index can still be produced within the existing specs, so we did not propose revisions and thus are not revising them at this time. As described in the NPRM, we are continuing to assess options for a heavy aromatics standard for market fuel, a potential future action that would provide another opportunity to adjust cert fuel specs.

6.7 – Class 3 test cycle

Comments by Organizations

Organization: Mercedes-Benz AG

EPA should also adopt the test cycles promulgated by ACCII LEV IV for the US06 Bag 2 and UDC cycle for heavier Class 3 vehicles. These test cycles are better aligned with how these vehicles are driven in the real world and will provide additional emissions reductions. [EPA-HQ-OAR-2022-0829-0623, p. 19]

EPA Summary and Response

Response:

The -7°C FTP test cycle is crucial to the final PM standard for MDV including Class 3 vehicles because it addresses uncontrolled cold PM emissions in Tier 3. As EPA explains in preamble Section III, there exists technology (e.g., MY 2022 GPF) that can achieve significant PM reductions in a wide range of operating conditions, including in cold conditions. The -7°C FTP test assures that MDVs are actually achieving these feasible emissions reductions across a wide range of operating conditions, including in cold conditions.

The full US06 cycle is a similarly crucial part of the PM standard. High load operation, which is common on MDVs, induces passive GPF regeneration and GPF regeneration can cause elevated emissions. As EPA explains in preamble Section III, there exists technology (e.g., MY 2022 GPF) that can achieve significant PM reductions notwithstanding high load operation and GPF regeneration. The US06 cycle results in GPF regeneration across different vehicle-GPF combinations, and it thus assures that MDVs are achieving feasible emissions reductions notwithstanding high load operation and GPF regeneration. The LA-92 usually does not induce GPF regeneration, and for this reason the US06 cycle is required for all light-duty vehicles and MDV in the final PM standard. Section III.D.3.iii of the preamble shows measurements indicating that the LA-92 does not cause substantial regeneration of an underfloor GPF on a Class 3 test vehicle.

Class 2b vehicles with power-to-weight ratios at or below 0.024 hp/pound will no longer replace the full US06 component of the SFTP with the second of three phases of the US06 for PM certification. Class 2b vehicles with low power-to-weight ratios will now use the full US06 test cycle. If a vehicle is unable to follow the trace, it should use maximum accelerator command to follow the trace as best it can, and doing so will not result in a voided test. This procedure mimics how vehicles with low power-to-weight tend to be driven in the real world.

7 - Regulatory amendments/additional changes to the regulatory language

7.1 – Voiding certificates and recall

<u>Comments by Organizations</u>

Organization: Alliance for Automotive Innovation

4. GHG IUVP / IUCP

a) Lack of Legal Authority for Certification Enforcement Programs and In-Use Remedies

Separate from the proposed MY 2027 and later multi-pollutant emissions standards, the NPRM proposes extensive and significant revisions to EPA's regulations used to enforce vehicle certification requirements and in-use standards. The NPRM sometimes does not even appear to recognize the significance of the substantive changes it would make to the current regulations and instead purports to merely "clarify" current regulations or restate the Agency's "understanding" of its authority.345 Those changes would expand EPA's current regulatory provisions for use of the void-ab-initio sanction from circumstances that generally involve intentional or reckless noncompliance to nearly any type of noncompliance, including situations involving good-faith error or honest disagreement about how to apply "good engineering judgment" in a specific technical context.346 [EPA-HQ-OAR-2022-0829-0701, pp. 232-234]

345 See, e.g., 88 Fed. Reg. 29184, 29,197, 29289 (May 5, 2023).

346 Auto Innovators does not believe that EPA has adequately explained why these changes are necessary. Section 307(d) of the Clean Air Act requires EPA to provide "a statement of its basis and purpose" for new or revised regulations. 42 U.S.C. § 7607(d)(3). More exacting than the Administrative Procedure Act, section 307(d) "requires EPA to give a detailed explanation of its reasoning at the 'proposed rule' stage" as

well as in the preamble of a final rule. Small Refiner Lead Phase-Down Task Force v. EPA, 705 F.2d 506, 519 (D.C. Cir. 1983); see also Ne. Md. Waste Disposal Auth. v. EPA, 358 F.3d 936, 949 (D.C. Cir. 2004) (apart from section 307(d), EPA is also expected to "satisfy the fundamental requirement of nonarbitrary administrative decisionmaking: that an agency set forth the reasons for its actions"); Ctr. for Biological Diversity v. EPA, 722 F.3d 401, 412 (D.C. Cir. 2013). In particular, Section 307(d) requires that the NPRM provide "the major legal interpretations and policy considerations underlying the proposed rule." 42 U.S.C. § 7607(d)(3)(A), (C). Failure to provide such a rationale thwarts full and effective public participation in the rulemaking and will trigger remand and possibly vacatur. See, e.g., Ne. Md. Waste Disposal Auth., 358 F.3d at 950.

i). Current Certification Enforcement Regulations

The proposal marks a significant change from the way EPA has historically handled certification enforcement. Congress established the basic framework for enforcing EPA's certification regulations almost 40 years ago. The 1970 Clean Air Amendments required new-vehicle certification of compliance with the emissions standards contained either in those Amendments or to be established by EPA, replacing prior provisions for voluntary certification of compliance with emissions limits.347 EPA sought to assist the auto industry in the transition from an earlier voluntary certification program to mandatory testing and certification by issuing "conditional" certificates of conformity, contingent on the successful completion of all required testing.348 In the same early days of implementing the 1970 Amendments the EPA General Counsel recommended that "vehicle[s] that did not conform to [the] description [in a certification application] would be considered uncertified."349 [EPA-HQ-OAR-2022-0829-0701, pp. 232-234]

347 See Pub. L. No. 91-604, §§ 7-8, 84 Stat. 1676, 1693-96 (prohibiting, among other things, distribution or sale of new motor vehicles "unless such vehicle[s] … [are] covered by a certificate of conformity" and authorizing EPA to issue such certificates based on a review of manufacturers' applications and on test results).

348 See 48 Fed. Reg. 33456, 33459 (July 21, 1983) (recounting issuance of conditional certificates in early years of post-1970 program "in an effort to avoid delays in product introduction dates where durability testing would not be completed on schedule").

349 EPA offce of Gen. Couns., 1 A Collection of Legal Opinions: December 1970 - December 1973 185 (1973).

EPA also took steps to ensure compliance with the Agency's nascent certification program. Early EPA regulations provided that the Agency would "deem void ab initio a certificate issued in reliance on information or data submitted by the manufacturer and known by him to be false, incomplete, inaccurate, or invalid."350 Failure to permit inspection of test facilities and records would likewise provide a basis to revoke or suspend a certificate ab initio, as would any action by a manufacturer that "render[ed] inaccurate or invalid any test data … or otherwise circumvent[ed] the intent of the [Clean Air] Act or of this subpart" of EPA's regulations, i.e., its new-vehicle regulations.351 In other cases in which certificates were to be suspended or revoked, the certification regulations provided that the suspension or revocation was to "[e]xtend no further than to forbid the introduction into commerce of vehicles previously covered by the certification which are still in the hands of the manufacturer."352 [EPA-HQ-OAR-2022-0829-0701, pp. 232-234]

350 39 Fed. Reg. 7545, 7545 (Feb. 27, 1974).

351 Id. at 7568.

352 Id. at 7551; see also 40 Fed. Reg. 27590, 27610 (June 30, 1975).

The early rulemakings never explained the origin or basis for EPA's claimed authority to suspend or revoke certificates ab initio—despite the requirements of section 307(d) and bedrock principles of administrative procedure.353 Indeed, it could not have done; such a claim is foreclosed by the text of the Clean Air Act. Section 206, as enacted in 1970 and today, provides that a certificate of conformity has a limited duration ("not in excess of one year"354), and the sole relevant purpose of the certificate is to permit the initial transaction in a vehicle or engine by the manufacturer with another person.355 Congress made no provision for suspending, revoking or voiding a certificate after it has served their purpose. [EPA-HQ-OAR-2022-0829-0701, pp. 232-234]

353 The 1973-1974 rulemaking includes in the final rule preamble a discussion of EPA's claimed authority to suspend or revoke certificates, see 39 Fed. Reg. at 7545-48, but nothing specific on suspension or revocation of certificates ab initio.

354 42 U.S.C. § 7525(a)(1).

355 See id. § 7522(a)(1).

Later revisions to the certification enforcement regulations neither provided an adequate rationale for certificate action reaching back past the year in which the certificate was effective, nor expanded the general circumstances under which EPA claimed authority to void certificates ab initio (with one exception noted below). That said, when EPA has adopted the void-ab-initio enforcement mechanism, the Agency has usually also indicated that its use would be limited to unusual, "egregious" situations.356 In addition, EPA's GHG regulations make the void-ab-initio sanction available when a manufacturer fails to cover a GHG fleet-average emissions deficit in the manner permitted by the regulations.357 [EPA-HQ-OAR-2022-0829-0701, pp. 232-234]

356 See, e.g., 63 Fed. Reg., 926, 960 (Jan. 7, 1998) (stating in preamble to National Low-Emission Vehicle proposed rule that for violations of record-keeping and reporting requirements, "EPA would only void a certificate ab initio for the most egregious … violations, where a manufacturer's records or reporting are so substantially incomplete that EPA cannot determine compliance with the fleet average NMOG standard or other requirements").

357 See, e.g., 40 C.F.R. § 86.1865-12(k)(7)(ii). In such a situation, a manufacturer would have had to decide not to comply with any of section 86.1865(k)'s provisions for covering shortfalls. Similar provisions had been included in earlier rulemakings for programs that permitted or required fleet averaging to demonstrate compliance with emissions standards, or that relied upon the phase-in on a multi-model-year basis of new or increasingly stringent emissions standards. For example, in the program for control of PM emissions from MY 1985 and later light-duty diesel vehicles, EPA's regulations provided for the voluntary use of fleet averaging to demonstrate compliance, which could be enforced (according to EPA) by voiding the certificates ab initio of vehicles that triggered noncompliance with fleet-average standards. See 48 Fed. Reg. at 33456, 33460; see also 54 Fed. Reg. 14426, 14490 (Apr. 11, 1989) (similar provision for "NOx averaging program" for methanol-fueled vehicles); 57 Fed. Reg. 31888, 31890 (July 17, 1992) (similar provision for phase-in of cold CO standards under the 1990 Clean Air Act Amendments); 56 Fed. Reg. 25724, 25734 (June 5, 1991) (similar provision for phase-in of "Tier 1" exhaust emissions standards under the 1990 Amendments); 65 Fed. Reg. 6698, 6714 (Feb. 10, 2000) (similar provision for "Tier 2" emissions standards).

Perhaps the closest that EPA came to offering a rationale for its claimed authority to void certificates ab initio occurred in the 1991 rulemaking to implement the "Tier 1" standards. There, the Agency maintained that "such actions are authorized where, pursuant to EPA's authority under Section 206(a) of the Act to condition certificates upon such terms as the Administrator ‘may prescribe’, EPA has placed a condition in the certificate.”358 Of course, accepting the general notion that the Agency can include some conditions in a certification of conformity does itself not provide a basis for placing arbitrary or capricious conditions on certification, nor does that proposition support a rule that is contrary to the text and structure of sections 203 and 206 of the Clean Air Act. [EPA-HQ-OAR-2022-0829-0701, pp. 232-234]

358 56 Fed. Reg. at 25734.

During the CAP 2000 rulemaking, EPA explained in its notice of proposed rulemaking its intended approach to an “explicit requirement that manufacturers exercise good engineering judgment in making decisions under the [CAP 2000] regulations” as follows: [EPA-HQ-OAR-2022-0829-0701, pp. 234-247]

Failure to apply good engineering judgment may result in EPA overruling the manufacturer’s decision. As long as manufacturers do not deliberately overlook information, use incorrect information, or make decisions without using a rational decision process, EPA is limiting the consequences of making incorrect good engineering judgments to future corresponding decisions. Also, the Agency is proposing that such overruled decisions be applied as soon as practicable. … The Agency is proposing harsher remedies for intentional and deliberate acts or decisions made without a rational basis. Intentional disregard for good engineering judgment could result in voiding certificates ab initio, with provisions for an administrative hearing, in addition to any civil or criminal enforcement actions which may result.359 [EPA-HQ-OAR-2022-0829-0701, pp. 234-247]

359 Control of Air Pollution From New Motor Vehicles; Compliance Programs for New Light-Duty Vehicles and Light- Duty Trucks, Notice of Proposed Rulemaking, 63 Fed. Reg. 39654, 39678 (July 23, 1998).

The CAP 2000 final rule followed through on the Agency’s stated intent in new section 86.1850- 01 of the certification regulations: [EPA-HQ-OAR-2022-0829-0701, pp. 234-247]

§ 86.1851-01 Application of good engineering judgment to manufacturers’ decisions.

(a) The manufacturer shall exercise good engineering judgment in making all decisions called for under this subpart, including but not limited to selections, categorizations, determinations, and applications of the requirements of the subpart.

(b) Upon written request by the Administrator, the manufacturer shall provide within 15 working days (or such longer period as may be allowed by the Administrator) a written description of the engineering judgment in question.

(c) The Administrator may reject any such decision by a manufacturer if it is not based on good engineering judgment, or is otherwise inconsistent with the requirements of this subpart.

(d) If the Administrator rejects a decision by a manufacturer with respect to the exercise of good engineering judgment, the following provisions shall apply:

(1) If the Administrator determines that incorrect information was deliberately used in the decision process, that important information was deliberately overlooked, that the decision was not made in good faith, or that the decision was not made with a rational basis, the Administrator may suspend or void ab initio a certificate of conformity.

(2) If the Administrator determines that the manufacturer's decision does not meet the provisions of paragraph(d)(1) of this section, but that a different decision would reflect a better exercise of good engineering judgment, then the Administrator will notify the manufacturer of this concern and the basis thereof.

(i) The manufacturer shall have at least 30 days to respond to this notice. The Administrator may extend this response period upon request from the manufacturer if it is necessary to generate additional data for the manufacturer's response.

(ii) The Administrator shall make the final ruling after considering the information provided by the manufacturer during the response period. If the Administrator determines that the manufacturer's decision was not made using good engineering judgment, he/she may reject that decision and apply the new ruling to future corresponding decisions as soon as practicable.

(e) The Administrator shall notify the manufacturer in writing regarding any decision reached under paragraph (d)(1) or (2) of this section. The Administrator shall include in this notification the basis for reaching the determination.360

360 Control of Air Pollution From New Motor Vehicles; Compliance Programs for New Light-Duty Vehicles and Light- Duty Trucks, 64 Fed. Reg. 23906. 23971 (May 4, 1999) (emphasis added).

Thus, as indicated in the italicized text, the regulations provide for voiding a certificate of conformity ab initio only when "important information was deliberately overlooked," or a decision "was not made in good faith" or lacked "a rational basis."361 By contrast, when EPA concludes through a final ruling only that "a different decision would reflect a better exercise of good engineering judgment," its ruling takes effect in "future corresponding decisions as soon as practicable," with no effect on a current certificate.362 [EPA-HQ-OAR-2022-0829-0701, pp. 234-247]

361 40 C.F.R. § 86.1851-01(d)(1).

362 Id. § 86.1851-01(d)(2)(ii).

In sum, EPA's prior regulations have generally recognized a distinction between willful or reckless error and misconduct (which can trigger ab initio voiding of certificates of conformity), and good-faith error or honest disagreement (which cannot). While the Agency has never provided a plausible rationale for any retroactive impacts on existing certificates, or explained how such an approach is consistent with sections 203 and 206, at least it adopted a bright- line rule that cabined the void-ab-initio sanction to a limited category of cases.363 [EPA-HQ-OAR-2022-0829-0701, pp. 234-247]

363 Failure to comply with fleet average standards and phase-in requirements, which could trigger the retroactive voiding of certificates for vehicles whose sale caused the exceedances (and not entire engine families or test groups), did not fit the general model, as such exceedances could have resulted from honest error. But such violations could easily be identified and were not likely to be in dispute. Up until the current rulemaking for MY 2027 and later vehicles, only those easily identified violations of conditions of certification, or acts or omissions involving scienter or recklessness, fell into the general category of conditions of certification that could lead to the voiding of certificates ab initio.

ii) The Proposed Revisions to the Certification Enforcement Regulations

The existing panoply of conditions for issuing new-vehicle certificates of conformity are contained in 40 C.F.R. §86.1848-10(c). Under the current version of section 86.1848-10(c), the only certificate conditions that can be enforced by deeming vehicles "not ... covered by the certificate" are those requiring (i) compliance with sales-based implementation schedules or fleet-average and phase-in regulations; 364 (ii) compliance with in-use testing and reporting requirements; 365 and (iii) conformity "in all material respects" with the contents of the certification application. 366 The NPRM here proposes to make failure to comply with any of the conditions listed in section 86.1848-10(c)-including run-of-the-mill failures to meet in-use emissions standards, a basis for determining that "any affected vehicles are not covered by the certificate" that authorized their introduction into commerce. 367 As a result, any such failure to comply with in-use standards, even by vehicles that would not be subject to recall under CAA section 207(c)(1), would create per-vehicle penalty liability. 368 [EPA-HQ-OAR-2022-0829-0701, pp. 237-239]

363 Failure to comply with fleet average standards and phase-in requirements, which could trigger the retroactive voiding of certificates for vehicles whose sale caused the exceedances (and not entire engine families or test groups), did not fit the general model, as such exceedances could have resulted from honest error. But such violations could easily be identified and were not likely to be in dispute. Up until the current rulemaking for MY 2027 and later vehicles, only those easily identified violations of conditions of certification, or acts or omissions involving scienter or recklessness, fell into the general category of conditions of certification that could lead to the voiding of certificates ab initio.

364 40 C.F.R. § 86.1848-10(c)(3), (7), (8), (9).

365 See id. § 86.1848-10(c)(5)).

366 See id. § 86.1848-10(c)(6)).

367 NPRM at 29434. Each of the proposed revisions to section 86.1848-10(c), and those to 40 C.F.R § 86.1850-01 identified in the next paragraph of these comments, is conveniently shown in what EPA staff calls a “Redline Version” of all the proposed changes in regulatory text in the NPRM placed on the docket by EPA. See EPA-HQ- OAR-2022-0829-0314 at 1, 91-96.

368 As explained elsewhere in these comments, the statute limits mandatory recall to situations in which a substantial number of vehicles in a properly defined class or category do not conform with EPA’s regulations and can be brought into compliance by repair.

The NPRM also proposes three important changes in current section 86.1850-01. First, it would delete the requirement in section 86.1850-01 that only "substantial" infractions of regulations can trigger suspension or revocation of a certificate, 369 Second, it would delete the current provision in section 86.1850-01 providing that in the absence of willful or reckless error, "[a]ny suspension or revocation of a certificate of conformity shall extend no further than to forbid the introduction into commerce of vehicles previously covered by the certificate which are still in the possession of the manufacturer.”370 Third, it would add to section 86.1850-01 a provision giving EPA authority to “void” ab initio, as well as to suspend or revoke, certificates of conformity.371 The upshot of all this would be that any infraction of the certification regulation could result in per-vehicle penalties, no matter how insubstantial.372 [EPA-HQ-OAR-2022-0829-0701, pp. 237-239]

369 See 88 Fed. Reg. at 29435.

370 40 C.F.R. § 86.1850-01(f).

371 See 88 Fed. Reg. at 29435; see also 40 C.F.R. § 1068.30 (“void” means “to invalidate a certificate ... ab initio”).

372 This, of course, assumes that EPA’s theory of CAA section 203(a)(1) penalty liability based on retroactive invalidation is credible.

The NPRM’s explanation for these proposed changes in sections 86.1848-10 and 86.1850-01 appears in a single paragraph in the NPRM, which melds discussion of the enforcement of fleet-average GHG requirements with other topics: [EPA-HQ-OAR-2022-0829-0701, pp. 237-239]

The overarching principle of compliance to the fleet average standards is that the calculated fleet average in the GHG report must accurately represent the actual fleet of vehicles a manufacture produced. If a manufacturer provides false, inaccurate, or unrepresentative data as part of their GHG report, the manufacturer may be subject to enforcement and EPA may void ab initio the certificates of conformity which relied on that data. Vehicles are covered by a certificate of conformity only if they are in all material respects as described in the manufacturer’s application for certification (Part I and Part II) including the GHG report. If vehicles generate substantially more CO2 emissions in actual use than what was reported, those vehicles are not covered by the certificate of conformity. EPA is proposing two changes to the regulatory language that are designed to clarify the Agency’s understanding of its authority to void certificates and/or find that vehicles were sold in violation of a condition of a certificate. Currently 40 CFR 86.1850 states that if a manufacturer submits false or incomplete information or renders inaccurate any test data which it submits, or fails to make a good engineering judgment, EPA may deny issuance of, suspend, or revoke a previously issued certificate of conformity. However, suspension or revocation of a certificate of conformity shall extend no further than to forbid the introduction into commerce of vehicles previously covered by the certificate which are still in the possession of the manufacturer. Since the GHG report is not required to be submitted until May 1 of the calendar year after the model year has ended, suspending or revoking a certificate is no longer a relevant remedy. Therefore, because of situations where certificate suspension or revocation is no longer relevant, EPA is proposing to allow the Agency to void ab initio a previously issued certificate of conformity in the list of possible actions the agency may take if a manufacturer commits any of the infractions listed in 40 CFR 86.1850(b). In addition, EPA is proposing edits to 40 CFR 86.1848 to make it clearer that any vehicles sold that fail to meet any condition upon which the certificate was issued are not covered by the certificate and thus were sold in violation of CAA 203(a)(1).373 [EPA-HQ-OAR-2022-0829-0701, pp. 237-239]

373 NPRM at 29289 (emphasis added).

This purported justification is objectionable on several fronts. First, the Agency's explanation does not even correctly identify the actual regulatory changes wrought by the proposed regulation. For instance, it states that the submission of "unrepresentative data" may be a ground for voiding a certificate, even though the proposed regulation itself only mentions "false" or "inaccurate" data. The submission of "unrepresentative" data is not covered by the regulations for enforcement or reporting of GHG fleet-average performance, and the NPRM does not define what the term means, apart from "inaccurate." In any event, statements in preambles cannot be used to alter the meaning of clear regulations. 374 [EPA-HQ-OAR-2022-0829-0701, pp. 237-239]

374 See, e.g., Natl. Wildlife Fed’n v. EPA, 286 F.3d 554, 569-70 (D.C. Cir. 2002) (preambles cannot “enlarge or confer powers on administrative agencies or offcers”).

Second, the timing of GHG reports provides no genuine basis for the Agency to expand the role of the void-ab-initio remedy. That a GHG report is not required until after the end of a model year is nothing new or unique to MY 2027 and later GHG regulations. If the timing of GHG reports were a valid rationale for voiding certificates ab initio, the rationale would have applied to any of the prior GHG regulations and EPA presents no concrete evidence of any newly emergent problems occasioned by the timing of a GHG report. In all events, the timing of a GHG report does not provide a rational basis for expanding section 86.1850-01's use of voiding- ab-initio to cover "any of the infractions listed in 40 CFR 86.1850 (b)."375 The NPRM provides no reason why good-faith differences between a manufacturer and EPA should not be remedied prospectively, without per-vehicle penalty liability. Prospective remedies are particularly appropriate in that context because EPA has offered no useful general definition of what it would consider to be "good engineering judgment." The definition of the term in Part 1068 refers generally to "judgments made consistent with generally accepted scientific and engineering principles and all available relevant information."376 Except in cases of willful error or recklessness, it is impossible to imagine a priori a decision on an engineering issue that would not meet that standard. Tellingly, the NRPM offers no examples of emerging problems with the current program that need to be addressed. It is black-letter administrative law that regulated parties must have “fair warning of [EPA’s] interpretation of [its] regulations.”377 The NRPM falls far short of complying with that principle. [EPA-HQ-OAR-2022-0829-0701, pp. 239-240]

375 NPRM at 29289 (emphasis added).

376 40 C.F.R. § 1068.30.

377 Gen. Elec. Co. v. EPA, 53 F.3d 1324, 1333 (D.C. Cir. 1995); accord United States v. Chrysler Corp., 158 F.3d 1350, 1354 (D.C. Cir. 1998); cf. Morton v. Ruiz, 415 U.S. 199, 231-33 (1974) (one purpose of the APA is “to avoid … inherently arbitrary … unpublished ad hoc determinations” of rights and duties); see also Ethyl Corp. v. EPA, 306 F.3d 1144, 1148-49 (D.C. Cir. 2002) (EPA failed to properly exercise its rulemaking authority in section 206(d) by establishing a framework to determine regulatory compliance rather than specific methods to determine compliance).

Third, the NPRM's one-sentence assertion that the proposed changes in section 86.1848-10 are merely designed to make the existing regulation "clearer" is wholly unconvincing. Unlike the current text of section 86.1848-10, the new text would provide that "any vehicles sold that fail to meet any condition upon which the certificate was issued are not covered by the certificate," as the NPRM preamble itself concedes. 378 In failing to even recognize that it is proposing a substantive change in section 86.1848-10, the NPRM surely fails to justify that proposed change. [EPA-HQ-OAR-2022-0829-0701, pp. 240-241]

378 NPRM at 29289.

The NPRM's failure to set forth a plausible rationale for the proposed changes to the certification enforcement regulations contravenes section 307(d)(3). If the Agency tried to move forward with those changes and if a petition for review was filed, section 307(d) would therefore "require" remand for further consideration of the proposed changes. 379 Additionally, because no such rationale for several of these changes is at all evident, it is far from clear whether EPA could adequately explain its reasons for the proposed changes, so as to avoid vacatur. Indeed, vacatur appears to be the most likely result-given that there isn't any evidence that vacatur would be "quite disruptive" to EPA's plans to set new multi-pollutant standards. 380 [EPA-HQ-OAR-2022-0829-0701, pp. 240-241]

379 See Ne. Md. Waste Disposal Auth., 358 F.3d at 949-50.

380 See id. (quoting Allied-Signal, Inc. v. Nuclear Regul. Comm'n, 988 F.2d 146, 151 (D.C. Cir. 1993)).

That said, because the NPRM's proposed changes to the emissions standards themselves are not inextricably tied to the enforcement-related amendments, the main portion of EPA's regulatory effort likely could proceed with the deficient amendments to the enforcement regulations severed. That would allow EPA and stakeholders to focus energies on the new standards and give them time to discuss and to try to reach agreements on changes to the certification enforcement regulations. Moreover, EPA should not consider any aspect of the void-ab-initio mechanism to be beyond judicial scrutiny. The sweeping changes the NPRM proposes to the Agency's certification enforcement regulations has reopened those issues, and EPA must explain not only its full rationale for including the conditions listed in section 86.1848- 10(c) in its regulations, but also its general endorsement of the entire void-ab-initio concept. After it has done so, EPA must reopen the docket and allow for public comment; failure to do so would, at minimum, not comply with section 307(d)(3).381 [EPA-HQ-OAR-2022-0829-0701, pp. 240-241]

381 See Kennecott Utah Copper Corp. v. Dep't of the Interior, 88 F.3d 1191, 1213-15 (D.C. Cir. 1996) (explaining doctrine of "constructive[]" reopener); see also Bluewater Network v. EPA, 370 F3d 1, 16 (D.C. Cir. 2004) (reopener "is dependent upon the entire context of the rulemaking" (cleaned up)).

iii) In-Use Remedies

The NPRM also includes a proposal to create new regulatory text concerning "recall order[s]." Specifically, the NPRM would add the following text to 40 C.F.R. § 86.1865-12:

(j)(3) EPA will issue a recall order as described in 40 CFR part 85, subpart S, if EPA or the manufacturer determines that a substantial number of a class or category of vehicles produced by that manufacturer, although properly maintained and used, do not conform to in-use CO2 emission standards, or do not conform to the monitor accuracy requirements in § 86.1815. The recall would be intended to remedy repairable problems to bring the vehicle into compliance; however, if there is no demonstrable, repairable problem that could be remedied to bring the vehicles into compliance, the manufacturer must submit an alternative plan for to address the noncompliance. For example, manufacturers may need to calculate a correction to its emission credit balance based on the GHG emissions of the actual number of vehicles produced. EPA may void credits originally calculated from noncompliant vehicles, unless traded, and will adjust debits. In the case of traded credits, EPA will adjust the selling manufacturer's credit balance to reflect the sale of such credits and any resulting credit deficit. Manufacturers may voluntarily recall vehicles to remedy such a noncompliance and submit a voluntary recall report as described in 40 CFR part 85, subpart T.382 [EPA-HQ-OAR-2022-0829-0701, pp. 241-245]

382 NPRM at 29438.

This new provision, however, stands in serious tension with longstanding, statutorily embodied principles for recalls. [EPA-HQ-OAR-2022-0829-0701, pp. 241-245]

In language unchanged by Congress since the 1970 Amendments, CAA section 207(c)(1) provides for mandatory recalls only when EPA determines that "a substantial number of any class or category of vehicles, although properly maintained and used," do not "conform with regulations prescribed under section 202, when in actual use" during their specified useful life.383 “[S]ection 207(c) provides for classwide remedies of classwide defects.”384 Since the 1980s, EPA has apparently not needed to compel an emissions recall. Yet, tens of thousands of vehicles have nevertheless been recalled voluntarily since that time. That is because the governing principles for recalls pursuant to section 207(c) have been clear for decades. Three such principles are important and relevant in the current rulemaking. [EPA-HQ-OAR-2022-0829-0701, pp. 241-245]

383 42 U.S.C. § 7541(c)(1).

384 General Motors Corp. v. Ruckelshaus, 742 F.2d 1561, 1568 (D.C. Cir. 1984) (en banc).

First, while inferences about emissions control performance from a sample of test vehicles is permitted, the test sample must be statistically robust in showing that the class of vehicles under investigation does not conform with the section 202 emissions standards. As Senator Muskie, the lead author of much of the 1970 Amendments, described the recall provision in section 207, “[t]he Administrator can test cars on the road, and can require recall if a representative sample fails the test.”385 Because the nonconformity must exist in a “substantial number” of vehicles, it is imperative for EPA to define the investigatory class no more broadly than the data permit. [EPA-HQ-OAR-2022-0829-0701, pp. 241-245]

385 Summary of the Provisions of Conference Agreement on the Clean Air Act Amendments of 1970, reprinted in 116 Cong. Rec. 42,384 (1970) (emphasis added).

Second, a classwide defect subject to recall can be exhibited only in “properly maintained and used” vehicles. In that language, Congress correctly recognized that manufacturers cannot design and provide at reasonable cost to a retail purchaser a vehicle that could meet emissions standards no matter how poor its maintenance and regardless of how it has been operated. “Unless the cause of the nonconformity is within the manufacturer’s control, an imposition of liability would be an unwarranted financial burden on the manufacturers, unrelated to the strategy of forcing technological progress.”386 In fact, attempts to amend section 207(c)(1) to trigger recall liability based on “normal,” rather than “proper[],” maintenance and use, were rejected in the 1990 Clean Air Act Amendments.387 Because of this statutory requirement, for recall testing, EPA is obliged to follow test-vehicle procurement protocol procedures aimed to limit testing to vehicles that could be demonstrated to have been “properly maintained and used.” During the CAP 2000 rulemaking, EPA acknowledged that “[s]ection 207(c) specifies the determination that EPA must make to issue a recall order,” and made it clear that the primary purpose of IUVP testing was “to obtain a randomly procured sample of in-[use] vehicles, not a sample on which to base a recall determination.”388 In IUVP testing, EPA explained, “sample vehicles would be eliminated only if they are found to be obviously tampered, were used for “severe duty (racing, snow plowing etc.), have experienced extensive collision damage, require repairs which to allow the vehicles to be tested would be excessively costly, or are found to be unsafe to test.”389 By contrast, “the purpose of the confirmatory test programs,” (i.e., IUCP) testing, “is to provide data upon which the agency can base a 209(c) recall determination,” which entails a “statutory requirement that such determinations address whether properly maintained and used vehicles conform” with emissions standards.390 [EPA-HQ-OAR-2022-0829-0701, pp. 241-245]

386 Chrysler Corp. v. EPA, 631 F.2d 865, 888 (D.C. Cir. 1980). See also id. (“[I]t would make little sense to impose liability on manufacturers for conditions of nonconformity caused by actions of vehicle owners or mechanics.”); Automotive Parts Rebuilders Ass’n v. EPA, 720 F.2d 142, 157 (D.C. Cir. 1983) (agency lacks power to make manufacturer responsible for nonconformities beyond its control). EPA regulations

themselves also acknowledge that in-use compliance with emissions standards depends in part on performance of proper maintenance by vehicle owners. Manufacturers provide instructions on vehicle maintenance to new-vehicle purchasers, and they are required to justify those instructions to EPA in the certification process as necessary, including a demonstration, if needed, that any scheduled maintenance "must have a reasonable likelihood of being performed in-use." 40 C.F.R. § 86.1834-0 1(b)(6)(ii).

387 Work on what became the Clean Air Act Amendments of 1990 began in 1987. Representative Henry Waxman introduced H.R. 3054, which sought to change "properly" to "normally" in the text of section 207(c)(1). Clean Air Act Amendments of 1987, H.R. 3054, 100th Cong., 1st Sess. § 207(d)(1) (1987) 43. The bill was the subject of hearings and went into markup but was not reported. In 1989, Representative Waxman introduced H.R. 2323 which contained the same amendment to section 207(c)(1). Clean Air Restoration Act of 1989, H.R. 2323, 101st Cong., § 505(b)(1) 1st Sess. (1989) 99. H.R. 2323 was replaced by H.R. 3030, which did not contain the same amendment and which, following Conference, provided the text for what became the Clean Air Act Amendments of 1990. The 1990 Amendments were the last major revisions to the statute. Legislative History of the Clean Air Act Amendments of 1990, P.L. 101-549, U.S. Government Accountability Office (GAO), digitized on Westlaw, 100th Congress, H.R. 3054; 101st Congress, H.R. 2323.

388 EPA, Response to Comments, CAP 2000 Final Rule, Mar. 15, 1999, EPA Air Docket No. A-96-50.V-C-01 19-20 (hereinafter "CAP 2000 RPC").

389 CAP 2000 RPC at 20; see 40 C.F.R. Pt. 86, Subpt. S App. II.

390 CAP 2000 RPC at 21. In a decision concerning state-law remedies, the U.S. District Court for the Northern District of California commented in dicta that, "If a manufacturer's vehicles do not pass these [IUVP] tests, or if EPA otherwise determines that 'a substantial number of any class or category of vehicles or engines, although properly maintained and used, do not conform to the regulations prescribed,' EPA has authority to recall those vehicles.." In re Volkswagen "Clean Diesel" Mktg., Sales Pracs., and Prods. Liab. Litig., 310 F. Supp. 3d 1030, 1041 (N.D. Cal. 2018) (quoting 42 U.S.C. § 7541(c)(1)), aff'd in part, rev'd in part, 959 F.3d 1201 (9th Cir. 2020). But the court did not address the distinction between IUVP and IUCP testing, and if taken literally, its dicta would confuse the two types of testing. If EPA takes a different view of the matter than does Auto Innovators, the Agency should explain fully why it does.

Third, the only remedy for in-use nonconformity permitted by section 207(c)(1) is recall, which has two fundamental components: notice to vehicle owners, and performance of a remedy (adjustment or replacement of a part or assembly, or recalibration of powertrain or emissions controls). EPA's recall regulations have properly implemented the statute. Those regulations make it clear that a "plan to remedy" the nonconformity must contain the "description of the proper maintenance and use" on which the manufacturer proposes to condition "eligibility for repair."391 As one court noted, "EPA's regulations … nowhere suggest that any remedy other than recall might be appropriate."392 [EPA-HQ-OAR-2022-0829-0701, pp. 241-245]

391 40 C.F.R. §§ 85.1802(a), 85.1803(a)(4) (emphasis added). EPA properly will not approve remedies that would degrade drivability, which would invite widespread tampering and likely reduce the vehicle capture rate.

392 Ctr. for Auto Safety v. Ruckelshaus, 747 F.2d 1, 5-6 (D.C. Cir. 1984) (Scalia, Circuit Judge). See also Gen. Motors Corp., 742 F.2d at 1568 (referring to section 207(c) as the "recall provision" and the "recall scheme"); accord In re Caterpillar, Inc., C13 & C15 Engine Products Liab. Litig., No. 1:14-CV-3722 JBS-JS, 2015 WL 4591236, at *8 (D.N.J. July 29, 2015); Navistar, Inc. v. Jackson, 840 F. Supp. 2d 357, 359 (D.D.C. 2012). Under the rule in Center for Auto Safety, the Administrator can stop short of making a nonconformity determination—a determination which would require him to order a recall—if the Agency and the manufacturer agreed on another method of addressing the nonconformity. The D.C. Circuit acknowledged such an alternative might be "best calculated to achieve the ends sought by Congress and to allocate [EPA's] available funds and personnel in such a way as to execute its policy efficiently and economically." 747 F.2d at 6 (quotation marks and citation omitted). But recall is the "exclusive"

mandatory remedy allowed by the statute, see id., and EPA's regulations permit no alternative to recall and repair.

The proposal in the NPRM concerning the recall remedy is entirely inconsistent with this history and precedent. The first problem with the NPRM's proposal is that the alternative remedy it proposes is disconnected from section 207(c)(1). Despite its good intention, the proposal rests on a "misinterpretation of the statute" because the "recall order" it contemplates would not include or depend upon notice to vehicle owners or any modification of the vehicle.393 To be sure, EPA is entitled to propose solutions to address exceedances of CO2 emission standards when there is no "demonstrable, repairable problem." But that solution cannot be shoehorned within the Agency's limited authority to conduct recalls, and indeed, when there is no "demonstrable, repairable problem" there is not even a nonconformity within the meaning of section 207(c)(1). [EPA-HQ-OAR-2022-0829-0701, pp. 241-245]

393 See Ctr. for Auto Safety, 747 F.2d at 6.

Therefore, if EPA has authority to require a correction of a GHG emissions credit balance, it cannot arise under section 207(c)(1). Certainly, the regulation that the NPRM is proposing is not an exercise of the Agency's rulemaking power under section 206(d) of the statute, which requires regulations to "establish methods and procedures for making tests," nor under sections 206(a)(4)(A)&(B) or 206(h), which similarly are concerned with test procedures.394 Nor, looking outside Title II, could EPA rely upon section 301, which is only "a source of procedural not substantive authority—it lets the agency pass rules to carry out powers granted by other provisions of the statute."395 [EPA-HQ-OAR-2022-0829-0701, pp. 241-245]

394 See 42 U.S.C. §§ 7525(a)(4)(A)&(B), (h).

395 Heating, Air Cond. & Refrig. Dist. Int'l v. EPA, No. 21-1251, 2023 WL4067167 at *5 (D.C. Cir. June 20, 2023).

That said, Auto Innovators believe that the solution to some exceedances of in-use CO2 emission standards that EPA has suggested is sensible, because it will protect the environment and is unlikely to engender unnecessary disputes with vehicle manufacturers. Even if EPA does not have authority to establish such a GHG-emissions-credit-adjustment mechanism through a legislative rule, it can presumably issue an interpretative rule or policy statement to establish this useful mechanism to address imbalances between GHG emissions control performance demonstrated during certification compared with in-use emissions test results. [EPA-HQ-OAR-2022-0829-0701, pp. 241-245]

The second issue with the proposed amendment to section 86.1865(j) is that it leaves open the possibility that an EPA "recall order" might not even take the reasonable approach suggested in its text: the credit-balance correction is offered only as an "example" of what EPA might require. That open-ended deviation from the clear strictures of section 207(c)(1) is objectionable and should be removed. Relatedly, the Agency cannot properly proceed with the proposed revision in section 86.1848-10(c)(2) that would treat as "not covered by the certificate" vehicles that do not comply with any of the "in-use emissions standards contained in subpart S."396 Apart from the lack of any reasoned explanation for the change, see supra pp. [12-15], again, the exclusive remedy for nonconformity of an in-use emissions standard is recall (ordered or voluntary) as provided in section 207(c)(1).397 [EPA-HQ-OAR-2022-0829-0701, pp. 241-245]

396 See NPRM at 29434. A reasonable, and indeed the only sensible, understanding of "comply" in the current version of § 86.1848-10(c)(2) has been that manufacturers must respond to lawful recall orders to bring their vehicles into compliance with applicable emission standards. To "comply" cannot be read to make a certificate conditional on never exceeding an in-use emissions standard in testing such as IUVP testing; such a reading could mean that a single failure by a vehicle inducted into IUVP testing, regardless of whether the vehicle had been properly maintained and used, would violate a condition of certification.

397 See Heating, Air Cond. & Refrig. Dist. Int'l, 2023 WL4067167 at *5.

iv) The IUCP Path to Recall

Finally, the NPRM's proposal to add in-use CO2 emission standards to the In-Use Confirmatory Test Program (IUCP) 398 contains significant ambiguities and does not adequately justify the decision to exclude a threshold such as the 1.3 factor used for criteria pollutants in combination with the 50% trigger for IUCP testing. In particular, it is unclear whether the 50% trigger would apply on a subconfiguration basis for a model year, or across all subconfigurations that used the same carryover data. We assume the former, and if not, EPA should clarify and permit comment after a reasonable period of time. We also assume that any recall based on IUCP testing would only apply to the subconfiguration and model year actually tested in the IUCP, because, for example, in-use factors can affect test results for specific subconfigurations differently. This is consistent with the relevant regulation at 40 C.F.R. § 1818-12(d) that establishes the in-use CO2 exhaust emission standard on a subconfiguration basis. [EPA-HQ-OAR-2022-0829-0701, pp. 245-246]

398 See 88 Fed. Reg. at 29,288-90.

We further assume that a recall could only be compelled based on the results of IUCP tests on a significant number of vehicles in the relevant subconfiguration for in-use CO2 emissions in a given model year, because the statute only allows recalls when the data permit a robust statistical inference. EPA previously determined that testing at least 10 vehicles in an Agency- designated subset (such as the subconfiguration grouping designated by EPA under 40 C.F.R. § 1818-12(d)) is sufficient to meet the testing adequacy requirement, 399 and we assume the same would be applied to any new IUCP program. If those assumptions are mistaken, EPA should so advise, and permit further comment in light of its corrections to those assumptions.400 [EPA-HQ-OAR-2022-0829-0701, pp. 245-246]

399 See 40 C.F.R. § 86.1846-01(d)

400 EPA's IUCP regulations assess criteria emissions test results on an emissions test group basis, but would not do so for CO2 emissions, presumably for physics-based reasons underlying the establishment of the CO2 emission in- use margin at 40 C.F.R. § 1818-12(d).

Organization: Stellantis

Certification Enforcement Programs and In-Use Remedies

Finally, separate from the issues raised regarding the proposed GHG and criteria pollutant standards, Stellantis agrees with the concerns discussed in the Auto Innovators' comments on EPA's proposed revisions to enforce vehicle certification and in-use standards. As detailed by Auto Innovators, EPA has not provided a plausible rationale for its proposed retroactive impacts on existing certificates and other proposed "clarifications." Similarly, it is unclear that EPA has the authority to add the proposed in-use "recall order" regarding CO2 emission standards/monitor accuracy requirements or CO_2 emission standards to the In-Use Confirmatory Test Program. Based on these shortcomings, EPA should not carry forward into the final rule the proposed "clarifications" or revisions to the enforcement programs and in-use remedies. [EPA-HQ-OAR-2022-0829-0678, p. 23]

Organization: Volkswagen Group of America, Inc.

In-Use Program – Fuel Economy and In-Use Verification Test Procedure Streamlining (Section III.F.5.iv) [EPA-HQ-OAR-2022-0829-0669, p. 11]

Volkswagen is in alignment with AFAI's GHG IUVP/IUCP comments. [EPA-HQ-OAR-2022-0829-0669, p. 11]

Volkswagen requests clarification in the language proposed in the NPRM to use its authority to make GHG credit adjustments based on IUVP CO_2 results. "EPA may use its authority to correct a manufacturer's greenhouse gas credit balance to ensure the manufacturer's GHG fleet average is representative of the actual vehicles it produces." Volkswagen feels this would be appropriately handled at the discretion of the regulator; however, future guidance on this topic would be desired to ensure a common understanding for all manufacturers. [EPA-HQ-OAR-2022-0829-0669, p. 11]

EPA Summary and Response

Summary:

The Auto Alliance commented that EPA has never provided a legal basis for voiding certificates. The Alliance states that CAA 206 creates a narrow purpose for certification, which is to facilitate introduction into commerce of qualified vehicles; it believes that the CAA does not authorize suspending, revoking, or voiding certificates after the certification has served its intended purpose. The Alliance further believes EPA implementation has historically limited voiding certificates to "egregious" cases, and it believes that while EPA's Tier 1 rule included a statement supporting voided certificates based on CAA 206(a) allowing EPA to prescribe conditions on certificates, such an argument is contrary to the text and structure of CAA 203 and 206.

The Auto Alliance commented that the CAP 2000 rule added good-engineering-judgment provisions that reinforce an approach that limits voiding certificates to egregious circumstances, such as deliberately overlooking important information, not operating in good faith, or lacking a rational basis. The Alliance claims that this approach still lacks a legal basis, but it at least limits voiding to a limited category of cases.

The Auto Alliance commented that 40 CFR 86.1848-10(c) currently defines specific conditions on certificates, whereas the proposal expands that to cover every emission result and any case of a vehicle not being covered by a certificate. It states that § 86.1850 similarly expands the scope of what may justify voiding certificates.

The Auto Alliance commented that the preamble improperly references "unrepresentative data" rather than the more specific "false or inaccurate data" in the regulation.

The Auto Alliance commented that the timing of a GHG report does not provide a rational basis for voiding certificates. The Alliance believes the NPRM provides no reason why good-faith differences between a manufacturer and EPA should not be remedied prospectively, without per-vehicle penalty liability. It further asserts that, with no examples of emerging problems that need to be addressed, EPA fails to meet the legal standard for giving fair warning of how it interprets its regulations.

The Auto Alliance commented that the preamble claims that the changes are for clarity, without even recognizing the changes are substantive. The NPRM's failure to set forth a plausible rationale for changing the certification enforcement contravenes CAA 307(d)(3).

The Auto Alliance commented that the proposed changes have reopened the general issue of voiding certificates, so the final rule needs to give a rationale both for any specific amendments and for voiding certificates generally. CAA 307(d)(3) would require reopening the docket for public comment.

The Auto Alliance commented that CAA 207(c) relies on several principles, among them: (1) test sample must be statistically robust to show that a substantial number of vehicles do not conform to the regulation; (2) defects for a recall determination must be based on properly maintained and used vehicles (in CAP 2000, EPA recognized that IUVP testing was intended to test vehicles without screening for proper maintenance and use, which leaves IUCP to provide information needed to make recall determinations); and (3) the only remedy for in-use noncompliance under CAA 207(c) is recall, which fundamentally requires notice to vehicle owners and performance of a remedy (the remedy (repair) depends on the manufacturer identifying how to qualify eligible vehicles for repair based on proper maintenance and use).

The Auto Alliance also commented that the changes to EPA's compliance and enforcement programs are severable from the remainder of the proposed rule, including changes EPA is making to the GHG and criteria pollutant standards.

Stellantis and Volkswagen stated that they supported the comments from the Auto Alliance as summarized in the preceding paragraphs. Stellantis concluded that EPA should not finalize the proposed "clarifications" or revisions to the enforcement programs and in-use remedies. Volkswagen further requested clarification to ensure a common understanding among manufacturers regarding the reference in the proposed rule for EPA to use its authority to make GHG credit adjustments based on IUVP CO2 results.

Response:

Without taking a position on the substance of the comments regarding voiding, EPA has decided not to finalize the changes to 40 CFR 86.1850 as proposed.

The Auto Alliance also claims that prior agency rulemakings, including those promulgated as early as 1974, 39 FR 7545, failed to provide a sufficient statutory basis for the agency's voiding authority. Statutory authority challenges to prior agency rulemakings are beyond the scope of the current rulemaking. In any event, the proposed rule here did not reopen EPA's general authority to void certificates, but rather proposed only discrete changes to characterize EPA decision-making with respect to such authority, changes which the agency is not finalizing.

The Auto Alliance commented that the preamble claims that changes to § 86.1848 are for clarity, without recognizing the changes are substantive. It also stated that the NPRM failed to set forth a plausible rationale for these proposed changes. EPA disagrees with these comments.

As explained in the preamble, these changes are simply for clarification. EPA interprets the regulations in § 86.1848 to have the same meaning with or without these changes.

Section 86.1848-01 has appeared in EPA's regulations and contained numerous conditions on certification since the CAP-2000 rule.[367] Additional conditions were added in the 2010 rule for LD GHG standards and codified in § 86.1848-10. The concept that certificates are granted only with certain conditions has been an integral component of EPA's compliance program since the 1970s.[368] The only plausible consequence for a particular vehicle that does not comply with an explicit condition of its certification is that such vehicle is a "misbuild"—it was not built under the terms of the certificate, and thus is not covered by that certificate. This is particularly true when the condition at issue cannot be tested until after many or all of the vehicles produced under that certificate had been sold, such as violations of the in-use standard.

EPA acknowledges that the text of § 86.1848-10 as promulgated in the 2010 rule might cause some confusion, given that certain conditions might have appeared to have explicit consequences while the consequences for others were not as specific. EPA's changes to § 86.1848-10 in the FRM are designed to allay any potential confusion and clarify that consequence for violating any of the conditions of certification is that violating vehicles will not be covered by the certificate. It is important to note that EPA did not propose and is not finalizing any changes to the conditions themselves.

The Auto Alliance commented that "the NPRM here proposed to make failure to comply with *any* of the conditions listed in § 86.1848-10(c) a basis for determining that" violating vehicles are not covered by the certificate. That is an accurate description of the compliance regime already applicable to certified vehicles before the finalization of the rule today, but overstates the impact of this action. The Auto Alliance's interpretation of EPA's current regulations would essentially read certain certificate conditions (which have appeared in EPA's regulations since at least 2000) completely out of the regulations. If the Auto Alliance were correct, EPA would not have been able to enforce any certificate conditions that did not have an explicit enforcement mechanism attached to them. Such an interpretation would also ignore the basic definition of a condition: "a provision making the effect of a legal instrument contingent upon an uncertain event."[369] For each vehicle sold by the manufacturer, a certificate is granted, contingent upon that vehicle meeting each of the conditions listed in § 86.1848. The logical conclusion is that if such vehicle does not meet one of the conditions, that vehicle was not covered by the certificate. The Auto Alliance does not present any alternative consequence for the violation of a condition.

The Auto Alliance also commented specifically that the Agency cannot properly proceed with the proposed revision in § 86.1848-10(c)(2) that would treat as "not covered by the certificate" vehicles that do not comply with any of the "in-use emissions standards contained in subpart S." The Auto Alliance also stated that the exclusive remedy for nonconformity of an in-use emissions standard is recall (ordered or voluntary) as provided in CAA section 207(c)(1). EPA

[367] 64 FR 2306, May 4, 1999.
[368] See, e.g., 39 FR 7545, 7546-7547 (Feb. 27, 1974); EPA Office of Gen. Couns., *A Collection of Legal Opinions: December 1970-1973* 185 (1973) (recommending regulations that would require that a "vehicle that did not conform to [the] description [in its certification application] would be considered uncertified.").
[369] *Condition*, Merriam-Webster.com/dictionary/condition, last accessed November 22, 2023.

disagrees with this assertion, based on both the structure of the statute and decades of EPA compliance and enforcement practice.

Beginning with section 207(c)(1), nothing in that section indicates it is an exclusive remedy for violation of in-use emissions standards. By contrast, section 203 broadly defines prohibited acts. For example, section 203(a)(1) prohibits manufacturers from introducing into commerce "any new motor vehicle or new motor vehicle engine, manufactured after the effective date of *regulations under this part* which are applicable to such vehicle or engine unless such vehicle or engine is covered by a certificate of conformity issued (and in effect) *under regulations prescribed under this part*." The prohibition thus relates to "regulations under this part," that is part A of the statute, section 202-219, which includes the statutory authority for promulgating in-use standards, e.g., section 202(a), (d). To take another example, section 203(a)(3)(A) makes it a prohibited act for "any person to remove or render inoperative any device or element of design installed on or in a motor vehicle or motor vehicle engine in compliance with regulations under this subchapter prior to its sale and delivery to the ultimate purchaser, or for any person knowingly to remove or render inoperative any such device or element of design after such sale and delivery to the ultimate purchaser." In other words, the statute expressly prohibits tampering with a vehicle that was "in compliance with regulations under this subchapter." An obvious example of this is a vehicle that met all the requirements for certification but then was tampered such that it only no longer meets the standards in-use. Thus, we think that section 203 unambiguously covers violations of the in-use standards.

More concretely, there are numerous examples of situations where EPA could proceed either under its 203 or 207 authority, including the below:

1) A manufacturer uses a vehicle with a defeat device in its certification testing; as such, all vehicles using that certification test (some portion of the test group/vehicle model) are producing significantly more emissions in-use than their certification value, violating the in-use standard. In this situation, EPA could (and likely would) begin an enforcement action under 203(a)(3)(A). However, EPA also has the clear authority to issue a notice of nonconformity under section 207(c)(1).

2) A manufacturer builds vehicles without installing the catalytic converters with which they were certified, causing the vehicles to fail their in-use standard. The vehicles would violate a condition of the certificate listed in § 86.1848-10(c)(6), which means they are explicitly not covered by the certificate. EPA can and has used its authority to prosecute violations of CAA section 203(a)(1) in such misbuild cases; EPA also could also use its authority under section 207(c) to require a recall.

3) A manufacturer produces vehicles with higher weight or greater road-load than that to which they were certified, and so the vehicles exceed the in-use GHG emissions standard. Such vehicles would not be covered by the certificate as stated in § 86.1848-10(c)(6), and may separately be susceptible to recall under CAA section 207(c).

EPA disagrees with the Auto Alliance's comment that EPA's proposed changes to § 86.1865 to make it clear that EPA will use recall authority to remedy GHG non-compliance stands in tension with longstanding, statutorily embodied principles for recalls.

To begin with, despite the Alliance's assertion that EPA is acting in tension with longstanding principles, the final rule is entirely consistent with the agency's position since the beginning of the LD GHG program in 2010. In that rule, the agency asserted authority to remedy GHG non-compliance including through credit adjustments. While stakeholders submitted many comments relating to the in-use standards and remedies for non-compliance, they did not raise any objections to the possible remedy of a credit balance adjustment. See 2010 LD RTC 5-344 ("Remedies for Noncompliance with In-Use Standards"). By contrast, stakeholders then expressed concern with the possibility a recall, noting that there may be no effective repair remedy in many cases. EPA noted, among other things, that "The CAA requires a vehicle to comply with emission standards over its regulatory useful life and affords EPA broad authority for the implementation of this requirement. As such, EPA has authority to require a manufacturer to remedy any noncompliance issues. The remedy can range from adjusting a manufacturer's credit balance to the voluntary or mandatory recall of noncompliant vehicles." 75 FR 25324 and 25474 (May 7, 2010). The final rule maintains this policy and further clarifies the agency's authority in this area and aligns the regulations with EPA's expressed intent in the 2010 rule.

In any event, we think the Alliance's specific allegations of tension are misplaced. The Auto Alliance stated that while inferences about emissions control performance from a sample of test vehicles is permitted, the test sample must be statistically robust to show that a substantial number of vehicles do not conform to the regulation. EPA agrees that a determination of non-compliance can be made based on a sampling of test vehicles, and that sample should be statistically robust. EPA has a longstanding practice to test a sample of 10 vehicle within a class or category of vehicles. For example, when EPA promulgated the CAP 2000 rule in 1999, EPA established the In Use Confirmatory Program (IUCP), which specifies a sample of 10 vehicles be tested when a certain number of vehicles in the In Use Verification Program (IUVP) exceed the applicable emissions standards. EPA does not see any reason for this longstanding practice to change when it comes to GHG non-compliance.

The Auto Alliance also stated that a classwide defect subject to recall can be exhibited only in "properly maintained and used" vehicles. Once again, EPA agrees with the Auto Alliance that a determination of non-compliance must be made based on "properly maintained and used" vehicles. The Auto Alliance further pointed out that in CAP 2000, EPA recognized that IUVP testing was intended to test vehicles without screening for proper maintenance and use, which leaves IUCP to provide information needed to make recall determinations. In this rulemaking, EPA proposed to set IUCP criteria based on the GHG in-use standards. While IUCP is not the only source of data that can be used for determining whether a substantial number of vehicles do not conform to the regulation, EPA agrees that is a useful process to gather such data. Again, EPA does not agree that there is any tension between the final rule and this longstanding principle.

Finally, the Auto Alliance stated that the only remedy for in-use noncompliance under CAA 207(c) is recall, which has two fundamental components: notice to vehicle owners, and performance of a remedy (adjustment or replacement of a part or assembly, or recalibration of powertrain or emissions controls). EPA does not see tension with the requirement to notify owners of a non-compliance issue. In fact, EPA sees the requirement to notify owners as an integral part of a remedy for a GHG non-compliance, and so such a requirement continues to exist in the regulations (albeit with certain modifications for practicality in the credit retirement context) regardless of the form of remedy. EPA believes that vehicle owners and the public in general have a right to know about such non-compliance. The regulations in 40 CFR part 85, subpart S, specify that the notice can be made by such means as approved by the Administrator, so the notification does not necessarily need to be in the form of a letter to each owner.

The Alliance stated that the only remedy for in-use noncompliance under CAA 207(c) is recall which, in the Alliance's view, fundamentally requires a repair to each vehicle. EPA disagrees that the language of CAA section 207(c) requires that a physical repair to each vehicle is the only form of a recall permissible to remedy a non-compliance under that section. The proposed credit-adjustment method would also remedy a GHG non-compliance for each vehicle involved. The Auto Alliance incorrectly asserted that the regulations in 40 CFR part 85, subpart S, require a "plan to remedy" the nonconformity which must contain the "description of the proper maintenance and use" on which the manufacturer proposes to condition "eligibility for repair." The regulation in 40 CFR part 85, subpart S, clearly states "[a] description of the proper maintenance or use, **if any**, upon which the manufacturer conditions eligibility for repair under the remedial plan" (emphasis added) and "[n]o maintenance or use condition may be imposed unless it is, in the judgement of the Administrator, demonstrably related to preventing the nonconformity." In other words, a manufacturer may condition the remedy based on proper maintenance or use but only when necessary, but is not obligated to place any such conditions on the remedy.

The Auto Alliance extensively cites *Center for Auto Safety v. Ruckelshaus*, 747 F.2d 1 (D.C. Cir. 1984), as support for its interpretation of the statute. While that case is relevant, it is not dispositive, and its reasoning is consistent with EPA's regulatory changes. The D.C. Circuit held that EPA could not approve a mandatory recall plan submitted by General Motors that, rather than remedying the nonconformities on the violating vehicles, would instead have required General Motors to over comply with the standard in the future to offset those nonconformities. First, the case is based on a simultaneous reading of the statute and EPA's regulations in place at the time ("the regulations…nowhere suggest that any remedy other than recall might be appropriate", *id.* at 5-6). Here, EPA is not attempting to agree to a novel remedy that does not comply with its own regulations; in fact, EPA is changing the regulations to allow for this remedy.

Second, EPA's interpretation that the statute allows for a remedy that does not explicitly require repair of the affected vehicles directly follows the logic of the case. "Absent evidence of contrary intent, the words in the statute must be presumed to bear their normal meaning of eliminating, rather than merely providing compensation for the effects of, the condition that is to be 'remedied.' Here that means eliminating the nonconformity of the . . . vehicles or engines." *Id.* at 4. And that is exactly what EPA's new regulations would do: eliminate the nonconformity of the specific violating vehicles, not other vehicles in the future. The "nonconformity" is that the vehicles do not comply with their in-use GHG standard, which means that the manufacturer of those vehicles earned more credits than they were due. EPA's remedy is to adjust the credit balances so that they reflect the actual GHG emissions of the vehicles the manufacturers are putting on the road.

It is true that the court's stated conclusion is written more broadly: that CAA section "207(c) requires recall and repair as the only statutory remedy for nonconformity." *Id.* at 6. However, the court reached that result under a different regulatory scheme and different facts. Again, the nature of the conformity here—vehicles not complying with their in-use GHG standard and thus erroneously earning more credits—is specifically addressed by the remedy of a credit balance adjustment. The remedy finalized today by EPA entirely "eliminate[s] the nonconformity of the [violating] vehicles or engines" and thus is consistent with both the statute and D.C. Circuit precedent.

If EPA's interpretations are challenged and a court rules that the Auto Alliance is correct that a vehicle repair is the only remedy for in-use nonconformity permitted by section 207(c)(1), that does not change EPA's authority or EPA's intention to use such authority to remedy GHG non-compliances. It would only change the remedy the manufacturer would need to implement. If under the Auto Alliance's interpretation, a manufacturer with substantial GHG in-use nonconformities is unable or unwilling to repair vehicles to bring them into compliance, then they may be required to buy the vehicles back and remove them from the fleet and/or pay civil penalties, as VW did as a result of the diesel consent decree. See Case No: MDL No. 2672 CRB (JSC) partial consent decree.

The Auto Alliance stated that the second issue with the proposed amendment to section 86.1865(j) is that it leaves open the possibility that an EPA "recall order" might not even take the reasonable approach suggested in its text: the credit-balance correction is offered only as an "example" of what EPA might require. In a strange turn, the Auto Alliance, who first stated that EPA does not have the authority to establish a GHG-emissions-credit-adjustment mechanism and the only possible remedy under section 207(c) is a recall with repair, is now concerned that EPA might actually "require" such a recall. They state that the open-ended deviation from the clear strictures of section 207(c)(1) should be removed. EPA disagrees with the comment. As stated in the proposal, EPA is simply making the intent of the 2010 rule clearer in the regulations. The 2010 rule stated, "The CAA requires a vehicle to comply with emission standards over its regulatory useful life and affords EPA broad authority for the implementation of this requirement. As such, EPA has authority to require a manufacturer to remedy any noncompliance issues. The remedy can range from adjusting a manufacturer's credit balance to the voluntary or mandatory recall of noncompliant vehicles." 75 FR 25324 and 25474 (May 7, 2010). As explained in the 2010 rule and in this rule, EPA anticipated the possibility that vehicles may exceed the GHG emissions standards when there is no obvious repairable cause of the exceedance. EPA explained that the Agency was not likely to pursue a recall unless there is a repairable cause of the exceedance. However, EPA anticipated scenarios where there may be repairable causes of exceedances, e.g., a defective oxygen sensor that causes a vehicle to burn excessive fuel. In such cases, EPA could pursue a recall. That said, EPA recall orders do not require a particular remedy, only that the manufacturer submit a plan. EPA has laid out two potential remedies that manufacturers could use to comply, depending on whether repair is appropriate.

The Auto Alliance also commented that the proposal did not adequately justify the decision to exclude a threshold such as the 1.3 factor used for criteria pollutants in combination with the 50% trigger for IUCP testing. EPA disagrees. EPA explained in detail the reasons why the 1.3 factor used for criteria pollutants was not adopted for GHG emissions. In any case, there is no statutory requirement to provide such a factor in setting the IUCP trigger. The Auto Alliance stated that is unclear whether the 50% trigger would apply on a subconfiguration basis for a model year, or across all subconfigurations that used the same carryover data. EPA disagrees; the proposal was clear that the 50% trigger applies to the vehicles tested within a test group. The Auto Alliance requested more time to comment. EPA does not agree that more time to comment is needed; indeed, the Alliance has sufficient time to submit very detailed comments on these issues. The Auto Alliance also stated that they assume that any recall based on IUCP testing would only apply to the subconfiguration and model year actually tested in the IUCP. This assumption will not always be correct. First, prior to beginning an IUCP, EPA may designate a subset of the test group for testing under this section in lieu of testing the entire test group under the proposed regulations in § 86.1846(j). EPA may designate a single subconfiguration if the data supports the decision to do so. Otherwise, the entire test group would be tested. Second, if a recall is needed, EPA determines the class or category of vehicles to be included in the recall. See § 85.1802. Generally, EPA works with the manufacturer to identify the root cause of the noncompliance and the affected vehicle population. The class or category of vehicles to be included in the recall is generally the population of vehicle affected by the cause of the failure. For example, if the cause of the non-compliance is a defective catalytic converter and that defective catalytic converter is used on multiple test groups over multiple model years, the affected vehicle population and therefore the class or category of vehicles to be included in the recall would be the vehicles which utilize the defective catalytic converter. The same principles would apply to a recall for a GHG non-compliance, so the category of vehicles to be included in the recall would not necessarily be limited to the subconfiguration and model year actually tested in the IUCP.

Stellantis commented that EPA should not carry forward into the final rule the proposed “clarifications” or revisions to the enforcement programs and in-use remedies based largely on the comments from the Auto Alliance. As stated above, EPA largely disagrees with the comments from the Auto Alliance and is finalizing many of the elements of the proposal as discussed above.

EPA agrees with the commenters that the changes to EPA’s regulations relating to compliance and enforcement of EPA’s GHG and criteria pollutant standards in this final rule are severable from the remainder of the rule, including the changes to GHG and criteria pollutant standards themselves. EPA has independently considered and adopted each of these portions of the final rule and each is severable should there be judicial review. If a court were to invalidate any one of these elements of the final rule, we intend the remainder of this action to remain effective, as we have designed the program to function sensibly and find each portion appropriate even if one or more other parts of the rule has been set aside. See Section IX.M of the preamble for further discussion of severability.

7.2 – Warranty

Comments by Organizations

Organization: Alliance for Automotive Innovation

3. Language Clarification on Emission Performance Warranty Section

Auto Innovators requests rewording of § 85.2107(e) and (f) in order to achieve more clarity on what this section is requiring. We recommend the following changes in § 85.2107(e):

(e) A warranty period of two years or 24,000 miles shall apply for light-duty vehicles, light-duty trucks, and medium-duty passenger vehicles, [EPA-HQ-OAR-2022-0829-0701, pp. 226-227]
(1) Except for the following specified major emission control components, which have a warranty period of eight years or 80,000 miles: [EPA-HQ-OAR-2022-0829-0701, pp. 226-227]

Additionally, for § 85.2103(f), we propose the following language:

(f) A warranty period of five years or 50,000 miles shall apply for medium-duty vehicles:
(1) Except for the major emission control components identified in paragraph (e)(1) of this section, which have a warranty period of eight years or 80,000 miles. [EPA-HQ-OAR-2022-0829-0701, pp. 226-227]

Finally, the language in § 85.2103(c)(2) should be clarified such that the warranty minimum performance requirements are at the discretion of the vehicle manufacturer. We propose the modification below:

(2) An electric vehicle or plug-in hybrid electric vehicle fails to meet the manufacturer-defined minimum performance requirement for useable bater energy for the specified period as determined by the vehicle's State of Health monitor, if applicable. [EPA-HQ-OAR-2022-0829-0701, pp. 226-227]

Lastly, § 85.2103(c) states,

"…of this section throughout the warranty period specified in §85.2108 at no cost to the owner if such nonconformity results or will result in the vehicle owner having to bear any penalty or other sanction (including the denial of the right to use the vehicle. [EPA-HQ-OAR-2022-0829-0701, pp. 226-227]

We believe that the reference of §85.2108 was an error. We recommend EPA revise the referred section to §85.2107. [EPA-HQ-OAR-2022-0829-0701, pp. 226-227]

EPA Summary and Response

The Auto Alliance suggested several changes to the regulatory text to achieve more clarity. EPA agrees with the recommended clarifications and has incorporated them into the regulations.

The Auto Alliance also suggested changing the proposed approach of basing the warranty period for battery-related issues on the Minimum Performance Requirement to instead allowing manufacturers to have the discretion to name their own warranty period. The proposed approach was to identify a failure to achieve the specified Minimum Performance Requirement as being covered by the performance warranty. We recognize that the performance warranty is appropriately associated with failing to meet emission standards and have therefore revised the warranty specifications related to battery durability to apply as a matter for the defect warranty. The defect warranty applies broadly for emission-related components, in most cases without any specification in the regulation to define what qualifies a component as being defective. Many times a defective part simply fails to function, but there are also many cases where a part becomes defective as a result of gradual or continuous aging. The final rule accordingly treats battery durability on the same basis as our approach for the defect warranty for other components, without defining an exact threshold for establishing a part as being defective. Market forces create a strong incentive for manufacturers to set a warranty threshold for battery durability that corresponds to what they need to do to conform to standards and requirements for certifying their vehicles. As such, we agree that manufacturers can use their declared values to identify when batteries become defective for purposes of applying warranty requirements.

The declared values apply as described above relative to State of Certified Energy. The warranty period in years is governed by statutory provisions as with all other components. We are therefore not changing the proposed warranty periods for battery durability.

7.3 – IUVP/IUCP/FEDV testing

Comments by Organizations

Organization: Alliance for Automotive Innovation

E. IUVP / FEDV Testing Requirements

1. Evaporative

a) Canister Base Load

As EPA states in this current NPRM, there are some potential issues that may arise when dealing with Non-Integrated Refueling Canister Only Systems (NIRCOS) fuel vapor handling designs.343 EPA goes on further to explain that NIRCOS systems initially release any tank vapors into the canister before the cap removal, and therefore the pressure must be released before the fuel cap is removed during refueling events. It was discovered that the ORVR test procedure does not account for the extra fuel vapor loading prior to the refueling event. As a result, we would like to request that EPA eliminate the requirement of refueling the base load of a canister for both IUVP and FEDV testing. [EPA-HQ-OAR-2022-0829-0701, pp. 230-231]

343 NPRM at 29275

Under the recent ACC II rulemaking by CARB, a design requirement was Specifically included within the regulation to address NIRCOS.344 The rule specifies an updated formula to calculate minimum canister size for vehicles with a NIRCOS fuel system of, as well as other vehicles that have fuel tank pressure exceeding a certain threshold. We therefore request that EPA harmonize with CARB as it pertains to IUVP and FEDV testing procedures, and to eliminate the requirement of refueling the base load of a canister for both IUVP and FEDV testing. [EPA-HQ-OAR-2022-0829-0701, pp. 230-231]

344 htps://ww2.arb.ca.gov/sites/default/files/2023-05/clean_acciifro_orvr_tps_2001%2Bfinal_2_24_23.pdf

b) Canister Load and Purge

Auto Innovators appreciates EPA's proposal to remove the canister loading and purging steps from the preconditioning for FEDVs to reduce butane consumption, time to run the tests, and ultimately the cost of running a test and improvement in fuel economy measurement accuracy. [EPA-HQ-OAR-2022-0829-0701, p. 231]

We request that EPA also remove the canister loading step from IUVP tailpipe emissions testing as an option while retaining canister loading for IUVP 2-Day evaporative and ORVR tests to demonstrate compliance. Due to a much larger number of IUVP test vehicles than FEDVs tested per year, an even more significant amount of butane consumption and time to run the tests could be reduced with this proposal. In addition, the canister loading process for IUVP vehicles is quite intrusive compared to a certification vehicle where quick disconnect lines can be pre- installed before or during vehicle build. Thus, the elimination of the canister loading step from IUVP tailpipe emissions also reduces cost from potential damage to customer vehicles due to accessing the canister. [EPA-HQ-OAR-2022-0829-0701, p. 231]

2. High Altitude IUVP

Additionally, in response to § 86.1845, we support eliminating the high-altitude testing for high mileage vehicles. Modern vehicles are all tuned to perform consistently and efficiently at all altitudes with appropriately set standards. Therefore, the need to conduct high altitude testing creates an undue and unnecessary burden on auto makers. [EPA-HQ-OAR-2022-0829-0701, pp. 231-232]

3. High Mileage IUVP

Likewise, we also request that EPA eliminate the testing of the full useful life of IUVP vehicles. It has become increasingly difficult to locate applicable high mileage vehicles with over 105k that can be used for IUVP testing. This creates another unnecessary burden and as a result, we respectfully request that this requirement be removed. [EPA-HQ-OAR-2022-0829-0701, pp. 231-232]

b) Technical Recommendations Concerning GHG IUVP / IUCP

In the event that EPA disagrees with the significant legal concerns set forth above, Auto Innovators offers the following technical comments on the GHG certification and IUVP / IUCP proposals in the NPRM. [EPA-HQ-OAR-2022-0829-0701, p. 246]

EPA requests comment on whether it should eliminate the 10% compliance factor adjustment for in-use CO2.401 The 10% compliance factor adjustment should not be eliminated. We agree with the agency's conclusion in the 2010 rulemaking that the factor accounts for test-to-test or production variability within a subconfiguration. [EPA-HQ-OAR-2022-0829-0701, p. 246]

401 NPRM at 29289.

We agree with the agency that reported CO2 values should be representative of a vehicle's performance over its useful life. However, the agency is suggesting a specific vehicle subconfiguration should be held to a "do not exceed" threshold established from model type average CO2 emissions. While aligned to criteria emissions requirements, we do not believe comparing an individual vehicle to an overall population average is appropriate for determining a pass/fail condition. By definition, a population average is a single value calculated using a population's individual values that are both higher and lower than the resultant average value. Therefore, comparing a single individual vehicle value to the population average could result in a violation simply because the specific subconfiguration procured for IUVP testing happens to fall above the population average by more than 10% by design. We don't believe that this indicates the model type average CO2 is unrepresentative, as sales weighting addresses these concerns. We simply believe that comparing an individual vehicle to a population average for the purposes of determining a violation would be inappropriate. For model types with high complexity, it is possible for the best to worst variant to have more than 10% CO2 difference. Even when the best and worst variants are tested, it is possible that the second-worst (untested for GHG) vehicle could fail the in-use model type average CO2 requirement even with normal/expected CO2 simply due to sales weighting. If model type average GHG includes an in- use "do not exceed" provision applicable to untested subconfiguration-specific GHG emissions with automatic IUCP escalation and GHG penalties, then the minimum data requirements and therefore overall stringency of the rule must be re-envisioned. We do not believe this is in the best interest of the industry, agency, or consumers. [EPA-HQ-OAR-2022-0829-0701, p. 246]

Further, EPA proposes two options to address their concern:

- Option 1: Maintain the 10% allowance on in-use CREE standards, and set IUCP threshold to be 50% or more of the vehicles for a test group exceed the in-use standard; or [EPA-HQ-OAR-2022-0829-0701, p. 247]

- Option 2: Set in-use standards at the vehicle-level emissions test results or model-type average value (for untested subconfigurations) and set IUCP threshold to be 50% of the test vehicles for the test group exceed the relevant in-use CO2 standard by at least 10%. [EPA-HQ-OAR-2022-0829-0701, p. 247]

Auto Innovators opposes the second of the two options, as it initially determines that any subconfiguration CO2 that exceeds original certification values is a failure. With perfect IUVP performance to certification levels, we would expect 50% of vehicles to exceed the original certification test simply due to test-to-test variation. Granted, most test groups would avoid IUCP given the threshold of 10% exceedance for 50% of the tested vehicles. However, it is not productive to have 50% of all initial tests be identified as failures. Rather, the IUVP program should be designed to find exceptions to expected performance. [EPA-HQ-OAR-2022-0829-0701, p. 247]

Instead, Auto Innovators supports the first of the two options that maintains the 10% allowance. We believe one enhancement is needed, though. Rather than subjecting an untested subconfiguration to a standard that is 110% of the model type CO2, we believe it would be more appropriate to compare the IUVP result of an untested subconfiguration to 110% of its theoretical performance generated using an analytically derived CO2 value (ADCO2). This would result in a more useful comparison of performance and would still be conservative since the ADCO2 method includes confidence factors intended to ensure ADCO2 results produce higher CO2 values than actual testing. This would also be more similar to the method used to assess tested subconfigurations. Also, we agree that the proposed 50% failure rate is a reasonable threshold for escalation to IUCP, and that EPA adjustments to a manufacturer's GHG credit balance to account for failures is one appropriate resolution given that OEMs likely could not resolve a difference via recall. Another option that should be available is for an OEM to take on an emissions-reducing project that offsets the shortfall. [EPA-HQ-OAR-2022-0829-0701, p. 247]

5. IUCP Trigger 40 CFR 1846-01(b)(1)

After careful review, Auto Innovators does not fully understand what EPA is proposing in this section. The language in the proposed NPRM is not clear if the mean is calculated for the entire test group or only for 50% + of vehicles. That would result in a change in the criteria if one were to exclude up to 50% of vehicles that did not exceed the standard. It is also unclear how OEMs are to pick which vehicles are included in the 50%. As a result, we propose the following language changes: [EPA-HQ-OAR-2022-0829-0701, pp. 247-248]

"…show mean exhaust emissions of any criteria pollutant for that test group to be at or above 1.30 times the applicable in-use [Strikethrough: standard for at least 50 percent of vehicles tested from the test group] [In red: when for at least 50 percent of vehicles tested from the test group exceed that standard]."402 [EPA-HQ-OAR-2022-0829-0701, pp. 247-248]

402 NPRM at 29433.

Organization: BMW of North America, LLC (BMW NA)

EPA has proposed to clarify and update the existing provisions related to in-use CO2 compliance to better meet the intention of the 2010 light-duty vehicle GHG rule and has proposed two regulatory options to align with that intent: [EPA-HQ-OAR-2022-0829-0677, pp. 4-5]

- Option 1: Maintain the 10% allowance on in-use CREE standards, and set IUCP threshold to be 50% or more of the vehicles for a test group exceed the in-use standard; or [EPA-HQ-OAR-2022-0829-0677, pp. 4-5]

- Option 2: Set in-use standards at the vehicle-level emissions test results or model-type average value (for untested subconfigurations) and set IUCP threshold to be 50% of the test vehicles for the test group exceed the relevant in-use CO2 standard by at least 10%.[EPA-HQ-OAR-2022-0829-0677, pp. 4-5]

For both above options, EPA proposes to clarify the regulation such that EPA has the authority to correct a manufacturer's GHG credit balance based on CO2 in-use test results that are consistently higher than the reported CO2 values in the fleet average report. [EPA-HQ-OAR-2022-0829-0677, pp. 4-5]

BMW NA understands and supports EPA in its proposal to align with the intent of the 2010 light duty GHG rule and is in favor of the "Option 1" approach listed above. Implementation of "Option 2" would lead to a high percentage of failure notifications reported to the agency even in a scenario where the average in-use test result is exactly in line with the reported CO2 value as some results are expected to be slightly higher and slightly lower. [EPA-HQ-OAR-2022-0829-0677, pp. 4-5]

Furthermore, BMW NA does not agree that the goal of EPA's proposal should be to maintain consistency between the GHG ABT program and other ABT programs. As EPA states in its proposal, Family Emission Limits (FEL) are determined such that manufacturers can establish a compliance margin to certify to a specific bin limit for criteria pollutant standards, but CO2 values for fleet average GHG are calculated on a model type basis and not a bin level and the intent is to determine an accurate CO2 value on a model type granularity. [EPA-HQ-OAR-2022-0829-0677, p. 5]

As stated above, BMW NA supports "Option 1" but also requests that EPA updates the proposal to clarify what is meant by "consistently higher" results with respect to GHG balance correction. BMW NA agrees that a 10% allowance to establish an in-use CREE standard is required to account for vehicle variation within a sub-configuration and test-to-test variability and that a 50% failure of the CREE standard is a reasonable condition to initiate an IUCP. This criteria is also reasonable to determine "consistently higher" CO2 in-use results and, therefore, correction of GHG credit balance should be tied to IUCP criteria and not broadly defined by non-descriptive language. By failing to define criteria for "consistently higher" CO2, EPA creates potential for GHG credit balance correction because of random vehicle selection with a high percentage of customer vehicles which may be worse than the reported CO2 but not exceeding the failure threshold. [EPA-HQ-OAR-2022-0829-0677, p. 5]

Organization: Environmental. and Public Health Organizations

B. EPA should eliminate the 10-percent compliance factor adjustment.

While EPA’s proposed clarifications will help ensure that its regulations better reflect in-use emissions performance, they also illustrate that the current in-use compliance margin is far too high. For EPA to detect systematic deviations in in-use emissions compared to certification, a manufacturer would have to be assured that variability is low enough that its vehicles would not emit above the 10% thresholds, despite certifying to an artificially low emissions level. This inherently means that the test-to-test variability and production variability within a subconfiguration or model type for which the 10% is supposed to account225 is actually much less than 10%.[EPA-HQ-OAR-2022-0829-0759, p. 93]

225 88 Fed. Reg. at 29288-9.

A 10% margin for error in in-use testing is quite high, particularly when considered in the context of the levels of improvement required under the standards: the average 2-cycle tailpipe certification value for a passenger car has decreased by just 19% from 2012-2021 and, for light trucks, just 18%. To put the 10% margin in perspective, take the example of the breadth of configurations of the Ford F-150: it is available in 3 body types, in rear- or four-wheel-drive, in trucks that vary in curb weight by 1600 pounds, with six different engines (including a hybrid), and additional high-payload and high-towing packages. And yet, the certified emissions levels from this vehicle span just 40%. The necessity of a 10% margin for a narrow slice of that spectrum (for one drivetrain, one engine, and one payload package) is implausibly high. [EPA-HQ-OAR-2022-0829-0759, p. 93]

We support EPA eliminating the 10% in-use compliance allowance as part of this rule.226 It is particularly relevant when considering EPA’s clarifications around manufacturers’ voluntary adjustments to certification, which would eliminate the need for such allowance. Shifting to a threshold for which additional testing is required supports the original intent of the allowance (to recognize testing variability) without undermining in-use emissions from vehicles regulated under the light-duty GHG program. [EPA-HQ-OAR-2022-0829-0759, p. 93]

HMG offers several suggested modifications to the Proposed Rule's in-use requirements [EPA-HQ-OAR-2022-0829-0554, p. 8]

HMG agrees with the AFAI comments regarding proposed in-use requirements. Furthermore, HMG provides additional input focusing on modifications to the Proposed Rule that will increase the feasibility and cost-effectiveness of compliance without negating the Proposed Rule' s sought-after environmental benefits. [EPA-HQ-OAR-2022-0829-0554, p. 8]

First, HMG proposes that EPA lower the 20% response rate requirement outlined in 40 CFR Appendix-I to-Subpart-S-of-Part-86 II. By reducing this requirement, testing can commence earlier, reducing mailing burdens and the consumption of ink and paper. We believe this change would contribute to a more streamlined and efficient compliance process. [EPA-HQ-OAR-2022-0829-0554, p. 8]

Second, HMG draws EPA' s attention to 40 CFR 86.1845-04(c)(2). EPA should consider reducing the mileage requirements for useful life vehicles. Finding adequate vehicles for testing with mileage of 105,000 or higher poses challenges, and adjusting this requirement would help ensure a more practical, realistic, efficient, and cost-effective testing process. [EPA-HQ-OAR-2022-0829-0554, p. 8]

Organization: Kia Corporation

Kia Supports Keeping the 10 Percent In-Use Standard Variability

Kia does not support the Agency's proposal to eliminate the 10-percent compliance factor adjustment for the in-use standard. EPA explains that there is an expectation that in-use vehicles should be designed to perform consistent with the values used to calculate the year end fleet average.25 Keeping this 10-percent variability, a standard that has been allowed for the last decade, is critical as EPA increases the stringency of criteria pollutants and GHG emissions 10-fold. EPA must allow automakers to focus resources on the full transformation to electric vehicles – an expensive and monumental task, not on incremental changes. Further, Kia urges EPA to consider removing the high-altitude requirement from in-use testing or allow a low sales volume threshold as an alternative.26 [EPA-HQ-OAR-2022-0829-0555, p. 15]

Testing Standards (Section III.C.5.iv)

Volkswagen supports the AFAI comments regarding the removal of carbon canister preconditioning and the second fuel drain/refill procedure for FEDVs. [EPA-HQ-OAR-2022-0829-0669, pp. 10-11]

Volkswagen would like to request, based on good engineering judgement, the optional removal of the 6-hour minimum duration between first fuel drain and fill and starting the fuel economy tests. Volkswagen cannot determine a historical reference for the 6-hour minimum between the first drain/fill and the start of the FE test. Volkswagen can theorize on certain evaporative effects that could be mitigated by the 6-hour soak, however, dyno road load adjustment is already completed and the 12-36 hour regular soak time exists to ensure the vehicle temperatures are thermally stable. Proposing this as optional removal, EPA has the option to confirm test results using the 6-hour minimum soak time. [EPA-HQ-OAR-2022-0829-0669, pp. 10-11]

SEE ORIGINAL COMMENT FOR Figure 1 of Section 1066.801-FTP test sequence [EPA-HQ-OAR-2022-0829-0669, pp. 10-11]

EPA Summary and Response

The Alliance for Automotive Innovation commented to EPA's concern that there are some potential issues that may arise when dealing with Non-Integrated Refueling Canister Only Systems (NIRCOS) fuel vapor handling designs with regard to fuel vapors which are released into the canister before the cap removal. The Auto Alliance also pointed out that CARB implemented a design requirement under the recent ACC II rulemaking to address NIRCOS. They requested that EPA harmonize with CARB as it pertains to IUVP and FEDV testing procedures, and to eliminate the requirement of refueling the base load of a canister for both IUVP and FEDV testing. We address amendments related to puff losses in Section 7.4 of the responses to comments; there is no need to make any corresponding changes to measurement procedures for IUVP or FEDV testing.

The Auto Alliance also requested EPA remove the canister loading step from IUVP tailpipe emissions testing as an option while retaining canister loading for IUVP 2-Day evaporative and ORVR tests to demonstrate compliance. They pointed out that there is a much larger number of IUVP test vehicles than FEDVs tested per year and the canister loading process for IUVP vehicles is quite intrusive. These requests are beyond the scope of the rulemaking as EPA did not propose or otherwise reopen the issue of eliminating the canister loading step for the EDVs or IUVP test vehicles in this rule. These requests can be considered in the future. However, EPA notes at this time that the primary purpose of IUVP testing is to confirm emissions compliance of in-use vehicles, so these tests should be conducted in the same manner as the emissions data vehicles (EDV).

The Auto Alliance also requested EPA eliminate the high-altitude testing for high mileage vehicles and eliminate the testing of the full useful life of IUVP vehicles (EPA understands this request to refer to the requirement to test one vehicle of each test group at the odometer mileage of 105,000 miles or 75 percent of the full useful life mileage, whichever is less). These requests are beyond the scope of the rulemaking as EPA did not propose or otherwise reopen the issue of eliminating the high-altitude testing requirement for high mileage vehicles or eliminating the testing of one vehicle of each test group at 75 percent of the full useful life during IUVP. These requests can be considered in the future.

Volkswagen commented that they support the AFAI comments regarding the removal of carbon canister preconditioning and the second fuel drain/refill procedure for FEDVs.

Volkswagen also requested that, based on good engineering judgment, the option to remove the 6-hour minimum duration between first fuel drain and fill and starting the fuel economy tests. This request is beyond the scope of the rulemaking as EPA did not propose or otherwise reopen the issue of eliminating the 6-hour minimum duration between first fuel drain and fill and starting the fuel economy tests. These requests can be considered in the future.

EPA requested comment on whether it should maintain the 10% allowance on in-use CREE standards, and set IUCP threshold to be 50% or more of the vehicles for a test group that exceed the in-use standard (option 1); or set in-use standards at the vehicle-level emissions test results (eliminating the 10% allowance on the in-use standard) or model-type average value (for untested subconfigurations) and set IUCP threshold to be 50% of the test vehicles for the test group that exceed the relevant in-use CO2 standard by at least 10% (option 2).

Environmental. and Public Health Organizations commented that they support eliminating the 10% in-use compliance allowance.

The Auto Alliance stated that they agree with the agency that reported CO2 values should be representative of a vehicle's performance over its useful life however they oppose the second of the two options. They expect under this option 50% of vehicles to exceed the original certification test simply due to test-to-test variation. They acknowledge that most test groups would avoid IUCP given the threshold of 10% exceedance for 50% of the tested vehicles. EPA does not agree with the Auto Alliance's conclusion that 50% of vehicles would necessarily be identified as failures because the Auto Alliance failed to consider EPA's proposal to allow manufacturers to establish a compliance margin by voluntarily raising the GHG values submitted in the GHG report much like they do when they set a Family Emissions Limit (FEL) for other fleet average emissions standards.

BMW NA commented that implementation of "Option 2" would lead to a high percentage of failure notifications reported to the agency even in a scenario where the average in-use test result is exactly in line with the reported CO2 value as some results are expected to be slightly higher and slightly lower. They also stated that BMW NA does not agree that the goal of EPA's proposal should be to maintain consistency between the GHG ABT program and other ABT programs. They pointed out that CO2 values for fleet average GHG are calculated on a model type basis and not a bin level and the intent is to determine an accurate CO2 value on a model type granularity. EPA does not agree that "Option 2" would necessarily lead to a high percentage of failure notifications reported to the agency because EPA's proposal would allow manufacturers to establish a compliance margin by voluntarily raising the GHG values submitted in the GHG report. EPA does not agree that the additional compliance margin would be less granular than a model type. In fact, manufacturers would have the opportunity to make the compliance margin much more granular than a model type level under EPA's proposal. EPA did not propose to establish bin levels for the GHG in-use standard. EPA proposed allowing manufacturers to set additional compliance margin at the subconfiguration level.

Kia commented that keeping the 10-percent in-use standard is critical as EPA increases the stringency of criteria pollutants and GHG emissions 10-fold.

EPA is not finalizing option 2. If EPA determines that manufacturers are exploiting the 10% allowance for the in-use standard to design and produce vehicles which consistently emit up to 10% more CO2 that accounted for in the fleet average calculations, EPA may revisit this option in the future.

The Alliance for Automotive Innovation commented that they support the first of the two options that maintains the 10% allowance. However, they state that they believe an enhancement is needed to compare the IUVP result of an untested subconfiguration to 110% of its theoretical performance generated using an analytically derived CO2 value (ADCO2) rather than the 110% of the model type CO2.

The Alliance's proposed enhancement was not considered during this proposal. The basis for the in-use standard for untested subconfigurations as being 110% of the model type CO2 was specified in the 2010 rule. EPA did not propose to change the basis for the 10% margin in this rule, only whether it should be applied to the in-use standard or the IUCP criteria. In the 2010 rule, the 10% margin was established in part to account for the variability within a model type. The Alliance's proposal could have been a viable alternative, however since the variability within a model type would essentially be removed and only the test-to-test variability would remain, the 10% margin would have needed reevaluation. At this point, if the process allowed the use of ADCO2 to establish the in-use standard for untested subconfigurations with the 10% margin applied, the result would be effectively to raise the in-use standard for those vehicles.

BMW NA commented that they understand and support EPA in its proposal to align with the intent of the 2010 light-duty GHG rule and are in favor of the "Option 1." However, they requested that EPA update the proposal to clarify what is meant by "consistently higher" results with respect to GHG balance correction.

EPA is finalizing option 1 and has clarified that by "consistently higher" results, EPA meant that a substantial number of vehicles in a class or category of vehicles fail to comply with the in-use GHG standards.

Hyundai America Technical Center, Inc. (HATCI) proposed that EPA lower the 20% response rate requirement outlined in Appendix I to Subpart S of 40 CFR part 86 and reduce the mileage requirements for useful life vehicles. This request is beyond the scope of the rulemaking as EPA did not propose or otherwise reopen this issue. These requests can be considered in the future.

7.4 – Puff losses

J. Evaporative Standards

1. NIRCOS System Design

EPA requests comment on the need to establish engineering design requirements on NIRCOS evaporative systems in place of modifying ORVR test procedures, to ensure that initial pressurized vapor loads are captured while leaving sufficient capacity to handle refueling vapors.290 Auto Innovators supports aligning with the CARB design-based requirement if EPA decides to act in this area. We also recommend against modifying the ORVR test procedure at this time. [EPA-HQ-OAR-2022-0829-0701, pp. 187-188]

290 NPRM at 29275.

Organization: California Air Resources Board (CARB) (Part 1 of 5)

As described further below, CARB recommends that U.S. EPA adopt elements of CARB's evaporative emission standards program. [EPA-HQ-OAR-2022-0829-0780, p. 27]

Evaporative Emission Standards

U.S. EPA has rightly recognized opportunities to achieve reductions from conventional vehicle evaporative emissions. Evaporative emissions, which result from fuel vapors escaping from the vehicle rather than tailpipe emissions from engine combustion, consist primarily of hydrocarbons that contribute to the formation of ozone and contain benzene, a toxic air contaminant. CARB supports U.S. EPA's efforts to adopt more stringent evaporative emission standards and recommends U.S. EPA adopt the following recommendations as it finalizes its proposal. [EPA-HQ-OAR-2022-0829-0780, p. 35]

Minimum Canister Size Requirement

U.S. EPA requested comment on the need for an engineering requirement for canister working capacity for vehicles with Non-Integrated Refueling Canister Only Systems (NIRCOS). California adopted this type of requirement in ACC II to compensate for a small shortcoming in the onboard refueling vapor recovery (ORVR) test procedure, which does not account for the extra fuel vapor loading that can occur with NIRCOS-equipped vehicles prior to the refueling event. CARB estimated that its canister size requirement will likely impact only about 6 percent of new vehicles, primarily PHEVs, and many of those already have canisters of sufficient capacity. 47 CARB expects manufacturers to readily be able to meet these minimum design requirements because all vehicles with combustion engines already have a canister and moderately increasing the size or capacity of this canister requires only minor modifications to existing designs. Rather than revising the ORVR test procedure, which would be a lengthy and complex process, establishing an engineering requirement for canister working capacity is a feasible, cost-effective approach to address the minor shortcoming in the ORVR test procedure. CARB therefore recommends that U.S. EPA adopt CARB's minimum canister size requirement. [EPA-HQ-OAR-2022-0829-0780, p. 36]

Estimate of percentage of new vehicles sold in the California which have a Non-Integrated Refueling Canister Only System (NIRCOS), CARB 2022www. August 2022. https://ww2.arb.ca.gov/sites/default/files/barcu/regact/2022/accii/2nd15daynotice.pdf.

Organization: Glenn Passavant

Based on the regulatory language in 40 CFR §86 Subpart B, puff loss control has been required for all gasoline-powered LDVs, LDTs, MDPVs, and HDVs with operating fuel tank pressures equal to or greater than 2.5 kPa since the end of the allowed phase-in period (i.e., the 1999 model year). The value of puff loss control is expressed by the grams HC/gallon of fuel system void volume emitted to the atmosphere as shown in the Ingevity presentation to EPA on July 24, 2023 and in the Ingevity written comments. What may not be clear is that these grams of HC are basically uncontrolled fuel tank headspace emissions. While these are mostly isomers of butane and pentane, they also contain benzene compounds which would be considered air toxics and many other HC compounds which are highly photochemically reactive in the creation of ozone according to its Carter Maximum Incremental Reactivity (MIR) value (see attached). These other compounds often are more reactive than the butanes and pentanes which remain for vehicles meeting Tier 3 evaporative and ORVR requirements. [EPA-HQ-OAR-2022-0829-1136, p. 1]

To illustrate the point, I have attached two different EPA reports which provide HC speciation data for a fuel tank headspace. The reports both use the same title “Hydrocarbon Composition of Gasoline Vapor Emissions from Enclosed Fuel Tanks,” (EPA-420-D-10-001, January 2010 and EPA-420-R- 11-018, December 2011), but the data is different in each report and the HC speciation data from both reports is useful. The speciation profiles show the fraction of the various HC compounds in the headspace for the fuels analyzed (E0, E10, E15) and consideration of these individual HC speciation values shows the value of puff loss control in reducing air toxics and photochemically reactive HC based on the MIR values for the various HC compounds. [EPA-HQ-OAR-2022-0829-1136, p. 1]

Organization: Ingevity Corporation

3. The need for an engineering requirement related to the canister working capacity of Non-Integrated Refueling Canister Only Systems (NIRCOS) for management of fuel vapors from fuel cap removal and refueling (also commonly referred to as puff losses) [EPA-HQ-OAR-2022-0829-0545, pp. 5-9]

On page 29275 of the NPRM, EPA discussed the issue of the impact of cap removal emissions on NIRCOS canister capacity and asked for comment on “the need for an engineering requirement related to the canister working capacity that would provide an increase in the capacity in order to properly capture this initial pressurized vapor load and still have the needed capacity to handle the vapors generated during the refueling event.” Generally, Ingevity supports the need for a requirement to help ensure that ORVR canisters have the capacity to handle a refueling emission load immediately after the canister has absorbed a puff loss load just prior to fuel cap removal8. [EPA-HQ-OAR-2022-0829-0545, pp. 5-9]

8 Note that section 202(k) of the Clean Air Act calls for evaporative emission standards to provide the “greatest degree of emission reduction achievable” The mass values for puff losses discussed in this section are not insignificant.

While the NPRM presents puff loss control as a new issue, the first steps in the consideration of the control of puff losses date back to prior to the 1990 amendments to the Clean Air Act. EPA Identified cap removal emissions (also referred to as “puff losses”) as an issue in the mid-1980s, estimating a value in the range of 3-5 grams per refueling based on the fuel RVP, EPA evaporative emission test procedures, and the low fuel tank pressures at that time.9 EPA proposed a specific test procedure in the Enhanced Evaporative NPRM in Jan 1990.10 The March 1993 EPA Enhanced Evaporative Emissions final rule deferred action on puff loss control, but included language similar to that adopted by the California Air Resources Board (CARB) in 1990 which read: “Fuel tank pressure during the running loss test may not exceed 10 inches of water (2.5 kPa), unless manufacturer shows that fuel vapors, other than refueling emissions, are vented to the evaporative canister when the fuel cap is removed.”11 There were no concrete provisions in terms of specific test procedures or standards to assess effectiveness of implementation of this requirement. A follow-on specific proposal and workshop was promised to address pressurized systems. EPA proposed a specific test requirement for cap removal emission (puff losses) in a May 1993 ORVR Supplemental NPRM.12 This would have involved cap removal after the ORVR preconditioning drive but before refueling test. This was not finalized, but action was promised as part of the workshop discussed in the Enhanced Evaporative rule mentioned above. It seems that successful rollout of Enhanced Evaporative and ORVR programs was more important at the time, and pressurized tanks were disappearing -- so future work on puff loss did not occur. The issue once again became important in the 2010 and later timeframe as some HEVs and PHEVs began to use sealed fuel systems (with higher fuel tank operating pressures) to help manage evaporative emissions generation in the fuel tank. [EPA-HQ-OAR-2022-0829-0545, pp. 5-9]

9 EPA memorandum: “Significance of 'Popping and Hissing' Emissions from an LDV Gasoline Tank, “Daniel P. Heiser, April 1984. public docket A-84-07, item I-B-19.

10 US EPA, Proposed Rule, “Control of Air Pollution From New Motor Vehicles and New Motor Vehicle Engines: Evaporative Emission Regulations for Gasoline and Methanol-Fueled Light-Duty Vehicles, Light-Duty Trucks, and Heavy-Duty Vehicles,” 55 FR 1913, January 19, 1990.

11 US EPA, Final Rule, “Control of Air Pollution From New Motor Vehicles and New Motor Vehicle Engines: Evaporative Emission Regulations for Gasoline and Methanol-Fueled Light-Duty Vehicles, Light-Duty Trucks, and Heavy-Duty Vehicles,” 58 FR 16001, March 24, 1993.

12 US EPA, “Control of Air Pollution From New Motor Vehicles and New Motor Vehicle Engines; Refueling Emission Regulations for Light-Duty Vehicles and Trucks and Heavy-Duty Vehicles,” Supplemental Proposal. NPRM, 58 FR 30731, May 27, 1993.

Regarding puff losses, Ingevity notes the following issues:

First, EPA is seeking comment on puff loss control for NIRCOS which use sealed fuel systems (nominally >####18.6 kPa absolute), even though the provision for puff loss control by venting to the canister dates back to the EPA’s enhanced evaporative rule in 1993. This calls for control if the tank pressure equals or exceeds 2.5kPa.13 We recommend that in the final rule the threshold for applicability needs to be set at tank pressure >#### 2.5 kPa gauge even if the fuel system design is not a NIRCOS. [EPA-HQ-OAR-2022-0829-0545, pp. 5-9]

13 The current CARB regulations at III. D. 8.1.10 or 8.2.5 within California Evaporative Emission Standards and Test Procedures for 2026 and Subsequent Model Year Passenger Cars, Light-Duty Trucks, Medium-Duty Vehicles, and Heavy-Duty Vehicles reads as follows “Manufacturer shall demonstrate in a separate test or an engineering evaluation that vapor would not be vented to the atmosphere if the fuel fill pipe cap was removed at the end of the test.”

There is a second issue related to a lack of a provision which specifies how to demonstrate that puff losses are in fact fully vented to the canister and not even in part to the atmosphere. These provisions should require that the manufacturer demonstrate that puff loss emissions are completely and fully vented to the canister when the fuel cap is removed and that the canister has capacity to control a puff loss and emissions from a refueling event from 10-100%. Such provisions were never adopted. [EPA-HQ-OAR-2022-0829-0545, pp. 5-9]

The third issue relates to a useful quantification of the puff loss mass if uncontrolled. There is modeling and measurement data available. With regard to modeling, we would refer EPA to work conducted by Sam Reddy. He developed the equation below regarding evaporative and refueling controls.14 Varying the parameters in the equation using values expected in use, the puff loss mass values in grams range from 3.3 to 23 grams at low altitude to 3.4 to 24.9 grams at high altitude. See attached graphic plots for low and high altitude for a full display of sensitivities. Note that the biggest sensitivities are to tank Δp, fuel temperature, tank volume, and tank fill fraction. [EPA-HQ-OAR-2022-0829-0545, pp. 5-9]

14 “Evaporative and Refueling Emission Control Training/Workshop Manual,” Sam R. Reddy, Ph.D., P.E. Evap Consulting, Inc, Version 8, November 2013.

Sam Reddy Equation: grams HC cap removal = ((Tv+U-F) *(Pt/Pa)-(TV+U-F)) *(Pt/Pa)*(ER); where

ER = [(vapor MW)(25.61)(Tt)(RVP)/(0.3187)(Tt)][exp(-2798.78/Tt)]

Tv = tank capacity (gallons) U = tank ullage (gallons)

F = tank fill fraction at cap removal

Pt = tank pressure (psi); based on tank pressure at cap removal; calculated as Pa + tank ΔP, Pa = atmospheric pressure (psi)

ER=emission rate (g/gal)

MW = vapor molecular weight for certification fuel at tank fuel temperature (Tt) prior to cap removal (g/mole)

Tt = fuel temperature in tank (K)

RVP = tank fuel vapor RVP for certification fuel (psi) [EPA-HQ-OAR-2022-0829-0545, pp. 5-9]

Vehicle measurements conducted in Japan in 2019 and 2020 show puff loss values at the lower end of the ranges presented in the attached graphics for the vehicle, temperatures and fuels evaluated in these experiments.15 This testing involved only one vehicle over several seasons with varying fuels but did not fully assess the impact of variations in the key parameters identified in the Reddy equation. [EPA-HQ-OAR-2022-0829-0545, pp. 5-9]

15 Hataa, Hiro, et al, “Evaluation of Gasoline Evaporative Emissions from Fuel-Cap Removal after a Real-World Driving Event,” Atmosphere, 2020, 11, 1110.

Control of puff loss emissions:

Generally, there are two means to address control of puff loss emissions. Each has advantages and disadvantages. [EPA-HQ-OAR-2022-0829-0545, pp. 5-9]

First, since puff loss emissions are normally associated with a refueling event (the fuel cap is most commonly opened prior to refueling), it would be ideal to assess the performance of a puff loss control system in a SHED as part of a refueling emissions test. Under this approach, any puff loss emissions not captured in the canister would be captured in the SHED and a lack of capacity in the canister could result in a higher level of refueling emissions in the SHED measurement. This approach would inherently address the need for a provision which specifies how to demonstrate that puff losses are controlled that has been lacking since 1996. However, there are two complications with this approach, both related to the current U.S. EPA test procedure. The first is that the procedures for traditional fuel system vehicles and NIRCOS would need to be revised to require removal of the fuel cap after the SHED door is closed and initial HC readings in the SHED are taken. This is doable as it is now required in the China 6 refueling test procedure for NIRCOS. The second complication is that the mass of puff loss emissions anticipated in the current refueling emission test procedure is small. The current U.S. EPA test procedure calls for a drain and 10% fill after the vehicle preconditioning drive followed by a vehicle soak at 80°F for 6-24 hours. Under these conditions only a small amount of puff loss would be expected since the tank Δp would be small.16 This shortcoming could be addressed by modifications to the refueling test procedure. However, it is recognized this approach would involve significant perturbations to otherwise stable and well-established test procedures with potential requirements for vehicle recertification. [EPA-HQ-OAR-2022-0829-0545, pp. 5-9]

16 US EPA memorandum, “Cap Removal Emissions,” Gary Holladay, November 22,1985 public docket A-84-07, item I-A-97.

Second, is an engineering evaluation approach designed to determine if a canister would have the capacity to control a puff loss and a refueling emission load. CARB recently adopted such an approach in their ACC II final rule based on the equation presented at paragraph D.14 of those test procedures.17 This takes effect for the 2026 MY. [EPA-HQ-OAR-2022-0829-0545, pp. 5-9]

17 California Evaporative Emission Standards and Test Procedures for 2026 and Subsequent Model Year Passenger Cars, Light-duty Trucks, Medium-duty Vehicles and Heavy-duty Vehicles., August 25, 2022.

The equation adopted by CARB is:

Minimum Canister nominal working capacity (grams) =

1.08 x 1.3 x [5.8 x 14.7/Ptvs x ((Ptvs x Vtvs)/14.7 - Vtvs) + Grefuel x 0.88 x Vfuelcap] [EPA-HQ-OAR-2022-0829-0545, pp. 5-9]

Where:

Nominal working capacity is as defined in section III.D.3.3.4 of the CARB evaporative emission regulation [EPA-HQ-OAR-2022-0829-0545, pp. 5-9]

Vtvs is vapor space volume. This is 90% of the total geometric volume of the fuel tank. Geometric volume is the sum of the fuel tank capacity and vapor space (gallons). [EPA-HQ-OAR-2022-0829-0545, pp. 5-9]

Vfuelcap is the nominal fuel tank capacity, which means the volume of the fuel tank(s), specified by the manufacturer to the nearest tenth of a U.S. gallon, which may be filled with fuel from the fuel tank filler inlet (gallons). [EPA-HQ-OAR-2022-0829-0545, pp. 5-9]

Grefuel is the vapor generation during refueling (grams/gallon); use 5 grams/gallon as default. [EPA-HQ-OAR-2022-0829-0545, pp. 5-9]

Ptvs is fuel tank’s maximum pressure in-use (absolute pressure in psi) 19 psia is the default pressure to use for Ptvs. [EPA-HQ-OAR-2022-0829-0545, pp. 5-9]

If EPA is to consider using this equation, we recommend two changes. First, the 0.88 value should be 0.90. That is the nominal fill from 10%-100% in a refueling to automatic shut-off as occurs in the EPA refueling emission test. Second, we believe that the definition for Vtvs adopted by CARB (shown above) underestimates the volume which could hold vapor which would be vented upon cap removal. It seems not to include all of the open fuel tank volume, all of the ullage, the volume of the fill pipe, and any vapor lines of the evaporative control system which may contain vapor when the tank is 10% full. [EPA-HQ-OAR-2022-0829-0545, pp. 5-9]

Specifically, in addition to the change of the 0.88 in CARBs equation to 0.90 we recommend that the definition of Vtvs be revised to read:

Vtvs is vapor space volume. This is 90% of the total geometric volume of the fuel tank, 100% of the tank ullage and 100% of the volume of the fill pipe, the fill pipe external vent line, and any other vent lines between the tank outlet and the canister or the tank outlet and the tank pressure control valve located between the fuel tank and canister. These volumes are to be determined and reported by the manufacturer as part of certification. As a simplification, EPA could offer a default value of 7 percent of Vfuelcap to add to the Vtvs value in the equation. [EPA-HQ-OAR-2022-0829-0545, pp. 5-9]

With these two changes and assuming the use of the 7 percent adjustment the revised equation would read:

Minimum Canister nominal working capacity (grams) =

1.08 x 1.3 x [5.8 x 14.7/Ptvs x ((Ptvs x 1.07 x Vfuelcap)/14.7 – 1.07 x Vfuelcap) + Grefuel x 0.90 x Vfuelcap] [EPA-HQ-OAR-2022-0829-0545, pp. 5-9]

We recommend that the final regulations specify that compliance with this minimum requirement be demonstrated using the tests prescribed at 40 CFR §86.132-96 (h)(1)(iv)(A)-(B). That is, the canister's nominal working capacity measured using those tests must exceed the minimum calculated using the equation for it to be considered as compliant with the requirement. [EPA-HQ-OAR-2022-0829-0545, pp. 5-9]

Finally, if EPA adopts control for puff losses, the regulatory text needs to address the scope of applicability (vehicle classes and fuels), the MY of applicability, and reporting requirements for certification. We recommend that the scope of applicability be the same as for all current evaporative/refueling emission standards after this final rule is promulgated. While the engineering evaluation approach would be more of a design standard than an emission standard, it would be reasonable to provide 3-4 MYs lead time since the use of canister models (of varying designs and capacities) across vehicle models in the various vehicle classes is common practice. Finally, as part of the information required for certification, the regulations should specify that the certifying manufacturer provide data on all of the values used in calculating the minimum canister capacity for each evaporative/refueling family. [EPA-HQ-OAR-2022-0829-0545, pp. 5-9]

Organization: MECA Clean Mobility

EPA should consider adopting additional requirements for SI vehicles with pressurized fuel systems for management of fuel vapors from fuel cap removal and refueling (also commonly referred to as puff losses). [EPA-HQ-OAR-2022-0829-0564, pp. 12-24]

With respect to Non-Integrated Refueling Canister Only Systems (NIRCOS), or any vehicle with a fuel tank pressure exceeding 2.5 kPa, MECA agrees with the EPA objective to continue to reduce evaporative emissions through adding a requirement designed to control for the release of fuel vapors from fuel cap removal and refueling (also commonly referred to as puff losses). We believe that the most effective way to control puff loss emissions is to set a performance-based test procedure to include the measurement of both "puff" and re-fueling emissions to ensure that the canister capacity is sufficient and that the entire system operates effectively under elevated ambient temperatures. Since puff loss emissions are normally associated with a refueling event (the fuel cap is most commonly opened prior to refueling), it would be ideal to assess the performance of a puff loss control system in a SHED as part of a refueling emissions test. A testing procedure approach has been used by EPA for all other evaporative emission standards going back to the 1970 model year. In addition, standards based on test procedures are more readily enforceable in-use over a certified vehicle's useful life. [EPA-HQ-OAR-2022-0829-0564, pp. 12-24]

Other major automotive regions have taken initial steps to control puff emissions, and we recommend, at a minimum, that EPA adopt the same approach as is used in the China 6 test procedures for NIRCOS, which is also currently under consideration for incorporation into Euro 7. This procedure includes the fuel cap opening as part of the refueling test in the SHED. Under this approach, any puff loss emissions not captured in the canister would be captured in the SHED and a lack of capacity in the canister could result in a higher level of refueling emissions in the SHED measurement. It ensures the canister is appropriately sized because if the puff goes to the canister and then the vehicle is refueled, the canister must be sized for both the puff loss load and refueling load; otherwise there will be emissions from the canister after it's saturated that the SHED will capture. A key limitation of this approach is that the amount of the puff loss loading is expected to be small under the conditions of the EPA refueling test (80°F soak temperature) and thus may not be representative of the higher puff loss loadings expected in-use (such as a refueling event after a long drive where the fuel system temperatures may be greater than 100°F). [EPA-HQ-OAR-2022-0829-0564, pp. 12-24]

CARB finalized in ACC II a design-based approach that uses an equation to define the minimum evaporative canister capacity for vehicles with sealed fuel tanks. While MECA supported the intent of CARB to control for puff losses, MECA reviewed the terms of the equation and provided written comments to CARB staff noting the deficiencies in this design-based approach.15 To evaluate the CARB design-based equation approach, MECA analyzed the U.S. EPA certification database16 to obtain the EPA certified canister capacities for 10 currently certified PHEV/NIRCOS models, including the most popular and top selling models for 2021 and 2022. The EPA certified canister capacities (as retrieved from the evaporative family name codes) of the PHEV/NICROS models were then compared with the predicted minimum canister capacity from the CARB equation using the manufacturer reported tank volume and the recommended default CARB inputs to the equations. Table 1 [See original comment for Table 1: EPA Certified Evaporative Canister Capacities Compared to Results Determined by the CARB Final Design-Based Equation] shows the calculated results from the equation compared to the currently certified canister capacities of PHEV models using sealed fuel tanks. Based on the data, MECA believes the design-based equation approach may lead to back sliding on canister volumes and that it does not provide a method to ensure puff losses are effectively controlled in-use. [EPA-HQ-OAR-2022-0829-0564, pp. 12-24]

15 https://www.meca.org/wp-content/uploads/2022/06/MECA-ACC-II-Comments-06092022-FINAL.pdf

16 US EPA Light-Duty Vehicle Certification Database, https://www.epa.gov/compliance-and-fueleconomy- data/annual-certification-data-vehicles-engines-and-equipment

If EPA is to consider using a design-based approach such as the CARB equation, MECA recommends EPA review the terms of the CARB equation to ensure that the application of the equation would efficiently control puff losses under conditions expected in-use while also not leading to back sliding on canister volumes. [EPA-HQ-OAR-2022-0829-0564, pp. 12-24]

Organization: Mercedes-Benz AG

Non-Integrated Refueling Canister Only Systems ("NIRCOS")

EPA's NPRM states there are some potential issues that may arise when dealing with NIRCOS designed fuel vapor handling designs.10 EPA further explains that NIRCOS systems initially release any tank vapors into the canister before the cap removal, and therefore, the pressure must be released before the fuel cap is removed during refueling events. It was discovered that the Onboard Refueling Vapor Recovery ("ORVR") test procedure does not account for the extra fuel vapor loading prior to the refueling event. [EPA-HQ-OAR-2022-0829-0623, p. 14]

10 NPRM at 29275.

CARB ACCII specifically included a design requirement within the regulation to address NIRCOS. The rule specifies an updated formula to calculate minimum canister size for vehicles with a NIRCOS fuel system, as well as other vehicles that have fuel tank pressure exceeding a certain threshold. [EPA-HQ-OAR-2022-0829-0623, p. 14]

Mercedes-Benz requests EPA harmonize with CARB for NIRCOS, in particular as it pertains to In-Use Verification Program ("IUVP") and Fuel Economy Data Vehicle ("FEDV") testing procedures and the elimination of refueling the base load of a canister for both IUVP and FEDV testing. [EPA-HQ-OAR-2022-0829-0623, p. 14]

Organization: National Association of Clean Air Agencies (NACAA)

In response to EPA's request for comment on canisters, NACAA recommends that EPA add a minimum canister size requirement to control "puff" emissions from sealed fuel systems (which exist mostly on plug-in hybrid electric vehicles) during refueling. [EPA-HQ-OAR-2022-0829-0559, pp. 6-7]

EPA Summary and Response

Summary:

The Alliance for Automotive Innovation supported aligning with the CARB design-based requirement if EPA decides to act in this area, and recommended against modifying the ORVR test procedure.

Mercedes Benz requested that EPA harmonize with the CARB design-based requirement, especially as it relates to IUVP and FEDV testing.

NACAA recommended that EPA add a minimum canister size requirement to control puff losses from sealed fuel systems during refueling.

CARB recommended that EPA adopt CARB's minimum canister size requirement for vehicles with nonintegrated refueling canister-only systems to account for fuel vapors that may be released to the canister before refueling (puff losses). CARB estimated that about six percent of new vehicles, primarily PHEV, would be affected, and suggested that all those vehicles could modestly increase canister capacity to account for the design requirement to account for the added vapor load. CARB recommended adopting their design requirement instead of accounting for the added vapor load by revising the test procedure.

MECA recommended that EPA add a testing requirement designed to ensure sufficient canister capacity to control puff losses from vehicles with fuel tank pressure exceeding 2.5 kPa, even at elevated ambient temperatures. MECA believed that controlling puff losses with an improved test procedure would create a requirement that is more readily enforceable in-use over a certified vehicle's useful life. MECA recommended adopting the procedure from China 6, which involves removing the fuel cap in the SHED as part of measuring refueling emissions. MECA recognized that the test condition at a nominal ambient temperature of 80 °F may underrepresent in-use puff-loss loading to canisters, such as may occur after long drives with fuel temperatures exceeding 100 °F.

MECA recognized that CARB has adopted a design-based approach to ensure that canister capacity is sufficient to account for puff losses. MECA recommended that if EPA takes that same approach, EPA should review the terms of the CARB equation to ensure that it would efficiently control puff losses under conditions expected in-use while also not leading to backsliding on canister volumes. MECA supported this concern with an analysis of EPA certification data from ten PHEV models, which led them to conclude that CARB's equation may lead to backsliding on canister volumes and that CARB's equation does not provide a method to ensure puff losses are effectively controlled in-use.

Ingevity generally supported requiring sufficient canister capacity to control puff losses, and believed the mass values for puff losses are not insignificant. Ingevity recounted EPA's history of considering control of puff losses as follows:

- EPA identified puff losses as an issue in the mid-1980s, estimating an emission rate of 3-5 grams per refueling event based on current test procedures and estimated in-use fuel tank pressures. EPA proposed a specific test procedure in January 1990, but in the corresponding final rule in March 1993 deferred action on puff loss control. The March 1993 final rule included a requirement to vent puff losses to the evaporative canister as follows: "Fuel tank pressure during the running loss test may not exceed 10 inches of water (2.5 kPa), unless manufacturer shows that fuel vapors, other than refueling emissions, are vented to the evaporative canister when the fuel cap is removed." This requirement included no concrete provisions for compliance assessment. EPA proposed in May 1993 to adopt a test requirement to remove the fuel cap after the ORVR preconditioning drive but before refueling test to address puff losses, but did not finalize this requirement, perhaps because pressurized fuel systems were becoming less common.[12] The issue became important again in the 2010 and later timeframe as some HEVs and PHEVs began to use sealed fuel systems with higher fuel tank pressure to comply with evaporative emission standards.

12 US EPA, “Control of Air Pollution From New Motor Vehicles and New Motor Vehicle Engines; Refueling Emission Regulations for Light-Duty Vehicles and Trucks and Heavy-Duty Vehicles,” Supplemental Proposal. NPRM, 58 FR 30731, May 27, 1993.

Ingevity noted the following issues: (1) The proposed rule identified puff losses as an issue for NIRCOS, which typically have tank pressure exceeding 18.6 kPa absolute, even though puff losses as a phenomenon were recognized back in 1993 as an issue for systems with tank pressure exceeding 2.5 kPa. Ingevity recommended adopting puff-loss requirements for any vehicle with tank pressure exceeding a gauge pressure of 2.5 kPa. (2) Ingevity recommended adopting provisions that require the manufacturer to demonstrate both that puff loss emissions are vented only to the canister when the fuel cap is removed and that the canister has capacity to control puff losses from a complete refueling event. (3) Ingevity shared the results of computer modeling to estimate puff loss emissions. Estimated values ranged from 3 to 25 grams per refueling event, with variability attributed mainly to altitude, tank pressure, fuel temperature, tank volume, and tank fill fraction. Ingevity also shared the observation that vehicle testing in 2019 and 2020 show puff loss values at the lower end of the modeled range, but they also observed that testing did not fully assess the impact of variations in the key parameters.

Ingevity considered it to be ideal to assess the performance of a puff loss control system in a SHED as part of a refueling emission test. Such a measurement would ensure that vapors are routed only to the canister, and that canister capacity is sufficient to account for puff losses. Ingevity recognized the complication of modifying the test procedure to remove the fuel cap from the vehicle in the SHED after testing has started, but notes that the China 6 procedure has adopted this as a testing requirement. Ingevity also recognized the complication that the current test includes at least six hours of vehicle soaking at 80 °F after the preconditioning drive, which would involve only a small mass of puff-loss emissions. Ingevity suggested that a modified refueling test could better address puff-loss emissions, but acknowledged that this approach would involve significant perturbations to otherwise stable and well-established test procedures.

If EPA adopts CARB’s approach of requiring manufacturers to make a design demonstration that canister capacity is sufficient for puff losses, Ingevity recommended that the final regulations specify that compliance with this minimum requirement be demonstrated using the tests prescribed at 40 CFR 86.132-96(h)(1)(iv)(A)–(B); specifically, the canister’s nominal working capacity measured using those tests must exceed the minimum calculated using the equation for it to be considered as compliant with the requirement. Ingevity further recommended making two changes to CARB’s formula for calculating canister capacity. First, the constant 0.88 should instead be 0.90 to represent refueling a vehicle from 10 percent to 100 percent full. Second, the vapor volume should be increased to account for the whole ullage, the volume of the fill pipe, and any vapor lines of the evaporative control system that may contain vapor when the tank is 10% full.

Ingevity included additional comments on implementing new requirements for controlling puff losses: (1) puff loss requirements should apply for all vehicle classes and fuels that are subject to evaporative and refueling emission standards; (2) tt would be reasonable to allow 3-4 years of lead time for meeting new requirements; and (3) the regulation should require manufacturers to provide data on all the values used in calculating the minimum canister capacity for each evaporative/refueling family.

Glenn Passavant stated that puff loss control has been required under part 86 since 1999, and that the chemical composition of puff loss emissions is generally representative of gasoline vapors in the tank headspace, which includes benzene and other toxic compounds with high photochemical reactivity in addition to butane and pentane isomers.

Response:

The existing refueling test procedures require vehicle stabilization with no fuel tank pressure before the vehicle enters the SHED for emission measurement. The fuel cap is removed before canister preconditioning, which means that any vapors from relieving fuel tank pressure are not represented in the refueling test. In contrast, the regulation includes a partial refueling test in which EPA may test a vehicle using a streamlined procedure. The partial refueling test requires driving followed by stabilizing the vehicle for one to six hours before the refueling test, without removing the fuel cap. The partial refueling test calls for the fuel cap removal (and tank depressurizing, as applicable) within two minutes of sealing the SHED for the refueling test. This approach includes the canister loading from puff losses, though it does not include SHED measurement to ensure that vapors from depressurizing are vented to the canister. Nevertheless, EPA testing using the existing partial refueling test can confirm with testing that refueling canisters are properly sized to control refueling emissions from vehicles with pressurized fuel tanks. This existing test accounts for puff losses, but that does not apply for manufacturers' testing for certification.

To address the disconnect between the two measurement procedures, we are adopting a requirement for manufacturers to attest in their application for certification that their vehicles with pressurized fuel tanks will meet emission standards when tested over the partial refueling emission test. We would expect manufacturers to use their engineering analysis from certifying their vehicles for CARB rules to meet this requirement. However, we are stopping short of adopting the specific requirement to follow the modeling and calculations that CARB specifies for ensuring adequate canister capacity. This approach allows us to accommodate any adjustments CARB makes to its requirements based on the several changes suggested in the comments. The result is an EPA policy conclusion that aligns with CARB regulations for all aspects of certification and testing.

The new attestation requirement related to puff losses applies for all vehicles exceeding the pressure threshold specified for the running loss test in 40 CFR 86.134. That threshold is 10 inches of water or 2.5 kPa. This aligns with the comment from Ingevity. We recognize Ingevity's observation that modifying the refueling test to account for puff losses would add significant complexity. We do not find that the incremental improvement from modifying the refueling test justifies that additional cost and complexity.

We recognize that controlling puff loss emissions is effective for controlling benzene and other toxic compounds in addition to butanes and pentanes, and expect the combination of emission standards, test procedures, and certification requirements work together to appropriately control these emissions.

7.5 – Evaporative emissions

Comments by Organizations

Organization: Alliance for Automotive Innovation

2. General Carry-Over of Tier 3 Evaporative Requirements and Unintended Impact of Redefining Light-duty Truck

Auto Innovators supports EPA's intent to continue use of Tier 3 evaporative emission requirements. However, the proposed redefinition of a light-duty truck and medium-duty passenger vehicle per § 86.1803-01 for Tier 4 tailpipe emissions, will have significant impacts to Tier 3 diurnal plus hot soak emission requirements. This definition change will cause some vehicles, currently classified as LDT2 and higher, to be considered passenger cars or medium-duty passenger vehicles with a corresponding lower standard that will require significant redesign. The light-duty truck and medium-duty passenger vehicles reclassifications for evaporative emissions compliance could result in the reduction of FWD penetrations and increased vehicle mass and ground clearances. [EPA-HQ-OAR-2022-0829-0701, pp. 187-188]

We don't believe it was EPA's intention to impact evaporative emissions standards or vehicle programs in this manner. We request that the evaporative standards, light-duty truck and medium-duty passenger vehicle definitions used under the Tier 3 evaporative emissions program apply without modification under Tier 4 for evaporative emission requirements. We would be happy to work with EPA to resolve issues of redefining light-duty truck or medium- duty passenger vehicle and their impact to evaporative emissions standards. [EPA-HQ-OAR-2022-0829-0701, pp. 187-188]

3. Test Fuel for Flex-Fueled Vehicle ORVR Testing

In the preamble for the Tier 3 rulemaking, EPA indicated that the test fuel for flex-fueled vehicle ORVR testing should be Tier 2 E0 fuel splash blended with 10% ethanol.291 In EPA's recent heavy-duty criteria pollutant rule,292 it is unclear if the splash blended test fuel or Tier 3 test fuel is required for heavy-duty incomplete vehicle ORVR testing. Clarification is requested regarding the test fuel for incomplete heavy-duty flex-fueled vehicle ORVR testing. We also recommend that Tier 3 test fuel be specified for all flex-fueled and non-flexed fueled ORVR certification testing regardless of the vehicle classification. [EPA-HQ-OAR-2022-0829-0701, p. 188]

291 81 Fed. Reg. 23509 (Apr. 28, 2014).

Organization: Ford Motor Company

Evaporative Family Definition Change to Exclude High Altitude Standards from Splitting Evaporative Families [EPA-HQ-OAR-2022-0829-0605, pp. 14-15]

In discussions with EPA staff in 2019, EPA agreed that revisions to the Evaporative Family definition (located in 40 CFR 86.1821-01(b)(10)) were necessary to clarify that manufacturers do not need to split Evaporative Families based on differences in the high-altitude evaporative emissions standards (which have different vehicle category groupings than the low altitude evaporative emissions standards). [EPA-HQ-OAR-2022-0829-0605, pp. 14-15]

Ford requests EPA make this change as part of this rulemaking action, and that the EPA further modify 40 CFR 86.1821-01(b)(10) to correct the following regulatory text: [EPA-HQ-OAR-2022-0829-0605, pp. 14-15]

- Current text: “Evaporative emission standard or family emission limit (FEL).” [EPA-HQ-OAR-2022-0829-0605, pp. 14-15]

- Revised text: “Low altitude evaporative emission standard or family emission limit (FEL).” [EPA-HQ-OAR-2022-0829-0605, pp. 14-15]

EPA Proposal to revise Light Duty Truck Definition to align with the GHG LDT Definition [EPA-HQ-OAR-2022-0829-0605, pp. 14-15]

The EPA has proposed to revise the LDT definition to align with the GHG regulations. Some vehicles greater than 6000lb GVWR would be reclassified as Passenger Cars using the proposed GHG LDT definition. This would result in a decrease in whole vehicle, sea level evaporative emissions standards from 500mg to 300mg. Ford does not believe that it was EPA’s intention to change the evaporative emissions standards as part of this rulemaking; therefore, Ford requests additional discussion about this concern. If EPA proceeds with the LDT definition change, we would request that the proposed regulatory language clarify that programs greater than 6000lb GVWR LDT which would be reclassified as Passenger Cars under the GHG definitions are provided the same 4-year lead time which was referenced with the re-definition of MDPVs. [EPA-HQ-OAR-2022-0829-0605, pp. 14-15]

Ford also request the addition of an allowance for emergency vehicles to remain in the same vehicle classification as the base program upon which the emergency vehicle is based. An example would be a greater than 6000lb GVWR SUV which is classified as a LDT based on standard 3 row seating; however, the emergency vehicle based on the SUV only includes two rows of seating. [EPA-HQ-OAR-2022-0829-0605, pp. 14-15]

Organization: Ingevity Corporation

4. Additional Considerations:

Fuel cap requirement for vehicle soaks and storage:

The NPRM language at §86.132-96 (a) requires that for future testing that the fuel cap always be in place when the vehicle is in soak or otherwise awaiting testing. We have no objection to this change and suggest that it apply to all evaporative and refueling emission testing covered in the vehicle regulations. EPA needs to specify a model year of applicability. [EPA-HQ-OAR-2022-0829-0545, pp. 10-11]

Removal of drain and fill after preconditioning UDDS drive:

The current evaporative emission test procedure at 40 CFR §86 132-96 calls for a drain and 40% fill of the fuel tank after the preconditioning drive (UDDS) at §86.132-96 (c). Instead, under this proposal, after the preconditioning drive, the vehicle would be driven and parked for the 12–36-hour soak before the canister preconditioning. This proposal would apply to diesel and gaseous-fueled vehicles (CNG/LPG), fuel economy data vehicles, and IUVP vehicles (not IUCP). This does not seem to apply for certification testing for evaporative or refueling emissions. This streamlining seems acceptable provided that it is clear that the full 40 CFR §86 Subpart B test procedure remains the primary test which could be used by EPA at its discretion. Perhaps it would be better to provide this as an option. EPA needs to specify a model year of applicability. [EPA-HQ-OAR-2022-0829-0545, pp. 10-11]

Canister preconditioning for fuel economy data vehicles and IUVP:

At the proposed §86.132-96 (h) and (j), EPA is proposing to remove the canister preconditioning step at 40 CFR §86 130.96 (for 3-day and 2-day) for fuel economy and IUVP tests. Once again, this streamlining seems acceptable provided that it is clear that the full 40 CFR §86 Subpart B test procedure remains the primary test which could be used by EPA at its discretion. Perhaps it would be better to provide this as an option. EPA needs to specify a model year of applicability. [EPA-HQ-OAR-2022-0829-0545, pp. 10-11]

Organization: Kia Corporation

Kia Supports Tier 3 Evaporative Emissions Standards [EPA-HQ-OAR-2022-0829-0555, pp. 11-12]

Kia supports EPA's intent to continue use of Tier 3 evaporative emissions requirements. [EPA-HQ-OAR-2022-0829-0555, pp. 11-12]

EPA Summary and Response

Summary:

Several commenters noted that the proposed changes to definitions for "light-duty truck" and "medium-duty passenger vehicle" would cause an increase in stringency of evaporative emission standards. The Automotive Alliance requested that we include regulatory language to prevent any change in evaporative emission standards. Ford requested that we include regulatory language to allow four years of lead time for meeting any change in standards resulting from the change in definitions.

The Alliance for Automotive Innovation requested that we address an ambiguity regarding the fuel specifications for refueling tests with flexible fuel vehicles, for both medium-duty vehicles and heavy-duty vehicles above 14,000 pounds GVWR. They also suggested that we amend the regulation to specify Tier 3 E10 as the fuel for the refueling test for all vehicle types.

Ford's comment included a request to modify the regulation to acknowledge that manufacturers do not need to split evaporative families based on differences in the high-altitude evaporative emissions standards.

Ford also requested that emergency vehicles retain their vehicle classification even if they are modified for emergency purposes in a way that causes them to fall into a different vehicle classification. The specific case was for light trucks that would qualify as passenger automobiles or light-duty vehicles in the emergency-vehicle configuration.

Ingevity had no objection to the change in vehicle handling before tests as specified in 40 CFR 86.132-96(a), but suggested that we apply it to all evaporative and refueling emission testing, and that we specify a model year of applicability.

Ingevity found the proposed omission of both the second refueling event and the canister preconditioning for fuel economy and IUVP testing to be acceptable, provided that EPA could perform testing with the full procedure to evaluate compliance. Ingevity suggested that it may be better to make those omissions optional, and that we should identify when the amendments start to apply.

Kia supports EPA's intent to continue use of Tier 3 requirements for evaporative emissions.

Response:

We agree with commenters observing that the changes to vehicle category definitions were not intended to achieve an increase in stringency for evaporative emission standards. At the same time, we are aware that the less stringent standards for light-duty trucks were originally intended to reflect differences in fuel tank volumes and other vehicle characteristics related to controlling evaporative emissions. It is apparent that vehicles affected by the changing definition of "light-duty truck" are not differentiated from light-duty vehicles based on such vehicle parameters related to evaporative emission control. From that perspective, the revised definition is likely to have the effect of accomplishing the original intent of applying standards corresponding to vehicles with expected evaporative-related characteristics for light-duty vehicles.

To address the concern for the incidental change in stringency, we are adding a provision to allow manufacturers to continue to meet the evaporative emission standards for light-duty trucks or medium-duty passenger vehicles even if their vehicles are recategorized based on the changed definitions, provided that those vehicle models continue to qualify for carryover certification. With this approach, manufacturers would do new testing to meet the more stringent standard only if they already need to do new testing to certify to the evaporative emission standards. To avoid extending this provision indefinitely, we are including a requirement for manufacturers to meet the more stringent evaporative emission standards for such vehicles starting in model year 2032, even if they would otherwise qualify for carryover certification. Meeting the more stringent standards will likely involve modestly increasing canister volume and upgrading various design features and parameters in line with the technology solutions used for other light-duty vehicles. The several years of lead time will allow manufacturers to plan for making those changes.

We recognize Ford's concern for emergency vehicles and have modified the definition of "light-duty truck" for the final rule to allow emergency vehicles to qualify as light-duty trucks if they are derived from vehicles that are light-duty trucks, even if they have been modified in a way that prevents them from meeting the criteria for light trucks in 40 CFR 600.002.

We recognize that flexible fuel vehicles today will be refueled with some combination of E10 gasoline and a high-level ethanol fuel. The scenario of splash blending ethanol with an E0 fuel is no longer something that in-use vehicles will experience. We are therefore revising the refueling test fuel specification for flexible fuel vehicles to align with the test fuel specification for evaporative emission testing under 40 CFR 86.1810-17(h). The refueling test fuel will instead be based on testing with a worst-case fuel that is either the high-level ethanol test fuel in 40 CFR

1065.725 or a blend of that fuel with Tier 3 gasoline (E10 with 9 psi RVP). This same conclusion applies for refueling tests with heavy-duty vehicles subject to standards under 40 CFR 1037.103.

We agree with Ford that it is appropriate to amend the regulation to reflect the current policy allowing manufacturers to include vehicles in the same evaporative family if they are subject to the same low-altitude standards even if they are subject to different high-altitude standards.

The amendment describing how to treat vehicles before testing was intended to provide a broader good-practice description for handling vehicles before evaporative testing. This involves replacing the instruction for removing fuel caps for outdoor parking with an instruction to prevent fuel contamination and preserve fuel-system integrity. It would not be appropriate to allow lead time for following this good-practice instruction. Also, evaporative and refueling tests are typically performed together. As a result, this single instruction already applies for all evaporative and refueling emission testing.

The evaporative testing amendments for omission of the second refueling event and canister preconditioning are both optional in the final rule. As a result, there is no need to allow lead time for those amendments. EPA testing would generally not include these optional steps if manufacturers do not include those steps for their testing.

We appreciate Kia's support for continuing to apply the Tier 3 evaporative emission standards.

7.6 – Miscellaneous amendments

I. Related Guidance / Regulatory Needs

1.Analytical Derivation Guidance / Regulation

EPA regulations allow a manufacturer to provide fuel economy, CO_2 emissions, and carbon-related exhaust emissions values derived from analytical expressions approved by the Administrator.249 These are generally referred to as "analytical derivations". [EPA-HQ-OAR-2022-0829-0701, pp. 139-140]

249 40 C.F.R. § 600.006.

EPA has provided guidance on analytical derivations multiple times, starting in 1983, and revising or providing new guidance in 1995, 2000, 2004, and in 2012.250 EPA also provided an analytical expression for chassis-certified medium-duty vehicles in regulation.251 [EPA-HQ-OAR-2022-0829-0701, pp. 139-140]

250 EPA Advisory Circular 83A (1984), Guidance CD-95-08 (1995), Guidance CD-00-04 (2000), Guidance CCD-04-06 (2004), and Guidance CD-12-03).

251 40 C.F.R. § 86.1819-14(g).

EPA guidance on analytical derivations has not been updated in over a decade. Auto Innovators suggests that it is timely now to update the guidance again, and/or to update the governing regulation as might be needed. There are two areas that we propose EPA should update: expanding analytical derivations to battery electric vehicles and expanding derivations to strong hybrid electric vehicles. Auto Innovators has provided supporting data and analyses to EPA to support these updates. If EPA would find it helpful, we would be happy to update our analyses again and share them with EPA. [EPA-HQ-OAR-2022-0829-0701, pp. 139-140]

Range and energy consumption testing of battery electric vehicles can be extremely time-consuming. While recent updates to SAE test procedures provide improved procedures to reduce some of this burden, the number of battery electric models continues to grow, challenging laboratory resources. As discussed elsewhere in these comments, EPA has not yet adopted the most recent SAE test procedures for battery electric vehicles and continues to use older procedures. Providing an approved means to analytically derive BEV range and energy consumption would reduce testing burden. [EPA-HQ-OAR-2022-0829-0701, pp. 139-140]

Guidance on analytical derivations for strong hybrid electric vehicles would also be helpful. When analytical derivation guidance was last updated, there were relatively few strong hybrid models available. While strong hybrids remain a relatively small part of the fleet, there are now significantly more models available to base a statistical analysis on. We suggest that EPA update analytical derivation guidance to include strong hybrids with conventional internal combustion engine vehicles, or to provide a separate equation for them, if needed. [EPA-HQ-OAR-2022-0829-0701, pp. 139-140]

Guidance for conventional ICE vehicles could also be updated concurrent with the above changes, but this is not a high priority for auto manufacturers. [EPA-HQ-OAR-2022-0829-0701, pp. 139-140]

2.High-Fuel Economy / Low-GHG Confirmatory Test Guidance

Manufacturers are required to perform confirmatory testing under a number of circumstances, including when the fuel economy on the FTP or HFET test is higher (or the CO2 emissions are lower) "than expected," and when the fuel economy is a "potential" fuel economy leader for a class of vehicles.252 EPA has historically provided and updated guidance on cut-points that trigger the need for a confirmatory test.253

252 See 40 C.F.R. §§ 86.1835-01(b)(1)(iii), (v), and (vi); and 600.008(b)(1)(iii) and (v).

253 See EPA guidance documents CD-15-22 and CD-99-06.

Updates to this guidance are particularly important at times when fuel economy of individual vehicles is rapidly improving, such as since roughly 2010. The cut-points are absolute numbers based on statistical analysis of a historical fleet's test results. Thus, as fuel economy is improved, an increasing number of models exceed the statistical threshold for high fuel economy (or low CO2 emissions). This increases the number of confirmatory tests required, consuming laboratory resources.

Setting aside temporary guidance that provided laboratory relief in response to the COVID-19 pandemic (which have since expired),254 guidance on confirmatory testing was last updated in 2015, eight years ago. Again, an increasing number of models are exceeding the given thresholds, resulting in additional confirmatory testing of vehicles that have high, but not statistically unusual fuel economy.

254 See EPA guidance documents CD-2021-02 and CD-2020-07.

Auto Innovators believes it is timely now to again update confirmatory test guidance. We would be happy to provide an updated analysis based on a recent model year if EPA would find that helpful to moving forward with this needed update. [EPA-HQ-OAR-2022-0829-0701, pp. 140-141]

F. Compliance With Fleet Average CO_2 Standards

EPA proposes to revise 40 C.F.R. § 86.1865-12(i)(1) and (2) introductory text to specify their applicability to model years through 2026. These paragraphs pertain to requirements to calculate separate fleet average carbon-related exhaust emissions for the passenger car and light truck fleets. It is unclear what EPA intends for manufacturers to do after model year 2026, and we could not identify any description of, or reasoning for this proposed change in the preamble. [EPA-HQ-OAR-2022-0829-0701, p. 248]

G. Electronic Vehicle Documents

Under this NPRM, EPA is also proposing changes to 40 CFR 86.1844-01(e) "Part 2 Application" clarifying that the "the part 2 application must include the part numbers and descriptions of the GHG emissions related parts, components, systems, software or elements of design, and AECDs including those used to qualify for GHG credits (e.g., air conditioning credits, off cycle credits, advanced technology vehicle credits) as previously specified in EPA guidance letter CD-14-19." We also understand that EPA is proposing changes to 40 CFR 86.1844-01(e) "Part 2 Application" and 40 CFR 85.2110 to establishing that paper copies of service manuals, owner's manuals, warranty booklets, and Technical Service Bulletins (TSBs) will no longer be accepted. Instead, the aforementioned documents will all need to be digitally accessed. We request that EPA allow the use of submitting a web address to view the required documents. [EPA-HQ-OAR-2022-0829-0701, p. 248]

Organization: Cummins Inc.

VIII. Inducements

10. EPA should allow manufacturers the option to use the new Selective Catalytic Reduction inducements in 40 CFR Part 1036 for chassis-certified vehicles

EPA recently finalized new requirements for selective catalytic reduction (SCR) inducements for HD engines in 40 CFR 1036.111. Cummins requests EPA to add an option allowing manufacturers who wish to harmonize SCR inducements across their product offerings to use 40 CFR 1036.111 inducements for chassis-certified LD and MDV as well. Such an option should recognize there may need to be differences in the inducement triggering conditions between HD and LD/MDV. [EPA-HQ-OAR-2022-0829-0645, p. 11]

Cummins also encourages EPA to continue work with industry and CARB to harmonize on SCR inducement strategies that reflect the inducement principles developed by EPA for the HD 2027 NOx proposal. [EPA-HQ-OAR-2022-0829-0645, p. 11]

Organization: General Motors, LLC (GM)

The following appendices provide further detailed regulatory and technical comments. Appendix A provides recommended edits to EPA's proposed regulatory text to clarify various parts of the regulatory language to ensure a successful and aligned set of EPA regulatory requirements. The other appendices provide confidential business information to help inform various technical aspects of the criteria emission and GHG standards. In many cases, an EPA final rule aligned with CARB's LEV IV in internal combustion engine criteria emission stringency and the associated test and certification procedures will help GM achieve significant emissions reductions for internal combustion engine products as soon as MY 2027 despite limited lead time, while continuing to transition to zero-emission vehicle technologies. [EPA-HQ-OAR-2022-0829-0700, p. 6]

[See original attachment for April 7, 2023 EPA Memorandum with subject: Redline Version of EPA's Proposed Regulations to Adopt New Standards for Light-Duty and Medium-Duty Vehicle Standards"] [EPA-HQ-OAR-2022-0829-0700, p. 6]

[See original attachment containing redacted confidential comments titled, "Summary of GM Technical Comments and Recommendations in Response to Environmental Protection Agency's (EPA) Notice of Proposed Rule Making (NPRM) for Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles (Tier IV)" [EPA-HQ-OAR-2022-0829-0700, p. 6]

Organization: Porsche Cars North America (PCNA)

9. Porsche recommends maintaining the current definitions for Light-Duty Truck (LDT)

Porsche does not support EPA's proposal to amend the definition of Light-Duty Truck in 86.1803-01 to include the provision that for Tier-4 (i.e., starting in MY2027), light-duty truck should use the definition in Part 600.002. The definition in Part 600 reflects the definition used within the NHTSA's CAFE regulation for non-passenger automobiles under that regulation's vehicle classification terms. Vehicle classification under CAFE has a long statutory history reflecting the congressional requirement for non-passenger automobiles (otherwise referred to as "light trucks") to have unique fuel economy requirements specific to that category of automobile. This statutory history reflects energy related policies specific to CAFE. Over the past several decades, NHTSA has updated their regulatory definition and policy interpretation of non-passenger automobile to reflect changes in vehicle designs and ongoing considerations of industry usage of the classification for determining fuel economy compliance. [EPA-HQ-OAR-2022-0829-0637, pp. 15-16]

NHTSA's CAFE regulation has a long-standing history that reflects a much higher degree of differential in the fuel economy targets between passenger automobiles and non-passenger automobiles. As such, NHTSA has been careful to consider vehicle classification throughout the regulatory history of their program and in changing how the agency views the applicability of the class by industry. Even during the most recent updates to CAFE, NHTSA continues to discuss future changes to the definition and such topics as physical measurement validations, applicability to accessories and build tolerance variation. [EPA-HQ-OAR-2022-0829-0637, pp. 15-16]

NHTSA’s policy can result in manufacturers having to split individual vehicles within a model type into passenger and non-passenger versions based on issues such as having to account for dealer installed accessories. For example, under recent NHTSA rulemaking discussions, the agency clarified that a non-passenger automobile that had an optional tow- hitch installed would have to be reclassified as a passenger automobile if the hitch violated the ground clearance requirements. While this reclassification may impact end of year CAFE compliance accounting, these vehicles would otherwise need no updates that would affect certification. [EPA-HQ-OAR-2022-0829-0637, pp. 15-16]

However, EPA’s emissions certification program needs more stability in the determination of vehicle classification. For example, if EPA were to abdicate vehicle classification for Light-Duty Truck to NHTSA, the vehicle that had to change from non-passenger automobile to passenger automobile for CAFE, and thus from Light-Duty Truck (LDT) to Light-Duty Vehicle (LDV) for emissions would face certification challenges. One example would be that this unique vehicle would require a new under hood VECI label. This would mean that the installation of an optional part could trigger relabeling for the vehicle or a whole new certification application. These types of sudden changes in classification could disrupt processes and, given that the emissions programs now have minimal differences in technical standards, would have no effect on environmental outcomes. [EPA-HQ-OAR-2022-0829-0637, pp. 15-16]

EPA's definition has provided industry and the agency with a stable, consistent basis for vehicle classification for several decades. Porsche sees no value in EPA now handing over their authority for vehicle classification for systems to NHTSA, especially as the difference between light duty vehicle and light-duty truck requirements continue to converge. NHTSA has already signaled that they will seek further changes to classification, both in regulatory updates, test procedures and policy interpretation. NHTSA will pursue these with regards to their statutory fuel economy policy and would be unaware, and not responsible for, any disruptions this might create for exhaust and evaporative emissions compliance. While it may appear convenient to harmonize definitions, in this instance, given the unique statutory goals specific to fuel economy, Porsche recommends EPA stay the course with their existing LDT definition. Porsche sees no added value specific to EPA’s air quality program in changing definitions, and to avoid any complications, proposes that EPA continue to utilize their existing definition and industry practice in Part 86. [EPA-HQ-OAR-2022-0829-0637, pp. 15-16]

10. Porsche recommends streamlining the FTP test procedure to remove the initial 6-hour minimum vehicle soak. [EPA-HQ-OAR-2022-0829-0637, p. 17]

In identifying further opportunities for test streamlining, Porsche reviewed the FTP test procedure flow-chart illustrated in 1066.801(e) and analyzed the relevancy of the initial 6-hour minimum soak period that follows the initial drain-and- fill. Porsche understands that the specific role of this initial 6-hour minimum soak period may have been to account for the possibility that fuel added to the vehicle could have been stored at different temperatures than the vehicle, for example if the fuel was in an underground tank. Or if the vehicle itself was stored at a temperature outside of the lab temperature and needed time to stabilize prior to preconditioning. In situations where the vehicle and fuel are otherwise already stabilized, it is unclear if this initial soak is relevant. Porsche recommends that EPA provide flexibility to manufacturers to use good engineering judgement to determine if the initial 6-hour minimum soak period can be skipped in order to help improve test facility efficiencies. Porsche recognizes that EPA, specific to confirmatory testing, would continue to use the 6-hour minimum soak period in order to have a consistent confirmatory process. [EPA-HQ-OAR-2022-0829-0637, p. 17]

[See original comment for Figure 2 EPA FTP test procedure flow-chart from 1066.801] [EPA-HQ-OAR-2022-0829-0637, p. 17]

EPA Summary and Response

Summary:

The Auto Alliance recommended updating the guidance and/or updating the governing regulation as might be needed regarding analytical derivations for fuel economy, CO_2 emissions, and carbon-related exhaust emissions values. They specifically recommended updating the provisions to expand analytical derivations to battery electric vehicles and derivations to strong hybrid electric vehicles.

The Auto Alliance also suggested updating guidance related to confirmatory testing requirements under 40 CFR 600.008.

The Auto Alliance asked how to understand the regulatory instruction for calculating fleet average CREE values after 2026 in § 86.1865-12, based on the proposed amendment to discontinue those provisions starting in 2027.

The Auto Alliance requested that EPA allow manufacturers to meet requirements for submitting electronic records by identifying a web address with the required information.

Cummins requested that EPA allow manufacturers the option to use the new Selective Catalytic Reduction inducements in 40 CFR 1036.111 for chassis-certified vehicles under 40 CFR part 86, subpart S, perhaps allowing for differences in the inducement triggering conditions between HD and LD/MDV.

General Motors included a scattering of suggested changes to the proposed regulation language in an appendix to their comments.

Porsche recommends not finalizing the proposed change to the light-duty truck definition to align with NHTSA definitions, because NHTSA decision-making creates an unstable categorization for purposes of meeting EPA emission standards.

Porsche recommended that EPA allow manufacturers to omit the 6-hour minimum soak period at the start of vehicle testing to help improve test facility efficiencies. Porsche recognized that manufacturers would still need to use good engineering judgment, for example, to ensure that the test fuel and the test vehicles as a whole would need to be temperature-stabilized before starting the test. Porsche also recognized that EPA testing should continue to use the 6-hour minimum soak period to ensure a consistent process for confirmatory testing.

Response:

We have amended the regulation to reference the latest version of SAE J1711 for the final rule, as suggested by the Auto Innovators. We will be mindful of the need and benefit for updating the guidance on analytically derived values after finalizing the rule.

We recognize that the instructions requiring manufacturers to perform additional confirmatory tests based on fuel economy test results is no longer necessary. The final rule therefore removes 40 CFR 600.008(b)(2)(iii)–(v).

We recognize the ambiguity of the proposed change to 40 CFR 86.1865-12(i)(1) and (2) and are revising the final rule to remove the proposed amendment.

Public websites are subject to change without notice. As a result, submitting a web address is not sufficient for meeting information submission requirements. However, manufacturers can create an electronic file from a website and submit the information as posted at that time.

We recognize that Cummins's suggestion to revisit the guidance related to inducement provisions for diesel vehicles certified under 40 CFR part 86, subpart S. At the same time, there is significant complexity to consider in the regulatory provisions from 40 CFR 1036.111, and some significant differences in vehicle design and operation for the mostly personal-use medium-duty vehicles certified under 40 CFR part 86, subpart S. We expect to revisit the existing inducement guidance for medium-duty vehicles to consider whether or how to expand that guidance to allow for inducement algorithms based on what we adopted for heavy-duty engines and vehicles in 40 CFR 1036.111.

The General Motors appendix with possible amendments to the regulation included no description or rationale. Many of their suggested changes overlap with their comments, and with the comments submitted by the Auto Alliance. We are therefore not addressing the amendments in their appendix file except as those are included in the text of written comments.

With respect to the proposed change to the definition of Light-duty truck, the proposed rule described our focus on the inconsistency with NHTSA definitions causing a single vehicle to qualify under EPA programs as a light-duty vehicle for GHG emission standards and as a light-duty truck for criteria emission standards. We are also aware that EPA's historical definition of Light-duty truck included ambiguity that creates too much flexibility for manufacturers to select vehicle categories to gain an advantage in reduced stringency of emission standards. We recognize that NHTSA's ongoing decision-making can cause manufacturers to be subject to different emission standards; however, we note that this circumstance has already applied for many years relative to GHG standards and certification. We also recognize that the Tier 4 standards substantially remove differences in exhaust emission standards between light-duty vehicles and light-duty trucks. As such, this reduces the impact on manufacturers of vehicles changing to a different type of vehicle. An exception applies for evaporative emission standards, which we address in RTC Section 7.4.

As described in RTC Section 7.3 in response to a similar comment, we are not amending the final rule to allow manufacturers to eliminate the six-hour soak at the start of the test procedure.

8 - Benefit cost analysis (BCA)

Comments by Organizations

Organization: American Fuel & Petrochemical Manufacturers

2. The Proposal's costs are vastly understated

EPA estimates that the Proposed Rule will cost $26 billion dollars but will produce between $200–$220 billion in net discounted benefits.221 EPA's conclusion is built on a shaky foundation of understated and hidden costs that when properly accounted for reveal that the costs of the Proposed Rule far exceed its benefits. [EPA-HQ-OAR-2022-0829-0733, pp. 48-49]

221 Proposed Rule at 29,361-62.

EPA assumes that significant ZEV sales would occur in the absence of the Proposed Rule but fails to acknowledge that the aggressive level of OEM investments are being bade in direct response to anticipated increases in fuel economy requirements.222, EPA excludes the vehicle costs associated with these ambitious automaker commitments that are linked to EPA standards. This is improper. In conducting the cost-benefit analysis EPA estimates that the rule will result in a 67 percent ZEV penetration rate and incorporates the emissions reductions associated with each of these vehicles. EPA cannot include the benefits of these ZEVs and exclude their costs. [EPA-HQ-OAR-2022-0829-0733, pp. 48-49]

222 ALLIANCE FOR AUTOMOTIVE INNOVATION "Auto Innovators Statement on Final EPA GHG Rule" (December 20,2021 available at https://www.autosinnovate.org/posts/press-release/statement-final-epa- ghg-rule

While we have not had sufficient time to fully analyze EPA's cost analyses, we have been able to identify several significant deficiencies, each of which understates the true costs of the Proposal: (1) EPA significantly understated the costs of batteries required by the rule; (2) EPA understated the costs of ZEVs by focusing only on their purchase price and ignoring the impacts of manufacturers' emissions trading and cross-subsidization strategies; (3) EPA's analysis of operating costs and other costs of ownership is incomplete; and (4) EPA misstates the costs of EVSEs and completely ignores the costs of grid upgrades that will be necessitated under the Proposed Rule. [EPA-HQ-OAR-2022-0829-0733, pp. 48-49]

Organization: Governing for Impact and Evergreen Action (GFI)

Perhaps most importantly, the Proposed Rule's projected compliance costs fall well-within the historical norms for 202(a) GHG standards. The EPA estimates that the Proposed Rule will cost automakers approximately $15 billion on an annualized basis.81 Those costs closely track the annualized automaker costs of the 2021 GHG tailpipe rule, which fall between $13.5-14.6 billion (adjusted for inflation).82 An apples-to- apples comparison with the agency's 2010 and 2012 GHG rules is difficult because those regulatory impact analyses report cost estimates differently; still, a rough-hewn sense of the 2012 rule's compliance burden can be drawn from the agency's overall cost estimates on an annualized basis, between $7.7-12.9 billion (adjusted for inflation).83 Finally, as the following table shows, the Proposed Rule's projected industry average per vehicle cost increase actually falls below similar estimates from past GHG rules. [EPA-HQ-OAR-2022-0829-0621, pp. 10-11]

81 Proposed Rule RIA at xlvii, Table 5.

82 2021 Final Rule RIA at 6–2, Table 6–1.

83 2012 Final Rule RIA at ii, Table 1. The 2010 rule's regulatory impact analysis does not appear to report either total or vehicle technology cost estimates on an annualized basis.

Note that previous GHG rules only encompassed carbon emissions (the Proposed Rule additionally sets criteria pollutant standards) and targeted a narrower class of vehicles (light-duty, whereas the Proposed Rule also targets medium-duty vehicles). That a multi-pollutant rule like the Proposed Rule nonetheless manages to closely track previous compliance cost figures suggests the EPA — far from charting a newly ambitious course — is diligently attempting to meet its statutory obligations without straying from its historical approach. [EPA-HQ-OAR-2022-0829-0621, pp. 10-11]

[Table:

Column "CAA §202(a) passenger vehicles GHG emissions rules.84": Row "2023 Proposed Rule.87"; Column "Vehicle technology costs, equivalent annualized values (2020 dollars).85": Row "$15 billion.88"; Column "Annual industry average per vehicle cost increase (2020 dollars).86": Row "$1,164 in 2032.89" [EPA-HQ-OAR-2022-0829-0621, pp. 10-11]

Column "CAA §202(a) passenger vehicles GHG emissions rules.84": Row "2021 GHG Final Rule.90"; Column "Vehicle technology costs, equivalent annualized values (2020 dollars).85": Row " $13.5-14.6 billion.91"; Column "Annual industry average per vehicle cost increase (2020 dollars).86": Row "$1,207 in 2026.92" [EPA-HQ-OAR-2022-0829-0621, pp. 10-11]

Organization: Travis Fisher

Specifically, the EPA’s DRIA regarding the impact of the Proposed Rule on the cost and reliability of electricity in the U.S. is gravely flawed. It should be redrafted to enable the EPA Administrator to give appropriate consideration to the cost and safety factors of the Proposed Rule, as required by section 202 of the Clean Air Act.1 Further, the DRIA should address the interactions between the Proposed Rule and other EPA rules—including the recently proposed rule on greenhouse gas emissions from power plants2—as required by Executive Order 12866.3 As written, the Proposed Rule: [EPA-HQ-OAR-2022-0829-0655, p. 1]

1 42 U.S.C. § 7521, https://www.law.cornell.edu/uscode/text/42/7521.

2 New Source Performance Standards for Greenhouse Gas Emissions From New, Modified, and Reconstructed Fossil Fuel-Fired Electric Generating Units; Emission Guidelines for Greenhouse Gas Emissions From Existing Fossil Fuel-Fired Electric Generating Units; and Repeal of the Affordable Clean Energy Rule, 88 FR 33240; May 23, 2023. Available at: https://www.federalregister.gov/documents/2023/05/23/2023-10141/new-source- performance-standards-for-greenhouse-gas-emissions-from-new-modified-and-reconstructed (accessed July 2, 2023).

3 Executive Order 12866, Regulatory Planning and Review, 58 FR 51735; October 4, 1993. Available at: https://www.archives.gov/files/federal-register/executive-orders/pdf/12866.pdf (accessed July 2, 2023).

1. Violates section 202 of the Clean Air Act by failing to adequately consider:

A. Impaired bulk power system reliability and

B. Increased retail electricity prices;

2. Does not comply with Executive Order 12866; and

3. Violates the Unfunded Mandates Reform Act. [EPA-HQ-OAR-2022-0829-0655, p. 1]

CONCLUSION

Thank you for the opportunity to comment on the Proposed Rule. For the foregoing reasons, the EPA should not move forward with this rule without first correcting the many dire flaws in the Proposed Rule: its violation of section 202 of the Clean Air Act and Executive Order 12866, its faulty cost-benefit analysis, and its woeful misunderstanding of the U.S. electricity sector as reflected in the DRIA. [EPA-HQ-OAR-2022-0829-0655, p. 10]

Organization: The Heritage Foundation (Kevin Dayaratna and Diana Furchtgott-Roth)

The Cost-Benefit Analysis of the Rule is Flawed

There are numerous problems with the cost-benefit analysis in the tailpipe rule. These include misinterpretation of vehicle ownership costs; miscalculated fuel savings; miscalculated losses from refueling time; calculation of transfers and tax credits; overestimation of light duty vehicle sales; overstatement of environmental benefits; overstatement of security benefits; and low discount rate. [EPA-HQ-OAR-2022-0829-0674, pp. 11-12]

EPA Summary and Response

Summary:

The American Fuel & Petrochemical Manufacturers commented that we had understated costs, particularly for batteries, and that the costs of the proposal would far exceed its benefits. They also commented that we had excluded costs of ZEVs in the no action case while simultaneously including the benefits provided by those ZEVs. They also argued that we focused on ZEV purchase price while ignoring emissions trading and cross-subsidization strategies. They also commented that our cost of ownership analysis was incomplete and that we had failed to fully consider costs of EVSEs, in particular costs of grid upgrades.

GFI commented in support of our benefit cost analysis, arguing that it fell within historical norms for 202(a) GHG standards.

Travis Fisher commented that benefit-cost analysis was fundamentally flawed and violated section 202 of the Clean Air Act and Executive Order 12866.

The Heritage Foundation commented that our benefit cost analysis had numerous problems including miscalculated costs and fuel savings and overstatement of security benefits and use of a low discount rate.

Response:

We disagree with comments that we have underestimated costs, specifically battery costs, in the final rule. The final rule analysis makes use of updated battery costs, based on the best available data and developed along with experts at the Department of Energy and the Argonne National Laboratory. Those battery costs are somewhat higher than the costs we estimated at proposal and are in general agreement with projections of battery costs by independent third parties (see section 12.2.1 of this RTC and Chapter 2.5 of the final RIA). Even with these higher battery costs, the monetized benefits of the rule substantially exceed the costs.

The American Fuel and Petrochemical Manufacturers assert that the proposal's No Action case includes ZEV costs that are themselves the result of automaker anticipation of what at the time were yet-to-be proposed standards. While EPA agrees that manufacture announced plans may, in general, reflect future regulations, the basis for the proposal's No Action case was informed using a range of third-party projections that preceded this rulemaking process. Such projections therefore provide a reasonable basis for a No Action case, since they consider a range of factors – including for this final rulemaking the effect of IRA incentives – but not the additional requirements of these standards through MY 2032. The comment also indicates some confusion over the focus on BEV purchase price while ignoring the impacts of manufacturers' emissions trading and cross-subsidization strategies. In our OMEGA compliance modeling, we do include estimates of cross-subsidization and emission trading (see Chapters 2 and 4 of the final RIA). Summarizing briefly here, EPA's compliance modeling assumes that manufacturers may choose to apply more technology or less technology than is needed to meet the GHG targets depending on whether it is most cost effective to reach full compliance using credits to sell, purchase, or not at all. Therefore, the purchase price used when estimating consumer demand for a vehicle is influenced by the cross-subsidy, credit trading, and technology application decisions made by the manufacturer, as well as by the incentives made available by the IRA. EPA notes that we do not use purchase price when reporting manufacturer costs. As such, while the consumer might consider that purchase incentive made available by the IRA, the manufacturer's cost would not reflect that incentive since that incentive goes to the consumer, not the manufacturer. This comment also suggests that the analysis of operating costs and other costs of ownership is incomplete. One argument made suggests that EPA compares the real world fuel economy of ICE vehicles while not considering the real world energy consumption of BEVs. This claim is erroneous as the analysis does consider the real world energy consumption of both ICE vehicles and BEVs and PHEVs and does so on an equal basis. Another argument made is that EPA's analysis failed to consider excise taxes and insurance costs. The final analysis includes insurance costs since they can be significantly higher for vehicles with higher value. Regarding excise taxes, i.e., taxes or fees meant to recover foregone fuel tax revenues, EPA has not included these in our benefit-cost analysis of program social costs and social benefits (although we do show these as part of our consumer ownership experience discussion in Chapter 4.2 of the final RIA) because of the wide variety of such taxes across the nation and because many states have yet to determine the approach they will take (e.g., additional registration fees applied to BEVs or road-use fees applied to all vehicles). If those taxes and fees were included, they would increase operating costs associated with BEVs and, perhaps, HEVs and PHEVs, although we would not expect the impact to result in higher operating costs than ICE vehicles. Importantly, these taxes or fees would not factor into our benefit cost analysis as they represent transfers and not social costs of the rule. Regarding costs of EVSE and grid updates, we have updated the analysis for the final rule and respond to related comments in Sections 17 and 18 of this document.

EPA agrees with the comments from Governing for Impact and Evergreen Action (GFI), specifically that "EPA — far from charting a newly ambitious course — is diligently attempting to meet its statutory obligations without straying from its historical approach."

EPA disagrees with the comments provided by Travis Fisher. EPA notes that, consistent with CAA section 202, in evaluating potential standards we carefully weighed the statutory factors, including the emissions impacts of the standards, and the feasibility of the standards (including cost of compliance in light of available lead time). We monetize benefits of the standards and evaluate other costs in part to enable a comparison of costs and benefits pursuant to E.O. 12866, but we recognize there are benefits that we are currently unable to fully quantify. EPA's practice has been to set standards to achieve improved air quality consistent with CAA section 202, and not to rely on cost-benefit calculations, with their uncertainties and limitations, as identifying the appropriate standards. Nonetheless, our estimated benefits, which exceed the estimated costs of the final program, reinforce our view that the final standards represent an appropriate weighing of the statutory factors and other relevant considerations. More specifically, for this rule our assessment that the rule has positive net monetized benefits, regardless of the magnitude of those positive net benefits, supports our view that the final standards represent an appropriate weighing of the statutory factors and other relevant considerations. EPA also notes that the analysis includes expected impacts of other federal rules that are final rules while not considering those that are proposed. This is consistent with past EPA practice and direction from the Office of Management and Budget. However, recognizing that EPA is undertaking multiple rules at this time that may have an impact on the electricity grid, EPA has evaluated, to the extent possible, the potential cumulative impact of these rules. EPA's evaluation of the potential impact of these rules on the power system can be found in Chapter 5 of the RIA, Section 18 of this RTC, and the Technical Memorandum for Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles, and Greenhouse Gas Emissions Standards for Heavy-Duty Vehicles – Phase 3. EPA judges that this rule, even considered together with the heavy-duty rule and several recent proposed rules regulating the EGU sector, as well as the IRA, will not result in significant increases in retail electricity prices (and there is no reason to expect that any increases in retail electric prices would offset all of the net total benefits for the rule). Please see Sections 21 and 23 of this document for more detailed responses on these issues. Note that our final analysis includes the results of the modeling efforts reflecting both the light- and medium-duty final rule and the heavy-duty phase 3 final rule. Further, we note that we will conduct comprehensive power sector modeling for the proposed rules regulating the EGU sector if and when they are finalized, and that the modeling of subsequent rules will account for prior rules, including this rule, in the baseline.

We disagree with the Heritage Foundation that the analysis is flawed. EPA has very carefully considered the costs and benefits associated with the final rule using the best available information at our disposal. For these reasons, we consider the analysis to be technically sound and appropriate. Moreover, EPA notes that we did not rely on the benefits and costs analysis in identifying the appropriate standards, but we find that these factors further support the reasonableness of this rule, as further discussed in Sections V and VIII of the preamble to this rule.

8.1 - General approach

Comments by Organizations

Organization: Alliance for Automotive Innovation

XI. Additional Comments on EPA's Draft Regulatory Impact Analysis

At the outset, Auto Innovators would like to commend EPA staff for the tremendous amount of work that went into preparing the Draft RIA. Auto Innovators particularly appreciates the efforts put into generating several analytic baselines and several regulatory alternatives for the proposed CO2 standards. The Alliance comments begin with the overall structure of the RIA and then proceed to specific technical concerns and suggestions that EPA should consider between now and the final rule. [EPA-HQ-OAR-2022-0829-0701, p. 279]

A. Structure of the Analysis

The preamble to the NPRM highlights the fact that the multi-pollutant rulemaking contains several distinct sets of regulatory programs and amendments: (1) new CO2 standards for model year 2027 to 2032 light-duty vehicles, (2) new CO2 standards for model year 2027 to 2032 medium-duty standards, (3) new criteria-pollutant standards for model year 2027 to 2032 vehicles, (4) new criteria pollutant standards for model year 2027 to 2032 medium-duty standards, (5) new battery durability and warranty requirements, and (6) new light-duty vehicle testing and certification improvements. [EPA-HQ-OAR-2022-0829-0701, p. 279]

B. Each Set of Regulatory Programs/Amendments Should Have its Own benefit- Cost Analysis Unless EPA Can Show that a Particular Requirement is Not a significant Change.

The DRIA presents separate benefit-cost analyses for the light- and medium-duty vehicle standards for CO2. However, Auto Innovators could not find in the DRIA separate benefit-cost analyses for each of the other regulatory programs and amendments that are embedded in the multi-pollutant rulemaking. Most of the Auto Innovators comments focus on the new CO2 standards because the agency did not prepare much analysis to support the other regulatory programs and amendments. OMB Circular A-4 specifically instructs agencies to go beyond an analysis of an entire rulemaking and prepare separate benefit-cost analyses of each program within a rulemaking. [EPA-HQ-OAR-2022-0829-0701, pp. 279-280]

C. A market-failure analysis should be provided to support each set of regulatory programs and amendments.

OMB Circular A-4, following textbook principles of benefit-cost analysis, instructs agencies to present a market failure analysis in support of each new regulatory requirement or amendment. Auto Innovators did not find any market-failure analysis in the DRIA. Without demonstrating a market failure, the agency does not have a solid justification for moving forward to a final rule. Auto Innovators believes this omission is especially glaring in the case of the battery durability and warranty requirements. It is also important in the case of the CO2 standards, since the agency is claiming that private benefits to motorists (fuel savings and maintenance/repair savings) are more than enough to pay for the private costs of the CO2 standards. If the agency's calculations are correct, why would not manufacturers, driven by consumer behavior, supply the BEV deployment and other technology improvements without EPA's proposed standards? The answer to this question requires a market-failure analysis. [EPA-HQ-OAR-2022-0829-0701, pp. 279-280]

D. Global vs. Domestic Impacts

The agency needs to decide whether the benefits and costs of the CO2 standards will include global impacts or only impacts in the United States, or whether separate analyses shall be prepared from global and U.S. perspectives. Once that decision is made, the regulatory impact analysis should adhere to that decision on a consistent basis on both the benefit and cost side of the ledger. [EPA-HQ-OAR-2022-0829-0701, p. 280]

As currently drafted, the regulatory impact analysis is inconsistent: it counts the global benefits of the CO2 standards due to reduced tailpipe emissions from U.S. vehicles but does not even consider the environmental damages that may occur around the world due to the rapid expansion of the supply chains for battery-electric vehicles to meet U.S. needs under the multi-pollutant rule. Examples of possible environmental damages include consumption of scarce water supplies in water-stressed areas of South America in the process of mining lithium, water pollution in China from the processing of mined materials for cathode makers, particulate air emissions at hard-rock mining sites in Australia, and carbon dioxide emissions throughout the global supply chain for battery-electric vehicles. [EPA-HQ-OAR-2022-0829-0701, p. 280]

We already know, from unfortunate historical experiences in the U.S. and abroad, that the expansion of the global supply chain for electric motors and lithium ion batteries will not be risk free. The agency should make a careful assessment of these environmental damages and weigh them against the global environmental benefits of CO2 control. To help get the agency started, here are some selected case studies of the environmental damages in the BEV supply chain. [EPA-HQ-OAR-2022-0829-0701, p. 280]

Organization: American Free Enterprise Chamber of Commerce (AmFree) et al.

Similar flaws mar the remainder of EPA's analysis. In comparing the rule's purported benefits with its costs, EPA unreasonably elides many costs by refusing to quantify them at all. And the costs and benefits that the agency does quantify rest largely on unreliable data, assumptions, or both. EPA also failed to meaningfully consider alternative approaches. It considered only slight vari- ations on the same theme, comparing new emissions standards of various levels of stringency, without exploring other solutions, such as the benefits available from renewable fuels. Only by considering its preferred proposal in a vacuum could EPA conclude that it is the optimal approach. [EPA-HQ-OAR-2022-0829-0683, p. 5]

EPA's Cost-Benefit Analysis Is Seriously Flawed In Several Respects

EPA estimates that the proposed rule will have vast net benefits of approx- imately $1.6 trillion, assuming a 3 percent discount rate. 88 Fed. Reg. at 29,362. This figure is the net of an estimated $487 billion in costs and $2.1 trillion in benefits. Id. Yet EPA's process for arriving at these amounts contains several serious flaws, detailed below, that unduly inflate the rule's purported benefits and depress its costs. Where an agency conducts a cost-benefit analysis as part of the justification for a proposed rule, as EPA has here, serious flaws like these render the rule arbitrary and capricious. See Nat'l Ass'n of Home Builders v. EPA, 682 F.3d 1032, 1040 (D.C. Cir. 2012). [EPA-HQ-OAR-2022-0829-0683, p. 61]

Fourth, when calculating the climate benefits that the proposed rule would generate, EPA relied on estimates from the Interagency Working Group on the Social Cost of Greenhouse Gases. See 88 Fed. Reg. at 29,371–79. This intro- duced two additional flaws into EPA's cost-benefit analysis. To start, it ren- dered the analysis internally inconsistent as to the discount rates used. For every other cost and benefit in the proposed rule, EPA followed OMB's guid- ance and used discount rates of 3 and 7 percent to calculate present values. See id. at 29,362. But the Interagency Working Group discounted its estimates at 2.5, 3, and 5 percent discount rates. Id. at 29,372. As a result, aside from its 3- percent scenarios, EPA was irrationally comparing costs and benefits valued using distinct discount rates. [EPA-HQ-OAR-2022-0829-0683, p. 64]

Organization: American Fuel & Petrochemical Manufacturers

The purported benefits in terms of reductions in cost, greenhouse gas emissions, and environmental impacts are based on flawed analyses and will not be realized by consumers. EPA's tailpipe-only approach is flawed, and the Agency needs to evaluate light- and medium-duty vehicles on a full lifecycle basis, regardless of whether those emissions result from electricity generation, battery production, or the combustion of liquid or gaseous fuels. Consumer benefits from the proposal are exaggerated by assuming an unrealistic baseline rate of ZEV-adoption, and inadequate assessments of ZEV purchase and ownership costs, charging costs, and road infrastructure costs. [EPA-HQ-OAR-2022-0829-0733, p. 3]

EPA's Proposed Rule here presents an analogous situation, albeit one with substantially greater costs. Mandating a rapid shift from ICEV to ZEV will reshape the American automotive market with profound collateral effects, making clear that EPA is encroaching upon an issue of "vast economic and political significance." As further discussed herein, the Proposal's direct compliance costs are enormous—even in the face of numerous errors and oversights in its analysis that materially understate these costs. EPA estimates that the cost of vehicle technology (not including the vehicle or battery tax credits) would be approximately $180 billion–$280 billion in addition to greater than $7 billion in electric vehicle supply equipment ("EVSE") costs through 2055. These figures do not include the transformation of the electric power sector and grid updates needed to meet the electricity demand created by the Proposed Rule, which is estimated to cost trillions of dollars.66 EPA acknowledges that auto manufacturers are spending over a trillion dollars by 2030, mainly for manufacturing facilities. By setting emissions standards requiring production of a different product, the Proposed Rule undoubtedly forces OEMs to meet production deadlines that would not exist but for EPA's new ZEV mandate. [EPA-HQ-OAR-2022-0829-0733, pp. 18-19]

66 Dan Shreve and Wade Schauer, Deep decarbonization requires deep pockets (June 2019), https://www.decarbonisation.think.woodmac.com/ (The U.S. needs to invest $4.5 trillion to fully transition the U.S. power grid to renewables during the next 10-20 years, annual investments exceeding the U.S. defense budget).

E. EPA's cost benefit analysis is impermissibly inadequate

Section 202(a) of the Clean Air Act does not mandate that EPA set standards to drive pollutant emissions down to zero. Rather, CAA section 202(a)(1) only requires that standards be promulgated for air pollutants which "may reasonably be anticipated to endanger public health or welfare." And in promulgating regulations, EPA must balance benefits to health and welfare against the time necessary to allow for the development and application of the requisite technology as well as costs of compliance.202 With regard to heavy duty vehicles or engines, including the MDVs subject to the Proposed Rule, EPA standards are to reflect "the greatest degree of emission reduction achievable through the application of technology which the [EPA] determines will be available" during the relevant model year.203 Rather than update ICEV standards, the Proposed Rule unlawfully forces a transition from ICEVs to ZEVs in the MY27–32 timeframe without properly evaluating all cost-effective means to address policy objectives and the time necessary for the development and application of requisite technology. EPA has not demonstrated that such a transition is feasible, let alone necessary. [EPA-HQ-OAR-2022-0829-0733, p. 44]

202 42 U.S.C. § 7521(a)(2).

203 42 U.S.C. § 7521(a)(3)(A)(i).

EPA ignores this real-world regulatory compliance pricing scheme. EPA should quantify and explain this issue of central relevance to the Proposed Rule even if it may undermine the Administration's stated goal of electrifying the transportation fleet. As noted above, E.O. 12866 requires EPA to be a neutral decisionmaker and to fairly assess the costs and benefits of this Proposal. The Agency has not met its obligations under relevant Executive Orders, the Administrative Procedure Act, or CAA section 202(a), which requires "appropriate consideration to the cost of compliance." EPA has instead understated the costs of this Proposal. [EPA-HQ-OAR-2022-0829-0733, p. 54]

vii. Costs to maintain road infrastructure

EPA fails to account for infrastructure impacts from increased operation of heavier ZEVs on the road including road and bridge deterioration and commensurate reduced funding for infrastructure from fuel tax collections. These excluded costs are known to EPA and must be included in EPA's analysis—another example of EPA's failure to address a major aspect of the proposal. [EPA-HQ-OAR-2022-0829-0733, pp. 60-61]

EPA must, therefore, conduct a full cost analysis to compare all costs that must be incurred in order to achieve the environmental benefits EPA is claiming in the Proposal. EPA cannot rationally claim an environmental benefit from its Proposal without also accounting for all the costs needed to bring about those environmental benefits. [EPA-HQ-OAR-2022-0829-0733, pp. 60-61]

Organization: American Petroleum Institute (API)

EPA fails to properly account for all of the cost increases associated with the enforcement of gasoline particulate filter (GPF) technologies. The GPF cost model is described in DRIA Chapter 3.2 and GPF cost is included in the OMEGA model. The model anticipates the direct manufacturing cost (DMC) for a bare downstream GPF, which ranges from $51 dollars for a 1.0-liter engine using a relatively low GPF 249 volume to engine displacement ratio, up to $166 dollars for a 7.0 liter engine using a relatively high GPF volume to engine displacement ratio. In the DRIA (page 3-60) GPF cost is based on the ICCT 2011 work, which is now over 10 years old. Further, the EPA assumes that the GPFs that OEMs will utilize to meet more stringent PM and GHG targets will be those new generation of MY 2022 GPFs with "high filtration efficiencies generally over 95 percent" and low backpressure. The assumed costs for MY 2022 GPF with higher efficiency appear to be unreasonably low and caused the modeling to overestimate feasibility. Furthermore, it is not clear if the associated equipment for effective operation of the GPF such as associated sensors and controllers are included in the cost assessment performed by EPA. The agency should reevaluate its assessment based on more realistic efficiency levels to avoid arbitrary and capricious action. [EPA-HQ-OAR-2022-0829-0641, p. 13]

Appendix B:

Detailed Look at the Assumptions Used in the EPA Analysis in the NPRM and the DRIA – Assessment Prepared by Martec

EPA referred to the proposed rule111 as “the most ambitious pollution standards ever for cars and trucks,” while also saving the “average consumer $12,000 over the lifetime of a light- duty vehicle.” EPA has also estimated that the benefits of the proposed standards would exceed costs by at least $1 trillion. In reaching its conclusions, the agency also expects the proposed regulations would require “67% of new light-duty sales” to be solely powered by batteries and new power generation facilities to “fuel” these new BEVs. These changes would require significant changes in the way vehicles are designed, built, and fueled. However, as these changes occur, the agency has promised large savings to the consumer and a net positive impact on the U.S. economy. The following is a detailed look at the assumptions used in the EPA analysis in the NPRM and the DRIA to determine if the claims made are valid. [EPA-HQ-OAR-2022-0829-0641, p. 42]

111 https://www.epa.gov/regulations-emissions-vehicles-and-engines/proposed-rule-multi-pollutant-emissions- standards-model.

EPA has failed to adequately explain several aspects of their analysis. In order to provide the public with meaningful ability to comment there are several aspects that need further clarification:

- The cost reduction model used in the analysis seems to be based on a model used for part cost reductions driven by improved economies of scale on fixed capital equipment. Given that raw materials make up a significant portion of battery costs, EPA should also use a raw material supply cost model that considers the increasing costs for raw materials with increased supply. [EPA-HQ-OAR-2022-0829-0641, p. 42]

- Cost and price are concepts that the agency uses interchangeably in the regulation. The true cost of the regulation is not fully calculated since the portion of the consumer- facing price is paid for by the government. The agency should fully account for the technical feasibility of any CO2-reducing technology on a cost basis as defined in the CAA regardless of governmental taxation breaks for electric vehicle technology production and sale. [EPA-HQ-OAR-2022-0829-0641, p. 42]

- The cost impact of “fueling” the significant number of electric vehicles assumed in the regulation (67% implied EV share by 2032) is not fully calculated or considered as part of the technical feasibility analysis and cost for the technology. The costs of adding additional solar, wind, and hydropower plants should be considered in the regulation as they are a necessary part of bringing electric vehicles to market. [EPA-HQ-OAR-2022-0829-0641, p. 42]

13.1.2.1 Proposed GHG Standards

Incremental Costs per vehicle for the proposed standards (compared to the No Action case) are summarized by regulatory class in Table 13-45 and by body style in Table 13-46 [EPA-HQ-OAR-2022-0829-0641, pp. 49-50]

Table 13-45: Projected Manufacturing Costs Per Vehicle, Proposed Standards

	2027	2028	2029	2030	2031	2032
Cars	$249	$102	$32	$100	$527	$844
Trucks	$891	$767	$653	$821	$1,100	$1,385

Total $633 $497 $401 $526 $866 $1,164 [EPA-HQ-OAR-2022-0829-0641, pp. 49-50]

We question the rationale for requiring 67% BEV sales for compliance by 2032 but not accounting for the cost of these BEVs over the existing regulation as part of the regulatory impact analysis. Using Argonne's battery cost values from BatPaC we would expect an average cost of ~$12,000 for the battery system to be accounted for in the analysis. Additionally, the agency also assumes a cost of ~$3,500 for electric drive units, inverters, and charging systems. [EPA-HQ-OAR-2022-0829-0641, pp. 49-50]

Removing the cost of the ICE powertrain and components from the vehicle would leave ~$7,500 to be accounted for in the regulation. With a 67% BEV market share assumption, this would be ~$5,000 compliance cost, not $1,164 as shown in the DRIA. [EPA-HQ-OAR-2022-0829-0641, pp. 49-50]

The agency needs to fully account for the costs of the regulation requiring 67% of BEVs to be sold by 2032 and not use incremental costs above the assumed volume of BEVs by the automakers themselves. [EPA-HQ-OAR-2022-0829-0641, pp. 49-50]

Required Updates

EPA must accurately assess the financial costs the proposed regulation would impart on the U.S. consumer. Accordingly, EPA should:

- Use a raw material supply cost model that considers the increasing costs for raw materials with increased supply. Automotive battery costs are largely driven by raw materials (63% of total cost) and sources for these raw materials are becoming increasingly more expensive. [EPA-HQ-OAR-2022-0829-0641, p. 51]

- Include the cost of all vehicles that are needed to meet the regulation not merely the additional volume of vehicles needed to meet the regulation over the assumed electric vehicle volumes of the automakers. [EPA-HQ-OAR-2022-0829-0641, p. 51]

- Fully account for the technical feasibility of any CO2-reducing technology on a cost basis as defined in the CAA regardless of governmental taxation breaks for electric vehicle technology production and sale. [EPA-HQ-OAR-2022-0829-0641, p. 51]

- Consider the costs of adding additional solar, wind, and hydropower plants in the regulation as they are a necessary part of bringing electric vehicles to market as described by EPA. [EPA-HQ-OAR-2022-0829-0641, p. 51]

Failure to do so would be arbitrary and capricious. [EPA-HQ-OAR-2022-0829-0641, p. 51]

Organization: Anonymous

3. EPA incorrectly models its baseline

EPA's analysis shows that the proposed standards will reduce the compliance cost to certain manufacturers. For example, Honda could save over a $1,000 per vehicle in 2027 and 2028 if it chose the compliance pathway selected by EPA. This makes no sense from a cost-benefit analysis. The takeaway here is that manufacturers are choosing to forgo reducing costs to sell the same or less vehicles, meaning vehicle manufacturers are acting irrationally. A proper baseline should assume that manufacturers will act rationally and will produce vehicles that maximize profits (either through reduced costs or increased sales). EPA's analysis fails this very basic tenet. [EPA-HQ-OAR-2022-0829-0565, pp. 3-4]

One justification that EPA proffers for this irregularity is how it employs learning curves. EPA assumes that technologies will become cheaper over time as manufacturers learn to produce vehicles. While this is generally an accepted fact of new technologies, EPA doesn't clarify why Ford producing more battery electric vehicles in 2027 because of EPA's proposed standards will reduce the cost to Honda and Tesla. In essence, EPA takes a very generalized concept of learning over a long-period of time across industry to incorrectly reduce the costs at a firm level. For this to actually happen, some manufacturer like Ford would have to inform other manufacturers about how they improved their battery production process and for that new process to have the same effect on another manufacturer AND that other manufacturer being able to employ that new technique within the same model year. All of these assumptions are ludicrous and do not reflect how competing firms protect their trade secrets or how long it takes to design or change a vehicle line. [EPA-HQ-OAR-2022-0829-0565, pp. 3-4]

Organization: Arizona State Legislature

2. The proposed rule fails to rely on a cost-benefit analysis. EPA did not rely on a cost-benefit analysis to select the standards in the proposed rule, in contravention of statutory and case-law requirements. [EPA-HQ-OAR-2022-0829-0537, p. 2]

Organization: California Air Resources Board (CARB)

Regulatory Impact Analysis

CARB has reviewed U.S. EPA's Draft Regulatory Impact Analysis (DRIA) and finds that U.S. EPA's estimates of the costs and benefits associated with the proposed standards are appropriate and broadly consistent, where applicable, with comparable assumptions California used in its rulemaking. In general, CARB finds that U.S. EPA has taken a conservative approach to estimating net benefits. Despite this conservative approach, there are dramatic net benefits from even the most stringent alternative. CARB has identified three specific areas where U.S. EPA is likely underestimating net benefits, explained below, although these are not intended to represent an exhaustive list. While CARB does not necessarily recommend that U.S. EPA revise its analysis based on these comments, these findings suggest that directionally the net benefits of the proposed standards are even greater than what U.S. EPA has assessed. [EPA-HQ-OAR-2022-0829-0780, p. 48]

Organization: California Attorney General's Office, et al.

Our States and Cities add three observations to EPA's analysis of costs and lead time. First, EPA's projected costs likely overstate the actual costs attributable to reaching the standards in the allotted lead time, due to conservative assumptions in EPA's no-action case that omit the myriad state and local actions to promote electric vehicle adoption. See supra 18-21; CARB Comment at 16. Second, state and local agencies are implementing ambitious programs to ready power grids and charging infrastructure for the increased adoption of electric vehicles and the associated increase in electricity demand, which further supports EPA's feasibility analysis. Third, although internal-combustion-engine vehicles will make up a smaller portion of the national fleet, it is imperative that EPA's standards continue to encourage the application of feasible, cost-effective emission-reduction technologies to these vehicles, as they still represent a significant source of GHG, criteria, and toxic pollutant emissions. [EPA-HQ-OAR-2022-0829-0746, p. 33]

First, while we agree with EPA's decision to project the proposed standards' technology costs out to 2055, to promote a robust comparison with the benefits also projected for the same period, id. at 29,364-5, EPA should enhance the public's understanding of this rule's costs by providing more context for these numbers. Because the automotive industry's light- and medium-duty fleets are so large, the technology costs projected through 2055 are relatively modest when distributed over the number of vehicles they cover: more than 400 million vehicles sold over almost three decades. EPA should consider disclosing the aggregate technology costs in Table 160 as per-vehicle costs, as it has done in other parts of the Proposal. See id. Per-vehicle cost figures are particularly informative, because auto manufacturers are likely to pass at least a portion of these costs down to consumers, who will more than recoup any such price increases through reduced operating and ownership costs. Id. at 29,328. And, in the same spirit that EPA explored sensitivities to ACCII coming into effect, id. at 29,335, EPA should disclose to what extent the proposed standards' projected costs through 2055 would be reduced if ACCII were included in the no-action scenario. [EPA-HQ-OAR-2022-0829-0746, p. 36]

Second, the auto industry has already invested hundreds of billions of dollars in transitioning to electric vehicles.189 These investments cover many of the technology costs that EPA anticipates the industry will expend to comply with the proposed standards. While it may be difficult to parse to what extent this investment responds to consumer demand, business strategy, or state policies and to what extent this investment anticipates federal regulation, EPA should note that the auto industry has committed at least some of the technology costs projected in Table 160 long before these standards were proposed. [EPA-HQ-OAR-2022-0829-0746, p. 37]

189 Noah Gabriel, $210 Billion of Announced Investments in Electric Vehicle Manufacturing Headed for the U.S., Atlas EV Hub (Jan. 12, 2023), available at https://www.atlasevhub.com/data_story/210-billion-of-announced-investments-in-electric-vehicle-manufacturing-headed-for-the-u-s/ ("Vehicle manufacturers and battery makers plan to invest $860 billion globally by 2030 in the transition to EVs. Nearly a quarter, $210 billion, is expected to be invested in the United States, more than in any other country.").

Organization: Clean Fuels Development Coalition et al.

The agency's proposal is audacious. Racing past the Biden administration's goal "to make half of all new vehicles sold in 2030 zero-emissions vehicles, including battery electric, plug-in hybrid electric, or fuel cell electric vehicles,"1 EPA has proposed that 60 percent of new light-duty vehicles be battery electric by 2030, and 67 percent by 2032. This electrification mandate is nominally in service of reducing greenhouse-gas emissions from the transportation sector. But EPA has chosen a staggeringly cost-ineffective way to achieve this end. By the agency's own math, the pro- posed rule would reduce CO2 emissions from the baseline by 232 million metric tons at cost of $86 billion during the compliance years of 2027 to 2032: roughly $370 per ton of CO2.2 That is a very bad deal. By way of comparison, reducing emissions by investing in nearly any other energy efficiency or renewable energy technology would be at least four times cheaper. See Kenneth Gillingham, The True Cost of Reducing Greenhouse Gas Emissions, International Monetary Fund, Finance & Development (Dec. 2019), https://www.imf.org/external/chinese/pubs/ft/fandd/2019/12/pdf/the true-cost-of-reducing-greenhouse-gas-emissions-gillingham.pdf. Given this, the proposal is illogical, unless it is EPA's intent to squander limited financial resources on the most expensive emission reductions, thus effectively increasing net emissions. [EPA-HQ-OAR-2022-0829-0712, pp. 1-2]

1 FACT SHEET: President Biden Announces Steps to Drive American Leadership Forward on Clean Cars and Trucks, White House Briefing Room (Aug. 5, 2021), https://www.whitehouse.gov/brief- ing-room/statements-releases/2021/08/05/fact-sheet-president-biden-announces-steps-to-drive-ameri- can-leadership-forward-on-clean-cars-and-trucks/.

2 Emissions reductions are from Table 135, 88 Fed. Reg. 29,348. Costs include EPA's calculated vehicle technology costs, Table 160, id. at 29,364–65 , Electric Vehicle Supply Equipment (EVSE) costs, Table 165, id. at 29,367, and refueling costs, Table 166, id. at 29, 367–68.

- Taxpayer subsidies: Taxpayers subsidize the sales of electric vehicles, charging infrastructure, roads, and the electricity generation, transmission, and distribution required to power these vehicles. The proposal currently ignores these costs, counting them instead as "transfers."5 88 Fed. Reg. 29,369. [EPA-HQ-OAR-2022-0829-0712, pp. 6-7]

5 As described below, the many direct subsidies (federal and state electric vehicle credits, charging credits, etc.) and regulatory subsidies (EPA multiplier credits, NHTSA multiplier credits, state ZEV credits, etc.) result in real costs to taxpayers and the consumers of the many products that cross-subsidize these "preferred" products. These costs cannot be treated as "transfers" that are cost-free, and they absolutely cannot be treated as "transfers" to circumvent the economic significance prong of the major questions doctrine.

C. The proposal manipulates timelines to inflate the benefits of the rule.

Finally, EPA's cost-benefit calculations are arbitrary because it extends its calculations to 2055. Thirty years into the future is far past the date when EPA can make reasonable projections. The agency only chose this time frame because it provides enough time for abstract and speculative benefits to "accrue," while very high initial costs of the proposal are averaged out or ameliorated by future adoption of currently nonexistent technologies, efficiencies, and improvements. This is all the more absurd when one considers that the social cost of carbon inputs rely on projections about costs and benefits 300 years in the future. This is the time horizon of science fiction and futurism, not technocratic policymaking under the Clean Air Act. In the long run, no doubt, the accounts all balance out, but only because "[i]n the long run we are all dead." J. Keynes, Tract on Monetary Reform 88 (1924) (emphasis omitted). [EPA-HQ-OAR-2022-0829-0712, pp. 22-23]

E. The sum of these miscalculations means that vehicle technology costs will be much higher than the agency projects.

Taken together, each of EPA's unreasonable projections dramatically reduced projected vehicle technology costs. Adding the additional costs missed by ignoring current cross subsidization, underestimated battery costs, and the limited availability of Clean Vehicle tax credits to the proposal's projected vehicle technology costs raises those costs from a total of $59.6 billion between 2027 and 2032 to between $339 billion and $1.09 trillion during the same span. See Figure 6. This is a cost of between $22,000 and $72,000 per electric vehicle sold. It would be impossible for automakers to sell more than a tiny share of electric vehicles if those vehicles were priced accordingly. Failing to account for the "cost of compliance" in this way violates the agency's statutory obligations and at the very least renders the rule arbitrary and capricious. [EPA-HQ-OAR-2022-0829-0712, pp. 24-25]

SEE ORIGINAL COMMENT FOR Figure 6: Projected vehicle technology costs accounting for cross subsidies, increased battery costs, and decreased availability of the Clean Vehicle Credit. [EPA-HQ-OAR-2022-0829-0712, pp. 24-25]

IV. The Proposed Rule Fails to Adequately Consider Other Costs.

When an agency relies "on a cost-benefit analysis as part of its rulemaking, a serious flaw undermining that analysis can render the rule unreasonable." National Ass'n of Home Builders v. EPA, 682 F.3d 1032, 1040 (D.C. Cir. 2012). EPA's cost- benefit analysis suffers from "serious flaw[s]" on both sides of the ledger. First, as detailed at length above, the proposal dramatically underestimates the vehicle costs. But the proposal also engages in an unreasonable cost-benefit analysis in several other ways. The proposal underestimates the costs of charging infrastructure while inflating the benefits of the rule: ignoring emissions when convenient, relying on outrageous social costs of carbon calculations that rely on projections of benefits hundreds of years in advance to inflate the present benefit, and gerrymandering vehicle class and compliance timelines to obscure the real impacts of the rule. These flaws render the proposed rule unreasonable. [EPA-HQ-OAR-2022-0829-0712, pp. 32-33]

Organization: Environmental. and Public Health Organizations

Alternative 1 also provides greater pollution reductions and societal benefits than the Proposed Standards. Under EPA's modeling, Alternative 1 would avoid 8,100 million metric tons (MMT) of CO_2 emissions through 2055 relative to the No Action scenario, id. at 29203, tbl. 14, in contrast to the 7,300 MMT avoided under the Proposed Standards, id. at 29198, tbl. 3. Alternative 1 also provides greater reductions in criteria pollutants and air toxics. Compare id. at 29198-99, tbls. 4 and 5, to id. at 29203-05, tbls. 13-16. In addition, Alternative 1 has greater societal net benefits: ranging from $1,500-2,500 billion through 2055, id. at 29205-06, tbl. 17 (3% discount rate), depending on the values used for the GHG emission reductions, versus a range of $1,400-2,300 billion under the Proposed Standards. Id. at 29200, tbl. 6. [EPA-HQ-OAR-2022-0829-0759, p. 25]

V. Outside Analysis Demonstrates the Significant Benefits of Stronger Emission Standards, Particularly Alternative 1 with a Steeper Increase in Stringency After 2030.

Outside analysis also shows the benefits of adopting final standards stronger than EPA proposed. Environmental Resources Management, Inc (ERM), one of the largest sustainability consultancies globally, was commissioned by NRDC to provide an independent, third-party analysis of EPA's proposed standards and alternative proposals, as well as a recommended approach. ERM's methodology, assumptions, and results are described throughout this section, and the ERM report is attached to this comment letter.104 ERM's analysis shows that Alternative 1 with a steeper increase in stringency after 2030 would produce significant societal benefits. [EPA-HQ-OAR-2022-0829-0759, p. 26]

104 Dave Seamonds, et al., ERM, Impacts of EPA Light-& Medium-Duty Multi-Pollutant Standards: National Scenario Results, June 2023 [hereinafter ERM, Impacts Report] (attached to this comment letter).

ERM's analysis employed a modeling framework that leveraged EPA's tools to inform and develop inputs to ERM's Benefit-Cost Analysis (BCA) framework. It is important to note that while this analysis is based on EPA's "baseline" scenario, we believe this "baseline" is ultimately not an accurate reflection of a "No Action" scenario, as it is overly conservative. We explore this further in Section XV, but ultimately the most relevant of the analyses that EPA considered supports baseline ZEV sales greater than the baseline levels projected in the "EPA No Action" scenario. [EPA-HQ-OAR-2022-0829-0759, p. 26]

Where possible, ERM mirrored EPA's methodology to keep its analytical approach and resultant comparisons consistent with EPA's approach in the Proposal, and to allow for an apples-to-apples comparison. [EPA-HQ-OAR-2022-0829-0759, p. 26]

ERM utilized EPA's CO-Benefits Risk Assessment (COBRA) Health Impacts Screening and Mapping Tool to assess the public health benefits of the scenarios. [EPA-HQ-OAR-2022-0829-0759, p. 28]

ERM conducted five interconnected analyses as part of this BCA:

- Fuel Use and Emissions: Specifically, ERM assessed changes in fuel consumption (for diesel, gasoline, and electricity) and the tailpipe and upstream emissions associated with each fuel change for GHGs (CO2, CH4, N2O) and criteria pollutants (NOx and PM) for the various policy scenarios. Reductions in emissions are then monetized using EPA's COBRA model and EPA's Social Cost of GHGs.107 Because EPA's analysis (which this is intended to mirror) neither reflects any policies to clean up the grid nor a future grid consistent with the administration's climate goals, this likely understates disparities between scenarios with differing electric car/light-truck deployment. [EPA-HQ-OAR-2022-0829-0759, p. 28]

107 ERM utilized the interim social cost of GHG values presented by EPA in DRIA Tables 10-13, 10-14, and 10-15 (3 percent discount rate). Costs were escalated to 2021$ to be consistent with other costs in the ERM model.

- Health Impacts: This analysis assumes reductions in NOx and PM under the various policy scenarios to understand the resulting public health implications associated with reducing these emissions and calculates changes in premature deaths, hospital visits, and lost workdays. The analysis also monetizes these net health benefits. As above, these impacts are inherently understated in an effort to mirror EPA's work. [EPA-HQ-OAR-2022-0829-0759, p. 29]

- Economic Analysis: ERM assessed changes in consumer purchasing behaviors and vehicle costs, fuel costs, and maintenance practices, and how these factors could change in a more electrified fleet. This analysis also examines capital expenditures for charging infrastructure investments (i.e., purchase, installation, and maintenance). [EPA-HQ-OAR-2022-0829-0759, p. 29]

- Utility Impacts Analysis: ERM assessed impacts on utilities and their customers, including an analysis of electricity used to charge vehicles and the incremental load to the grid. The analysis also calculates utility net revenue (revenue minus costs) and potential reduction in electric bills for all utility customers that results from this net revenue. The gap analysis shows the infrastructure needs and associated costs under the different policy scenarios. [EPA-HQ-OAR-2022-0829-0759, p. 29]

C. EPA Should Better Contextualize the Proposed Rule's Economic Significance, in Both Relative and Absolute Terms

EPA could better insulate the Proposed Rule from a future major questions challenge by providing a more nuanced discussion of economic effects, both as compared to prior EPA tailpipe rules and in absolute terms.64 In terms of relative costs, the Proposed Rule already notes that the estimated average cost to manufacturers per vehicle is within the range of costs projected in prior tailpipe rules.65 EPA could strengthen this point by also providing a table that comprehensively describes annualized costs of prior tailpipe rules updated for inflation.66 This table would bolster EPA's conclusion that the costs of the Proposed Rule are not exceptional. [EPA-HQ-OAR-2022-0829-0601, pp. 10-12]

64 EPA does make clear that the projected BEV penetration rate of 67% by 2032 should be compared to the projected 39% penetration under the No Action case, not today's penetration rate. Compare Proposed Rule, 88 Fed. Reg. at 29,329 tbl. 80, with id. tbl. 81.

65 Proposed Rule, 88 Fed. Reg. at 29,343.

66 Governing for Impact & Evergreen Action, Comment Regarding NPRM "Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles" 10–12 (July 5, 2023).

EPA should further underscore this point by explaining that this cost similarity with prior regulations obtains even though the Proposed Rule would simultaneously establish GHG and criteria pollutant standards, instead of only one or the other. [EPA-HQ-OAR-2022-0829-0601, pp. 10-12]

In terms of absolute economic significance, EPA discusses BEV adoption primarily in terms of the annual percentage of new vehicle sales,67 but an even more useful statistic would be the percentage of BEVs out of all the vehicles on the road at a given time. First and foremost, doing so would help the public better comprehend the rule's anticipated effects. It may be easier to conceptualize increased vehicle electrification in terms of the percentage of vehicles on the road, rather than the percentage of new sales. Presenting the data in this way would also help the public to better understand how the Proposed Rule would affect transportation emissions, the need for charging infrastructure, the demand for gasoline, and the demand for vehicle repair and maintenance services. [EPA-HQ-OAR-2022-0829-0601, pp. 10-12]

67 Proposed Rule, 88 Fed. Reg. 29,329 tbl.80.

In terms of the major questions doctrine, reporting such data would provide compelling context regarding economic significance. For example, under the proposed program, in 2032, new vehicle sales would be 67% BEVs compared to 39% under the No Action case.68 But BEVs would comprise only 21.2% of the total fleet compared to 15% for the No Action case.69 [EPA-HQ-OAR-2022-0829-0601, pp. 10-12]

68 Id. & id. at 29,329 tbl.81.

69 This presentation would also enable a more apt comparison to the stock numbers of electricity generation that the Supreme Court noted in West Virginia's background section. West Virginia, 142 S. Ct. at 2593.

The RIA provides two figures that relate to this issue: Figure 9-1 depicts the total number of internal combustion engine (ICE) vehicles on the road every year under the proposed program, and Figure 9-2 does the same for BEVs.70 Using EPA's data underlying these two figures,71 Policy Integrity generated the table below showing percentage rates by year for the No Action case, EPA's proposed program, and Alternative 1. (For brevity, this table provides figures annually from 2027–2032, and then every five years beginning in 2035.) EPA should provide such a table or similar information in the regulation. [EPA-HQ-OAR-2022-0829-0601, pp. 10-12]

70 RIA at 9-2 tbls. 9-1, 9-2.

71 Optimization Model for Reducing Emissions of Greenhouse Gases from Automobiles, EPA (Apr. 2023), https://www.epa.gov/regulations-emissions-vehicles-and-engines/optimization-model-reducing-emissions- greenhouse-gases (download "Light- and medium-duty effects (zip); select "20230315_091353_effects_central"; select "20230315_091353_cost_effects_annual.csv"; refer to "registered_count").

Table 1: Share of BEVs in U.S. Fleet by Year

Year	No Action BEV %	Proposed Program BEV %	Alt. 1 BEV %
2027	5.2%	5.7%	5.7%
2028	6.9%	8.1%	8.3%
2029	8.9%	11.1%	11.2%
2030	11.0%	14.3%	14.6%
2031	13.1%	17.7%	18.0%
2032	15.0%	21.2%	21.6% [EPA-HQ-OAR-2022-0829-0601, pp. 10-12]
2035	19.2%	30.8%	31.7%
2040	24.6%	44.1%	46.0%
2045	27.4%	52.6%	55.3%
2050	28.4%	56.6%	59.8%
2055	29.2%	58.1%	61.5% [EPA-HQ-OAR-2022-0829-0601, pp. 10-12]

As Table 1 illustrates, under both the proposed program and Alternative 1, the share of BEVs out of all cars in the U.S. vehicle fleet compared to the No Action case increases gradually, reaching less than seven percentage points higher than the No Action case by 2032. This difference increases in later years. This relatively slow growth—particularly when viewed in comparison to the share of all vehicles sold per year, which EPA provides in the Proposed Rule—is not surprising given that cars remain on the road for many years, and the new cars sold in a single year reflect a small percentage of vehicles on the road at that time. [EPA-HQ-OAR-2022-0829-0601, pp. 10-12]

B. EPA Should Conduct Additional Analysis Using the Discounting Approach Laid Out in the Draft Update to Circular A-4

In economics, a discount rate translates impacts that occur at different times into a common present value—the higher the annual discount rate, the less impacts further into the future are valued relative to impacts closer to the present. In the Proposed Rule, EPA generally follows the default approach to discounting laid out in the Office of Management and Budget's Circular A-4 by applying annual discount rates of 3% and 7%.84 While it is reasonable for EPA to rely on the discount rates provided by federal guidance, it is now widely recognized that Circular A-4's discount rates are outdated and too high.85 [EPA-HQ-OAR-2022-0829-0601, pp. 14-15]

84 OFF. OF MGMT. & BUDGET, CIRCULAR A-4: REGULATORY ANALYSIS 33–34 (2003).

85 See, e.g., Peter H. Howard et al., U.S. Benefit-Cost Analysis Requires Revision, 380 SCIENCE 803 (2023); COUNCIL OF ECON. ADVISERS, DISCOUNTING FOR PUBLIC POLICY: THEORY AND RECENT EVIDENCE ON THE MERITS OF UPDATING THE DISCOUNT RATE.

In April, the Office of Management and Budget published a draft update to Circular A-4 that, among other revisions, called for extensive changes in discounting to ensure that long-term benefits and costs receive proper consideration in regulatory impact analysis ("Draft Circular A-4 Update").86 Specifically, the Draft Circular A-4 Update proposes to lower the default, risk-free consumption discount rate used in regulatory impact analysis from the current 3% to 1.7%, based on updated data and extensive economic scholarship.87 Also reflecting current economic literature, the update would eliminate the use of the opportunity cost of capital discount rate (currently estimated at 7%) and replace it with the shadow price of capital approach.88 These updates are consistent with the best available evidence and widely supported by the field's leading experts.89 [EPA-HQ-OAR-2022-0829-0601, pp. 14-15]

86 OFF. OF MGMT. & BUDGET, CIRCULAR A-4: DRAFT FOR PUBLIC REVIEW 9–11 (Apr. 6, 2023) [hereinafter DraftvCircular A-4 Update].

87 Id. at 75–76.

88 Id. at 78–80.

89 Howard et al., supra note 85.

EPA should apply the discounting approach from the Draft Circular A-4 Update in sensitivity analysis if it finalizes this regulation before OMB finalizes that update, and consider applying that approach in its primary analysis should OMB finalize the Circular A-4 Update before this rule is finalized. [EPA-HQ-OAR-2022-0829-0601, pp. 14-15]

Table 3 shows the net benefits of the Proposed Rule and Alternative 1 using the 1.7% discount rate from the Draft Circular A-4 Update (except for climate benefits), which Policy Integrity generated using OMEGA and inputting the 1.7% discount rate. A full result table with all rows from EPA's benefit-cost tables is presented below in the Appendix, as Table A-1. [EPA-HQ-OAR-2022-0829-0601, pp. 14-15]

Table 3: Net Benefits Using 1.7% Social Discount Rate (2020$ Billion)

Proposed

Program Alternative 1

3% discount rate, 3% average SC-GHG from Interagency Working Group 1600 1800

3% discount rate, 2% average SC-GHG from EPA's 2022 Draft Update 2500 2800

1.7% discount rate, 2% average SC-GHG from EPA's 2022 Draft Update 3200 3500 [EPA-HQ-OAR-2022-0829-0601, pp. 14-15]

As Table 3 illustrates, the net benefits of both the proposed program and Alternate 1 roughly double when a 1.7% social discount rate is applied (with a 2% near-term discount rate applied to climate impacts consistent with EPA's draft SC-GHG update). As these updated discount rates are used, the net benefits of Alternate 1 relative to the proposed program also increase. [EPA-HQ-OAR-2022-0829-0601, pp. 14-15]

II. Extensive Justification Supports EPA's Decisions to Omit a 7% Discount Rate and To Discount Long-Term Climate Impacts at a Lower Range of Discount Rates than the Proposed Rule's Shorter-Term Impacts

EPA applies the social cost of greenhouse gases estimates calculated at discount rates of 2.5%, 3%, and 5%,111 consistent with the Working Group's current recommendations, and justifies its decision to return to its prior conclusion that a 7% capital-based discount rate is inappropriate for climate effects. EPA's return to a reasonable range of discount rates to assess climate impacts is well supported—in fact, as recognized by both the Working Group in its 2021 update112 and EPA in the Draft SC-GHG Update,113 discount rates of 2% or lower are appropriate for valuing climate damages. [EPA-HQ-OAR-2022-0829-0743, p. 17]

111 Note that just as there is growing evidence that the discount rate should be below 2%, there is growing evidence that 5% is much too high a discount rate. The values at 5% should be considered a very conservative lower bound.

112 2021 TSD, supra note 4, at 16–22 (offering extensive evidence for the use of lower discount rates and recommending that agencies "consider discount rates below 2.5 percent" for valuing the social cost of greenhouse gases); see also id. at 4 ("Consistent with the guidance in E.O. 13990 for the IWG to ensure that the SC-GHG reflect the interests of future generations, the latest scientific and economic understanding of discount rates discussed in this TSD, and the recommendation from OMB's Circular A-4 to include sensitivity analysis with lower discount rates when a rule has important intergenerational benefits or costs, agencies may consider conducting additional sensitivity analysis using discount rates below 2.5 percent.").

113 In the Draft SC-GHG Update, EPA applies a central near-term discount rate of 2%, with additional valuations using near-term discount rates of 1.5% and 2.5%. The discount rates in the Draft SC-GHG Update also decline over time. See Draft SC-GHG Update, supra note 9, at 3 tbl.ES-1; id. at 52–61 (explaining discounting module).

The RIA cites the Working Group's arguments that, for long-term policies with intergenerational effects, uncertainty and ethical considerations make a 7% capital-based discount rate inappropriate.114 These arguments provide sufficient reason for EPA's approach to discount rates. Moreover, additional justifications support EPA's discounting choices. [EPA-HQ-OAR-2022-0829-0743, p. 17]

114 RIA at 10-11 to 10-12.

First, there is widespread consensus that the consumption rate of interest (which the 3% rate in the current Circular A-4 represents, and the Draft Circular A-4 Update pegs at 1.7%) supplies the correct framework for the analysis of climate effects—not the opportunity cost of capital. While the current Circular A-4 suggests that 7% should be a "default position" that reflects regulations that primarily displace capital investments, it also explains that "[w]hen regulation primarily and directly affects private consumption . . . a lower discount rate is appropriate."116 The 7% discount rate is based on a private sector rate of return on capital, as private market participants typically have short time horizons. By contrast, climate change concerns the public well-being broadly rather than market participants narrowly. Indeed, the Draft Circular A-4 Update acknowledges this consensus, providing an updated consumption rate of interest as the default risk-free discount rate and eliminating the use of the opportunity cost of capital approach in regulatory impact analysis.117 [EPA-HQ-OAR-2022-0829-0743, p. 18]

116 Id. at 33.

117 Draft Circular A-4 Update, supra note 10, at 75–76, 78–80.

Third, a 7% discount rate also ignores catastrophic risks and the welfare of future generations. As EPA showed in a recent cost-benefit analysis, the 7% rate truncates the long right-hand tail of social costs relative to the 3% rate's distribution.124 The long right-hand tail represents the possibility of catastrophic damages. Thus, the 7% discount rate effectively assumes that present-day Americans are barely willing to pay anything at all to prevent medium- to long-term catastrophes. Given that Congress expressed its goal for the Clean Air Act Amendments of 1977 to "[e]nsure the protection of the public health and the environment, both of this and future generations," it would not be reasonable for EPA to discount climate impacts at such a high rate as to effectively ignore the welfare of future generations.125 Moreover, as noted above, NEPA requires agencies to consider the "long-range character of environmental problems,"126 and citing this statutory requirement, the Council on Environmental Quality has advised agencies to apply climate-damage valuations that "discount future effects at rates that consider future generations."127 The 7% discount rate simply does not meet that standard. [EPA-HQ-OAR-2022-0829-0743, p. 19]

126 42 U.S.C. 4332(2)(F).

127 Council on Env't Quality, National Environmental Policy Act Guidance on Consideration of Greenhouse Gas Emissions and Climate Change, 88 Fed. Reg. 1196, 1203 (Jan. 9, 2023).

Fourth, long-term time horizons counsel particularly strongly against applying a capital-based rate. For instance, recent scholarship from Dr. Qingran Li and Dr. William Pizer finds that, given their best estimate of the shadow price of capital, the appropriate social discount rate collapses to the consumption-based rate within just several decades. Consequently, the longer the time horizon of analysis, the less the capital-based rate is applicable— making the opportunity cost of capital approach entirely inappropriate for long-term effects like climate change.128 Citing this scholarship, OMB's Draft Circular A-4 Update centralizes the consumption-based discount rate, which it estimates at 1.7%, as the appropriate risk-free social discount rate for regulatory analysis.129 Particularly given the long time horizon that analysis of climate policies demands, therefore, the capital-based rate is inapplicable. [EPA-HQ-OAR-2022-0829-0743, p. 19]

128 Qingran Li & William A. Pizer, Use of the Consumption Discount Rate for Public Policy Over the Distant Future, 107 J. ENV'T ECON. & MGMT. 1 (2021); Qingran Li & William A. Pizer, Discounting for Public Benefit- Cost Analysis, RES. FOR THE FUTURE 3 (2021).

129 Draft Circular A-4 Update, supra note 10, at 76.

Sixth, a 7% discount rate is inappropriate because it is based on outdated data and diverges from the current economic consensus. Circular A-4's default assumption of a 7% discount rate was published twenty years ago and was based on data from even earlier.132 As OMB's Draft Circular A-4 Update reflects, the economic consensus now supports the use of much lower discount rates. In fact, that update drops the opportunity cost of capital approach altogether and endorses a default, risk-free discount rate of 1.7% for all regulatory impact analyses.133 In a recent article in Science, nearly 20 experts expressed strong support for OMB's proposed discounting update, explaining that the proposal is consistent with the leading scholarship in the field.134 Likewise, the Council of Economic Advisers has called for the use of lower discount rates in regulatory analysis dating back to 2017.135 [EPA-HQ-OAR-2022-0829-0743, p. 20]

132 The 7% rate was based on a 1992 report; the 3% rate was based on data from the 30 years preceding the publication of Circular A-4 in 2003. Id. at 33–34.

133 Draft Circular A-4 Update, supra note 10, at 76.

134 Peter H. Howard et al., U.S. Benefit-Cost Analysis Requires Revision, 380 SCIENCE 803 (2023). Dr. Howard and Max Sarinsky, the other corresponding author of the Science letter, are signatories on this comment.

135 CEA Issue Brief, supra note 121, at 1; see also id. at 3 ("In general the evidence supports lowering these discount rates, with a plausible best guess based on the available information being that the lower discount rate should be at most 2 percent while the upper discount rate should also likely be reduced.").

Seventh and finally, a 7% rate is inappropriate because it is now widely recognized that social discount rates reflecting the opportunity cost of capital, even when appropriate, are far below 7%. The 7% opportunity cost of capital rate reflects numerous factors that do not reflect social returns including a private risk premium, land and resource rents, private returns to social externalities, and market power.136 Recent scholarship from Newell et al. adjusts for these factors and finds an opportunity cost of capital discount rate below 3%.137 [EPA-HQ-OAR-2022-0829-0743, p. 20]

136 Peter Howard & Jason Schwartz, Valuing the Future: Legal and Economic Considerations for Updating Discount Rates, 39 YALE. J. ON REG. 595, 619–20.

C. EPA Should Update the Baseline to Ensure Full Consideration of the Inflation Reduction Act

In regulatory impact analysis, the baseline refers to "the best assessment of the way the world would look absent the proposed action."90 Developing an accurate baseline is important for conducting benefit-cost analysis, but challenging when baseline conditions are in flux. That is the case here given last year's passage of the Inflation Reduction Act (IRA). [EPA-HQ-OAR-2022-0829-0601, pp. 15-16]

90 Circular A-4, supra note 86, at 15.

To model the baseline for the Proposed Rule, EPA adopts key variables from the Annual Energy Outlook 2021 (AEO 2021), such as fleet size, new vehicle sales shares, fuel prices, electricity prices, and vehicles miles traveled.91 However, AEO 2021 was developed before the IRA's passage and thus does not include the effects of that law. While it was reasonable for EPA to rely on AEO 2021 in this proposal, it should consider adjusting the baseline in the final rule to fully incorporate the IRA's impacts. In particular, according to the 2023 version of Annual Energy Outlook (AEO 2023), the IRA will decrease both short-run and long-run electricity prices relative to the no-IRA case.92 AEO 2023 also projects that the IRA will decrease long-run gas prices, with a minimal short-run impact.93 Gasoline and electricity prices are important modeling inputs, as they affect the relative cost of ownership between ICE vehicles and BEVs and thereby influence the sales of these vehicles. These prices also affect the fuel-cost savings, the rebound effect, and related environmental impacts. [EPA-HQ-OAR-2022-0829-0601, pp. 15-16]

91 See RIA at 9-1.

92 See infra p. 30 fig.2 (difference between AEO 2023 with IRA (solid-blue line) and AEO 2023's "No IRA" case (dotted-blue line)).

93 See infra p. 30 fig.1 (difference between AEO 2023 with IRA (solid-blue line) and AEO 2023's "No IRA" case (dotted-blue line)).

There are several potential options for EPA to consistently account for the IRA across modeling inputs. One option is for EPA to adopt AEO 2023 for parameters where it currently uses AEO 2021. This would presumably also entail updating future BEV penetration, which, although EPA models separately, is based in part on parameters from AEO 2021. If EPA updates its baseline to incorporate AEO 2023, it should beware that AEO 2023 models only certain aspects of the IRA but does not include the producer-side battery tax credit.94 To blunt the resulting potential underestimate of the IRA's full impact, EPA should consider using the "High uptake of the IRA" sensitivity case provided in AEO 2023. [EPA-HQ-OAR-2022-0829-0601, pp. 15-16]

94 U.S. Energy Information Administration, Transportation Demand Module Assumptions 26 (Mar. 2023), https://www.eia.gov/outlooks/aeo/assumptions/pdf/TDM_Assumptions.pdf.

If updating the baseline to AEO 2023 is infeasible, a more feasible alternative may be for EPA to continue to use AEO 2021 as its baseline and then add the IRA's impact on other parameters on top of that. Data within AEO 2023 enables this type of assessment, as AEO 2023 provides sensitivity analysis in which it models the world with and without the IRA.95 This enables a direct comparison to assess the IRA's effect on key parameters, including electricity prices and gas prices.96 As noted above, EPA should consider adopting the "High uptake of the IRA" sensitivity case in AEO 2023 for comparison purposes.97 [EPA-HQ-OAR-2022-0829-0601, pp. 15-16]

95 See Projection Tables for Side Cases, Annual Energy Outlook 2023, https://www.eia.gov/outlooks/aeo/tables_side_xls.php (providing tables for "No IRA" case).

96 EPA acknowledges that it has estimates of future retail electricity prices that account for the IRA and that these estimates exhibit lower prices compared to a scenario without the IRA. But due to the absence of corresponding information on gasoline price estimates under the IRA and a desire for consistency across variables and model components, EPA opts not to use these estimates. RIA at 2-84.

97 See Projection Tables for Side Cases, supra note 95 (providing tables for “High uptake of the IRA” case).

This modeling adjustment could have meaningful effects (though it’s unclear whether this would increase or decrease net benefits overall, and it would almost certainly not change the sign or ordering of net benefits). According to projections from AEO 2023, the retail electricity price for transportation could be lower by an average of 0.45 cents per kWh from 2027 to 2032 under a high-IRA uptake scenario compared to a scenario without the IRA. This could translate to a decrease of about $50 in the “generalized cost,” 98 i.e. the purchase price net of vehicle ownership and operation costs.99 The lower cost of operating an electric vehicle would translate to greater BEV uptake than EPA projects in its baseline fleet. This suggests, among other implications, that the Proposed Rule’s compliance costs may be lower than EPA projects, since automakers may already be closer to complying with the proposed standards under the baseline than EPA recognizes. [EPA-HQ-OAR-2022-0829-0601, pp. 15-16]

98 Considering the average EV efficiency at 3 miles per kWh, a reduction of 0.45 cent per kWh equates to a savings of 0.15 cents per mile. Incorporating EPA’s assumptions for consumer fuel-cost calculations in their purchase decision—with an annual mileage of 12,000 miles, a 2.5-year fuel-cost valuation period, and a fueling efficiency factor of 0.9—this saving translates to around $50 = 2.5(years) ×{0.15(¢/mile)×12,000(miles/year)÷100(¢/$)}÷0.9.

99 Both producers and consumers use this metric in their decisionmaking processes. See RIA at 4-2 to 4-4.

The Appendix below includes four figures illustrating the data presented in this section. [EPA-HQ-OAR-2022-0829-0601, pp. 15-16]

In addition to EPA’s consideration of international reciprocity and cooperation in prior rulemakings, agencies have also considered transboundary spillover effects in making key decisions. As one example, when considering the “public interest” in the certification of natural gas exports under the Natural Gas Act,102 the Department of Energy routinely “consider[s] international trade policy, foreign policy, and national security interests.”103 As another example, the Food and Drug Administration also frequently considers international effects as part of its regulatory decision making, and has recognized that such costs are particularly relevant because “a portion of foreign costs could be passed on to domestic consumers.”104 [EPA-HQ-OAR-2022-0829-0743, pp. 16-17]

102 15 U.S.C. § 717b(a).

103 New Policy Guidelines and Delegation Orders from Secretary of Energy to Economic Regulatory Administration and Federal Energy Regulatory Commission Relating to the Regulation of Imported Natural Gas, 49 Fed. Reg. 6684, 6688 (Feb. 22, 1984).

104 Requirements for Additional Traceability Records for Certain Foods, 87 Fed. Reg. 70,910, 71,071 tbl.2 (Nov. 21, 2022).

Courts have confirmed that agencies may—and, in some cases, must—take into account international spillover effects. In 2020, the U.S. Court of Appeals for the Ninth Circuit rejected a Bureau of Ocean Energy Management approval of an offshore oil drilling and production facility after the agency concluded that domestic extraction would not affect international fossil-fuel supply and consumption.105 As the court explained, because domestic production causes "foreign consumers [to] buy and consume more oil"—and because that consumption "can be translated into estimates of greenhouse gas emissions" that harms the United States—the agency had an obligation to consider those increased foreign emissions resulting from domestic action.106 Two subsequent district court opinions similarly faulted Department of Interior analyses for omitting the effects of domestic production on foreign demand and consumption.107 The fact that courts have required agencies to consider the spillover impacts from foreign greenhouse gas emissions provides strong support for EPA's consideration of spillovers from domestic emissions. [EPA-HQ-OAR-2022-0829-0743, pp. 16-17]

105 Ctr. for Biological Diversity v. Bernhardt, 982 F.3d 723, 738 (9th Cir. 2020).

Consistent with these examples, the Draft Circular A-4 Update recognizes that relevant benefits and costs to consider in regulatory impact analysis include both effects that "result directly from a regulation's domestic applicability" and those that result "indirectly from a regulation's impact on foreign entities."108 With regard to the latter category, the Draft Circular A-4 Update explains that relevant impacts "include the effects of a regulation on U.S. strategic interests, including the potential for inducing strategic reciprocity or other policy changes from actors abroad or effects on U.S. government assets located abroad," which "are particularly likely to occur when [a] regulation bears on a global commons or a public good."109 Additionally, the Draft Circular A-4 Update states that relevant impacts include "those that occur entirely outside the United States when they affect U.S. citizens and residents."110 [EPA-HQ-OAR-2022-0829-0743, pp. 16-17]

As all of these examples illustrate, EPA's consideration of climate damages on a global scale is consistent with how EPA and other agencies have exercised regulatory authority in numerous contexts. [EPA-HQ-OAR-2022-0829-0743, pp. 16-17]

A. EPA Is Required to Value Climate Damages, and Doing So Provides Balance to EPA's Cost-Benefit Analysis

One objection to agency usage of the Working Group's estimates is that Congress, not the executive branch, should set policy with respect to climate change. But EPA has broad authority to assess climate impacts, and judicial precedent suggests that it must value climate- change impacts as part of its regulatory impact analysis. In fact, assessing climate damages as part of its regulatory impact analysis provides rationality and balance to EPA's approach—and does not, as critics have suggested, inappropriately skew the analysis. [EPA-HQ-OAR-2022-0829-0743, p. 22]

Organization: International Council on Clean Transportation (ICCT)

The total benefits of the proposal exceed the total cost. Per EPA's estimate, the overall technology cost of the proposal ranges from $180 billion to $280 billion for automakers (in 2020 dollars) through 2055. However, the consumers will benefit from the pre-tax fuel savings that range from $450 to $890 billion, and repair and maintenance savings from $280 to $580 billion. In addition, the social benefits include $330 billion in climate benefits and between $63 and $280 billion in criteria pollutant reduction benefits. [EPA-HQ-OAR-2022-0829-0569, p. 55]

The proposal states that the estimated average costs for automakers to meet the proposed standards would range from $200 to $1,600 (in 2020 dollars) per vehicle in MY 2032, across the range of sensitivities. Per EPA's analysis, this estimated MY 2032 average costs of $1,200 represent under three percent of the average cost of a new vehicle today (about $46,000 in 2022). This cost resonates with previous 2012 and 2021 rules which estimated that the cost to meet standards were about $1,800 (2010 dollars) and $1,000 (2018 dollars) per vehicle. Similarly, previous ICCT analysis shows that the cost for an ICE vehicle to meet the 2012 rules or Tier 2 standards would range from $405 to $690.145. [EPA-HQ-OAR-2022-0829-0569, p. 55]

Organization: Jack Spencer

The proposed rule's impact on low-income Americans is vastly under analyzed in the proposed rule's publication in the Federal Register and the Draft Regulatory Impact Analysis. [EPA-HQ-OAR-2022-0829-0681, pp. 1-2]

Fully Monetize the Proposed Rule's Impact on Low-Income Households [EPA-HQ-OAR-2022-0829-0681, pp. 1-2]

Though the proposed rule acknowledges "that increases in upfront purchase costs are likely to be of particular concern to low-income households," it goes on to state on page 29368 that "we look more closely into, but do not monetize, the effects of the standards on low-income households and on consumers of low priced new vehicles and used vehicles." [EPA-HQ-OAR-2022-0829-0681, pp. 1-2]

Neglecting to fully account for the monetized impact of a proposed rule on disproportionately impacted populations is an inexcusable oversight and matter of gross negligence. Academic research has long demonstrated that environmental regulations impose a higher cost on low-income Americans as compared to the population generally.2 [EPA-HQ-OAR-2022-0829-0681, pp. 1-2]

2 Graham, John D., "Saving Lives Through Administrative Law and Economics," University of Pennsylvania Law Review," P. 521, 2008-2009, (https://biotech.law.lsu.edu/blog/graham157upalrev3952008pdf.pdf)

The reality is that environmental regulations increase vehicle costs substantially. One academic study investigated the combined costs of all National Highway Traffic Safety Administration, Environmental Protection Agency, and California Air Resources Board light duty-regulations and found that they increased vehicle prices by $6,000 to $7,000. Put another way, environmental regulation increases the purchase price of most vehicles by 15-20 percent. [EPA-HQ-OAR-2022-0829-0681, pp. 1-2]

Given that 12.8 percent of Americans live in poverty3 and that the mean income for the lowest two quintiles of American incomes is $13,165 and $34,7674, respectively, low-income Americans are already being financially disadvantaged by environmental regulation. According to Kelly Blue Book, the five least expensive sedans available in 2023 cost between $16,490 and $18,500.5 At current prices, a new car is already beyond the reach of most low-income Americans, which is one reason why only around 17 percent of low-income households purchase new cars.6 Given that, according to Cars.com, the top five least expensive electric vehicles (EVs) range from $27,495 to $35,4857, the proposed rule will undoubtedly make new vehicles unaffordable for nearly all low- income Americans and make purchasing even used vehicles more difficult, if not impossible. [EPA-HQ-OAR-2022-0829-0681, pp. 1-2]

7 “Here are the 11 Cheapest Electric Vehicles You Can Buy,” Cars.com, June 23, 2023, (https://www.cars.com/articles/here-are-the-11-cheapest-electric-vehicles-you-can-buy-439849/).

This is an unacceptable outcome for any regulation as research firmly establishes that access to a car comes with a litany of positive social benefits including upward economic mobility, public safety benefits, and healthcare and education opportunities.8 Any public policy that could threaten access to autos for low-income households should be a nonstarter. [EPA-HQ-OAR-2022-0829-0681, pp. 1-2]

8 Klein, N. J., “Subsidizing Car Ownership for Low-Income Individuals and Households,” Journal of Planning Education and Research, 2020, (https://doi.org/10.1177/0739456X20950428).

Conclusion

Research shows that low-income Americans too often carry the disproportionate financial burden of environmental regulation. That is bad enough but this regulation goes further by making car ownership more expensive and putting it out of reach of more people. Given that car ownership is a key component for many Americans to lift themselves out of poverty, any regulation that threatens such should be a nonstarter. Though ceasing any action on this regulation would be the best outcome, I implore you to at the very least, take the time to fully monetize and account for the financial burdens you are asking America’s low-income families to endure [EPA-HQ-OAR-2022-0829-0681, p. 3]

Organization: Kentucky Office of the Attorney General et al.

The Agency's cost-benefit assessment is wrong, too, in large part because it leans so heavily on the shaky "social cost of greenhouse gases" metric. And in EPA's rush to press forward "with haste and ambition" to tackle climate change, Timothy Puko, Biden to remake U.S. auto industry with toughest emissions limits ever, Wash. Post (April 12, 2023), https://bit.ly/3qBALKe, EPA blows past red flags about the very possibility of achieving the Proposed Rule's aims—as well as the serious consequences along the way. A more careful look at these issues shows why the Proposed Rule, if left uncorrected, would damage our economy, tax our electrical grids and the families and businesses who depend on them, and threaten our national security. For these and other reasons explained below, the undersigned Attorneys General urge EPA to reconsider the Proposed Rule. [EPA-HQ-OAR-2022-0829-0649, p. 3]

Organization: Office of Wyoming Governor Mark Gordon

The University of Wyoming, School of Energy Resources' Center for Energy Regulation and Policy Analysis published a briefing paper on the proposed rule which analyzes the estimated economic impact of the rule in its current form. There is a drastic difference in the EPA's claimed economic benefits and the reality of the available data. I ask that the EPA take a hard look at the valid disparities listed, and adjust their claims accordingly. If the EPA is pushing for mandated EV technology, the full picture should be available for public examination. [EPA-HQ-OAR-2022-0829-0675, p. 1]

Organization: Our Children's Trust (OCT)

We also ask that the EPA revise its Draft Regulatory Impacts Analysis so that it reflects the true costs of climate change, the true benefits of more swiftly electrifying the transportation sector, and utilizes no discount rate or a discount rate that does not discriminate against children and future generations. EPA must align its rulemaking with the best available science to protect children. [EPA-HQ-OAR-2022-0829-0542, p. 1]

Organization: Paul Bonifas and Tim Considine

The Environmental Protection Agency (EPA) claims that the benefits outweigh the costs for their proposed Electric Vehicle (EV) Rule and purport $1.6 trillion ($1,600 billion) in "net benefits" through 2055 (3% discount rate, with 3% SC–GHG). After reading through the 263 pages of the EPA's proposed rule1 and the accompanying 688 pages of their Draft Regulatory Impact Analysis (RIA)2, the EPA bases its $1.6 trillion "estimated benefits" on faulty premises, biased data, and narrow economic snapshots. When updating the EPA's assumptions to realistic values based on sound economics and real consumer data, their arguments hold no water and their claimed "$1.6 trillion in net benefits" is reduced by nearly $3 trillion dollars and becomes a realistic net $1,376 billion loss, as shown in Table 1 below. [EPA-HQ-OAR-2022-0829-0551, p. 2]

1 https://www.govinfo.gov/content/pkg/FR-2023-05-05/pdf/2023-07974.pdf

2 https://nepis.epa.gov/Exe/ZyPDF.cgi?Dockey=P10175J2.pdf

Estimated Impact of EPA's EV Rule ($ billions)

Cost Category	EPA	Realistic	Difference of EPA vs Realistic
Pre-Tax Fuel Saving:	$890	($108)	EPA underestimated $998 billion
Vehicle Technology Costs	($280)	($1,228)	EPA underestimated $948 billion
Maintenance Savings	$410	$72	EPA underestimated $338 billion
Climate Benefit (3% SC–GHG)	$330	$22	EPA underestimated $308 billion
EVSE Port Costs (charging stations) + Grid Upgrades	($120)	($330)	EPA underestimated $210 billion
Repair Savings	$170	($4)	EPA underestimated $174 billion
Energy Security Benefits	$41	$41	Did not quantify
Air Pollutant Benefits	$249	$249	Did not quantify
Increased Refueling Time & Misc. Costs	($90)	($90)	Did not quantify
Estimated Net Impact	$1,600	($1,376)	The EPA's EV rule would cost the US economy $1,376 billion, an underestimation of $2,976 billion from the EPA. [EPA-HQ-OAR-2022-0829-0551, p. 2]

Table 1 – The estimated impacts of the EPA's EV Rule for both the EPA assumptions and realistic assumptions. [EPA-HQ-OAR-2022-0829-0551, p. 2]

Vehicle Technology Costs

The EPA vastly underestimates the added cost of EVs compared to their internal combustion engine (ICE) counterparts. The EPA attempts to deceive the American people by using manufacture-EV costs instead of consumer-EV costs that owners pay when purchasing their vehicle. Correcting these EPA half-truths results in a more realistic "vehicle technology cost" of $1,228 billion, a $948 billion cost increase from the EPA's calculations. [EPA-HQ-OAR-2022-0829-0551, p. 3]

EPA Claimed Costs: $280 billion

Realistic Costs: $1,228 billion [EPA-HQ-OAR-2022-0829-0551, p. 5]

The EPA admits their proposed rule will increase the cost of building EVs. They claim the rule will increase costs by an average of $1,200 per vehicle resulting in $280 billion (present value at 3 percent discount rate). However, they are not upfront about their claim, and the true cost to the American economy is more than 4X greater. [EPA-HQ-OAR-2022-0829-0551, p. 5]

The EPA is not comparing apples to oranges with their “vehicle technology costs.” Notice the other categories in their analysis such as “repair” or “maintenance” are costs paid by the consumer, aka the owners of the EVs. However, for “vehicle technology costs” the EPA chooses to use the costs paid by the manufacturers, which is far less than the costs paid by consumers, and EPA gives no justification or acknowledgment of their inconstancy. The EPA’s rule states “These projected vehicle technology costs represent the incremental costs to manufacturers”14 [1] and the EPA’s RIA states “The costs in this section represent compliance costs to the industry and are not necessarily the same as the costs experienced by the consumer when purchasing a new vehicle”15. [EPA-HQ-OAR-2022-0829-0551, p. 5]

To find the true cost paid by consumers, one does not have to look for third-party information….the EPA themselves provide the purchase prices of new EV and ICE vehicles in their analysis on page 296 of the RIA. The EPA shows that:

- An EV sedan/wagon will cost $5,200 more than an equivalent ICE vehicle,
- An EV CUV/SUV will cost $7,100 more than an equivalent ICE vehicle, and
- An EV pickup will cost $3,500 more than an equivalent ICE vehicle.

This average is $5,266 more that an ICE owner can expect to pay for their new vehicle, 338% more than the $1,200 claimed by the EPA. Scaling the EPA’s costs up by 338% increases the estimated “vehicle technology costs” from $280 billion to $1,228 billion ($1.288 trillion). This lone category nearly wipes out the entire “net benefit” of $1.6 trillion claimed by the EPA. [EPA-HQ-OAR-2022-0829-0551, p. 5]

Organization: Steven G. Bradbury

Second, I will explain how the EPA has failed adequately to acknowledge and con- sider the true scope of the colossal costs and burdens these proposals, if finalized, would impose on American families, the U.S. economy, and our nation’s security, and how, at the same time, the Agency has wildly overestimated the benefits it claims will result from these proposed rules. Because the key analyses and assumptions on which these proposals are based are so faulty and ill-considered, if the rules were finalized in the form proposed, they would be arbitrary and capricious in violation of the APA.7 [EPA-HQ-OAR-2022-0829-0647, pp. 2-3]

7 See id. § 706(2)(A) (providing that the reviewing court shall strike down a final rule found to be “arbitrary, capricious, an abuse of discretion, or otherwise not in accordance with law”).

This miracle of regulatory cost-benefit accounting cannot hold up under scrutiny. [EPA-HQ-OAR-2022-0829-0647, pp. 11-12]

EPA’s consideration of direct cost factors is inadequate and incomplete. [EPA-HQ-OAR-2022-0829-0647, pp. 11-12]

EPA estimates that the light- and medium-duty rule will impose an additional technology cost on automakers of between $180 billion and $280 billion,25 which EPA asserts will translate into an average increase of $1,200 in the purchase price of a typical vehicle, an increase EPA considers modest.26 The derivation of these cost estimates is murky and fundamentally not credible. [EPA-HQ-OAR-2022-0829-0647, pp. 11-12]

25 88 FR at 29200.

26 Id. at 29201.

EPA's estimates assume that in the "no-action world" (the future world as it would exist without the proposed rules), battery-electric vehicle sales would ramp up rapidly from today's levels and would plateau at around 40 percent of total U.S. light-duty vehicle sales by model year 2030, remaining at 39 percent through model year 2032.27 [EPA-HQ-OAR-2022-0829-0647, pp. 11-12]

27 See id. at 29296-97, Figure 20.

This assumption depends on full implementation of the Agency's own prior carbon dioxide emissions rule from 2021 (covering model years 2023 through 2026),28 which is currently facing legal challenge in the U.S. Court of Appeals for the D.C. Circuit. It also appears to depend on implementation of CARB's previously finalized ZEV mandates and carbon dioxide emissions restrictions (those that preceded CARB's Advanced Clean Car II proposals).29 Once again, these CARB rules are only in effect because EPA approved them in a special waiver for California, another EPA action under challenge in the D.C. Circuit. [EPA-HQ-OAR-2022-0829-0647, pp. 11-12]

28 See id. at 29296.

29 See id. at 29296-97.

The combined effects of all three sets of regulatory edicts—the current proposals, EPA's 2021 rule, and the CARB rules—are closely interrelated and flow from the same policy choices of the Biden administration. An accurate accounting of cost would recognize that these three regulatory actions are part of a single integrated policy implemented through EPA. They are intended to build upon each other, and in fact they do. EPA is presenting a deceptively compartmented picture of the regulatory costs of its actions by treating the effects of its own 2021 rule and the CARB rules that it authorized through its waiver decision as if they were exogenous background facts. They are not. [EPA-HQ-OAR-2022-0829-0647, pp. 11-12]

EPA's benefits analysis is flawed and arbitrary.

On the benefits side of the ledger, EPA claims sky-high monetized benefits from the asserted reductions in carbon dioxide emissions—to the tune of upwards of a trillion dollars.64 These estimates are based on predicted reductions in the amount of gasoline and diesel fuel that would be burned if the U.S. auto fleet converts to EVs at the rates projected by EPA. But they completely ignore the very large increase in carbon dioxide emissions that would necessarily occur from the projected expansion in the production of EV batteries. They also ignore the upstream emissions of carbon dioxide from the increased electricity generation that would be needed to charge the projected fleet of EVs. [EPA-HQ-OAR-2022-0829-0647, pp. 22-23]

64 See id. at 29200, 29344.

EPA's refusal to account for these huge offsetting emissions of carbon dioxide fundamentally distorts its analysis of net benefits in a manner that arbitrarily favors the Agency's preferred regulatory outcome. It is, in fact, false and misleading to label EVs "zero-emission vehicles" when the production of EV batteries and the charging of the batteries over the life of the vehicles both generate enormous amounts of carbon dioxide. [EPA-HQ-OAR-2022-0829-0647, pp. 22-23]

EPA's projections of benefits from carbon dioxide reductions are primarily based on the so-called "social cost of carbon" models. However, as summarized in analyses pub- lished by my colleague from The Heritage Foundation, Kevin Dayaratna, these models are deeply flawed and unreliable. Among other things, they depend on outdated assumptions and fail to account for the positive agricultural effects of higher carbon dioxide levels. Using more appropriate assumptions, these models would show a social cost of carbon dioxide emissions that effectively approaches zero.65 [EPA-HQ-OAR-2022-0829-0647, pp. 22-23]

65 See Kevin D. Dayaratna, "Climate Change, Part IV: Moving Toward a Sustainable Future," Testimony before Subcommittee on Environment Committee on Oversight and Reform, U.S. House of Representatives, September 24, 2020; Kevin Dayaratna and David Kreutzer, Loaded DICE: An EPA Model Not Ready for the Big Game, Backgrounder No. 2860, The Heritage Foundation, November 21, 2013, https://www.heritage.org/environment/report/loaded-dice-epa-model-not-ready-the-big-game; Kevin Dayaratna and David Kreutzer, "Unfounded FUND: Yet Another EPA Model Not Ready for the Big Game," Backgrounder No. 2897, April 29, 2014, http://thf_media.s3.amazonaws.com/2014/pdf/BG2897.pdf; Kevin Dayaratna, Ross McKitrick, and David Kreutzer, "Empirically Constrained Climate Sensitivity and the Social Cost of Carbon," Climate Change Economics, Vol. 8, No. 2 (2017), pp. 1750006-1-1750006-12, https://www.worldscientific.com/doi/abs/10.1142/S2010007817500063; and Kevin Dayaratna, Ross McKitrick, and Patrick Michaels, "Climate sensitivity, agricultural productivity and the social cost of carbon in FUND," Environmental Economics and Policy Studies, 22: 433-448 (2020), https://link.springer.com/article/10.1007/s10018-020-00263-w.

Furthermore, EPA's proposal to count the purported benefits of carbon dioxide reduc- tions on a global basis, as opposed to confining its estimates to domestic U.S. effects, is flawed and inappropriate. Even if they were accurately estimated, which they are not, these global benefit forecasts could not properly and reasonably justify the regulatory costs that the proposed rules would impose on businesses and individuals in the U.S. It is more appro- priate and consistent with the purposes of regulatory cost-benefit analyses for federal agen- cies to consider only the estimated benefits that a proposed rule is expected to have domes- tically on the U.S. economy and on persons in the United States.67 [EPA-HQ-OAR-2022-0829-0647, pp. 23-24]

67 Generally, federal agencies are authorized only to promulgate rules that apply domestically, unless the federal statute under which the agency is acting clearly and expressly authorizes the agency to issue rules to achieve benefits outside the territorial reach of the United States. Correspondingly, absent such a clear statutory mandate, the requirement of a regulatory cost-benefit analysis imposed under Executive Order 12,866 and administered by OMB's Office of Information and Regulatory Affairs (OIRA) is properly limited to considering only the benefits the rule is expected to produce for the American people in the U.S.

These estimated values are the EPA's main focus in evaluating the claimed benefits of carbon dioxide reduction. EPA pointedly avoids claiming that its proposed rules will achieve any specific reduction in global temperatures. That is not surprising. Apparently, EPA wishes to save itself the embarrassment of predicting a vanishingly small effect. Using the UN Climate Panel's model for global average temperature effects, Bjorn Lomborg has shown that if every country in the world achieved its stated EV targets by 2030, the total savings in carbon dioxide emissions would be expected to reduce global temperature by only 0.0002 degree Fahrenheit by the year 2100.68 [EPA-HQ-OAR-2022-0829-0647, pp. 23-24]

68 See Bjorn Lomborg, "If Electric Vehicles Are So Great, Why Mandate Them?," Wall Street Journal , September 10, 2022, https://www.wsj.com/articles/policies-pushing-electric-vehicles-show-why-few-people-want-one-cars-clean-energy-gasoline-emissions-co2-carbon-electricity-11662746452.

Organization: The Heritage Foundation (Kevin Dayaratna and Diana Furchtgott-Roth)

Transfers and tax credits should be calculated as negative costs rather than positive benefits Incorrectly, the study treats government subsidies and taxes as positive benefits rather than costs. (See Tables 167 – 169.) These transfers are costs that the federal government incurs for the purpose of altering consumer behavior. These transfer costs are not benefits to consumers but instead are costs that taxpayers incur. The study incorrectly treats them as benefit. All of the numbers in these tables, even if otherwise correctly calculated, should be negative, not positive. [EPA-HQ-OAR-2022-0829-0674, p. 13]

Low discount rate

The study uses two discount rates, 3% and 7%. The 3% discount rate is below current federal standards, and below rates used by private businesses in making business decisions, and below rates used by private households in making household decisions. More realistic rates would be 7% and 10%. [EPA-HQ-OAR-2022-0829-0674, pp. 14-15]

Organization: U.S. Chamber of Commerce

If these assumptions are indeed overly optimistic, then the ultimate costs of the rule could be underestimated by tens of billions of dollars. This could in turn negatively impact not only sales and auto sector employment, but it would also undermine the rule's potential emissions reductions, as lack of affordability drives consumers to drive older, more polluting cars for longer. In order to address this potentially major issue and better inform stakeholders and the public of the rule's potential ramifications, the Chamber urges EPA to conduct sensitivity analyses modeling sales and emissions reductions under a range of tax credit eligibility, income limitations, and technology cost assumptions. [EPA-HQ-OAR-2022-0829-0604, p. 3]

In addition, the Chamber is concerned that EPA projections regarding a number of subjective and uncertain assumptions impacting vehicle technology costs and sales may be unrealistic. For example, we have concerns with EPA's conclusion that it's standards will only increase vehicle technology costs by an average of $1,200 per vehicle. This forecast is dependent on a number of optimistic assumptions regarding technology progress, critical material input costs and availability, as well as vehicle tax credit eligibility and individual MSRP restrictions. There are similar questions related to total vehicle ownership savings stemming from charging costs, vehicle maintenance, repair, insurance, etc. [EPA-HQ-OAR-2022-0829-0604, p. 3]

- Impacts on grid reliability and resiliency. The electric grid will be called upon to handle increased demand during its own period of transition. By EPA's own estimates, deployment of EVs as envisioned by the proposed rule would increase power demand by 114 terawatt-hours (2.25 percent) nationwide by 2035. Some geographic regions and subregions will experience higher changes on a percentage basis, and as EPA notes in the proposed rule, EV charging will result in "large and abrupt electricity demand peaks" during certain periods of the day. This presents a major challenge for an electricity system that is now facing its most difficult reliability challenges in decades, and in which an already accelerated loss of existing dispatchable generating capacity could be exacerbated by EPA's concurrently proposed rule targeting these same types of electric generating facilities. The Chamber urges EPA to undertake thorough analysis of the impact of recent and forthcoming regulations and other policies on the cost and feasibility of this proposal. [EPA-HQ-OAR-2022-0829-0604, p. 3]

Organization: Valero Energy Corporation

D. EPA fails to adequately consider economic impacts of the proposed rule.

1. EPA's consideration of program costs is limited to manufacturers and purchasers.

EPA claims it is required to consider the costs only to the motor vehicle industry to come into compliance with the new emissions standards. That is incorrect, at least with regard to these rules that transform the vehicle market and are designed to address social policy. The cases EPA relies upon—Motor & Equipment Manufacturers Association Inc. v. EPA, 627 F.2d 1095, 1118 (D.C. Cir. 1979) and Coalition for Responsible Regulation v. EPA, 684 F.3d 120, 128 (D.C. Cir. 2012)—are inapposite because they were not addressing "social cost" and were not creating transformative changes to force a change from traditional combustion vehicles to ZEVs that require wholly different manufacturing and fueling sources, consumer choices, and changes to vehicle infrastructure. EPA must consider all the costs of compliance that are substantially affected by its new standards, including costs on the manufacturers of the vehicles, manufacturers of the batteries (including miners, refiners, and manufacturers of the battery source materials) and other component parts of traditional combustion engines, manufacturers and sellers of the fuels (whether electric or liquid fuels), consumers who must change their types of vehicles and fuels, and any others who will be substantially impacted by these new mandates. [EPA-HQ-OAR-2022-0829-0707, pp. 31-33]

EPA has not quantified the following program costs:

- Costs to utilities for upgrades of local electrical distribution systems to accommodate increased PEV charging;" [EPA-HQ-OAR-2022-0829-0707, pp. 31-33]

- Costs to utilities for actively managing charging behavior to mitigate potential risks to the electrical grid;156 [EPA-HQ-OAR-2022-0829-0707, pp. 31-33]

156 EPA's Multi-Pollutant LMDV Proposal at 29312 and DRIA at 5-37, 11-16.

- Costs to ratepayers, especially economically-disadvantaged communities, who lack the flexibility to charge off-hours and may incur higher electricity costs; [EPA-HQ-OAR-2022-0829-0707, pp. 31-33]

- Costs to states and communities relating to road wear by heavier vehicles, which cannot necessarily be recouped via EV registration fees; [EPA-HQ-OAR-2022-0829-0707, pp. 31-33]

- Lost state revenue due to loss of gas tax, which cannot necessarily be recouped via EV registration fees; [EPA-HQ-OAR-2022-0829-0707, pp. 31-33]

- Full impacts to drivers, including:

- o Loss of flexibility due to charging “dwell time;”
- Accounting for impacts to vehicles operating in remote areas, where higher daily VMT are needed;
- o Accounting for impacts to drivers operating in areas with higher electricity rates;
- o Loss of value in the secondary LMDV market; and
- o Costs associated with battery replacements;
- o Higher auto insurance premiums; and
- • Impacts to taxpayers footing the bill for BIL and IRA tax credits. [EPA-HQ-OAR-2022-0829-0707, pp. 31-33]

Organization: Zero Emission Transportation Association (ZETA)

We are concerned that EPA relies on MY 2019 as the base year fleet for its analysis131 The auto industry is in a period of rapid change. For example, the EV sales share grew from just 1.7 percent in MY 2019 to 4.4 percent in MY 2021132 Preliminary data show the sales share roughly doubling in MY 2022 to approximately 8 percent.133 In previous regulatory actions, the agency stated that the vintage of the base year will “not normally have a significant impact” but that certain broad shifts in the market, such as the average vehicle power-to-weight ratio, can affect the incremental cost-effectiveness of technology application in the modeling.134 The significant growth in the EV market in recent years—a trend not yet visible in the MY 2019 data—would seem to constitute a “broad market shift” with potential impacts on agency compliance modeling. For example, greater BEV volumes in the base year fleet could affect credit-trading and technology application decisions in the model. If nothing else, greater EV volumes in the base year fleet would imply greater growth potential and higher penetrations of this technology by the end of the timeframe covered by the proposed standards and could support greater stringency than the agency currently proposes. We encourage incorporation of the most recent base year data available for the final rule in accordance with typical practice.135 [EPA-HQ-OAR-2022-0829-0638, p. 27]

131 See DRIA at 9-1

132 “Explore Trends Detailed Data,” U.S. Environmental Protection Agency, accessed June 30, 2023 https://www.epa.gov/automotive-trends/explore-automotive-trends-data#DetailedData

133 See DRIA at 3-5

134 Revised 2023 and Later Model Year Light-Duty Vehicle Greenhouse Gas Emissions Standards, 86 Fed. Reg. 151, 43,769 - 43,770 (Aug. 10, 2021)

135 EPA “will often attempt to utilize the most recent base year data,” per Revised 2023 and Later Model Year Light-Duty Vehicle Greenhouse Gas Emissions Standards, 86 Fed. Reg. 151, 43,769 (Aug. 10, 2021)

EPA Summary and Response

Summary:

The Alliance for Automotive Innovation commented that EPA must conduct a separate benefit-cost analysis for each regulatory program and amendments that are embedded in the multi-pollutant rulemaking, stating that Circular A-4 specifically instructs agencies to do so. The Alliance also comments that a market failure analysis should be done to show why manufacturers are not providing what consumer behavior should be demanding based on the savings versus costs as presented in the NPRM. The Alliance also suggested that EPA must decide whether to consider global or domestic climate impacts. The Alliance suggests that the analysis is flawed since it considers global climate benefits but fails to consider environmental damages that may occur due to the rapid expansion of supply chains for batteries.

AmFree commented that EPA had failed to properly consider the benefits of all possible approaches to control, such as renewable fuels. AmFree also pointed out the inconsistency between discount rates used for estimating program costs and benefits and those used for estimating some of the climate benefits.

The American Fuel & Petrochemical Manufacturers argued that EPA must conduct a full life-cycle analysis. They also suggested that EPA was mandating a rapid shift from ICE to ZEV thereby reshaping the American automotive market. They argued that the EPA was mandating a transition from ICE to BEV without properly considering the availability of the technology in the given timeframe and without considering all possible means of addressing policy objectives. This commenter suggested that EPA had underestimated the costs of the rule. This commenter also expressed concern over road wear and bridge deterioration caused by BEVs that are heavier than ICE vehicles and lost tax revenues for road and bridge repair due to reduced gasoline consumption.

The American Petroleum Institute (API) had several comments about GPF costs and feasibility. API also commented that the cost reduction model used in battery cost estimation seems to be based on a model used for part cost reductions driven by improved economies of scale on fixed capital equipment. API suggests that raw material costs tend to increase with increased supply. API also argues that EPA uses the concept of cost and price interchangeably and that EPA should consider technical feasibility based on manufacturer costs regardless of governmental taxation breaks for electric vehicles. API also argues that EPA should consider the costs of additional solar, wind and hydropower plants since they are a necessary part of bringing BEVs to market. API also seems to suggest that EPA consider the total costs of the rule, not only the incremental costs of the rule over a no action future.

An anonymous commenter said that EPA's analysis suggests that manufacturers are acting irrationally since some manufacturers have negative compliance costs in some years. This commenter also suggested that EPA's learning curves imply that some manufacturers will share trade secrets with other manufacturers since learning is applied across the industry rather than at a firm level.

The Arizona State Legislature commented that the proposed rule failed to rely on a cost-benefit analysis in contravention of statutory and case-law requirements.

The California Air Resources Board (CARB) identified three specific areas where EPA is likely underestimating net benefits: 1) use of the interim SC-GHG values; 2) vehicle demand elasticity too high in absolute magnitude thereby overstating the effects of vehicle price increases; and, 3) not properly considering possible lower cost residential charging in the EVSE infrastructure cost estimates.

The California Attorney General's Office, et al., commented that EPA's analysis had overstated costs by not considering state programs to promote electric vehicle adoption. This commenter also argued for standards that would encourage the application of feasible, cost-effective emission-reduction technologies on ICE vehicles given that they will continue to represent a significant source of GHG, criteria, and toxic pollutant emissions. This commenter also suggested that EPA present aggregate costs on a per vehicle basis and that EPA acknowledge that much of the investment in electrification estimated in the NPRM has already been incurred by auto makers and much of that was done, perhaps, for market reasons and not regulatory requirements.

The Clean Fuels Development Coalition et al. commented that the proposal was racing past the Biden administration's goal of 50 percent BEV sales by 2030. The commenter also appears to consider the CO2 reductions during 2027 through 2032 and compares those to the costs in 2027 through 2032 and suggests that the cost effectiveness of that CO2 control is a "very bad deal." This commenter also suggested that taxpayers subsidize the sale of electric vehicles, charging infrastructure, etc., and the proposal ignores these costs and instead counts them as "transfers." This commenter also accuses EPA of manipulating timelines to inflate the benefits of the rule by extending calculations to 2055.

Environmental and Public Health Organizations commented in support of more stringent standards on the basis that the benefits would be even greater.

The Institute for Policy Integrity at New York University School of Law suggested that EPA provide a table that comprehensively describes annualized costs of prior tailpipe rules updated for inflation to bolster the conclusion that the costs of the Proposal Rule and not exceptional. They also commented that EPA should present not only the share of new sales that are BEV but also the share of vehicles on the road that are BEV to better inform the public about the effects of the rule. This commenter also suggested that EPA use discounting practices laid out by the Office of Management and Budget in a draft update to Circular A-4 and suggested that EPA use a discount rate of 1.7 percent and eliminate use of 7 percent. They also expressed support for valuing the global impacts of climate benefits. They also suggested an update to the baseline by moving away from use of AEO 2021 in favor of AEO 2023 to better reflect impacts of the IRA on fuel and electricity and how those impact the effects of the rule. Further, the commenter suggests that EPA use the high uptake sensitivity provided in AEO 2023 to better reflect the producer-side battery tax credit of the IRA. This commenter also suggested that EPA consider spillover impacts from domestic action on foreign oil consumption and emissions noting that the Draft Circular A-4 Update recognizes that relevant benefits and costs to consider in regulatory impact analysis include both effects that "result directly from a regulation's domestic applicability" and those that result "indirectly from a regulation's impact on foreign entities. With regard to the latter category, the Draft Circular A-4 update explains that relevant impacts "include the effects of a regulation on U.S. strategic interests, including the potential for inducing strategic reciprocity or other policy changes from actors abroad or effects on U.S.

government assets located abroad," which "are particularly likely to occur when [a] regulation bears on a global commons or a public good." Additionally, the Draft Circular A-4 Update states that relevant impacts include "those that occur entirely outside the United States when they affect U.S. citizens and residents."

Our Children's Trust commented that EPA should revise the analysis so that it utilizes either no discount rate, or a discount rate that does not discriminate against children and future generations, to reflect the true costs of climate change and benefits of electrifying the transportation sector.

Jack Spencer commented that EPA did not fully account for the monetized impact of a proposed rule on disproportionately impacted populations. and that the proposed rule will make new vehicles unaffordable for nearly all low-income Americans and make purchasing even used vehicles more difficult, if not impossible. This commenter encourages EPA to fully monetize and account for the financial burdens to America's low-income families.

The Kentucky Office of the Attorney General et al., echoed by Steven G. Bradbury, commented that the cost-benefit assessment is wrong in large part because it leans so heavily on the climate benefits and that the rule would damage our economy, tax our electrical grids and the families and businesses who depend on them while also threatening our national security. The commenter encouraged EPA to reconsider the Proposed Rule.

The Office of Wyoming Governor Mark Gordon pointed to a briefing paper submitted by Paul Bonifas and Tim Considine at the University of Wyoming that estimated the economic impact of the NPRM which showed a drastic difference in economic benefits compared to EPA's analysis. Governor Gordon also suggested that EPA is pushing for a mandated EV technology and suggested that the full picture should be available for public examination.

Paul Bonifas and Tim Considine commented that EPA's estimated benefits were based on faulty premises, biased data, and narrow economic snapshots. Paul Bonifas and Tim Considine also commented with respect to EPA's vehicle technology costs claiming that EPA had misrepresented our own costs in the presentation of our analysis.

Steven Bradbury commented that EPA had failed to adequately estimate the costs of the rule since it built on the combined effects of three sets of regulatory edicts by CARB and EPA and treated the effects of those edicts as if they were exogenous background facts which, in the commenter's opinion, they are not. This commenter also argued that EPA ignored the increase in carbon dioxide emissions that would occur from the expansion in production of EV batteries and that EPA ignored the carbon dioxide emissions from the increased electricity generation needed to charge BEVs. This commenter also commented that the social cost of carbon models failed to account for the positive agricultural effects of higher carbon dioxide levels. This commenter also commented that it is inappropriate for EPA to consider the global climate effects rather than limiting the effects to domestic impacts.

The Heritage Foundation commented that EPA had incorrectly characterized the transfers (i.e., IRA tax credits) by showing them as benefits rather than costs incurred by taxpayers. This commenter also took exception to our use of a 3 percent discount rate as being below federal standards and below rates used by private businesses and households. The commenter suggested more realistic rates of 7 percent and 10 percent.

The U.S. Chamber of Commerce suggested EPA conduct additional sensitivities to assess sales and emissions reductions under a range of tax credit eligibility, income limitations, and technology cost assumptions. This commenter also expressed concern over grid reliability.

Valero commented that EPA had failed to adequately consider all costs associated with the transformation of the fleet to BEVs. The commenter also incorrectly suggested that the rule was a mandate for BEVs. The commenter also stated that we have failed to consider costs associated with road wear from heavy BEVs, charging "dwell time," electric utility and distribution costs, loss of value in the secondary LMDV market, battery replacements, insurance and cost for taxpayers footing the bill for BIL and IRA tax credits.

The Zero Emission Transportation Associated (ZETA) expressed concern that we were using a MY 2019 base year fleet which has too few BEVs thus impacting available compliance credits in the OMEGA modeling.

Response:

Regarding comments about vehicle demand elasticity, we respond to such comments in Section 14 of this document.

Regarding comments from the Alliance, EPA disagrees that OMB Circular A-4 requires federal agencies to conduct a benefit-cost analysis for each regulatory program and amendments in the rule. OMB Circular A-4 (2003) is guidance designed to assist regulatory agencies by defining and standardizing regulatory analysis. The guidance itself acknowledges that, "You will find that you cannot conduct a good regulatory analysis according to a formula. Conducting high-quality analysis requires competent professional judgment. Different regulations may call for different emphases in the analysis, depending on the nature and complexity of the regulatory issues and the sensitivity of the benefit and cost estimates to the key assumptions." An analysis such as that suggested by the commenter would require a large number of assumptions about how to allocate costs and benefits among various program elements and would not affect our consideration of the final standards. EPA's benefit-cost analysis considers the entirety of the sets of emissions standards and provisions included in this final rule. and EPA consulted with the Office of Management and Budget during interagency review in developing the proposal and again before finalizing this rule.

Regarding the claim that a market failure analysis should be conducted, EPA disagrees with this comment since it implies that the action is being taken to provide consumers with operating cost savings through lower fuel, repair and maintenance costs. This is not the goal nor purpose of the action – we are issuing these standards under EPA's specific authority under the Clean Air Act section 202, as described in Section III of the preamble for the final rule. As described by OMB Circular A-4 (2003), "Before recommending Federal regulatory action, an agency must demonstrate that the proposed action is necessary. If the regulatory intervention results from a statutory or judicial directive, you should describe the specific authority for your action, the extent of discretion available to you, and the regulatory instruments you might use." Under EPA's authority to protect human health and welfare in the Clean Air Act section 202, the final standards will address the market failure of air pollution, which is an environmental externality borne by the public and not by the regulated entities. While the action is expected to provide savings to consumers, those effects are ancillary to the purpose of the rule in reducing harmful air pollutants. Market failures, however, do also help to explain why this rule is expected to result in savings to consumers and are discussed as they relate to vehicle sales in RIA Chapter 4.4, which accompanies this final rule.

Regarding the lack of consideration of environmental impacts associated with the battery supply chain, see Section 19.1 of this document for more detailed responses regarding life cycle analysis. It should be noted that in addition to vehicle emissions we also assessed the upstream emissions impacts of EGUs and refineries, as discussed in Sections VI and VIII of the preamble to this final rule.

Regarding the AmFree comment that EPA should have considered renewable fuels, EPA responds to such comments in Section 19 of this document. As discussed in Section X of the NPRM, section 211(c) requires a different regulatory framework and process for reducing emissions through fuels standards and this rule was adopted under section 202(a) not 211(c). Nothing in this rule precludes consumers from being free to purchase renewable fuels where available or retailers from selling such fuels, and EPA continues to require increased use of renewable fuels through the RFS program. See 88 FR 44468 (July 12, 2023). We note that our modeled compliance paths are not required nor necessarily intended to show an "optimal approach." Instead, our analysis is meant to show possible approaches that manufacturers could choose to take in meeting this rule's performance-based standards, and the costs and benefits associated with those potential approaches. In the final rule, we included analysis of several possible pathways that could lead to compliance, including one pathway that considered a possible future with no more BEVs than exist today (see Section IV.G of the preamble). Manufacturers are free to adopt any of these pathways, or entirely different pathways, in developing compliance strategies.

Regarding comments from the American Fuel & Petrochemical Manufacturers, we disagree that our analysis should be done on a life-cycle basis. Please see Section 19.1 of this document for more responses related to life-cycle analysis. Also, EPA disagrees that the rule is a mandated transition from ICE to BEV technology. Please see Section 2 of this document for more responses noting that the rule is not a mandate. Regarding road wear, we respond to this comment in our response to Valero here in Section 8.1 of this document. Regarding foregone fuel tax revenues, we present those in our discussion of transfers in Section VIII of the preamble and Chapter 9 of the RIA. We also present there the estimated impacts on state sales tax revenues.

Regarding API's comments surrounding GPF costs and feasibility, please see Sections 4 and 12.3 of this document for responses related to this issue. API incorrectly states that EPA's "cost reduction model" is used for cost reductions driven by economies of scale. It is not meant to do so and instead is meant to reflect cost reductions from learning-by-doing. Regarding the suggestion that costs for raw materials increase with increasing supply, please refer to Section 15 of this document for comments related to raw materials. Regarding cost and price being used interchangeably, we have made every effort not to do so. Importantly, EPA does fully account for the cost of technology independent of the purchase tax credit which is considered by consumers in determining the demand for BEVs and PHEVs but not by manufacturers in calculating their costs. In EPA's analysis, the battery tax credit is considered as part of the manufacturer's costs, which we believe is appropriate since that tax credit serves to reduce costs incurred by manufacturers. The Clean Air Act stipulates that EPA consider the costs to manufacturers, among other factors, in determining the appropriate standards, and we believe it is most appropriate to consider not only the costs of the technologies themselves, but the fuller picture of manufacturer costs which also encompasses the manufacturer incentives under the Inflation Reduction Act. The purpose of these IRA provisions is to incentivize particular actions by manufacturers, and we consider that disregarding these provisions would make our modeling less useful in projecting what options are available to manufacturers. Regarding the API comments that costs associated with additional wind and solar and hydropower should be included in our analysis, we note that the IPM and Retail Price Modeling that was done in support of the final rule includes consideration of all expected future power sources—renewables, coal and natural gas. How those costs would be reflected in electricity prices is included in our estimates. Regarding API's suggestion that EPA consider total costs rather than incremental costs, EPA's benefit-cost analysis follows guidance from OMB Circular A-4 regarding the establishment of a reference, or "No Action," case against which to compare the effects of the regulatory action.

Regarding comments from an anonymous commenter related to compliance costs, we respond to such comments in Section 12 of this document. Regarding comments related to our learning effects being applied industry-wide rather than by firm, we have done so because most automotive parts and the costs for those parts, i.e., those to which we refer to as "direct manufacturing costs," are purchased by automakers from suppliers. In the context of our analysis, the learning that results in reductions to, for example, battery costs occurs not at the vehicle manufacturer but rather at the relatively few battery suppliers to those vehicle manufacturers. Furthermore, we account for the need for automakers to undertake continuing R&D into batteries and other topics via our retail price equivalent (RPE) markups which account for R&D at the individual firm.

Regarding comments from the Arizona State Legislature, as also explained in Section 2 of the RTC, EPA disagrees that our standard setting must rely on cost-benefit analysis. Consistent with CAA section 202, in evaluating potential standards we carefully weighed the statutory factors, including the emissions impacts of the standards, and the feasibility of the standards (including cost of compliance in light of available lead time). We monetize benefits of the standards and evaluate other costs in part to enable a comparison of costs and benefits pursuant to E.O. 12866, but we recognize there are benefits that we are currently unable to fully quantify. EPA's practice has been to set standards to achieve improved air quality consistent with CAA section 202, and not to rely on cost-benefit calculations, with their uncertainties and limitations, as identifying the appropriate standards. Nonetheless, our conclusion that the estimated benefits exceed the estimated costs of the final program reinforces our view that the standards are appropriate under section 202(a).

Regarding comments from CARB, we note that we have updated our SC-GHG values (see Chapter 9 of the final RIA for details). Regarding the vehicle price elasticity, please see RTC Section 14. Regarding our EVSE cost estimates, we respond to such comments in Section 17 of this document.

The California Attorney General's office commented that EPA should consider state programs that encourage BEV adoption. EPA has conducted a sensitivity analysis considering the Advanced Clean Car II (ACC II) program adopted by California and Section 177 states as part of the No Action case. (See Section IV.F.1 of the preamble). We have not included the ACC II program in our central analysis for the rule because an EPA waiver for that program has not yet been issued. See Section 2 of the RTC for further discussion. We note that while costs of the EPA program would be reduced by inclusion of the ACC II program in the No Action case, so too would the benefits of the EPA program (see Section IV.F.1 of the preamble). This commenter also suggested that EPA's program should encourage more emission control of ICE vehicles. The final program is expected to provide significant reductions in GHG and criteria pollutant emissions from the light- and medium-duty fleet via a set of performance standards that allow for several different pathways toward compliance. This is the traditional method taken by EPA for mobile source emissions and allows for auto makers to choose which set of technologies is best suited for their fleets to meet the standards, which could include a focus on reducing emissions from ICE technologies.

Regarding comments that EPA present aggregate costs on a per vehicle basis, we do this through 2032, the final year of new standards, which is consistent with our past practice. This commenter also suggested that EPA acknowledge that much of the investment needed for the transition to electrified powertrains has already been made or that EPA otherwise attempt to parse the auto industry investment into electrification for market purposes from that done for regulatory purposes. We note that the cost estimation approach we have taken—estimating indirect costs including R&D and other such investment—via a retail price equivalent markup requires that all products sold into the market carry its share of that indirect cost burden. As such, arguing that some or much of the investment has been made, thereby reducing the need for investment going forward, would be inconsistent with the approach of the analysis. The analysis essentially assumes that product sales are funding ongoing operations and that future sales must do the same.

Regarding the cost-effectiveness calculation done by the Clean Fuels Development Coalition et al., we note that it is highly inappropriate to consider the costs of vehicles sold during the years 2027 through 2032 and compare those costs to the emissions reductions of those vehicles during those same years when, in fact, most of those vehicles will continue to operate and provide emission reductions relative to their No Action emissions for another 25 or more years. The commenters' approach includes the full cost of the technology but only a small fraction of the benefits. Furthermore, we note that if the cost-effectiveness calculation included cost-savings in the numerator, the cost-effectiveness measure would actually be a measure of the net savings to consumers per ton of CO_2 reduced, which provides an unusually favorable calculation. Regarding taxpayers paying for portions of the rule via tax credits, we disagree that we have ignored these costs. We present them in full transparency in Table 210, Section VIII.G of the preamble. However, since these tax credits do not represent new taxes but rather new uses of taxpayer dollars, they do in fact represent transfers and should not be included as social costs of the rule. Regarding assertions that EPA manipulated timelines, we disagree. EPA has followed long-standing practice for mobile source rules of conducting our analysis far enough into the future such that the majority of the on-road fleet can be reasonably expected to be "turned over" to vehicles meeting the revised emissions standards. In this case, we selected an analysis year of 2055, which is 23 years in advance of the final year of phase-in of the revised standards, 2032. Because new vehicles tend to continue operating in the fleet for over 23 years, it is likely that the light-duty fleet will not be fully "turned over" by 2055, meaning that EPA's analysis is somewhat conservative and not capturing the fullest representation of emissions reductions under the final standards. This practice is also consistent with OMB Circular A-4 guidance that states

"…the time frame for your analysis should cover a period long enough to encompass all the important benefits and costs likely to result from the rule."

EPA agrees with Environmental and Public Health Organizations that more stringent standards would provide greater benefits. However, EPA must balance factors under the Clean Air Act, and while we did consider the greater emission reductions of more stringent standards, we also considered factors such as costs and lead time for the manufacturers, as required considerations under the Clean Air Act. EPA's consideration of this balancing of factors to arrive at the final standards is discussed in detail in Section V of the preamble. We note that, while our analysis does not reflect EPA policies that are not yet set forth via final regulation, the analysis does reflect projections that the Inflation Reduction Act incentives will result in a cleaner electric grid.

Regarding comments from the Institute for Policy Integrity at New York University School of Law, we note that we have added some context regarding the final rule and how it compares to past rules in the preamble (e.g., Section V of the preamble) and elsewhere in this RTC. We note also that we have added a presentation of BEV and PHEV vehicles as part of the stock of vehicles in the fleet, in addition to sales, to better inform the public of the rate of transition to electrification within the fleet (see Chapter 8 of the final RIA). EPA agrees that the global valuation of climate benefits is appropriate, and we respond to issues surrounding the SC-GHG values in Section 8.4 of this document. Regarding suggestions to update the baseline by moving toward AEO 2023, EPA agrees and AEO 2023 is in fact being used in the final analysis. Regarding foreign spillover effects resulting from this domestic action, we respond to related comments in Section 8.4 of this document.

In response to commenters who suggested that EPA use a discount rate lower than 3 and 7 percent, or no discount rate whatsoever, we note that we have applied a 2 percent discount rate in the benefit cost analysis to accompany discount rates of 3 and 7 percent. While we were conducting the analysis for the final rule, OMB finalized an update to Circular A-4, in which it recommended the general application of a 2 percent discount rate to costs and benefits. The effective date of the updated Circular A-4 guidance does not apply to the final rule; however, we updated the analysis to reflect the updated discount rate guidance and to be consistent with discount rate assumptions used to estimate the updated SC-GHGs (see Section 8.4 of this RTC document). The application of a lower discount rate did not affect our consideration of the final standards, nor did it change our conclusion that the total benefits of both the proposal and the final rule far outweigh the total costs and therefore result in positive net benefits. Current guidance does not recommend that federal agencies utilize a discount rate of zero in their benefit-cost analyses.

Regarding comments from Jack Spencer and the rule's impacts on low-income Americans, we respond to such comments in Section 13 of this document.

Regarding comments from the Kentucky Office of the Attorney General et al., that the analysis is wrong because it leans so heavily on the SC-GHG metric, we note that the rule is net beneficial even before considering the climate benefits. The climate benefits only make it more so. As discussed in Section V of the preamble, EPA is, consistent with its consistent past practice, setting standards to achieve improved air quality consistent with CAA section 202 and is not relying on cost-benefit calculations, with their uncertainties and limitations, in identifying the appropriate standards. Nonetheless, our estimated benefits, which exceed the estimated costs of the final program, reinforce our view that the final standards represent an appropriate weighing of the statutory factors and other relevant considerations. More specifically, for this rule our assessment that the rule has positive net monetized benefits, regardless of the magnitude of those positive net benefits, supports our view that the final standards represent an appropriate weighing of the statutory factors and other relevant considerations. Thus, EPA disagrees that it is leaning heavily on the SC-GHG metric, because regardless of the method used in quantifying the monetized benefits of GHG reductions for purposes of this rulemaking, EPA would still find the emissions reductions, in light of the cost of compliance, available lead time and other factors, would justify adoption of these standards.

EPA disagrees that the rule would damage our economy. On the contrary, this rule will be beneficial for U.S. competitiveness; automakers compete in a global economy and the rest of the world also is transitioning toward cleaner transportation technologies. EPA also disagrees that the rule will adversely affect our electrical grid and the families and businesses who depend on them (see Section 18 of this document for our responses to grid reliability issues). Lastly, we disagree that the rule will threaten our national security. In fact, as our reliance on foreign sources of energy is reduced, we see benefits associated with energy security (see Section 21 of this document for comment responses related to energy security).

Regarding comments from the Governor of Wyoming, we note first that we respond to the Paul Bonifas and Tim Considine comments directly below. EPA also notes that the final rule is not a BEV mandate but rather a set of performance standards under which manufacturers choose the technologies they believe are best suited for their fleets, and that can be met via several different pathways. We make this clear in Section IV of the preamble where we show compliance with the standards via several technology pathways including one pathway that involves no more BEVs than exist in the fleet today.

Regarding comments from Paul Bonifas and Tim Considine, EPA disagrees with the assertion that our analysis is based on faulty premises, biased data, and narrow economic snapshots. EPA has relied on the best available information in the public record, including consideration of updated data submitted by commenters, in the final rule analysis, including the benefit-cost analysis. The commenters provided more detailed comments regarding the line items in the table included in the comment excerpt above and we respond to those comments elsewhere in this document. For example, we respond to comments regarding vehicle technology costs in Section 12 of this document, fuel savings in RTC Section 8.3, maintenance and repair in RTC Section 8.2, climate in RTC Section 8.4, and air pollutant benefits in RTC Section 8.5.

Regarding vehicle technology cost comments from Paul Bonifas and Tim Considine, the commenter asserts that EPA has underestimated new vehicle purchase prices. The commenter points to EPA's own numbers of $5,200, $7,100 and $3,500 for a new sedan/wagon, CUV/SUV and pickup, respectively. The commenter then does a straight average of these three values (i.e., not a sales-weighted average) to arrive at a result of $5,266 as the average price increase per vehicle. The commenter notes that this amount is in sharp contrast to the $1,200 increase cited by EPA. The commenter then incorrectly argues that EPA has reduced the price paid by consumers to arrive at the $1,200 value by assuming the full $7,500 purchase tax credit available via the Inflation Reduction Act. First, EPA did not in the proposal and still does not in this final rule assume the full $7,500 purchase tax credit would be realized on all BEV sales. The NPRM analysis applied an average level of purchase tax credit to all BEV sales meaning that, while some BEVs might receive the full credit others might receive less. The result in the NPRM analysis being an average credit of $3,750 in 2023 ramping up to $6,000 in 2032 with a value of $7,500 never reached, on average.

Importantly, Bonifas and Considine are mixing and matching numbers in the EPA analysis. First, the $1,200 value reported by EPA was the average incremental cost for a new vehicle under the proposed standards relative to the cost of a new vehicle under the No Action scenario. In contrast, the $5200/$7100/$3500 values noted by the commenter and reported by EPA in Table 4-7 of the draft RIA, were estimated prices of ICE vehicles versus BEVs under the proposed standards. Comparing these numbers, the $1,200 to the $5200/$7100/$3500 is not consistent since the $5200/$7100/$3500 values are not relative to a No Action scenario but are instead comparisons of one powertrain to another within a scenario. This makes moot the scaling of EPA's technology costs upward by 338% as suggested by the commenter. The commenter also argues that the purchase tax incentive is paid by taxpayers and, therefore, does not increase nor decrease the "net benefit" to the US economy. EPA agrees and that is why we do not include the purchase tax credit as part of our net benefits calculation. EPA regrets that the commenter may have misunderstood the point of the analysis presented in Table 4-7 of the draft RIA. It was not meant to reflect the incremental costs of the proposal, nor was it meant to reflect the Benefit Cost Analysis or net benefits of the proposal. Instead, it was meant to inform the public of the out-of-pocket expenses that might occur for future buyers considering a BEV versus an ICE purchase under the proposed standards.

Regarding comments from Steven Bradbury that we had failed to account for three CARB and EPA edicts that were built into our analysis reference case, we note that those past programs are final rules and final EPA actions which should not be considered in the cost or benefit accounting of this action but rather, as we have done, as the reference case (No Action case) from which this action should be measured. We disagree with the commenter that we are in error on this issue. We also disagree that we have ignored power sector emissions that are expected to charge the electrified vehicles we project under this rule. EPA has in fact considered these power section emissions; please see Chapter 8 of the final RIA for an accounting of those emissions. We acknowledge that we have not considered the emissions that would occur from the manufacture of batteries while also noting that we do not consider the emissions that occur, or any reduction that might occur, from manufacturing ICE vehicles and engines. See Section 19.1 of this RTC for additional discussion of life cycle emissions. As for the global vs. domestic accounting of climate benefits, we respond to such comments in Section 8.4 of this document. The commenter is correct that we have not estimated temperature impacts for many reasons, as discussed in RTC Section 8.4.

Regarding the Heritage Foundation comments regarding transfers being shown as benefits, we disagree with the assertion. The sign used in the table, positive rather than negative as suggested by the commenter, was not meant to reflect benefit or cost. Instead, the mentioned tables simply present the magnitude of the transfers. In the final rule, we have included state sales taxes so now we present some transfers with positive and some with negative signs and make clear the nature of the signs used. Further, while taxpayers do in fact provide the government with the money necessary to pay those transfers, those payments by taxpayers do not reflect new costs. Instead, this is money already paid by taxpayers and being used as appropriated by Congress. We consider them neither a cost nor a benefit and, instead, a transfer. Regarding discount rates, we follow the guidance set forth in OMB Circular A-4.

Regarding the U.S. Chamber of Commerce, EPA has conducted additional sensitivities in the final analysis although not necessarily those suggested. For example, we believe our sensitivities regarding faster and slower BEV adoption and higher and lower battery costs generally address the commenters' concerns about assessing a range of technology cost assumptions and a range of eligibility for tax credits. We believe that we have conducted a sufficient set of multiple sensitivity analyses to show that the final rule is reasonable and achievable. As for grid reliability, we respond to such comments in Section 18 of this document.

Regarding comments from Valero, we disagree that section 202(a) should be interpreted differently for this rulemaking than for prior rulemakings under section 202(a). EPA is engaged in the exact same exercise, pursuant to the same grant of authority from Congress, as in prior rulemakings. EPA is tasked with assessing what standards are appropriate in order to reduce harmful air pollution, taking into consideration the "cost of compliance" with the available lead time. It is well-established in case law, as the commenter notes, that "cost of compliance" here refers to costs to the automakers. EPA disagrees that these rules are transforming the vehicle market—as discussed in the preamble EPA is reflecting a significant shift in the vehicle market but that shift is largely occurring due a broader set of factors, including Congressional action, international markets, and automaker investments and business strategies. However, even if these rules are contributing to that shift, there is no basis for altering the meaning of section 202(a). Moreover, EPA notes that we have, consistent with our prior practice, considered a full range of social costs, for purposes of the benefit-cost analysis, that go well beyond the costs to automakers and encompass many of the topics identified by the commenter.

Thus, we have fully considered the costs associated with the BEV and PHEV technologies relative to ICE technologies. We note that we are not requiring any consumers to change their types of vehicles and fuels. In fact, we expect that under the final rule there will be a diversity of vehicles for consumers to choose from, according to their preferences and needs. We fully expect that ICE vehicles and hybrids will continue to be sold and that some consumers will choose PHEV technologies. We respond to comments regarding EVSE charging and the grid in Sections 17 and 18 of this document. We acknowledge that we have not quantified road wear costs from BEVs. We disagree with the commenter that there is evidence that the increased weight of BEVs attributable to this rule will result in a significant impact on road or bridge degradation.[370] At this time, we have not seen data to indicate that EVs will increase degradation of roads or bridges, and we are not aware of any attempts to quantify the associated potential costs. (See Section 11.1 of this RTC for more discussion of road wear and vehicle weight.) We have indeed considered the costs of driver "dwell time" during charging. Please see Chapter 4.3.5 of the final RIA. We have not considered loss of value in the secondary market because at this time we have not seen data to indicate this is a valid concern. We have not considered costs of battery replacements because we do not believe that is a concern for the light/medium-duty vehicle market (see Chapter 1 of the final RIA and Section 12.2.5 of this RTC). For the final rule, we

[370] We note that, as shown in Table 8-5 of the RIA, the projected increase in weight within vehicle classes is small and is dwarfed by the increase in weight due from the shift from cars to light trucks and SUVs, which is unrelated to the increased sale of BEVs.

have included insurance costs for all vehicles in our benefit cost analysis. Regarding taxpayers and tax credits, see our response above to the Heritage Foundation.

Regarding comments from ZETA, we agree that the base year fleet should be updated, if possible, to reflect the most recent data available. As such, we have updated the base year fleet for the final analysis and are now using a MY 2022 vehicle base year fleet.

8.2 - Non-emission costs and benefits

Comments by Organizations

Organization: Alliance for Consumers (AFC)

Most notably, while "EPA projects lower maintenance and repair costs for several advanced technologies (e.g., battery electric vehicles)," EPA has failed to properly consider the likelihood, frequency, or expense of repairing or replacing a light-duty or medium-duty vehicle's battery due to wear, accident, or malfunction; a repair or replacement of a battery for an electric vehicle could potentially undo any cost savings projected by EPA in terms of "lower maintenance and repair costs" for "battery electric vehicles." Indeed, as some sources have pointed out: "[t]here will be scenarios in which a new EV battery will cost more than the vehicle's value." Ronald Montoya, Electric Car Battery Replacement Costs, Edmunds.com, May 2, 2023; see also id. ("On one hand, [battery replacement] costs might be cheaper than buying a new EV, but spending $15,000 on a new pack for a car that might be worth $10,000 is a tough sell.").2 EPA has failed to properly consider this aspect of the problem. [EPA-HQ-OAR-2022-0829-0534, p. 4]

2 Available at https://www.edmunds.com/electric-car/articles/electric-car-battery- replacement-costs.html.

Failure To Adequately Consider All Aspects Of The Problem

An agency rule is arbitrary and capricious if "the agency has relied on factors which Congress has not intended it to consider, entirely failed to consider an important aspect of the problem, offered an explanation for its decision that runs counter to the evidence before the agency, or is so implausible that it could not be ascribed to a difference in view or the product of agency expertise." Motor Vehicle Mfrs. Ass'n of U.S., Inc. v. State Farm Mut. Auto. Ins. Co., 463 U.S. 29, 43 (1983). [EPA-HQ-OAR-2022-0829-0534, p. 4]

Here, EPA has failed to adequately consider all aspects of the problem and adequately address crucial consideration that go to the validity of the proposal. This includes failure to properly consider the rising price of electric vehicles in the wake of the Inflation Reduction Act, the limits on credits and subsidies that have resulted from this surge in electric vehicle pricing, and the true cost of repairing electric vehicles over a relevant time horizon. [EPA-HQ-OAR-2022-0829-0534, p. 4]

Organization: American Fuel & Petrochemical Manufacturers

Shockingly, EPA provides no analysis of the impact of this rule on the U.S. biofuels or agricultural industries. The U.S. is the world's largest biofuels producer, yet a search of the DRIA reveals that the only mention of biofuels comes in a footnote describing the contents of an

EIA Annual Energy Outlook table. Considering the implications for the biofuels industry, as well as the significant impact it will have on the agricultural producers that supply the industry, this glaring omission underscores the arbitrary nature of this rulemaking. [EPA-HQ-OAR-2022-0829-0733, pp. 10-11]

The DRIA also relies on out-of-date cases from EIA's AEO 2021. In EIA's AEO 2023 released earlier this year, U.S. crude production is higher, as are U.S. net exports of petroleum products, petroleum consumption is lower and U.S. refining capacity is lower. These changes call into question the validity of EPA's estimate of the reduction in U.S. imports of crude oil that result from the proposed rule. [EPA-HQ-OAR-2022-0829-0733, pp. 10-11]

Finally, EPA used a Low Economic Growth case from AEO 2021 to estimate the impact of the proposed rule on oil imports, rather than carrying out an analysis specific to the changes in demand that EPA projects to result from the proposed rule. Although demand in the Low Economic Growth Case is lower than in the Reference Case, the oil demand decreases in the Low Economic Growth case differ from the oil demand decreases EPA projects in Table 9-42 and there is no consideration of how those differences affect the oil security analysis. [EPA-HQ-OAR-2022-0829-0733, pp. 10-11]

Second, EPA concludes that the costs of the proposed rule would be offset by a $580 billion reduction—which EPA counts as a "benefit"—in "mainte-nance and repair costs" that it expects consumers to realize by shifting to elec-tric vehicles. 88 Fed. Reg. at 29,372, 29,385. As support for this enormous sum, EPA points to a single study suggesting that lifetime repair-and-maintenance costs for electric vehicles will be less than for combustion-engine vehicles. See Draft RIA at 4-32. In so doing, the agency unreasonably ignores countervailing sources suggesting the opposite. For instance, Consumer Reports has found that consumers report more problems with electric vehicles than combustion-engine vehicles—including issues with battery packs, charging, electric drive motors, and heating and cooling systems unique to electric vehicles. Jake Fisher, Tesla and Nissan Make the Most Reliable Electric Vehicles, Consumer Reps. (Dec. 14, 2022), https://tinyurl.com/mryx9z6c. It also takes longer, and costs more, for problems with electric vehicles to get resolved. Charette, Convincing Consumers. And there are fewer qualified technicians to resolve them: out of 229,000 auto-repair technicians in the United States, only 3,100 are certified for electric vehicles. Id. Moreover, if a manufacturer goes out of business (much more common in the nascent electric-vehicle industry), purchasers of that com-pany's vehicles will be on their own in seeking to repair the vehicles, without standard manufacturer-servicing support. Beia Spiller et al., Medium-and Heavy-Duty Vehicle Electrification: Challenges, Policy Solutions, and Open Research Questions, Res. for the Future, at 13 (May 2023). Any final rule must explain why EPA's fuel-savings figures are realistic in the face of this contrary evidence. [EPA-HQ-OAR-2022-0829-0683, pp. 62-63]

Organization: Anonymous

As explained below, EPA has placed its thumb on the scale to make it appear that BEVs are perfect vehicles with no drawbacks, and that their proposal will increase the prevalence of these magic vehicles at no costs to the American public. While BEVs are necessary to help address climate change, EPA's analysis goes from neutral observer to biased participant. EPA should revise its analysis to more holistic to the costs and benefits of BEVs and give the public an opportunity to comment on these changes before finalizing any standards given that EPA has 4 years before the first year of their proposed standards are set to take effect. [EPA-HQ-OAR-2022-0829-0565, pp. 1-3]

1. Repair and Maintenance

EPA uses a non-rigorous, unscientific DOE study to selectively calculate maintenance and repair benefits that favor their proposed action, which leads to inflating the projected net benefits by half a trillion. EPA should not be estimating such a large and important factor using an unscientific methodology, and if they are attempting to measure maintenance and repair costs, they need to do so more comprehensively rather than just estimating the costs of maintaining and repairing ICE engines. [EPA-HQ-OAR-2022-0829-0565, pp. 1-3]

For maintenance, EPA uses DOE's service schedule to estimate the differences in routine maintenance between powertrains. In constructing the schedule, DOE admitted "[t]here was a lack of publicly available real-world data" to directly estimate maintenance costs; instead, DOE created schedules by looking at manufacturer recommended service intervals of 15 vehicles (Comprehensive Total Ownership Report, Burnham, Gohlke, et al. 2021, 81). However, instead of just sticking to what manufacturers' advised best practices, the authors augmented the schedules by including more maintenance items based on "guidance from several experts". DOE does not explain which services and mileages were derived from manuals and which were derived from 'experts', but just generally cites to three sources. (The first source is from another DOE report from 2012 (Vyas 2012); the Comprehensive Total Ownership Report notes that maintenance costs decrease overtime on a per mile basis (72), which begs the question whether a report, which isn't even based on data, from over a decade ago is still a valid 'estimate'). DOE also excluded or misrepresented some obvious items. For example, manufacturers generally recommend BEVs have a battery maintenance check every 6months to 2 years (see https://www.quirkchevy.com/electric-vehicle-service-maintenance-best-practices/#:~:text=Like%20every%20other%20car%2C%20truck,how%20your%20battery%20is%20performing and https://lucidmotors.com/media/document/Owner's+Manual+-+Lucid+Air-enUS_2022_30_1.pdf). [EPA-HQ-OAR-2022-0829-0565, pp. 1-3]

Another issue with DOE's report is the assumption that maintenance schedules are based exclusively on how much a vehicle is driven rather than time. EPA's maintenance estimate fails to consider that maintenance is also a function of an environment, rather than just use. For example, EPA assumes that brake calipers will last 50% longer on BEVs than Ice vehicles because of regenerative braking. But this assumption ignores that calipers can rust and erode in the presence of salt, which would indicate that the lifetime is a measurement of time and exposure to the elements. (see https://www.wagnerbrake.com/technical/parts-matter/automotive-repair-and-maintenance/why-rust-on-my-brakes.html#:~:text=For%20those%20that%20live%20in,that%20can%20corrode%20brake%20components.) [EPA-HQ-OAR-2022-0829-0565, pp. 1-3]

In general, the DOE and EPA approach is tilted towards BEVs from a methodological approach. EPA assumes that the owner of an ICE or hybrid vehicle will maintain their vehicle in perfect condition through the first 15 years of its life, while owners of electrified vehicles will not maintain their vehicle's battery or other BEV specific parts, nor experience any corresponding decrease in utility due to diminished capacity, such as battery range reducing over time. [EPA-HQ-OAR-2022-0829-0565, pp. 1-3]

The repair estimates contained in the DOE report that EPA relies upon are even more egregious. The single DOE study that EPA relies upon, extrapolates repair estimates based on 3 BEV models: BMW i3, Fiat 500e, and the Soul Electric. The DOE study also assumes that these three vehicles are comparable to the BMW 3 series, Fiat 500, and the Kia Soul, respectively. Besides the extremely limited amount of observations which cannot produce statistically significant results and prone to large errors, DOE's assumption that those vehicles are comparable is misguided. For example, the BMW i3 was not built on the same chassis as the 3 series (https://www.klipnik.com/best-used-cars/bmw-i3-model-history-and-buyers-guide/), is a different body type (the i3 is a hatchback while the 3 series is a sedan), and assumes that the performance and style of the two vehicles are comparable despite the i3 being less stylish with less interior room and slower acceleration (compare, for example, the 2021 i3 https://www.caranddriver.com/bmw/i3 with the 2021 3 series https://www.caranddriver.com/bmw/3-series-2021). Perhaps the largest difference is how a consumer would use an i3 compared to a 3 series. The i3 consistently had less than a 100 mile range. It is absurd to expect that the i3 had the same consumer base and usage patterns that would make it a strong data point to compare the maintenance and repair cost differential between ICE and BEVs, and leads to a clear underestimation of how much an electric 3-series would actually cost to repair (and maintain). DOE used those 3 similar-dissimilar BEV-ICE vehicles to determine that BEVs have a 33% lower repair cost. This was not derived from any statistically significant review of repair costs, and it's unclear how much VMT was driven in the BEVs over the same time period as their ICE counterparts. Lower VMT could obscure the fact that on a per mile basis, BEVs are costlier to repair. [EPA-HQ-OAR-2022-0829-0565, pp. 1-3]

The 'statistical methodology' portion of DOE's analysis is just as wanting. DOE uses MSRP as a proxy instead of directly estimating repair costs and discounts based on the differences observed in the three BEV/Ice vehicle pairings noted in the previous paragraph. This methodology implicitly assumes that the most expensive ICE vehicles have comparable BEV vehicles which are also included in the analysis, which in 2019 and earlier, is baseless. Hence DOE implicitly compares the costs to repair and maintain a small, affordable BEV like the leaf to something like a GM Hummer. A similar absurd analysis would be to look at the Toyota Prius compared to the eHummer and assume that ICE vehicles on par use less energy to operate, are cheaper to buy, and cheaper to maintain and replace than BEVs. [EPA-HQ-OAR-2022-0829-0565, pp. 1-3]

Perhaps the largest omission in EPA's analysis is considering what happens if BEV needs a battery replaced. Battery replacements can cost well into the tens of thousands (https://www.jdpower.com/cars/shopping-guides/how-often-do-tesla-batteries-need-to-be-replaced), and there's some evidence that some BEVs are 'totaled' even with minor damage because it doesn't make sense to repair and replace the battery pack (for example, https://www.caranddriver.com/news/a42709679/tesla-insurance-fixes-expense/). however, this consideration is not included in EPA's analysis of repair and maintenance nor elsewhere in the rule. This unaccounted for cost obscures the true cost of ownership, and if included, could flip the estimated cost per mile of repair and maintenance costs from BEVs being net positive compared to ICE vehicles to net negative. [EPA-HQ-OAR-2022-0829-0565, pp. 1-3]

The DOE study that EPA relies upon also declines to estimate the maintenance costs of other GHG reducing technologies, such as mass reduction, as they assume the cost would be equivalent across powertrains; that assumption, however, can't be applied to the delta between EPA's baseline and alternatives as those technologies will be applied in response to their proposed standards. [EPA-HQ-OAR-2022-0829-0565, pp. 1-3]

An ancillary maintenance and repair item excluded from EPA's analysis is the impacts of BEVs on road maintenance. https://www.energylivenews.com/2023/06/27/evs-cause-twice-the-road-damage-of-petrol-vehicles-study-reveals/. BEVs are generally heavier than their ICE counterparts, which causes more wear and tear on roads. If EPA is using a per VMT maintenance cost, they can also easily include the increase in road maintenance costs. [EPA-HQ-OAR-2022-0829-0565, pp. 1-3]

If EPA wants to include an estimate of maintenance and repair costs that shows 500 billion in savings, it needs to be based on a scientific, rigorous and transparent process, and should be derived from data that is statistically significant, otherwise, EPA is inflating the net benefits based of imprecise estimates that have less than a 40 cents difference on a per mile basis. [EPA-HQ-OAR-2022-0829-0565, pp. 1-3]

Organization: Arizona State Legislature

6. The proposed rule relies on speculative and erroneous estimates for repair and maintenance. EPA's assumption that electric vehicles will have lower maintenance and repair costs than fossil fuel-powered vehicles is contradicted by data for service and repair visits and insurance claims. [EPA-HQ-OAR-2022-0829-0537, p. 2]

VI. The proposed rule is arbitrary and capricious because it relies on speculative and erroneous estimates for repair and maintenance.

EPA believes "lower maintenance and repair costs for several advanced technologies (e.g., battery electric vehicles)" from the proposed rule "would result in significant savings for consumers." 88 Fed. Reg. 29,199, 29,201. EPA relies on a single government-funded study, which includes significant assumptions and data limitations. Id. at 29,384 n.794. Based on this sole study, EPA calculates the proposed rule will save a staggering $75 billion in combined repair and maintenance costs. Id. at 29,362. [EPA-HQ-OAR-2022-0829-0537, pp. 23-24]

EPA's conclusions are contradicted by widely available data. An analysis of the service and repair visits for about 19 million vehicles between the 2016 and 2021 model years found that electric vehicles cost more to repair than gas-powered vehicles.24 The study found that electric vehicles were 2.3 times more expensive than gas-powered vehicles to service in the first three months of ownership, and 1.6 times more expensive at the twelve-month mark.25 The study blamed the increased time that technicians spent as well as the fewer number of technicians that could work on electric vehicles charging a higher hourly rate.26 [EPA-HQ-OAR-2022-0829-0537, pp. 23-24]

28 Id.

EPA also does not calculate the frequency or likelihood that a light-duty or medium-duty vehicle will need to replace its battery due to wear or accident. Nor does EPA calculate the cost of battery replacement. Battery replacement for a passenger vehicle can cost between $5,000 and $15,000.29 One battery replacement could obviate any cost savings estimated by EPA for that vehicle. [EPA-HQ-OAR-2022-0829-0537, p. 24]

Organization: Charles Forsberg

We conducted a series of workshops and wrote multiple papers on replacing all crude oil-domestically and internationally. By definition, this includes everything covered in the proposed EPA rule and all other uses of oil-based products. Based on those studies, the likely consequences of the proposed EPA rulemaking are much higher costs for light vehicles, failure to meet greenhouse gas reduction goals by decades, significant reductions in life expectancy and major reductions in incomes of the bottom 60% of the U.S. population. A summary of the basis for those conclusions and recommendations for EPA is provided herein. The recently published open-access paper (below) provides more detail and includes references to support these conclusions. [EPA-HQ-OAR-2022-0829-0738, p. 1]

C. W. Forsberg, "What is the Long-Term Demand for Liquid Hydrocarbon Fuels and Feedstocks?" Applied Energy, 341, 121104 (2023) https://doi.org/10.1016/j.apenergy.2023.121104 [EPA-HQ-OAR-2022-0829-0738, p. 1]

4. Feasibility and implementation.

Chevron is concerned that the rapid increases in forecasted BEV sales rate are optimistic and may overstate the benefits of the proposals. The proposals may limit choices and increase costs for consumers, including those in economically disadvantaged groups and smaller businesses. [EPA-HQ-OAR-2022-0829-0553, p. 6]

BEV sales forecasts may rely on optimistic expectations for increased electricity generation and charging infrastructure. EPA should conduct an assessment to account for the costs and timing associated with upgrades to the nation's grid infrastructure, including new and upgraded generation, transmission, and distribution, and the costs associated with the installation of public and private electric vehicle chargers. If it is not feasible to complete expansion and improvements for the current grid, it may not be possible to meet the additional demand created by the proposed regulation. [EPA-HQ-OAR-2022-0829-0553, p. 6]

Organization: Clean Fuels Development Coalition et al.

These aggregate costs include:

- Vehicle maintenance and repair costs. EPA underestimates maintenance costs in several ways, not the least of which is by ignoring the massive expense of replacing an electric vehicles battery. For example, a Tesla battery typically costs between $12,000 and $20,000 to replace and is out of warranty after only 8 years. [EPA-HQ-OAR-2022-0829-0712, pp. 5-6]

- Insurance costs. Electric vehicles are more costly to insure than conventional vehicles both because they have a higher upfront sticker cost and "because of higher repair and replacement costs for damaged parts." Mark Rosanes, Do Electric Vehicles Cost More to Insure Than Gasoline Powered Cars?, Insurance Business (Oct. 28, 2022), https://www.insurancebusiness-mag.com/us/news/auto-motor/do-electric-vehicles-cost-more-to-insure- than-gasolinepowered-cars-425631.aspx; see also Benjamin Preston, Electric Vehicles May Cost More to Insure Than Gasoline-Powered Cars, Consumer Reports (Apr. 27, 2023), https://www.consumerre-ports.org/money/car-insurance/electric-vehicles-cost-more-to-insure-than- gasoline-powered-a6372607024. [EPA-HQ-OAR-2022-0829-0712, p. 6]

Organization: Consumer Energy Alliance (CEA)

Struggling with access to affordable transportation, however, is just one of the equity impacts that has not been addressed by the U.S. EPA How will U.S. EPA address the systemic inequity and energy injustice issues embedded in this rule beyond the financial burden that will be caused? [EPA-HQ-OAR-2022-0829-0788, pp. 3-4]

For example, the practical use of EVs benefit wealthier users as well. Charging infrastructure Is a critical component for EV usage, with access to chargers (and specifically fast chargers) a major consideration in purchasing an EV. Wealthier users are far more likely to live In single family homes where installation of a fast charger costing thousands of dollars is simply a matter of fact. Lower income families who are more likely to reside in apartments or rented properties do not have the option of installing their own personal dedicated fast chargers. [EPA-HQ-OAR-2022-0829-0788, pp. 3-4]

Even the location of charging infrastructure tends to benefit the wealthier, whiter, male demographic that makes up 75% of the individuals who purchase EVs. A recent MIT study on EVs and equity noted7:

"According to Hsu and Fingerman (43], Black and Hispanic neighborhoods only had 0.7 times the access to public chargers as the no-majority reference group in California. They also determined that even when income, proximity to the nearest highway, and multi-family housing were controlled for, White-majority census block groups were 1.5 times more likely to have access to public charging stations compared to Black- and Latino-majority census block groups." [EPA-HQ-OAR-2022-0829-0788, pp. 3-4]

7 sciencepolicvreview.org/2021/08/equity-transition-electric-vehicles/

They also noted that public charging, when available to lower income communities, typically costs more than home charging stating:

"This higher cost would disproportionately affect low-income households who already pay a higher proportion of their income towards transportation." [EPA-HQ-OAR-2022-0829-0788, pp. 3-4]

By creating disparities in access to the "fuel" through charging network realities this further exacerbates the differences in transportation equity between rich and poor. Combine that with what is sure to be higher electricity prices from the requisite generation, distribution and transmission infrastructure buildout required to meet growing electricity demand as is often the case the poor will just keep getting poorer. [EPA-HQ-OAR-2022-0829-0788, pp. 3-4]

Organization: Consumer Reports (CR)

3. The Proposed Standards Will Save Consumers Money

Over the past two decades, clean car standards such as EPA's GHG Standards for Model Years 2023-2026, harmonized with the Department of Transportation (DOT) National Highway Traffic Safety Administration's (NHTSA) Corporate Average Fuel Economy (CAFE) standards, have delivered $7,000 in lifetime fuel savings and a 30% reduction in greenhouse gas emissions from the average new vehicle over the last two decades.11 At the same time, vehicles have become safer, larger, and more powerful; but, most impressively, all of those improvements were delivered with no (inflation-adjusted) increase in vehicle prices. [EPA-HQ-OAR-2022-0829-0728, pp. 8-10]

11 Vehicle Price Trends: Fuel Economy and Safety Improvements Come Standard, Consumer Reports, February 21, 2023, https://advocacy.consumerreports.org/wp-content/uploads/2023/02/CR-Vehicle-Price-Trends-Feb-21-202 3.pdf.

EPA estimates that its latest proposed standards for MY27+ will save consumers over $1 trillion through 2055 while reducing GHG emissions by over 7 gigatons. This result is consistent with CR's analysis from 2021 which found that reducing emissions from new vehicles by 60% by 2030 would save consumers $1.6 trillion through 2050.12 This proposal, when combined with EPA's previous rule for model years 2023 to 2026, is consistent with that trajectory of 60% reduction in emissions by 2030. [EPA-HQ-OAR-2022-0829-0728, pp. 8-10]

12 Meeting Emissions Goals Will Save Consumers A Lot of Money, Consumer Reports, March 2021, https://advocacy.consumerreports.org/wp-content/uploads/2021/03/Consumer-Reports-Vehicle-Emissions-Standards-Fact-Sheet-3.22.21-FINAL.pdf.

CR analysis shows that at an average gas price of $3.50/gallon, close to the national average gas price in June 2023, an electric SUV would deliver an average of $1,700 in fuel and maintenance savings every year.13 A 2020 analysis by CR found that the most popular EVs were already cheaper to own than the most popular and highest-rated gasoline vehicles in their class, even factoring in the higher purchase prices of EVs.14 That analysis has been updated for 2023 in Section 5 of this comment letter. The findings are consistent with the previous analysis; however now all 6 EVs analyzed show consumer savings in the very first year of ownership when financed. This means that the average American buying a new, mainstream vehicle doesn't have to wait for some point in the future to start saving money with an EV. [EPA-HQ-OAR-2022-0829-0728, pp. 8-10]

13 New Consumer Reports analysis shows rising gas prices ramp up savings for EV owners, Consumer Reports, March 10, 2022, https://advocacy.consumerreports.org/press_release/new-consumer-reports-analysis-shows-rising-gas-pri ces-ramp-up-savings-for-ev-owners/.

14 New analysis from CR finds that the most popular electric vehicles cost less to own than the best-selling gas-powered vehicles in their class, Consumer Reports, October 8, 2020, https://advocacy.consumerreports.org/press_release/new-analysis-from-cr-finds-that-the-most-popular-ele ctric-vehicles-cost-less-to-own-than-the-best-selling-gas-powered-vehicles-in-their-class/.

Overall, EVs save an average of 60% on fuel and 50% on repairs and maintenance compared to comparable gasoline vehicles.15 Importantly, the 2020 study found that while EVs were usually cheaper to own for a first owner who drove the vehicle for the first seven years, the largest chunk of the savings flowed to a second owner who purchased the vehicle used. This is because used vehicle buyers will pay less of a premium to purchase an EV, but will encounter similar fuel savings, and even greater maintenance cost savings due to increasing maintenance requirements for older ICE vehicles. [EPA-HQ-OAR-2022-0829-0728, pp. 8-10]

15 Id.

Additionally, recent federal investments give consumers even more options to save on the initial purchase or lease of an EV. The Inflation Reduction Act (IRA) offers tax credits of up to $7,500 for the purchase of new EVs that meet certain manufacturing, vehicle pricing, buyer income, and critical minerals requirements. A 2023 study from the International Council on Clean Transportation estimated that these tax credits would make the average new qualifying EV cheaper to purchase than the average new conventional vehicle by 2025, resulting in a large boost in EV demand.16 The IRA also includes tax credits of up to $4,000 for the purchase of used EVs subject to certain income and vehicle price limits, helping to make EV's more accessible to consumers who buy used vehicles. [EPA-HQ-OAR-2022-0829-0728, pp. 8-10]

16 Analyzing the Impact of the Inflation Reduction Act on Electric Vehicles Uptake in the United States, The International Council on Clean Transportation, January 2023, https://theicct.org/wp-content/uploads/2023/01/ira-impact-evs-us-jan23-2.pdf.

6.6. Inclusion of Maintenance and Repair Savings in Cost Benefit Analysis

CR supports EPA including maintenance and repair savings in their cost benefit analysis. CR's research has found that in real world operations BEVs and PHEVs can both deliver around 50% savings compared to conventional gasoline powered vehicles.47 CR is in the process of updating this analysis with more recent data and will share the results with EPA once it is complete. [EPA-HQ-OAR-2022-0829-0728, p. 23]

47 New analysis from CR finds that the most popular electric vehicles cost less to own than the best-selling gas-powered vehicles in their class, Consumer Reports, October 8, 2020, https://advocacy.consumerreports.org/press_release/new-analysis-from-cr-finds-that-the-most-popular-ele ctric-vehicles-cost-less-to-own-than-the-best-selling-gas-powered-vehicles-in-their-class/.

Organization: Daniel Hellebuyck

Weight: An EV can weigh up to 1 ½ times a comparable internal combustion engine (ICE) vehicle. This creates more safety issues in a collision and more weight that our crumbling infrastructure has to absorb. Furthermore, insurance companies may be charging higher premiums to all customers to pay for the increased risk of injury and the larger costs involved in repairing EVs versus and ICE vehicle. [EPA-HQ-OAR-2022-0829-0526, p. 1]

Organization: Delek US Holdings, Inc.

V. The Proposed Rule Severely Underestimates the Costs of BEVs

EPA claims that the Proposed Rule will somehow result in $200 to $220 billion in net benefits for calendar year 2055, which represents less than the cost of vehicle technology and associated electric vehicle supply equipment ("ESVE") required to meet the associated standards.30 As industry experts have asserted, "the derivation of these cost estimates is murky and fundamentally not credible," especially as EPA's estimate of the no-action alternative from which all other proposals are compared to deceptively ignores the regulatory costs of the Administration's current efforts to rapidly escalate electrification and automatically assumes that "American car buyers will suddenly drop their resistance to EVs."31 [EPA-HQ-OAR-2022-0829-0527, p. 7]

30 Proposed Rule at 29,200 (based on present value (PV) of net benefits for calendar years 2027 through 2055, with discounting to 2027 using a 3 percent discount rate).

31 Steven G. Bradbury, THE HERITAGE FOUNDATION, Prepared Statement for the hearing entitled "Driving Bad Policy: Examining EPA's Tailpipe Emissions Rules and the Realities of a Rapid Electric Vehicle Transition," before the Subcommittee on Economic Grown, Energy Policy, and Regulatory Affairs of the U.S. House of Representatives Committee on Oversight and Accountability, at 10 (May 17, 2023) available at https://oversight.house.gov/wp-content/uploads/2023/05/Bradbury-Prepared-Statement-for- 17-May-2023-Oversight-Hearing.pdf.

Despite the substantial price differences between ZEV and ICE vehicles, EPA's cost analysis concludes—with little to no concrete support—that "the proposal would result in significant savings for consumers from fuel savings and reduced vehicle repair and maintenance" and that "[t]hese lower operating costs would offset the upfront vehicle costs."32 Instead of fully accounting for these obvious costs, EPA relies heavily on incentives under the IRA, which apply to a limited number and type of vehicles and taxpayers, and ignores the fact that incentives from the IRA are still a "cost" to tax-paying consumers.33,34 EPA oddly accounts for potential purchase incentives from the IRA for net consumer prices in its analysis, once again despite the fact that this cushion is limited.35 Beyond the direct costs to the consumer, EPA fails to account for costs associated with infrastructure impacts from increased operation of increased driving it anticipates, including road and bridge deterioration and commensurate reduced funding for infrastructure from fuel tax collections. Finally, EPA's failure to quantitatively analyze these costs——is fatal to its analysis. [EPA-HQ-OAR-2022-0829-0527, p. 7]

32 DRIA at xlviii.

33 See, e.g., DRIA at 2-86–87; Proposed Rule at 29,328.

34 See, e.g., IRS, "Credits for New Clean Vehicles Purchased in 2023 or After" (Apr. 17, 2023), available at https://www.irs.gov/credits-deductions/credits-for-new-clean-vehicles-purchased-in-2023-or-after (citing IRA, § 30D).

35 Proposed Rule at 29,371.

b. BEV charging consumes significantly more time than refueling ICE-powered vehicles.

The Proposed Rule fails to consider the impact that increased charging times will have on consumer adoption rates and whether end users will be willing to such disruptions to daily travel in addition to the increased prices and upfront costs. According to DOT, Level 1 EVSE, which provides charging through a 120-volt AC outlet, can take 40–50+ hours to fully charge (80%) a BEV from empty; Level 2 EVSE, which offers a higher-rate AC charging and is typically used for home, workplace and public charging, can take 4–10 hours to fully charge a BEV from empty; and direct current fast charging EVSE, which provides rapid charging along heavy-traffic corridors where already installed, can take up to an hour to fully charge a BEV from empty.42 Regardless of fast charging, most PHEVs currently on the market do not work with the DCFC equipment.43 But under any scenario, these ZEVs will incur additional downtime for more frequent, and longer, charging times as compared to the equivalent ICE. And faster charging infrastructure is larger and more expensive, making it difficult for the average consumer to comfortably travel unless there is sufficient access to fast and convenient charging. Yet the Proposed Rule fails to consider whether, in light of these impacts, consumers will purchase ZEVs at the rate necessary to meet EPA's targets regardless of whether a manufacturer can produce them. [EPA-HQ-OAR-2022-0829-0527, p. 9]

Organization: Environmental Defense Fund (EDF) (1of 2)

A. Feasibility, cost, and lead time support final Class 2b and 3 standards at least as protective as the proposal.

i. Costs for Class 2b and 3 ZEVs are rapidly declining.

Like light-duty passenger vehicles, the costs of zero-emitting medium-duty passenger vehicles (Class 2b and Class 3) are rapidly declining. A recent study by Roush analyzed the upfront cost and TCO of MY 2027 and MY 2030 Class 2b and 3 BEVs compared to their ICEV counterparts.115 The study also looked at the effect of IRA credits on BEV and charger purchase price and TCO in the 2023 and 2027 timeframes. Roush assumed three different scenarios that reflect increasing levels of cost: 1) the cost of electrification when migrating from a high-cost ICEV to a low-cost BEV (lowest incremental cost); 2) the cost of electrification when migrating from a medium-cost ICEV to a medium-cost BEV; and 3) the cost of electrification when migrating from a low-cost ICEV to a high-cost BEV (highest incremental cost). Gasoline price projections from the EIA's high oil price sensitivity case are used in Scenario 1, reference case gasoline prices are used in Scenario 2, and gasoline prices from the low oil price case are used in Scenario 3. [EPA-HQ-OAR-2022-0829-0786, pp. 45-46]

115 H. Saxena, V. Nair, and S. Pillai, “Electrification Cost Evaluation of Class 2b and Class 3 Vehicles in 2027–2030,” May 2023. Roush. (Attachment T)

Figure 13 illustrates the incremental cost of electrifying Class 2b–3 vehicles under Scenarios 1, 2, and 3, without considering the impacts of the IRA. In Scenario 1 (the lowest incremental cost of electrification), the powertrain cost of all BEVs analyzed is less than the equivalent ICEV in the 2027–2030 timeframe, except in the case of the Class 3 pickup BEV300 (only MY 2027) and BEV400. And in all scenarios (except for Class 3 pickup and delivery (P&D) trucks and Class 3 vans in Scenario 3 in 2027), the powertrain cost of a BEV150 is less than the equivalent ICEV. However, in Scenarios 2 and 3, BEVs with a 250-mile or greater range in all Class 2b–3 vehicle types have more expensive powertrains than a comparable ICEV in MY 2027 and MY 2030. In the case of the Class 3 pickup truck, introducing a longer-range BEV (300 and 400 miles) necessitates a heavier, costlier battery pack, motor and power electronics, resulting in a more expensive electric vehicle. However, these costs are based on NMC811 battery technology, and several technologies that are currently being developed to support higher efficiency and lower production costs are expected to be available in the future. [EPA-HQ-OAR-2022-0829-0786, pp. 45-46]

[See original attachment for Figure 13: Projected incremental cost of BEV over ICE powertrain in 2027 and 2030 for Class 2b and 3] [EPA-HQ-OAR-2022-0829-0786, pp. 45-46]

Source: Roush, Electrification Cost Evaluation of Class 2b and Class 3 Vehicles in 2027-2030 [EPA-HQ-OAR-2022-0829-0786, pp. 45-46]

While the upfront cost of some medium-duty BEVs is higher than the ICEV counterpart, this study concludes that over the life of ownership of all Class 2b–3 vehicles, BEVs are almost universally less expensive to own and operate than comparable ICEVs, as shown in Figure 14. Across the vehicle types and three cost scenarios considered by Roush, the TCO of BEVs averages $0.334 per mile (ranging from $0.291 per mile to $0.39 per mile) while the TCO of ICEVs averages $0.428 per mile (ranging from $0.336 per mile to $0.574 per mile). [EPA-HQ-OAR-2022-0829-0786, pp. 46-48]

[See original attachment for Figure 14: Projected range of total TCO per mile for Class 2b and 3 BEVs and ICEVs in 2027 and 2030]

Source: Roush, Electrification Cost Evaluation of Class 2b and Class 3 Vehicles in 2027-2030 [EPA-HQ-OAR-2022-0829-0786, pp. 46-48]

As shown in Figure 15 below, BEVs produce significant cumulative net savings compared to ICEVs over their assumed lifetime of 12 years. Scenario 1 has the highest savings and Scenario 3 has the lowest savings. With the exception of certain vehicle types in Scenario 3 in 2027, all BEVs across the three scenarios produce considerable savings compared to ICEV ownership. On average, this study shows that consumers and fleets who switch to BEVs can save about $20,000 for a MY 2027 purchase and $25,000 for a MY 2030 purchase over the lifetime of the vehicle. [EPA-HQ-OAR-2022-0829-0786, pp. 46-48]

[See original attachment for Figure 15: Projected cumulative net savings of BEVs over ICEVs over their lifetime] [EPA-HQ-OAR-2022-0829-0786, pp. 46-48]

Source: Roush, Electrification Cost Evaluation of Class 2b and Class 3 Vehicles in 2027-2030 [EPA-HQ-OAR-2022-0829-0786, pp. 46-48]

Roush's study also evaluated the time it would take for BEVs purchased in MY 2027 and MY 2030 to achieve TCO parity with equivalent ICEVs. Table 13 below shows that under Scenario 1, all vehicles purchased in 2027 and 2030 achieve TCO parity within the first year of ownership, except the BEV400 pickup, which achieves parity after the first year. Under Scenarios 2 and 3, longer range BEVs take additional time to reach TCO parity. [EPA-HQ-OAR-2022-0829-0786, pp. 48-50]

[See original attachment for Table 13: Time (in years) for BEVs to achieve TCO parity with comparable ICEVs purchased in 2027 and 2030] [EPA-HQ-OAR-2022-0829-0786, pp. 48-50]

Source: Roush, Electrification Cost Evaluation of Class 2b and Class 3 Vehicles in 2027-2030 [EPA-HQ-OAR-2022-0829-0786, pp. 48-50]

To estimate the sensitivity of the TCO of ICEVs to recent high fuel prices, a sensitivity analysis was performed using summer 2022 fuel prices. With ongoing geopolitical crises and volatility in the oil and gas sector, per the EIA, the price of retail gasoline reached an all-time high in 2022. Such high fuel prices have a direct impact on ICEV's operating expenses and TCO. Using 2022 peak fuel prices, even the class 3 BEV400 pickup achieved TCO parity within 1-2 years of ownership. These results make a compelling case, especially from a consumer and fleet savings standpoint, to electrify the class 2b–3 segment. [EPA-HQ-OAR-2022-0829-0786, pp. 48-50]

Roush's study also examined the potential impacts of the IRA on Class 2b–3 BEV costs in the near term (MY 2023) and the long term (MY 2027). They assumed economies of scale and sufficient raw material supply to meet demands in the production of MY 2023 BEVs. The study found that the incentives made available by the IRA will have a profound positive impact on the cost of MYs 2023 and 2027 Class 2b–3 BEVs, helping to offset higher purchase prices of BEVs. The results of this IRA impact analysis show acceleration of purchase price and TCO parity across all vehicle types purchased in 2023 and 2027 under Scenario 1. In 2027, purchase parity and TCO parity accelerate across all vehicle types and all scenarios. All BEVs achieve parity within the first year of ownership upon purchase, except for the Class 3 pickup truck BEV400, which achieves parity within 2 years of purchase. With clean vehicle credits (§30D) and charger credits, BEVs' cumulative net TCO savings in MYs 2023 and 2027 average about $5,000 and $27,000, respectively. And with qualified commercial clean vehicles (§45W) and charger credits, BEVs' cumulative net TCO savings in MYs 2023 and 2027 average about $6,000 and $23,000, respectively. Roush concludes that the purchase credit (§30D) and advanced manufacturing production credit (§45X) can provide OEMs with a financial buffer against potential market disruptions while also enabling them to produce BEVs at a competitive cost. On average, battery pack costs could reach as high as $218/kWh, almost 187% more than the estimated pack cost of $76/kWh, and still allow for purchase price parity within the first year of BEV ownership in MY 2027. Expected advancements in battery technology will further reduce battery costs and drive down the TCO of BEVs even below the estimates developed in the analysis. [EPA-HQ-OAR-2022-0829-0786, pp. 48-50]

Roush conducted a second study for EDF which expanded this analysis to PHEVs.116 As described in Figure 16 (Figure 6 from the Roush report), Roush projects that PHEV50s in the Class 2b-3 segment will be very cost competitive with BEVs. Therefore, we encourage EPA to include PHEV technology pathways in its analysis of GHG emission control from Class 2b-3 vehicles in the final rule. [EPA-HQ-OAR-2022-0829-0786, pp. 48-50]

E. EPA Should Consider a Range of Rebound Effect Assumptions for BEVs While Upholding Its Current Assumption for ICE Vehicles EPA-HQ-OAR-2022-0829-0601, pp. 18-20]

The "rebound effect" refers to "the additional energy consumption that may arise from the introduction of a more efficient, lower cost energy service."118 In the Proposed Rule, EPA reasonably, and consistently with prior rules, assumes 10% rebound for ICE vehicles119—meaning that for every 1% improvement in fuel efficiency, there is a 0.9% drop in total fuel use and a corresponding increase in vehicle miles traveled. EPA's adoption of a 10% rebound rate for ICE vehicles is consistent with the literature.120 EPA-HQ-OAR-2022-0829-0601, pp. 18-20]

118 RIA at 4-13.

119 Id. at 4-16.

120 See generally Inst. for Pol'y Integrity, Comments on Revised 2023 and Later Model Year Light-Duty Vehicle Greenhouse Gas Emissions Standards (Sep. 27, 2021),

While a wealth of economic literature supports a small rebound effect for ICE vehicles, there is comparatively little economic research on the rebound effect for BEVs. Based on the research available, EPA assumes a rebound effect of 0% for BEVs.121 This rebound assumption has two implications. First, it assumes that drivers do not switch their driving behavior when they switch from an ICE vehicle to a BEV,122 despite cost differences.123 Second, it assumes that any change in per-mile cost for BEVs, including from the introduction of more efficient BEVs or fluctuations in electricity prices, does not affect driving behavior. In effect, EPA's projection of no rebound for BEVs over the long term presumes that there is something fundamentally different about consumer perceptions of BEVs compared to ICE vehicles, and not simply an issue of familiarity or technological constraints that will be overcome in the future. EPA-HQ-OAR-2022-0829-0601, pp. 18-20]

121 RIA at 4-16.

122 Id. at 4-17 (stating that "BEVs are not driven more than ICE vehicles").

123 According to predictions from OMEGA, under the Proposed Rule, the average per-mile fuel cost of BEVs is projected to be approximately 62% lower than that of ICE vehicles between 2022 and 2055. This data is sourced from the '20230315_091353_MY_period_costs.csv' file in the '20230315_091353_effects_central' folder, downloadable from the 'Light-and medium-duty effects' section on EPA's website: https://www.epa.gov/regulations-emissions-vehicles-and-engines/optimization-model-reducing-emissions-greenhouse-gases

EPA's assumption of no rebound effect for BEVs relies on the empirical evidence available, namely Chakraborty et al. (2022) and Nehiba (2022).124 Although insightful, these studies leave reason for uncertainty. For instance, both studies employ cross-sectional data and do not fully address the endogeneity between vehicle choices and usage, which is discussed further below. This correlation between consumer vehicle choices and usage could significantly vary between early adopters of BEVs and average ICE vehicle owners, thereby impacting the study conclusions. While these studies contribute to the emerging body of research in this field, their findings should thus be interpreted with some caution. Beyond Chakraborty et al. (2022) and Nehiba (2022), we are aware of several other studies that purport to use better data and identifying assumptions and also find zero rebound for electric vehicles (but do not yet have working papers available).125 EPA-HQ-OAR-2022-0829-0601, pp. 18-20]

124 RIA at 4-14.

125 Wendan Zhang et al., Brookings Institution Electric Vehicle Adoption and Combustion Mile Displacement Across Demographics: Short Run Evidence and Implications For Policy, 2023 AERE Presentation (finding a negative rebound effect for electric vehicles.); Beia Spiller, Kenneth Gillingham & Marta Talevi. The Electric Vehicle Rebound Effect, 2023 AEA Conference.

While the available research provides some support for a 0% rebound rate for BEVs based on historical evidence, there is reason to believe that effect may not hold in the future. One potential explanation for the current BEV rebound findings is that "[c]onsumers are quite price inelastic, because they are inattentive."126 With the costs of BEV charging often consolidated into electricity bills, this alteration in cost perception could augment price inelasticity, rendering BEV owners less sensitive to per-mile cost variations.127 But this effect may become less pronounced as BEVs become more common. In particular, as infrastructure grows, electricity price salience may increase as gas stations convert to charging stations and prominently display electricity prices. Relatedly, the current literature could be shaped by the demographic profile of past and current BEV owners—predominantly early adopters—who may not reflect the population that purchases BEVs in the future.128 As BEV penetration accelerates, the associated rebound effect could potentially deviate from current estimates: Outside the vehicle context, economic literature documents a small rebound effect as electrical appliances become more efficient,129 which could hint at similar patterns in the future for BEVs. EPA-HQ-OAR-2022-0829-0601, pp. 18-20]

127 See generally Ben Gilbert & Joshua Graff Zivin, Dynamic Salience with Intermittent Billing: Evidence from Smart Electricity Meters, 107 J. ECON. BEHAVIOR & ORG. 176 (2014) (finding that households tend to decrease their consumption in response to billing information—an effect that wanes as the bill's salience fades); Steven Sexton, Automatic Bill Payment and Salience Effects: Evidence from Electricity Consumption, 97 REV. ECON. & STAT. 229 (2015) (finding that automatic bill payments decreases price responsiveness).

128 RIA at 4-14 (acknowledging that the available data is "not likely representative of the current and future general population of car buyers and their driving behavior").

129 Kenneth Gillingham et al., The Rebound Effect is Overplayed, 493 NATURE 475, 476 (2013) (finding a 10% rebound effect). Later, Gillingham et al. (2016) also highlight that the rebound effect for both gasoline and electricity generally falls within a range of 5% to 40%, with the majority of studies suggesting a rebound effect between 5% and 25%. Kenneth Gillingham et al., The Rebound Effect and Energy Efficiency Policy, 10 REV. ENV'T ECON. & POL'Y 68, 75 (2016).

In light of these complexities and uncertainties, EPA should consider exploring a range of possible rebound estimates for BEVs, including the same 10% assumption used for ICE vehicles. EPA should conduct sensitivity analysis to assess the implications of a range of rebound effects between 0% and 10%. EPA-HQ-OAR-2022-0829-0601, pp. 18-20]

Notably, such an analysis would have a very limited impact on EPA's assessment of net benefit. Policy Integrity reran OMEGA using a 10% rebound rate for BEVs and found that this change decreased total net benefits by just 0.43–0.71%, leaving the rule highly net beneficial overall. In fact, when total net benefits were rounded to two significant figures, as EPA does in the Proposed Rule and RIA, they appeared unchanged. (See Table A-1 in the appendix below for full results.) This is likely because additional BEVs resulting from the Proposed Rule make up a small share of the total fleet, particularly in the earlier years in the analysis that are weighted more as a result of discounting. In future standards, the BEV rebound effect could become more significant as BEVs make up a larger share of the vehicle fleet. [EPA-HQ-OAR-2022-0829-0601, pp. 18-20]

Organization: John Graham

The DRIA does include an assessment of maintenance and repair costs for different propulsion systems. The underlying study relied upon by EPA finds that the HEV has lower maintenance and repair costs than ICEs. The BEV assessment is based on three low-volume BEVs that are not representative of the BEV market. The assessment is tilted to favor BEVs by omitting two significant impacts on maintenance and repair costs for BEVs; BEV weight and long-term battery durability. [EPA-HQ-OAR-2022-0829-0585, p. 19]

The higher weight of BEVs will cause tires and brakes to wear out faster and the instant torque response of BEVs may also increase tire wear, increasing BEV maintenance costs compared with hybrids. However, the proposed rule states, "Specific to tires and tire replacement, an issue often cited with respect to BEVs versus ICE vehicles, the authors noted that their analysis assumed that tire life and replacement costs are the same for all powertrains." (DRIA page 4-33). In reaching this conclusion the authors discussed irrelevant factors such as tire rolling resistance, instead of acknowledging the impact of the higher BEV weight and instant torque response – factors that clearly underpin the Goodyear claim "that traditional tires wear 30 percent faster when installed on BEVs" (Burnham, Gohlke, et al. 2021, 83). [EPA-HQ-OAR-2022-0829-0585, p. 19]

The DRIA page 4-33 also states, "the authors assumed that brake pad, rotor, and caliper replacement intervals could be extended by 33% for HEVs and by 50% for PHEVs and BEVs, relative to ICE vehicles". When considering only regenerative brake effects this is likely accurate, but it does not account for the impact of the higher weight of the BEV on brake life. When weight is also considered, the brake replacement intervals are likely to be similar for BEVs and HEVs. [EPA-HQ-OAR-2022-0829-0585, p. 20]

Of course, the impact of increased BEV weight on tire and brake replacement intervals can be addressed by installing larger tires and brakes, but this would both increase new vehicle cost and would make replacement tires and brake parts more expensive. In either case, the impact of higher BEV weight on tire and brake costs must be included in the Final Rule. [EPA-HQ-OAR-2022-0829-0585, p. 20]

The Repair Costs Section 4.3.6.2 (DRIA pages 4-35 to 4-37) does not specify how – or even if - battery replacements were included in BEV repair costs. Given the 30+-year vehicle lifetime in OMEGA used for assessing repair costs (Figure 4-9), it is indefensible to assume zero battery replacement costs for BEVs, especially for BEVs more than 10 years old. Given the extreme cost of BEV battery repair/replacement, the repair cost curves in Figure 4-9 are likely to significantly understate the repair cost for older batteries in BEVs. [EPA-HQ-OAR-2022-0829-0585, p. 20]

The BEV model with the longest run of real-world experience, the Nissan Leaf, has experienced troublesome rates of battery degradation within the first half of the Leaf's expected life (Graham, 2021). It is instructive that most battery warranties for BEVs do not extend beyond 8 years or 100,000 miles of vehicle life.26 The NPRM refers to a claim that BEV batteries will last longer than the life of the vehicle but, as noted by NAS in 2021, that claim is based on laboratory tests. Real-world driving conditions are much more diverse (e.g., extreme temperature conditions, extreme uses of batteries and so forth) and may contribute to battery degradation in ways that lab tests do not cover.27 One specific concern with laboratory tests is that they can only simulate cycle life, not battery life, and real-world experience with battery life beyond about 10 years is completely lacking. Since battery replacement costs are so large, they must be addressed in the Final Rule. [EPA-HQ-OAR-2022-0829-0585, p. 20]

26 For data on the Leaf's rate of battery degradation and battery warranty policies, see John D. Graham. The Global Rise of the Modern Plug-In Electric Vehicle: Public Policy, Innovation, and Strategy. Elgar House Publishing, UK, 2021, 44-46.

27 National Academy of Sciences. Improving Light-Duty Vehicle Fuel Economy: 2025 to 2035. National Academies Press. Washington, DC., 2021, 115.

It is worth noting here that the smaller batteries in HEVs do tend to last at least as long as the life of the vehicle. However, that is due to the HEV's battery management system, which restricts the range of the battery charge level, usually between 30% and 70% of a full charge. BEVs require deeper charging cycles to accomplish the driving ranges that customers demand. It is well known that deeper charging cycles contribute to the rate of battery degradation. Unlike HEVs,28 BEVs also need to be designed to recharge as fast as possible, which also increases the rate of battery degradation. [EPA-HQ-OAR-2022-0829-0585, p. 20]

28 John D. Graham. 2021, 154 (see footnote 26 above for full reference).

Another factor that has previously been ignored is vehicle insurance costs. "For many electric vehicles, there is no way to repair or assess even slightly damaged battery packs after accidents, forcing insurance companies to write off cars with few miles - leading to higher premiums and undercutting gains from going electric."29 "According to online brokerage Policygenius, the average U.S. monthly EV insurance payment in 2023 is $206, 27% more than for a combustion-engine model."30 [EPA-HQ-OAR-2022-0829-0585, p. 21]

29 Scratched EV battery? Your insurer may have to junk the whole car, Reuters March 20, 2023; https://www.reuters.com/business/autos-transportation/scratched-ev-battery-your-insurer-may-have-junk-whole-car- 2023-03-20/?utm_source=CAR+General+Mailing+List&utm_campaign=afebc6e55f-EMAIL_CAMPAIGN_2023_02_08_09_40_COPY_01&utm_medium=email&utm_term=0_-59328f5e21-%5BLIST_EMAIL_ID%5D.

30 ibid.

Compounding the problem, part of the forecasted future reduction in battery cost is integration of the battery pack into the vehicle structure to reduce manufacturing cost. However, this will just make the insurance problem worse:

"Sandy Munro, head of Michigan-based Munro & Associates, which tears down vehicles and advises automakers on how to improve them, said the Model Y battery pack has "zero repairability." "A Tesla structural battery pack is going straight to the grinder," Munro said."31 [EPA-HQ-OAR-2022-0829-0585, p. 21]

31 ibid.

The repairability problem can be improved, although not eliminated, by making batteries in smaller sections, or modules, that are easier to fix, but this will increase battery pack costs. [EPA-HQ-OAR-2022-0829-0585, p. 21]

Given the high amount of embedded GHG emissions during battery manufacturing, the repairability problem will also significantly reduce the GHG benefit of BEVs. [EPA-HQ-OAR-2022-0829-0585, p. 21]

The intertwined issues of repairability, insurance cost, battery cost, and impacts on GHG benefits should be incorporated into the final rule. [EPA-HQ-OAR-2022-0829-0585, p. 21]

Organization: Missouri Farm Bureau (MOFB)

Similar to EPA's proposed HD rule, this proposal picks winners and losers by doubling-down on electric vehicle (EV) technology, while increasing in adoption in the light-duty sector, only represents 8.4 percent of light-duty production in MY 2022.2 While the proposed rule cites a reduced total cost of ownership, EPA estimates it will raise "average upfront per-vehicle costs to meet the proposed standards to be approximately $1,200 in MY 2032, as estimated using 2020 dollars."3 The proposed rule estimates that in order for automakers to comply with the emissions standards, Battery Electric Vehicles (BEVs) will comprise up to 67 percent of new passenger vehicle sales by 2032 and up to 46 percent of medium-duty vehicle sales.4 In addition to increased purchase costs for EVs, MOFB is concerned about the lack of available public charging stations to accommodate the vast number of EVs mandated by this rule, especially in rural Missouri where most of our members live and work. [EPA-HQ-OAR-2022-0829-0590, pp. 1-2]

2 U.S. EPA Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles, Vol. 88, Fed. Reg. 29184, p. 29189 (May 5, 2023) (to be codified at 40 CFR pts. 85, 86, 600, 1036, 1037 & 1066).

3 Ibid., 29201.

4 Ibid., 29189, 29331.

Organization: National Automobile Dealers Association (NADA)

EPA forecasts that the average marginal per-vehicle cost for regulated manufacturers (OEMs) to comply with its proposed light-duty mandates will rise from $633 in MY 2027 to $944 in MY 2031, and projects that the marginal per vehicle cost of compliance will jump to approximately $1,200 in MY 2032.12 For medium-duty vehicles, EPA's estimated average marginal per vehicle OEM cost of compliance ranges from $364 in MY 2027 to approximately $1,800 in MY 2032.13 [EPA-HQ-OAR-2022-0829-0656, p. 3]

12 88 Fed. Reg. at 29201, 29328, 29343; See also EPA's Draft Regulatory Impact Analysis (DRIA) at l (able 11), 4-17, 13-25 (Table 13-45).

13 88 Fed. Reg. at 29328; DRIA at 13-52 (Table 13-127).

Importantly, these costs are in addition to those imposed by EPA in prior rules, which are necessarily built into the cost of MY 2027 and later vehicles. EPA asserts, however, that higher light- and medium-duty costs will be offset by purchase incentives arising from the Inflation Reduction Act (IRA), and by lower EV operating costs.14 [EPA-HQ-OAR-2022-0829-0656, p. 3]

14 88 Fed. Reg. at 29201, 29328-29, 29344, 29364.

Organization: Nebraska Farm Bureau Federation (NEFB)

NEFB is Nebraska's largest farm and ranch organization representing all sectors of Nebraska agriculture. Without a doubt, renewable fuels and the renewable fuels industry have been a tremendous success story for the country and the rural economy. Nebraska's ethanol industry alone contributes over $4.5 billion per year to Nebraska's economy according to a study conducted by the University of Nebraska-Lincoln. [EPA-HQ-OAR-2022-0829-0660, p. 1]

Organization: Paul Bonifas and Tim Considine

Maintenance savings: The EPA relies on unrealistic maintenance schedules pushed by car salesmen and manufacturers instead of real data. This is an example of government bureaucrats ignoring the simple real-world consumer data to sell a narrative to citizens. The myth that EVs don't require maintenance is false, and because most mechanics have neither the training nor the technology to work on EVs, EV maintenance commands a price premium. When switching to realistic and reliable consumer maintenance cost information from Kelley Blue Book, the maintenance savings decrease from the EPA's claimed $410 billion to a realistic $72 billion, a $338 billion savings decrease from the EPA's calculations. [EPA-HQ-OAR-2022-0829-0551, p. 3]

Repair Savings: Like their maintenance calculations, instead of using real-world consumer data, the EPA relied on elaborate multi-variable mathematical equations that include a "multiplier" that inherently makes ICE vehicles ~50% more expensive to repair than EVs. Though EVs are supposedly in the shop less frequently, they're more expensive to repair when they do go in5. This is in part due to the battery costs, which can be up to 50% of the entire EV's cost. The battery health of an EV's contributes significantly to its depreciation and replacement costs. Scaling the EPA's repair estimates using realistic and reliable consumer repair cost information from Kelley Blue Book, the repair "savings" decrease from the EPA's claimed $170 billion to a realistic NEGATIVE $4 billion, a $174 billion savings decrease from the EPA's calculations. [EPA-HQ-OAR-2022-0829-0551, p. 3]

5 https://www.gobankingrates.com/saving-money/car/experts-factors-to-consider-before-switching-to-ev-electric- car/

Maintenance Savings

EPA Claimed Savings: $410 billion

Realistic Savings: $72 billion [EPA-HQ-OAR-2022-0829-0551, p. 6]

The EPA overestimates the maintenance cost savings in their proposed rule. They support their maintenance cost estimates for the 15-year life of a vehicle (15,000 miles driven, per year) from Argonne National Laboratory's study from 2021 17. The EPA claims a lifetime maintenance cost for an Internal Combustion Engine (ICE) vehicle of $20,050 compared to

$12,675 for a Battery Electric Vehicle (EV)18. This corresponds to a maintenance cost for the first-five-years of ownership of $3,710 for an ICE vehicle and $2,555 for an EV, a supposed 45% cost increase for ICE vehicles… [EPA-HQ-OAR-2022-0829-0551, p. 6]

17 https://www.osti.gov/biblio/1780970

18 Page 310 of EPA's Draft Regulatory Impact Analysis - https://nepis.epa.gov/Exe/ZyPDF.cgi?Dockey=P10175J2.pdf

However, the EPA and Argonne base their calculations on "factory-recommended actions at periodic mileage or calendar intervals." These maintenance schedules are unilaterally set by automobile manufacturers and dealerships who are incentivized to boost their bottom line with after-purchase services and don't necessarily have the best interest of the consumer in mind. NADA, the National Automobile Dealers Association, reports that 49.6% of dealerships' profits come from the service and parts departments compared to only 26% profit from the sale of new vehicles19. The question is: how many people follow the exact schedule of recommended maintenance for their vehicle? The EPA admits this oversight by writing "in practice, not everyone follows the recommended service intervals", yet they choose to ignore it in their maintenance cost estimates and follow the biased, inaccurate schedule of car salesmen. [EPA-HQ-OAR-2022-0829-0551, pp. 6-7]

19 https://www.edmunds.com/car-buying/where-does-the-car-dealer-make-money.html

In contrast, the widely trusted Kelley Blue Book (KBB) company provides a "5-year cost to own" figure20 based on continuously updated real-world consumer data instead of "factory-recommended actions." KBB reports that ICE owners spend $4,583 and EV owners spend $4,246 on maintenance during the first five years, only an 8% difference21. Compare that to EPA's claimed 45% increase from EV to ICE and it is clear the EPA severely overestimated the maintenance savings associated with their proposed rule. Scaling the EPA's maintenance cost saving down from 45% to 8% dramatically reduces the estimated maintenance benefit from $410 billion to $72 billion. [EPA-HQ-OAR-2022-0829-0551, pp. 6-7]

20 https://www.kbb.com/new-cars/total-cost-of-ownership/

21 https://www.nada.org/nada/nada-headlines/beyond-sticker-price-cost-ownership-evs-v-ice-vehicles

The EPA has many holes in its maintenance analysis, the largest bein g that they are not using real-world consumer data. Furthermore, they are purposefully ignoring differences in EVs that they are aware of, namely the EV tire problem. EV tires are more expensive and more advanced because of the heavy battery weight of EVs and their faster initial acceleration, and their need for noise reduction22. The EPA states "Specific to tires and tire replacement…, the authors noted that their analysis assumed that tire life and replacement costs are the same for all powertrains… Some BEVs are equipped with tires that differ from those on typical ICE vehicles to address tread wear and the instant torque of BEVs making the issue raised by the authors a valid issue for consideration… The authors did reiterate a Goodyear claim that traditional tires wear 30 percent faster when installed on BEVs"23. Therefore, though the EPA is aware of the increased maintenance cost for tires on EVs, they do NOT include that in their analysis. [EPA-HQ-OAR-2022-0829-0551, p. 7]

23 Page 309 of EPA's Draft Regulatory Impact Analysis - https://nepis.epa.gov/Exe/ZyPDF.cgi?Dockey=P10175J2.pdf

Though there are relatively fewer moving parts in an EV than in an ICE vehicle, EVs still require maintenance. Most mechanics do not have the training or the technology to work on EVs, causing a supply constraint on EV mechanics for maintenance. Because of the lack of options, mechanics that provide EV maintenance tend to charge a price premium, have long wait-times, and are not located within proximity of all EV owners24. [EPA-HQ-OAR-2022-0829-0551, p. 7]

24 https://www.gobankingrates.com/money/financial-planning/hidden-costs-of-electric-vehicles/

For these reasons and more, overall EV owner customer service satisfaction is 42 points lower than ICE owner satisfaction. Automotive News reports that recall rates are double among EVs and a lack of service advisor knowledge contributes to the lower satisfaction rating25. [EPA-HQ-OAR-2022-0829-0551, p. 7]

25 https://www.autonews.com/service-and-parts/lexus-bright-spot-disappointing-jd-power-service-survey

The National Automobile Dealers Association (NADA) also agrees, stating that contrary to popular belief, EV owners pay more for repairs than their ICE counterparts. Though EVs are in the shop less frequently, they're more expensive to repair when they do go in39. [EPA-HQ-OAR-2022-0829-0551, p. 10]

39 https://www.gobankingrates.com/saving-money/car/experts-factors-to-consider-before-switching-to-ev-electric- car/

Generally, mechanics do not have the training or the technology to work on EVs, causing a supply constraint on EV mechanics for repairs. Because of the lack of options, mechanics that do repair EVs have long wait-times and high prices, as the consumers have no alternative choices. It may also lead to needing to travel for hours to reach a mechanic capable of repairing an EV [EPA-HQ-OAR-2022-0829-0551, p. 10]

Though the number of miles on an ICE engine is a good indicator of the health of the vehicle, the same cannot be said for EVs. Instead, the conditions an EV battery was subjected to have a significant impact on its future life. Things that degrade a battery include an EV being exposed to cold weather, or being exposed to hot weather, or if it was fast-charged, or if it was left on low-battery, or charged above 90%43. Because up to 50% of an EV's value is the health of its battery, there is significant depreciation and replacement costs associated with battery status. [EPA-HQ-OAR-2022-0829-0551, p. 11]

43 https://www.businessinsider.com/electric-car-vehicle-resale-value-mystery-tesla-2023-1

Also, because the average price-tag of EVs is 23% more than their ICE counterpart, repair costs in case of collisions are also more expensive44. [EPA-HQ-OAR-2022-0829-0551, p. 11]

44 https://www.gobankingrates.com/money/financial-planning/hidden-costs-of-electric-vehicles/

Likewise, among the many things the EPA doesn't consider in its analysis is how EV suspensions are likely to wear out sooner due to EVs higher weights thanks to their hefty batteries45. [EPA-HQ-OAR-2022-0829-0551, p. 11]

45 https://www.businessinsider.com/tesla-differences-between-gas-and-electric-vehicles-maintenance-2020-4

Organization: The Heritage Foundation (Kevin Dayaratna and Diana Furchtgott-Roth)

EPA's cost estimate does not include battery replacement.37 With the proposed standards taking effect in 2027, and some of the cost and savings estimates being extrapolated out through 2055, even if Tesla can be the first EV manufacturer to achieve a battery that lasts 20 years, a replacement will be a requirement. Based on the EPA's chosen 100 kWh capacity and the Department of Energy's 2022 estimated cost of manufacturing of $153/kWh, a new battery without labor, disposal fees, and other associated expenses would cost the consumer $15,300. [EPA-HQ-OAR-2022-0829-0674, p. 10]

37 "Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles." EPA, Apr. 2023, www.epa.gov/system/files/documents/2022-12/420d22003.pdf (accessed 5 July 2023).

Table 4-5, which outlines the studies used to justify the proposal, shows that all but one study either came from California or New York. The claimed national study only contained 862 vehicles and therefore poses insignificant statistical relevance. It also shows that the entirety of the country is not represented. While the Census Bureau splits the United States at 80% urban and 20% rural living, New York and California cannot be considered as viable representations of the county's entire population. Due to differences in infrastructure, state-imposed regulations and laws, population density, and other factors, it is likely that differences could be found even between major cities throughout the country. [EPA-HQ-OAR-2022-0829-0674, p. 10]

On page 4-34, when referring to maintenance costs over the 225,000-mile life of a vehicle, EPA does not mention the need for battery replacement. [EPA-HQ-OAR-2022-0829-0674, p. 10]

Misinterpretation of vehicle ownership costs

"Vehicle Technology Costs"—the costs of purchasing and maintaining a vehicle excluding fuel costs—are assumed to be lower (a benefit) under the proposed rule than absent the rule. (See Table 160.) This result makes no sense, and the value should be negative, a cost to American households. Empirically, we observe that the vast majority of vehicles sold in America—even with substantial tax credit incentives—are not electric vehicles. American consumers are rational, not irrational. If purchasing an electric vehicle led to lower ownership costs of purchase, maintenance, and repair, then most purchases today would be for electric vehicles, particularly given the substantial tax benefits. Americans make a different choice with their hard-earned dollars. Consequently, the vehicle technology costs presented in Table 160 should all be negative, not positive. [EPA-HQ-OAR-2022-0829-0674, p. 12]

2.5. Conclusion

A deeper analysis of global and IRA-compliant critical mineral supply and demand is needed to support the Final Rule. The proposal's cursory assessment results in erroneous conclusions that "critical battery mineral supply is likely to be adequate to meet anticipated demand, in some cases by a significant margin."9 The proposal lacks the evidence to support this finding. Demand for critical minerals are higher today than in the years referenced in the proposal due to new government policies and automaker targets. Future demand growth for PEVs is unclear given the uncertain geo-political considerations and supply chain operations beyond the control of manufacturers and EPA. It is highly plausible the tight supply-demand for lithium and graphite will lead to volatile prices. The proposal fails to consider how this could suppress demand and annual PEV market share. The Final Rule must include a significantly more robust and clear-eyed analysis based on a boarder array of sources. It must also reconsider how the global supply chain for mineral mining, refining, cell production, and battery production are most likely to evolve in order to better understand the extent to which IRA or other financial incentive can be considered in the cost analysis supporting the rule. [EPA-HQ-OAR-2022-0829-0620, p. 14]

b) EPA does not adequately quantify vehicle maintenance and repair costs.

In its analysis of maintenance and repair costs, EPA relies on data gathered and summarized by Argonne National Laboratory (ANL) in their evaluation of TCO for vehicles of various sizes and powertrains.176 However, the BEV models relied upon in ANL's and EPA's analyses – the BWM i3, Fiat 500e and Kia Soul Electric177 – are limited in breadth and not representative of new light-duty and medium-duty BEV sales in the U.S.: [EPA-HQ-OAR-2022-0829-0707, pp. 35-38]

176 EPA's Proposed Rule at 29384 (Burnham et al., Comprehensive Total Cost of Ownership Quantification for Vehicles with Different Size Classes and Powertrains, Argonne National Laboratory. ANL/ESD-21/4. April 2021).

177 EPA DRIA at 4-32 and Burnham et al at 69.

- In 2022, the BMW i3 held a 0.0 percent market share in the U.S. with 9 total sales178 and has since been discontinued;179

- The Fiat 500e is not currently available for sale in the U.S.;180 and

- The Kia Soul EV will be discontinued after the 2023 model year.181 [EPA-HQ-OAR-2022-0829-0707, pp. 35-38]

178 Kelley Blue Book, "Electric Vehicle Sales Report – Q4 2022", January 16, 2023, https://www.coxautoinc.com/wp- content/uploads/2023/01/Kelley-Blue-Book-EV-Sales-and-Data-Report-for-Q4-2022.pdf.

179 See https://www.bloomberg.com/news/features/2022-12-12/bmw-s-discontinued-i3-is-already-an-ev-cult-classic#:~:text=By%202021%20the%20company%20was,like%20the%20brand%27s%20other%20models.

180 See https://insideevs.com/news/621727/fiat-500e-confirmed-us-debut-2024/.

181 See https://www.guideautoweb.com/en/articles/70428/r-i.p-kia-soul-ev-another-small-electric-car-bows- out/#:~:text=Another%20small%20electric%20car%20is,of%20the%202023%20model%20year.

Furthermore, all three BEV models are subcompact cars and SUVs, not at all representative of EPA's projections for model year 2027 to 2032 sales.182 [EPA-HQ-OAR-2022-0829-0707, pp. 35-38]

182 DRIA at 1-4 and 1-5.

In addition to the questionable nature of the input data for EPA's application in this rulemaking, EPA diverges from ANL's approach (and from any of the other above-referenced peer-review sources) in its establishment of maintenance costs curves on a per-mile basis.183 Not only is EPA's approach to establishing maintenance cost curves lacking in independent peer review – it is also illogical. [EPA-HQ-OAR-2022-0829-0707, pp. 35-38]

183 DRIA at 4-34 and 4-35.

EPA cites the following example outcome of its maintenance costs curves:

"For example, an ICE vehicle having an odometer reading of 120,000 miles would have a maintenance cost per mile of $0.10 []. If that vehicle travels 10,000 miles in the given year, then its estimated maintenance costs would be $1,000 in that year. If that vehicle were to instead travel 15,000 miles in that year, its estimated maintenance costs would be $1,500."184 [EPA-HQ-OAR-2022-0829-0707, pp. 35-38]

184 DRIA at 4-35.

This simply does not comport with logical projections using the input data that EPA adopts from ANL.185 As demonstrated below in Tables 4 and 5, if the ICE vehicle referenced by EPA having an odometer reading of 120,000 miles travels 10,000 miles in the given year, its projected maintenance costs would be $315. And if that vehicle travels 15,000 miles in the given year, its projected maintenance costs would be $505. EPA's approach to establishing constant-slope maintenance cost per mile curves produces flawed results that contradict the conclusions of the literature sources upon which EPA relies and to which it cites. [EPA-HQ-OAR-2022-0829-0707, pp. 35-38]

Total cost of maintenance between 120,000 and 135,000 miles $505 [EPA-HQ-OAR-2022-0829-0707, pp. 35-38]

191 DRIA at 4-34.

192 DRIA at 4-34.

193 Calculated as 120,000 miles divided by the service interval specified by EPA (e.g., 7,500 miles), rounded down to the nearest integer.

194 Calculated as 135,000 miles divided by the service interval specified by EPA (e.g., 7,500 miles), rounded down to the nearest integer.

195 Calculated as the difference in the number of maintenance events incurred at 135,000 miles versus 120,000 miles (e.g., 18 - 16 = 2 engine oil service events), multiplied by the cost per event specified by EPA.

e) EPA omits the costs of unrepairable battery packs.

In the evolution of EV design, battery packs that were once organized into modules are being replaced by a single large battery packs that are integrated into the structure of the vehicle.219, 220 With a modular design, if a single battery cell is damaged, the specific module can be replaced without incurring the cost of replacing the entire battery pack.221 If an integrated battery pack is damaged, there is no way to access and repair the damaged pack – as a result, the Tesla Model Y has been characterized as having "zero repairability", and reports also indicate repairability problems with EVs from Nissan, Hyundai, Stellantis and BMW.222 [EPA-HQ-OAR-2022-0829-0707, p. 41]

219 Kyle Field, Elon Musk Shares History Of Tesla Battery Modules & Why They Are Going Away, CLEANTECHNICA, Feb. 2, 2020, https://cleantechnica.com/2020/02/02/elon-musk-shares-history-of-tesla-battery-modules-why-they- are-going-away/

220 Nick Carey et al., Insight: Scratched EV battery? Your insurer may have to junk the whole car, REUTERS, Mar. 20, 2023, https://www.reuters.com/business/autos-transportation/scratched-ev-battery-your-insurer-may-have-junk- whole-car-2023-03-20/

221 Id.

222 Id.

The integrated design has created unexpected problems for motorists and insurers. Following an accident in which some of the battery cells in a pack are damaged, insurers are forced to write off the EV or pay the cost of a complete battery replacement, potentially at costs exceeding $20,000.223 Yet EPA's analysis of repair costs assumes that EVs have lower repair cost per mile than ICEVs, at a ratio of 0.91 for HEVs, 0.86 for PHEVs, and 0.67 for BEVs and FCEVs.224 [EPA-HQ-OAR-2022-0829-0707, p. 41]

223 Brengt Halvorson, EVs still cost much more than gas cars to insure—even hybrids, GREEN CAR REPORTS, Apr. 27, 2023, https://www.greencarreports.com/news/1139493_evs-still-cost-much-more-than-gas-cars-to-insure-even- hybrids

224 DRIA at 4-36.

Unsurprisingly, insurance premiums for EVs have increased to reflect their inability to be repaired; the online brokerage Policygenius estimates that the average monthly insurance payment for a U.S. EV is $206, 27% more than for an average ICEV.225 EPA relies on outdated data in its analysis, finding that insurance costs are roughly the same for BEVs and ICEVs and making no adjustments for insurance premium differences.226 [EPA-HQ-OAR-2022-0829-0707, p. 41]

225 Nick Carey et al., Insight: Scratched EV battery? Your insurer may have to junk the whole car, REUTERS, Mar. 20, 2023, https://www.reuters.com/business/autos-transportation/scratched-ev-battery-your-insurer-may-have-junk- whole-car-2023-03-20/

226 DRIA at 4-22.

I. EPA fails to adequately consider the environmental justice impacts of the proposed rule.

Disadvantaged communities already face significant access barriers to electric vehicles, such as: higher upfront costs to electric vehicle ownership; a lack of existing charging infrastructure available to them in low-income, minority populated, and rural areas; and costlier and time-intensive charging due to a greater reliance on public charging infrastructure, particularly for individuals living in multi-family housing. [EPA-HQ-OAR-2022-0829-0707, p. 55]

EPA's EJ analysis must be thorough and inclusive of factors that may impact the price of transported goods, such as ZEV affordability, the availability of public charging, reasonable charging practices, and a lifecycle analysis of electric vehicles and power generation emissions. Without doing so, EPA runs the risk of intensifying price disparities and access to transport relative to the baseline for EJ communities. EPA's EJ analysis must be thorough and inclusive of electric vehicle affordability, the availability of public charging, reasonable charging practices, and a lifecycle analysis of electric vehicles and power generation emissions. Without doing so, EPA runs the risk of intensifying price disparities and access to transport relative to the baseline for EJ communities. These impacts can be both quantitively and qualitatively characterized.300 EPA's silence on these disparities is especially worrisome given EPA's prior binding commitments to EJ analysis for the benefit of disadvantaged and low-income communities. [EPA-HQ-OAR-2022-0829-0707, p. 55]

300 See, i.e., supra.

To date, the target electric vehicle customer base for OEMs consists of "mostly male, high-income, highly educated, homeowners, who have multiple vehicles in their household and have access to charging at home."301 Additionally, according to the U.S. Department of Transportation (DOT), "the rate of EV adoption in rural areas is roughly 40% lower than it is in urban areas, and EV charging infrastructure expansion has mostly been concentrated in cities and along major highways".302As a result, electric vehicle ownership remains primarily concentrated in affluent, large metropolitan and urban areas.303 By contrast, the supporting electricity generation necessary to support EPA's proposal is predominantly located in more remote, rural regions that are geographically isolated from urban centers. [EPA-HQ-OAR-2022-0829-0707, pp. 55-56]

301 Scott Hardman*, Kelly L. Fleming, Eesha Khare, and Mahmoud M. Ramadan, A perspective on equity in the transition to electric vehicles, MIT SCIENCE POLICY REVIEW (Aug. 30, 2021) available at https://sciencepolicyreview.org/2021/08/equity-transition-electric-vehicles/.

302 U.S. Department of Transportation, Community Benefits of Rural Vehicle Electrification (last updated February 2, 2022), available at https://www.transportation.gov/rural/ev/toolkit/ev-benefits-and-challenges/community- benefits.

303 See, i.e., Shuocheng Guo, Eleftheria Kontou, Disparities and equity issues in electric vehicles rebate allocation, Energy Policy, Volume 154, 2021, 112291, ISSN 0301-4215, available at https://doi.org/10.1016/j.enpol.2021.112291.

EPA's proposal directly impacts EJ communities by contributing to additional, local emissions to meet electric vehicle charging demand. Consequently, in theory, EJ communities incur an incremental burden in exchange for the subsidization of electric vehicles for more affluent consumers. And this subsidy occurs at expense of our most vulnerable communities burdened by emissions as a direct result of the proposal, with no corresponding benefit, since electric vehicles are likely to remain concentrated in affluent areas. Further, these communities remain unable to afford EPA's chosen mode of transport and are particularly vulnerable to rising electricity costs. [EPA-HQ-OAR-2022-0829-0707, pp. 55-56]

Notwithstanding EPA's hope that its proposal may serve to incentivize the purchases of electric vehicles, these vehicles are significantly more expensive on average than their ICE vehicle counterparts and unaffordable for many households. These are costs are also likely understated as each electric vehicle already enjoys thousands of dollars' worth of Federal and state subsidies, which are ultimately funded by taxpayers. Additionally, an automakers' ability to sell electric vehicles to consumers depends on substantial price subsidies in the form of credit support. EPA ignores the reality that many EJ stakeholders are currently unable to afford the upfront costs of purchasing an electric vehicle in the first place. With the cost of transition minerals expected to escalate exponentially in the coming years as a function of limited supply and increasing demand, the costs to manufacture and purchase electric vehicles will likely rise. [EPA-HQ-OAR-2022-0829-0707, p. 56]

EPA should also consider the effects of the proposal on electricity prices, as low-income populations often spend a larger percentage of their earnings on essential utilities compared to the rest of the United States. Reliance on electric vehicles has been shown to spur increases in load and demand during peak periods, which impact electricity prices. Because EPA lacks expertise in the area of electrical grid management and economics, EPA should consult with other agencies and credible experts in these areas in order to adequately evaluate these impacts.304 EPA should ensure that the proposal meets reliability and affordability criteria and helps EJ communities make informed decisions about their own energy needs. Additionally, EPA's EJ assessment fails to acknowledge the likelihood that many owners will lack access to residential charging, which will substantially increase their operating expenses. Consistent reliance on fast charging also shortens electric vehicle battery life, resulting in a need to replace the battery and/or the vehicle more frequently. [EPA-HQ-OAR-2022-0829-0707, pp. 56-57]

304 See, West Virginia, 142 S.Ct. at 2612-13 (stating that EPA admitted that opining on trends in electricity transmission, distribution, and storage requires technical and policy expertise not traditionally needed in EPA regulatory development and finding that there is little reason to think Congress assigned such decisions to the EPA).

If EJ is truly a commitment for EPA, it should carefully consider criticisms like those leveled by The Two Hundred, which point out the disproportionate impacts to working and minority communities as a result of California's climate approach regarding electrified transport; those impacts and concerns remain true, and indeed are magnified under the proposed standards.305 [EPA-HQ-OAR-2022-0829-0707, pp. 56-57]

305 See Plaintiffs' Complaint, The Two Hundred for Homeownership, et al. v. California Air Resources Board, et al., No. 1:22-CV-01474.

It is critical from the outset to design standards to minimize the potential for price shocks and supply disruptions. As written, the proposal ultimately benefits electric vehicle manufacturers at the expense of disadvantaged communities by subsidizing unaffordable transportation that is not fit for the purposes of commuting to and from EJ communities. At minimum, EPA should perform a thorough EJ assessment specific to its LDV proposal that is comprehensive of both transport challenges and impacts faced by EJ stakeholders and the government-wide Justice40 Initiative. [EPA-HQ-OAR-2022-0829-0707, pp. 56-57]

The average purchase price of EV cars in 2022 was approximately $65,000, which is more than what 46 percent of American households earn in income in a year.306 While the average "used" EV sold for $42,895 in March of 2023.307 While EPA's DRIA anecdotally indicates that "emerging consensus suggests that purchase price parity is likely to occur by the mid-2020's for some vehicle segments and models"308, Ford CEO Jim Farley told attendees at its 2023 Capital Markets Days that EV cost parity may not come until after 2030.309 Moreover US auto makers are focusing their efforts on producing higher priced electric SUVs and trucks, including Fords $100,000 F150 Lightening Platinum310 and GM's announcement that its luxury brands, Cadillac and Buick, will be its first all-electric product lineups.311 While smaller EV's like the Chevy Bolt, touted by the Biden Administration as being affordable alternatives, are being discontinued.312 The reality is that most middle- and lower-income families simply cannot afford to purchase a new or used EV, even when taking into account available tax incentives and rebates. In fact, middle – and lower -income families are more likely to purchase older used vehicle, due to their lower upfront costs, and to hold onto those vehicles for longer periods.313 [EPA-HQ-OAR-2022-0829-0707, pp. 56-57]

EPA Summary and Response

Summary:

Regarding maintenance and repair costs:

Commenters expressed dissatisfaction with EPA's use of the Argonne National Lab Total Cost of Ownership study as the basis for the maintenance cost analysis (American Fuel & Petrochemical Manufacturers, Betsy Cooper, Paul Bonifas and Tim Considine). Commenters also argued that EPA had failed to consider routine battery maintenance checks that auto makers recommend every 6 months to 2 years and that the analysis is tilted in favor of BEVs by ignoring factors such as environmental impacts on BEV brakes and diminished BEV battery capacity (Anonymous), and by omitting impacts of BEV weight and battery durability (John Graham). Other commenters, in support of EPA's inclusion of repair and maintenance costs and savings in the benefit cost analysis, stated their finding that BEVs and PHEVs can deliver around 50 percent savings compared to conventional gasoline vehicles (Consumer Reports).

Commenters asserted that the higher weight of BEVs will cause tires and brakes to wear out faster and the instant torque response may increase tire wear (John Graham).

Commenters expressed concerns regarding the use of the ANL study to support the EPA repair cost estimates (Anonymous, Arizona State Legislature). Commenters pointed out the different types of vehicles considered by ANL and noted that the BEVs were not comparable to the ICE vehicles and that EPA's repair and maintenance costs failed to consider road maintenance costs associated with heavier BEV vehicles (Anonymous, Valero).

Some commenters provided considerable detail regarding repair and maintenance costs suggested that EPA had overestimated repair and maintenance savings (Paul Bonifas and Tim Considine). They argued that the maintenance savings should be $72 billion rather than EPA's calculated $410 billion and that repair savings should be negative $4 billion (i.e., a cost, not a savings) compared to EPA's estimated $170 billion.

Other comments took exception to EPA's approach of generating a cost curve for maintenance costs rather than using a constant cost per mile value (Valero).

Commenters expressed concern over the cost of battery repairs (Alliance for Consumers) and higher insurance costs due to those repairs and possible battery replacements (Clean Fuels Development Coalition et al., John Graham). Other commenters asserted that is was indefensible not to include battery replacement costs in the analysis (John Graham).

Regarding biofuels and agriculture:

Commenters expressed concern that EPA had not considered the impact of the rule on the U.S. biofuels or agriculture industries (American Fuel & Petrochemical Manufacturers, Charles Forsberg).

Regarding crude oil import impacts:

Commenters noted EPA's use of AEO 2021 in the rule's analysis thus calling into question the validity of EPA's estimates of reductions in crude oil imports resulting from the rule (American Fuel & Petrochemical Manufacturers).

Commenters expressed dissatisfaction with EPA's use of the Low Economic Growth case from AEO 2021 to estimate the impact of the proposed rule on oil imports (American Fuel & Petrochemical Manufacturers).

Regarding the electric grid and infrastructure:

Commenters encouraged EPA to conduct an assessment to account for the costs associated with upgrades to the nation's grid infrastructure including upgraded generation, transmission, and distribution, and installation of public and private chargers (Chevron). Other commenters expressed concern over charging availability (Missouri Farm Bureau). Other comments argued that EPA had failed to consider annual operating and maintenance costs for EVSE (Valero).

Regarding consumer savings:

Commenters noted that past EPA rules have delivered savings while, at the same time, vehicles have become safer, larger, and more powerful with no (inflation-adjusted) increase in vehicle prices (Consumer Reports).

Regarding IRA incentives and consumer costs:

Commenters argued that EPA was not fully accounting for costs by relying on incentives under the IRA and that EPA oddly accounts for potential purchase incentives for net consumer prices (Delek US Holdings, Inc.).

Regarding medium-duty vehicles:

Commenters provided detailed analysis of medium-duty electrification costs, ownership costs along with supporting information regarding PHEVs to support the stringency of the medium-duty standards (Environmental Defense Fund).

Regarding time spent refueling BEVs:

Commenters argued that BEVs take more time to refuel than ICE vehicles, noting that recharging with a level 1 charger can take 40 to 50 hours to fully charge while level 2 charging can take 4 to 10 hours (Delek US Holding, Inc.). Commenters also noted that most PHEVs do not work with DC fast chargers (Delek US Holding, Inc.).

Regarding vehicle weight and insurance costs:

Commenters argued BEVs, being heavier than comparable ICE vehicles, create more safety issues in a collision and more weight that our crumbling infrastructure has to absorb. Furthermore, insurance companies may be charging higher premiums to all customers to pay for the increased risk of injury and the larger costs involved in repairing EVs versus and ICE vehicle (Daniel Hellebuyck).

<u>Response:</u>

Regarding certain comments presented in this Section 8.2, we respond to specific comments regarding environmental justice and equity in Section 9 and 13 of this document, consumer impacts in Section 13 of this document, critical minerals in Section 15 of this document, battery replacement and battery replacement costs in Section 16 of this document, and grid reliability in Section 18 of this document.

The Arizona State Legislature pointed to a story by Sean Tucker of Kelly Blue Book showing BEV repair costs exceeding ICE repair costs in the first 12 months of ownership. The Sean Tucker story was actually quoting a study done by a predictive analytics organization called "We Predict." Not surprisingly, the Sean Tucker story pointed to labor as the source of the higher repair costs. The story states, "EV repair is a specialized service at the moment. But it won't remain a rare specialty forever." The story also states, "The newness of EVs also means there are few older EVs to study. But We Predict believes that EVs may prove less expensive in the long run. 'The cost of keeping the vehicle in service for the EV, even as the EV gets older, becomes smaller and smaller and actually less than keeping an ICE [internal combustion engine] vehicle on the road,' We Predict CEO James Davies told reporters. 'That's not just maintenance costs, but all service costs.'" The story referenced by the Arizona State Legislature appears to be more supportive of the ANL study and EPA's use of the ANL study than of the position taken by the commenter. The Arizona State Legislature also pointed to a Forbes story that showed higher repair costs for BEVs than for ICE vehicles. The Forbes story notes that, "However, those results come with a string of asterisks. The short version is, sample sizes may be too small, and the growth in EV share may be too new, to draw lasting conclusions from the data that's available so far, said Susanna Gotsch, director and Industry Analyst at CCC." The Forbes story also notes that, "EV repairs can take longer, until technicians get accustomed to the new routines."

Regarding the maintenance and repair savings estimated in the final analysis, EPA continues to make use of the ANL study as a reasonable source of repair and maintenance data despite the issues noted by the commenter that some of the vehicles had low market shares, and we are not aware of other sources of repair data that are any more complete or reliable. EPA notes that, while the maintenance and repair savings are significant, the final rule is net beneficial even without consideration of the maintenance and repair savings we have estimated. Regarding the repair and maintenance cost/savings analysis conducted by Paul Bonifas and Tim Considine, the commenters used a different source for their estimates (a story from NADA[371] which the commenters suggested used Kelley Blue Book data but this is not clear in the NADA story) which showed maintenance costs for ICE vehicles of $4,583 and for BEVs $4,246 which represents a lower savings for BEVs than estimated by the ANL study and EPA. As noted, it is not clear where the NADA estimates came from and, although we recognize that not everyone follows the exact schedule of recommended maintenance, EPA believes most people do follow automaker recommendations for proper maintenance and it is reasonable to base maintenance costs on manufacturer-recommended maintenance actions as ANL and EPA have done. Importantly, the commenters' analysis still suggested a $68 billion net savings to consumers. We also note that, while we have not estimated battery replacement costs (because we do not believe it is necessary or appropriate to do so as further discussed in Section 12.2.5 of this RTC), we have similarly not estimated the savings associated with the reduced number of transmission replacements and overhauls, catalyst replacements, etc.

EPA appreciates the comments from Consumers Reports and agrees that BEVs and PHEVs can provide repair and maintenance savings relative to traditional ICE vehicles, as we have included in our analysis (see Section VIII.B.3 of the preamble).

Regarding the detailed maintenance costs submitted by Valero, it appears that the commenter understands the approach used by EPA but takes exception to the example provided in the NPRM which stated that, "If that vehicle has a maintenance cost of $0.10 per mile and travels 10,000 miles in the given year, then its estimated maintenance costs would be $1,000 in that year. If that vehicle were to instead travel 15,000 miles in that year, its estimated maintenance costs would be $1,500." This was simply meant to be an example of the way maintenance costs are dependent on maintenance costs per mile and the number of miles driven, not an actual calculation within OMEGA. OMEGA works exactly as the commenter laid out in its tables and the example has been removed from the final RIA to avoid confusion. We believe the source

[371] https://www.nada.org/nada/nada-headlines/beyond-sticker-price-cost-ownership-evs-v-ice-vehicles, accessed February 5, 2024.

study is consistent with the literature on which we base our estimates and is the most appropriate approach for our analysis.

Regarding brake and tire wear, we respond to such comments in Section 11.1 of this document.

Regarding IRA incentives and the impact on net consumer prices, we note an apparent misunderstanding of our analysis by commenters. While we do consider the IRA incentives in the consumer choice elements of the compliance modeling—that is, when consumers consider purchase prices and out-of-pocket expenses along with potential operating savings and how that might impact product offerings by auto makers—we do not include the IRA purchase incentives when calculating the social costs and benefits of the rule. So, while the consumer choice decision might reflect a vehicle purchase of $40,000 less an IRA incentive such that the purchase is something less than $40,000, the cost would include the full $40,000 value. As such, the analysis does not fail to account for the costs to society of that vehicle purchase. Note that we present transfers, including the purchase incentives, in Section VIII.G of the preamble.

Regarding medium-duty vehicle standards and costs, we appreciate the work of commenters and have considered these comments in updating our final rule analysis. We have updated our medium-duty technology costs along with most of our technology costs.

Regarding BEV weight and safety and impacts on insurance costs, as noted in our earlier responses in this section, we have included insurance costs for all vehicles with that cost incumbent on the value of the vehicle (price less depreciation). Given that BEVs are higher value vehicles, at least in their early years, we have included the higher insurance costs for them (see Section VIII.B.2 of the preamble).

Regarding time spent refueling (or recharging) BEVs, the analysis is meant to reflect only mid-trip refueling events, those that occur as a necessity to continue with a given trip. Such trips happen routinely with ICE vehicles, HEVs and PHEVs. However, for BEVs, they tend to occur only on occasion since most BEV charging is expected to occur over night or during work hours or while shopping, etc. As such, mid-trip BEV recharging is not expected to occur at level 1 chargers or even many level 2 chargers in the future and will instead occur at DC fast chargers that recharge at rates up to and exceeding 400 miles per hour of charging. This may take longer than a typical ICE vehicle refueling event, but is expected to occur at a lower frequency than a typical ICE vehicle refueling event. As for PHEVs not being able to recharge at a DC fast charger, we would not expect that to be an issue since the PHEV can refuel with liquid-fuel. We recognize that while BEVs ability to charge at home is an advantage over ICE vehicles, the additional time to charge on longer road trip is a disadvantage. We have considered whether insufficient charging infrastructure will adversely affect consumer acceptance of BEVs and for the reasons discussed elsewhere we have concluded that charging infrastructure will be sufficient and will not adversely affect BEV adoption. However, we also note that our central analysis is only one of many possible ways in which manufacturers could comply with the standards, and as illustrated by our sensitivity analyses, the standards are feasible even with significantly lower rates of BEV adoption.

8.3 - Fueling impacts

<u>Comments by Organizations</u>

Organization: American Enterprise Institute

I. Fuel Savings Are Not an Appropriate Economic Benefit of the Proposed Rule

The conceptual purpose of any proposed regulation is the correction of some set of purported inefficiencies inherent in market allocational outcomes, usually assumed to result from some social resource or other cost not reflected in market prices. This is the standard definition of an externality.2 The value of fuel savings measured as a function of market prices represents no such divergence between market prices and resource costs apart from the climate effects (discussed below); other such assumed impacts not reflected in market prices already are regulated under different provisions of the Clean Air Act. [EPA-HQ-OAR-2022-0829-0571, pp. 3-4]

2 I shunt aside here the issue of whether government can be predicted to adopt policies yielding systematic allocational improvement. See section IV at https://www.aei.org/wp-content/uploads/2023/06/Zycher-comment- OMB-Proposed-Circular-A-4-Regulatory-Analysis-June-2023.docx.pdf.

Accordingly, fuel savings per se are not relevant analytically. The inclusion of fuel savings is illegitimate as a component of the "benefits" of the proposed rule because the economic benefits of fuel savings are captured fully by consumers of fuels. There is no "externality" attendant upon fuel consumption per se, and if "fuel savings" are to be considered relevant for purposes of benefit/cost analysis, then the adverse effects or costs of a (forced) reduction in fuel consumption in terms of the quality of transportation services must be included in the analysis. The EPA claims that the fuel savings attendant upon implementation of the proposed rule would yield benefits in present value terms of $380-$770 billion (net of EVSE port costs), depending on the choice of discount rate.3 Those figures are much greater than any other of the asserted benefits from the proposed rule, except for the purported climate benefits, which, as discussed in section II, are wholly artificial constructs. [EPA-HQ-OAR-2022-0829-0571, pp. 3-4]

3 See the proposed rule at Table 6.

That the proposed rule would force consumers of fuels to change their consumption patterns in ways that would not be observed without the proposed rule demonstrates that the "fuel savings," even if we accept the underlying calculations, must be accompanied by some explicit or implicit costs in terms of forgone quality dimensions of transportation services, which in turn must be greater than the value of the purported fuel savings. That obviously is why we do not observe the allocational outcomes envisioned in the proposed rule as a result of market forces. Why does market behavior not yield fuel consumption for the vehicle fleet envisioned in the proposed rule? Or does EPA believe that consumers of motorized transportation services powered with conventional fuel simply are stupid? [EPA-HQ-OAR-2022-0829-0571, pp. 3-4]

In order to see this clearly, suppose that the proposed rule were simply to outlaw entirely the use of motor fuels by cars and light trucks, forcing consumers massively to use bicycles, horse-drawn carts, and similar substitutes technologically backward. It is no answer to say that electric vehicles and the like would be substituted without loss of value in terms of the quality of transportation services; the fact that such technologies have not been adopted by markets in the aggregate, even given the subsidies embedded in current policies, demonstrates that these technologies must impose some set of disadvantages in terms of costs and/or performance. The data reported by the Energy Information Administration show that in 2021 expenditures on motor gasoline alone in the transportation sector were about $386.9 billion.4 Under the EPA methodology, that “fuel saving” in total would be an annual benefit of such a hypothetical rule outlawing the use of motor fuels, and the disadvantages of bicycles, horse-drawn carts, and the like — the marginal benefits of using motor vehicles — would be irrelevant. Under the methodology underlying the proposed rule, the more stringent the constraint imposed upon fuel use, the greater the purported benefit from “fuel savings.” In other words, the market spends scarce resources on the consumption of transportation fuels without any offsetting benefits at all! Amazingly, this implicitly is the analytic framework underlying this part of the estimated benefits asserted in the proposed rule. It is not to be taken seriously. [EPA-HQ-OAR-2022-0829-0571, pp. 3-4]

4 See https://www.eia.gov/state/seds/sep_sum/html/pdf/sum_ex_tra.pdf.

Organization: American Fuel & Petrochemical Manufacturers

EPA incorrectly assumes that ZEV owners will pay the national average residential electricity price to charge their vehicles. EPA fails to consider that the majority of ZEVs in the U.S. are located in utility service territories with some of the highest electricity rates in the country and that the average EV owner currently pays a much higher price to charge their ZEV at home than the national average residential electricity rate. Given that EV penetration has varied widely across the U.S., it would be arbitrary to assume that EVs will, unlike in the past, penetrate uniformly across the U.S. and thus that the average electricity price would be representative of the actual cost electricity. For example, California, which has roughly 40 percent of all registered ZEVs in the U.S., has a residential electricity rate that is roughly double the national average. Considering that EPA is modeling its rule after a California-like approach to mandate ZEVs, it would be more appropriate for EPA to assume similar real-world costs (at a minimum, given California’s temperate climate). Moreover, EPA fails to consider that mandating such a high ZEV sales rate will necessarily require exponential increases in commercial ZEV charging at rates that are currently three, four or five times higher than the current national average residential electricity rate, depending on location and charging speed. Those customers who are not homeowners and not able to install their own charging stations and take advantage of charging at low-cost times will be adversely impacted. Instead, EPA uses a residential rate for electricity and does not consider peak power or time of use charges. California electric prices rose 42 percent - 78 percent between 2010 and 2020 and are projected to rise an additional 50 percent by 2030 as shown in Figure 9. [EPA-HQ-OAR-2022-0829-0733, pp. 57-58]

SEE ORIGINAL COMMENT FOR Historic and Forecasted Residential Average Rates Based on Most Recent 5-year Average Rate Increase. Figure 9:

Source: Michael Shellenberger, Twitter (citing California Public Advocate’s Office data), April 27, 2021). [EPA-HQ-OAR-2022-0829-0733, pp. 57-58]

Heaping additional demand for EV charging into this market could exacerbate already high electricity prices. This will be especially impactful to lower-income homeowners who may not be able to install dedicated charging units, forcing them to pay more out of pocket for charging during peak demand periods.265 [EPA-HQ-OAR-2022-0829-0733, pp. 57-58]

265 Hardman, Scott, et al., “A Perspective on Equity in the Transition to Electric Vehicles.” MIT Science Policy Review, (Aug. 20 2021), available at https://sciencepolicyreview.org/2021/08/equity-transition-electric-vehicles/ (accessed June 29, 2023).

EPA must revise its analysis to account for realistic electricity prices. The proposed ZEV mandate will require an enormous investment in power generation and distribution, resulting in nationwide increases in electricity bills that EPA has not considered. Of course, considering the additional trillions of dollars in costs would paint a clear picture that the costs of forced electrification far exceed even the inflated benefits EPA presented in the Proposed Rule. [EPA-HQ-OAR-2022-0829-0733, pp. 57-58]

Third, EPA asserts that consumers will receive $890 billion in fuel savings— in other words, that operating electric vehicles will be cheaper than operating combustion-engine vehicles because consumers will no longer need to purchase fuel directly. See 88 Fed. Reg. at 29,362. But this figure depends on consumers’ choosing to switch from their familiar combustion-engine vehicles to electric vehicles in overwhelming numbers. Even if all of the obstacles to manufacturing and charging electric vehicles discussed above could be overcome, the fuel savings EPA posits still would not materialize unless individuals decide to pur-chase those vehicles. For the reasons already noted, there is ample reason to doubt that consumers would do so, including based on concerns about electric vehicles’ higher up-front costs and perceptions that charging and maintenance facilities are inadequate. [EPA-HQ-OAR-2022-0829-0683, pp. 63-64]

To the extent EPA believes that the prospect of fuel and other operational savings itself would motivate consumers to adopt electric vehicles in sufficient numbers, experience thus far indicates otherwise. As EPA acknowledges, if abandoning combustion-engine vehicles in favor of electric vehicles actually resulted in net operating savings, rational users of combustion-engine vehicles would likely already be switching to electric vehicles in much greater numbers than they are today. See 88 Fed. Reg. at 29,397; Draft RIA at 4-38–39 (noting that “[c]onventional economic principles” would lead “people [to] buy [electric vehicles]”). The fact that consumers are not doing so—but instead currently “tend to favor [combustion-engine] vehicles over” the electric vehicles that are available now even “when two vehicles are comparable in cost and capability,” 88 Fed. Reg. at 29,342—is a strong indication that EPA’s asserted savings do not in reality outweigh the costs of switching to electric vehicles. [EPA-HQ-OAR-2022-0829-0683, pp. 63-64]

EPA attempts to sidestep this problem by invoking a supposed “energy efficiency gap,” positing a market failure that is responsible for skewing consumers’ decisions away from purchasing electric vehicles. 88 Fed. Reg. at 29,397. But EPA provides no evidence demonstrating that low adoption of electric vehicles is actually the result of any such market failure, as opposed to well-founded concerns about the drawbacks of the technology. EPA offers only a hope that nothing “immutable within consumers or inherent to” electric vehicles will “irremediably obstruct[] acceptance.” Id. at 29,312. But in light of the gap between the data and consumer behavior on the one hand, and EPA’s rosy savings estimates on the other, any final rule must explain why EPA’s fuel-savings figure is realistic and why it is an appropriate offset for the rule’s costs. See Am. Pub. Gas Ass’n v. DOE, 22 F.4th 1018, 1027–28 (D.C. Cir. 2022). EPA cannot justify an economy-altering rule by invoking an ill-defined, unsubstantiated market failure of its own imagining. [EPA-HQ-OAR-2022-0829-0683, pp. 63-64]

Organization: American Highway Users Alliance

The proposed rule would also place downward pressure on sorely needed highway investment by triggering a reduction in revenue into the Federal Highway Trust Fund (HTF) as, unlike internal combustion engine (ICE) vehicles, EVs do not generate payment of fuel taxes into the HTF. [EPA-HQ-OAR-2022-0829-0696, p. 2]

Further, the two lengthy NPRMs and the lengthy draft Regulatory Impact Analysis (RIA) for each of them do not appear to include any consideration of the adverse impacts of the proposal on revenues flowing to the Highway Trust Fund (HTF) and resulting Federal highway infrastructure investment. The proposed rules in the two dockets seek to accelerate a shift from the public's use of ICE vehicles to EVs. A substantial erosion of revenue into the HTF would result,3 placing major downward pressure on needed highway and bridge investment, which already faces an investment backlog of $786 billion per USDOT's latest "Conditions and Performance Report." Moreover, that $786 billion estimate was developed before recent significant inflation. [EPA-HQ-OAR-2022-0829-0696, pp. 3-4]

3 The draft RIA for the heavy-duty vehicle NPRM includes a brief reference (page 429) that, under the proposed rule, fuel consumption would be "reduced." Fuel sales, which are subject to a Federal excise tax, generate the largest share of HTF revenue.

Failure to Consider Adverse Impact on Highway Investment

As noted earlier, the lengthy NPRM and its draft Regulatory Impact Analysis in this docket and in the heavy-duty vehicle Phase 3 docket do not evidence any consideration of the adverse impacts of the proposals on revenues flowing to the Highway Trust Fund (HTF) and resulting Federal highway infrastructure investment. For decades, the largest source of Federal transportation infrastructure funding has been the HTF, which is largely dedicated to highway funding distributed to states. The proposed rules in this docket, and in the heavy-duty vehicle Phase 3 NPRM, seek to massively accelerate a shift from the public's use of ICE vehicles to EVs. A substantial erosion of revenue into the HTF would result, placing major downward pressure on needed highway investment, which already faces an investment backlog of $786 billion per USDOT's latest "Conditions and Performance Report." [EPA-HQ-OAR-2022-0829-0696, pp. 5-6]

Moreover, that backlog estimate was developed before recent inflation of 50% or more just from Q1 2021 to Q3 2022 in the Federal Highway Administration's national highway construction cost index. That index also shows significant inflation from 2017 through the third quarter of 2022 –approximately 72%.6 EPA must reconsider what it proposes after seriously weighing, among other issues noted, the impact of the proposal on the HTF and highway investment, particularly given all of the benefits from those investments for highway safety and the economy. [EPA-HQ-OAR-2022-0829-0696, pp. 5-6]

6 For the NHCCI see – https://explore.dot.gov/views/NHIInflationDashboard/NHCCI?%3Aiid=1&%3Aembed=y&%3AisGuestRedirectFromVizp ortal=y&%3Adisplay_count=n&%3AshowVizHome=n&%3Aorigin=viz_share_link The last entry for 2022 is an index reading of 2.786 (with 2003 as 1.000), while the index was at 1.62 at the start of 2017 (thus, an increase of 72% since the start of 2017).

Organization: Chevron

EPA should also consider the impacts associated with the loss of revenue for the highway trust fund resulting from increased sales of BEVs. Reductions in excise taxes and local sales taxes on gasoline will impair the ability of state and local governments to maintain and improve roadways, resulting in more traffic congestion, longer travel times, and added depreciation and repair costs. [EPA-HQ-OAR-2022-0829-0553, p. 6]

Organization: Departments of Transportation of Idaho, Montana, North Dakota, South Dakota and Wyoming

The proposed rule would, among other actions, set standards that would exponentially reduce the permissible level of tailpipe emissions of various substances, including but not limited to CO2 and other greenhouse gases (GHGs), from newly manufactured light-duty and medium-duty vehicles. The reductions would be phased in over model years (MYs) 2027-32. [EPA-HQ-OAR-2022-0829-0525, p. 1]

A major erosion of revenue into the Highway Trust Fund (HTF) would result from such drastic changes, as the new EVs encouraged by the proposed rule would generate wear and tear on the highways without paying fuel taxes into the HTF. This would place significant downward pressure on highway and bridge investment, which already faces an investment backlog of $786 billion per U.S. Department of Transportation's latest "Conditions and Performance Report" for highways, bridges and transit. Moreover, that backlog estimate was developed before recent inflation of approximately 50% from Q1 2021 to Q3 2022 in the Federal Highway Administration's (FHWA's) highway construction cost index. [EPA-HQ-OAR-2022-0829-0525, p. 1]

> 1 For the NHCCI see – https://explore.dot.gov/views/NHIInflationDashboard/NHCCI?%3Aiid=1&%3Aembed=y&%3AisGuestRedirectFromVizpor tal=y&%3Adisplay_count=n&%3AshowVizHome=n&%3Aorigin=viz_share_link

Further, the HTF is the main funding source for investment to maintain and improve our states' highways and bridges. A transportation network in good condition is essential for people and business. It enables safe and reliable access to markets, schools, health services and other important destinations. Proposed policies that would seriously weaken the flow of revenue into the HTF place downward pressure on our ability to maintain and improve the transportation network. That, in turn has adverse impacts on access to markets and the ability of people and business to access essential services, including schools, work, food and other basic shopping, health services and more. [EPA-HQ-OAR-2022-0829-0525, p. 1]

Summary and Conclusion

While there are many issues raised by the NPRM, we emphasize here that EPA must reconsider what it has proposed after seriously considering the impact of the proposal on the HTF and highway investment, particularly given the many benefits from those investments for highway safety, the economy, and personal mobility. After reconsidering, EPA should pivot to a much more gradual approach to reducing tailpipe emissions that is not singularly focused on favoring EVs. A more gradual approach would provide policymakers more time to consider and find ways to make up for HTF revenue loss caused by EPA tailpipe emission rules so as to better fund needed highway investments that provide so much public benefit. [EPA-HQ-OAR-2022-0829-0525, p. 2]

Significantly, at the same time that EPA has issued this NPRM, it has also issued a separate proposed rule calling for reduced tailpipe emissions of CO2, other GHGs, and other substances from heavy-duty vehicles. See 88 Fed. Reg. 25926 (April 27, 2023). That proposal would accelerate growth in EVs as a percentage of new heavy-duty vehicles and erode revenue into the HTF. [EPA-HQ-OAR-2022-0829-0525, p. 2]

However, even though these proposed tailpipe emission rules are high profile initiatives, and the HTF and the programs it supports are high profile programs, the lengthy NPRM in this docket and its lengthy draft Regulatory Impact Analysis (RIA) do not appear to include any consideration of the adverse impacts of the proposal on revenues flowing to the Highway Trust Fund (HTF) and on highway investment – again, as the new EVs encouraged by the proposed rule would generate wear and tear on the highways without paying fuel taxes into the HTF. As the HTF has been, for decades, the Federal Government's largest source of funds for highway investment, proposed policies that would greatly erode revenue into the HTF raise important concerns that must be seriously considered by regulatory agencies. [EPA-HQ-OAR-2022-0829-0525, p. 2]

Organization: Donn Viviani

2) Errors/omissions in the proposal and the RIA.

Not addressed in the RIA is the effect the IRA incentivizing carbon capture and sequestration (CCS) used for enhanced oil recovery (EOR) will have on fuel prices . Setting aside the unsettled question of how much net car- bon is sequestrated after the oil produced in turn emits additional CO2, as not germane to the EV rule.15 What is germane is that the oil will be produced at marginally lower cost. While the rebound effect is taken into con- sideration in the RIA based on increased vehicle milage efficiency, the de- creased cost of fuel from EOR is not. Cheaper fuel will also have a re- bound effect, encouraging more driving, and reducing the pressure to transition to a BEV.16 This effect needs to be reflected in the RIA, otherwise the RIA is incomplete and presents a distorted projection. [EPA-HQ-OAR-2022-0829-0697, p. 5]

15 It's estimated a ton of injected CO2 will produce about 2 barrels of oil which when combust- ed, will emit about a ton of CO2

Organization: Environmental. and Public Health Organizations

B. Even the 10% rebound effect is too high, and EPA should consider using a rebound effect of a lesser magnitude.

The two most reliable rebound estimates based on U.S. national data from EPA's preferred studies are 10% (Greene (2012)) and around 4% (Hymel and Small (2015)).621 Hymel and Small (2015) noted that their data indicated that fuel economy rebound could be lower than fuel price rebound, meaning that even the 4.0% and 4.2% values could be too high.622 Moreover, another paper in the list of EPA's seven preferred studies, Gillingham et al. (2015), estimates the rebound effect at 10%. But the study also found that "a high percentage of vehicles are almost entirely inelastic in response to gasoline price changes" and that "the lowest fuel economy vehicles in the fleet drive the responsiveness, with higher fuel economy vehicles highly inelastic with respect to gasoline price changes."623 While Gillingham et al. (2015) does not offer an alternative best rebound estimate for higher fuel economy vehicles, it is fair to assume that the 10% estimate is at the high end of reasonable estimates for the vehicles impacted by this rulemaking. [EPA-HQ-OAR-2022-0829-0759, p. 191]

621 See Kenneth A. Small, Comment Letter on Proposed MY 2021-2026 Standards, NHTSA-2018-0067-7789, at 1 (Sept. 14, 2018) ("A better characterization of the most recent study would be that it finds a long-run rebound effect of 4.0 percent or 4.2 percent under two more realistic models that are supported by the data.").

622 Hymel K. & K. Small, The Rebound Effect for Automobile Travel: Asymmetric Response to Price Changes and Novel Features of the 2000s, 49 Energy Econ. 93, 97 (2015); see also Greene, D., Rebound 2007: Analysis of U.S. Light-Duty Vehicle Travel Statistics, 41 Energy Pol'y 14 (2012) (although fuel prices "had a statistically significant impact on VMT, . . . fuel efficiency did not.").

623 Kenneth Gillingham et al., Heterogeneity in the Response to Gasoline Prices: Evidence from Pennsylvania and Implications for the Rebound Effect, 52 Energy Economics S41–S52 (2015).

Other factors would also suggest that even the best and most relevant existing studies could lead to a rebound estimate that is too large. For example, the rebound effect's magnitude diminishes over time, largely due to increasing income and decreasing driving costs, a fact that EPA has historically understood.624 As incomes rise over time, any fuel efficiency improvement will have less of an effect on the total vehicle miles traveled, and thus the rebound effect will decline. In both 2010 and 2012, EPA chose to use a 10% rebound effect as "a reasonable compromise between historical estimates and projected future estimates."625 The 2012 Final Rule noted, however, that several high-quality studies indicated that the rebound effect's magnitude is significantly diminishing over time as incomes rise.626 This income effect on rebound makes clear that the projected future estimates are in fact much more accurate than historical estimates. Moreover, more than 15 years will have passed since the 2010 Final Rule found a 10% rebound effect to be a good compromise and the implementation of the Proposed Standards, and income has continued to grow since that time, supporting a substantially diminished rebound effect. [EPA-HQ-OAR-2022-0829-0759, p. 192]

624 See, e.g., 2016 Draft TAR at 10-14 and 10-20; 77 Fed. Reg. at 62924, 62995; accord Small K. & K. Van Dender, Fuel Efficiency and Motor Vehicle Travel: The Declining Rebound Effect, 28 Energy J. 25 (2007); Hymel, K. et al., Induced Demand and Rebound Effects in Road Transport, 44 Transp. Rsch. Part B 1220 (2010).

625 77 Fed. Reg. at 62924.

626 NHTSA, Corporate Average Fuel Economy for MY 2017-MY 2025 Passenger Cars and Light Trucks: Final Regulatory Impact Analysis, at 851-52 (2012) (citing Small & Van Dender (2007) (finding average rebound to be 22% for 1966-2001, but declining to 11% when looking at only 1997-2001); Hymel et al. (2010) (finding that average rebound for 1966 through 2004 was 24%, but rebound by 2004 was only 13%); Greene, D., Rebound 2007: Analysis of Light-Duty Vehicle Travel Statistics (Mar. 2010) (internal EPA research) (estimating the rebound effect would be 10% in 2010 and 8% in 2030, using 1966-2007 data); see also Greene (2012) (same)).

EPA should give more weight to the fact that the rebound effect varies with income over time. In the 2021 rule, the agency cited Gillingham (2014) to assert that the evidence of how the rebound effect varies with income is "mixed," but then also correctly excluded that study from its list of preferred studies. Gillingham (2014) specifically considers the response to the 2008 gasoline price shock in California. EPA is correct to conclude that this was "an unusual period when gasoline prices were particularly salient to consumers." 2021 RIA at 3-6 to 3-7. As EPA noted, Gillingham explained in a follow-up paper in 2020 that the Gillingham (2014) results should not be used for developing an estimate of the VMT rebound effect for fuel economy or GHG standards. 2021 RIA at 3-7. The Gillingham (2014) paper is equally irrelevant to the question of the income effect on rebound. Various papers have confirmed that the rebound effect is declining over time and one study certainly should not be used as the basis for giving this factor "less weight," especially a study whose own author acknowledges its irrelevance to this rulemaking context and to which EPA gives little to no weight otherwise. Because of this, EPA should more fully consider the impacts of the income effect on rebound, and in doing so, could support a rebound effect of a magnitude lower than 10%. [EPA-HQ-OAR-2022-0829-0759, p. 192]

In fact, the income effect on rebound is particularly important in the context of setting LDV GHG emissions regulations for two reasons. First, even the most recent relevant studies on which rebound estimates are based consider data only from 2013 and earlier. The historical growth rate of per capita personal income was 1.4% between 2001 and 2019,627 and thus income growth since 2013 would indicate a declining rebound effect even in the time since the most recent data utilized were collected. Second, EPA's final standards will affect the fuel efficiency—and therefore the rebound effect—for vehicles for the next 30 years or more. Private forecasts have estimated approximately 1.6% growth in real personal income per year over the next 30 years, see 85 Fed. Reg. at 24675 n.1763, meaning that when most vehicles subject to the regulations are retired, incomes will be at least 61% higher than they are today (which are already higher than during the time periods in which the available rebound studies were conducted).628 More recent projections in AEO 2023 anticipate incomes rising even more than prior estimates—an average of 2.4% per year through 2050.629 This income growth would be expected to cause a large reduction in the magnitude of the rebound effect, supporting a rebound effect for the vehicles subject to EPA's final standards of a magnitude well below 10%. [EPA-HQ-OAR-2022-0829-0759, pp. 192-193]

2. EPA's Fuel Savings Analysis Is Unclear and Incomplete.

Despite acknowledging that its proposed mandates will result in increased electricity consumption and expenditures, EPA claims that consumers will nevertheless experience fuel savings that will help offset higher upfront EV purchasing costs.40 EPA appears to have premised its conclusion on the modeling of liquid fuel and electricity consumption levels. EPA does not explain how it converted modeled consumption levels into monetary values to show actual consumer savings, and it makes no comparison of fueling costs and electricity rates based on modeled consumption levels. Nor is information provided on individual consumer savings. Thus, the basis for EPA's consumer fuel savings conclusion is unclear, at best. [EPA-HQ-OAR-2022-0829-0656, pp. 8-9]

40 88 Fed. Reg. at 29365-66.

EPA's savings assertion seems questionable. Conceivably, liquid fuel costs could decrease more than electricity costs increase if the proposal is adopted, but even then, EPA's analysis seems to overstate the fuel savings from switching to EVs. According to the Energy Information Agency (EIA), the average American household uses 886 kilowatt hours of electricity per month,41 and EPA reports that the average EV consumes 36 kilowatt hours of electricity per 100 miles driven.42 If the average household drives an EV 15,000 miles per year, or 1,250 miles per month, and the EV is charged at home to the tune of 450 kilowatt hours of electricity per month, the household's electricity bill will increase by around 50 percent. [EPA-HQ-OAR-2022-0829-0656, pp. 8-9]

41 See Frequently Asked Questions (FAQs) - U.S. Energy Information Administration (EIA).

42 See Comparison: Your Car vs. an Electric Vehicle | US EPA.

Moreover, as EV sales increase, electricity rates are likely to rise due to increased power demands. Higher electricity prices will also reflect the cost of increased transmission and generation infrastructure, which some estimates indicate will need to increase 60 percent by 2030, and even more over the following two decades.43 EPA must account for these higher electricity costs when determining accurately whether, and to what extent, commercial and noncommercial purchasers/lessees operating EVs will benefit from any fuel savings. [EPA-HQ-OAR-2022-0829-0656, pp. 8-9]

43 See Queued Up… But in Need of Transmission | Department of Energy.

Organization: Office of Wyoming Governor Mark Gordon

There is also concern among the Department of Transportations in western and rural states about this rule's impact on the Highway Trust Fund (HTF). States look to lose hundreds of billions of dollars that maintain our nation's infrastructure by removing the HTF's main source of funding. There is no consideration in the proposed rule on the effects of mandating the removal of gasoline powered vehicles to the current structure of highway funding. [EPA-HQ-OAR-2022-0829-0675, pp. 1-2]

My office, along with Wyoming's state agencies, look forward to working with the EPA in a meaningful collaborative and cooperative manner. In addition to these comments, attached are comment letters from the University of Wyoming, School of Energy Resources' Center for Energy Regulation and Policy Analysis and Wyoming Department of Transportation's joint comments along with Idaho, Montana, North Dakota, and South Dakota. [EPA-HQ-OAR-2022-0829-0675, pp. 1-2]

Organization: Paul Bonifas and Tim Considine

Fuel cost "savings": The EPA claims gasoline prices will increase when demand for gasoline decreases, even though that directly contradicts basic economic theory and real-world examples; when government restrictions forced less drivers on the road during the COVID pandemic, demand for gasoline dropped, plummeting the prices of oil and retail gasoline. [EPA-HQ-OAR-2022-0829-0551, p. 2]

Pre-Tax Fuel Savings

EPA Claimed Savings: $890 billion

Realistic Savings: NEGATIVE $108 billion [EPA-HQ-OAR-2022-0829-0551, p. 4]

The EPA vastly overestimates the savings in fuel costs from their proposed rule. They define fuel cost savings as the difference between higher electricity costs associated with charging EVs less the avoided costs of liquid fuel consumption. They underestimate electricity costs and overestimate savings in liquid fuel costs. [EPA-HQ-OAR-2022-0829-0551, p. 4]

Under their rule, EPA estimates that eventually annual liquid fuel consumption would be 49 billion gallons lower, or 3.2 million barrels lower per day7. This significant reduction in liquid fuel demand would lower equilibrium prices for liquid fuels by about 50%, assuming an oil supply elasticity of 0.6 8, thereby reducing their liquid fuel cost savings from $1.3 trillion to $620 billion. During the COVID pandemic, liquid fuel demand also dropped significantly and, as a result, so did oil prices. [EPA-HQ-OAR-2022-0829-0551, p. 4]

7 Page 182 of EPA's Rule - https://www.govinfo.gov/content/pkg/FR-2023-05-05/pdf/2023-07974.pdf

8 Considine, T.J. (2006) "Is the strategic petroleum reserve our ace in the hole?" The Energy Journal, 27, 3, 91-112.

EPA also assumed unrealistically low electricity rates. Not all households have access to home charging ports. The average rate for charging at a Tesla super-charger is 25 cents per kilowatt hour (Kwh)9. In contrast, EPA assumes electricity rates for EV charging are 10.3 cents per kwh in 2027 and fall to 9.3 cents per kwh by 205510. 63 percent of households in the US have garages or car ports, which provides an upper bound for home charging11. Accordingly, 47 percent of households would be paying much higher commercial rates for EV charging. If we assume Tesla's price, this implies that EPA underestimated electricity rates paid for EV charging by 55%. [EPA-HQ-OAR-2022-0829-0551, p. 4]

9 https://www.leafscore.com/tesla/how-much-does-it-cost-to-charge-a-tesla

10 Page 168 of EPA's Draft Regulatory Impact Analysis - https://nepis.epa.gov/Exe/ZyPDF.cgi?Dockey=P10175J2.pdf

11 https://www.energy.gov/eere/vehicles/fact-958-january-2-2017-sixty-three-percent-all-housing-units-have- garage-or-carport

Moreover, the EPA did not factor in the impact on electricity rates from their recent power plant rule that would essentially force all remaining coal and natural gas power plants to cut emissions by 90%12. [EPA-HQ-OAR-2022-0829-0551, p. 4]

12 https://www.nbcnews.com/science/environment/biden-administrations-power-plant-rules-underscore-reality- epa-limits-rcna84201

This rule is like the Clean Power Plan proposed by the Biden Administration. The US Energy Information Administration conducted a study of the Clean Power Plan and found that average retail electricity rates would increase upwards of 3-7%.13 Taking the mid-range of this price increase, or 5%, the proposed rule would raise the previous electric rate increase of 55% to 58% and increase electricity costs for EV charging from EPA's estimate of $460 billion to $728 billion. [EPA-HQ-OAR-2022-0829-0551, p. 5]

13 https://www.eia.gov/analysis/requests/powerplants/cleanplan/

This $728 billion in higher electricity expenditures more than offsets the savings in reduced liquid fuel spending of $620. On balance, the fuel cost savings are a NEGATIVE $108 billion in contrast to EPA's estimated pre-tax fuel savings of $890 billion. This is a nearly $1 trillion difference. So, under rather conservative but realistic assumptions and elementary economic analysis, the proposed EV rule will not save consumers money but instead will lead to higher electricity costs, especially for poor and lower to middle class households living in rental units. [EPA-HQ-OAR-2022-0829-0551, p. 5]

Organization: The Heritage Foundation (Kevin Dayaratna and Diana Furchtgott-Roth)

The last detrimental aspect of this arbitrary benchmark is that part of the cost analysis done by EPA included refueling time. With larger batteries come longer recharge times, which again add to the cost. While EPA might argue that the high-speed chargers will make up for that, EPA does not want to address the fact that rapid charge or discharge of a battery accelerates its lifecycle. Every time a consumer inputs or draws large amounts of power from a battery, it damages it more than a slower input or draw, thereby decreasing the timeline for the battery's replacement and moving that expense up sooner in the timeline of EV ownership. [EPA-HQ-OAR-2022-0829-0674, p. 9]

Miscalculated fuel savings [EPA-HQ-OAR-2022-0829-0674, pp. 12-13]

The study finds substantial fuel savings costs from the rule. (See Tables 163 and 164.) Curiously, these values increase nearly 100-fold from 2027 to 2055. The retail fuel savings are approximately $1 billion in 2027, or approximately $7.50 for each of the 130 million households in the United States in 2022. There will doubtlessly be more households in 2027, and consequently the per-household benefit will be less. [EPA-HQ-OAR-2022-0829-0674, pp. 12-13]

By 2055, the total benefit is predicted to be closer to $100 billion, or approximately $750 per household, a consequential amount. The Net Present Value (NPV) in either the 3% case or the 7% from fuel savings account for over half of the total net benefits recorded in the summary in Table 156 ($1.1 trillion out of $1.4 trillion in the 3% discount rate case and $550 billion out of $610 billion in the 7% discount rate case.) [EPA-HQ-OAR-2022-0829-0674, pp. 12-13]

But the numbers on fuel savings are almost certainly wrong. They appear to presume a substantial increase in gasoline prices and a constant electricity price. These assumptions ignore two market realities. First, gasoline prices are set in a global petroleum market, not by federal policy. Global petroleum markets have had fairly predictable prices in a range of $40-$100 barrel for the past two decades or more. Federal policy can raise those prices artificially, but those policies are unlikely to remain steadily increasing over the next 30 years, as the study assumes. If their analysis is correct, then EVs will significantly crowd out ICE autos, which will result in a drastic reduction in demand, which should also result in lower gasoline prices. [EPA-HQ-OAR-2022-0829-0674, pp. 12-13]

Second, electricity prices are very much affected by domestic policies. Current Administration policy is to substantially reduce electricity generation capacity with new capacity limited to high-cost renewable sources. While future Administrations may reverse these policies, new generation capacity takes many years to bring online, and rational electric utilities will be reluctant to invest in efficient electricity generation that may be outlawed every few years. The net result is that electricity prices, unlike gasoline prices, will predictably increase over the next few decades under most plausible policy scenarios. [EPA-HQ-OAR-2022-0829-0674, pp. 12-13]

Consequently, the assumptions in the study that fuel costs under the proposed rule will decrease substantially are almost certainly incorrect in magnitude, and quite likely in direction as well. [EPA-HQ-OAR-2022-0829-0674, pp. 12-13]

Miscalculated costs of increased refueling times

The study correctly finds increased refueling times with electricity vehicles. (See Table 166.) But the magnitude of the costs of such increased refueling times are trivially small. In 2027, increased refueling times are estimated to cost -$0.1 billion, or $0.75 per household. Those refueling time costs are predicted to increase to $8.2 billion in 2055, or approximately $63 per household, assuming the number of households does not increase. If average wages are around $30/hour, this means that a median household is expected to lose approximately an additional 2 hours waiting to refuel in the entire year 2055 under the proposed rule relative to the non-rule case. If a vehicle is refueled even once every two weeks, this means that each refueling is predicted to take no more than additional five minutes or so. (120 minutes/26 refueling). This seems implausible. [EPA-HQ-OAR-2022-0829-0674, p. 13]

Organization: U.S. Chamber of Commerce

Finally, it is incumbent upon EPA and its federal partners to analyze and address the spillover impacts of this rulemaking on the quality of America's roadways. Since 1956, federal highway projects have been funded by the Highway Trust Fund, designed to be a self-sustaining source of funding that is refilled regularly by revenues from a series of dedicated taxes, primarily the gas and diesel fuel tax. While this revenue source has successfully funded projects for decades, the balance of the trust fund has declined in recent years, becoming insolvent for the first time in 2008. As a result of declining revenues, for eight of the last ten years Congress has had to transfer funds from the general fund to the Trust Fund to ensure continued funding of highway projects. The most significant reason for the reduction in contributions is decreased fuel tax revenue as fuel economy standards change and more customers purchase electric vehicles that do not contribute to the Trust Fund, despite benefiting from the infrastructure Trust Fund revenue provides. [EPA-HQ-OAR-2022-0829-0604, pp. 3-4]

According to the proposed rule, fuel sales would be reduced by 21 billion gallons in 2035, rising to 34 and 48 billion gallons in 2040 and 2050, respectively. This equates to lost Trust Fund revenues of $3.9B in 2035, $6.3B in 2040, and $165B through 2055. Absent a plan to replace these revenues, the adverse impacts of a rapid EV transition proposed in the rule stand to exacerbate this depletion as the number of vehicles contributing to the Trust Fund decreases with no alterative revenue stream to take the place of ICE vehicle contributions. A high-quality transportation network is vital for American businesses and consumers, and a sharp reduction in contributions over the next several years as a result of this rule would result in significant degradation of our nation's roads and bridges. Record high inflation is already reducing buying power under recently passed laws such as the Infrastructure Investment and Job Act, further degradation to reduced Trust Fund contributions would adversely impact access to medical facilities, schools, employers, grocery stores, and other basic needs necessary for the American public. [EPA-HQ-OAR-2022-0829-0604, pp. 3-4]

Organization: Valero Energy Corporation

9. EPA fails to account for the rising cost of electricity over the regulatory period. [EPA-HQ-OAR-2022-0829-0707, p. 10]

EPA estimates future pre-tax and retail gasoline, diesel, and electricity prices based on the "reference case" projections in the Energy Information Administration's (EIA's) Annual Energy Outlook 2021 (AEO2021).46 However, the AEO2021 Reference case assumes:

46 DRIA at 2-85.

• Current laws and regulations as of September 2020 remain unchanged,47 and

• Gasoline and flex fuel vehicles will account for 79% of new-LDV sales by 2050.48 [EPA-HQ-OAR-2022-0829-0707, p. 10]

47 U.S. EIA "AEO2021 Press Presentation" at 5, https://www.eia.gov/pressroom/presentations/AEO2021_Release_Presentation.pdf.

48 U.S. EIA "AEO2021" at page 24, https://www.eia.gov/outlooks/archive/aeo21/pdf/AEO_Narrative_2021.pdf.

In its projection of future electricity prices, EPA fails to account for the impacts of mass electrification (increased electricity demand), the transmission infrastructure upgrades and battery storage that will be needed to support a transition to renewable generation sources, and the potential impacts to electrical grid costs and reliability from EPA's recently proposed New Source Performance Standards for GHG emissions from power plants.49 [EPA-HQ-OAR-2022-0829-0707, p. 10]

49 88 Fed. Reg. 33240 (May 23, 2023).

EPA also fails to account for the fact that most EV ownership and charging occurs in parts of the country where electricity prices are well above U.S. average. [EPA-HQ-OAR-2022-0829-0707, p. 10]

EPA projects home charging to account for ~77% of total charging demand in 2028, declining to ~61% of total charging demand in 2055.50 Most of the non-residential charging is projected by EPA to occur at level 2 and DCFC public chargers;51 however, EPA does not account for the increased electricity fuel costs associated with public charging, which are around $0.30/kWh for Level 2 and $0.40/kWh for DC fast charging.52 [EPA-HQ-OAR-2022-0829-0707, p. 10]

50 DRIA at 5-29.

51 DRIA at 5-29.

52 https://driveclean.ca.gov/electric-car-charging.

Organization: Western Energy Alliance

Refueling Time: EPA makes the unfounded claim that the benefits of the rule will include, "…the value of reduced refueling time needed to refuel vehicles" (p. 29199) Assuming "…time spent refueling vehicles would be reduced due to the lower fuel consumption of new vehicles…" (p. 29200) is simply absurd. EPA seems to be willfully twisting the well-know disadvantage of long EV charging times. Whereas an ICEV takes a matter of minutes to refuel, charging times can be over an hour. Even fast charging stations, if available without a long wait due to their scarcity, require 30 minutes for 125 miles and an hour for 250 miles, well in excess of ICEV refueling times but with vastly less range.9 [EPA-HQ-OAR-2022-0829-0679, pp. 5-6]

9 "How Long Does It Take to Charge an Electric Car?", J.D. Power, March 26, 2020.

Limited charging infrastructure could drag refueling times to hours beyond what is needed by the driver. Further, were EPA's projection that 67% of new sales of light-duty and 46% of medium-duty vehicles will be EVs by 2032 attained, the strain on the grid would mean governments and utilities would likely enforce refueling times after hours, well past when a driver would need. Californians, just days after learning of the state's ban on ICEVs by 2035, were asked not to charge their EVs during the peak hours of 4 – 9pm because of the strain on the grid.10 Rather than being a benefit, EPA should consider how this rule would limit Americans mobility, as limited electricity capacity would cause drivers to run out of fuel when they need it for vital activities such as driving to work and school while making long roadtrips impractical. Even though EPA finds a net cost regarding refueling times, the value for that cost is likely much lower, given the assumptions EPA makes in the analysis. [EPA-HQ-OAR-2022-0829-0679, pp. 5-6]

10 "California asks residents not to charge electric vehicles, days after announcing gas car ban," John Clark, August 31, 2022.

EPA Summary and Response

Summary:

Commenters argued that fuel savings were not an appropriate economic benefit of the rule (American Enterprise Institute, American Fuel & Petrochemical Manufacturers). The commenter argued that the inclusion of fuel savings is illegitimate as a component of the "benefits" of the proposed rule because the economic benefits of fuel savings are captured fully by consumers of fuels. There is no "externality" attendant upon fuel consumption per se, and if "fuel savings" are to be considered relevant for purposes of benefit/cost analysis, the commenter believes then the adverse effects or costs of a (forced) reduction in fuel consumption in terms of the quality of transportation services must be included in the analysis (American Enterprise Institute). Similarly, commenters asked, "Why does market behavior not yield fuel consumption for the vehicle fleet envisioned in the proposed rule (American Enterprise Institute)

Commenters suggested that EPA should revise its analysis concerning charging time and continue with promulgating a final rule for future emissions standards that accounts for the reality of today's automotive market and not the public pronouncements of the automotive industry, a single state or group of states, or other unsupported estimates of future market growth (American Fuel & Petrochemical Manufacturers).

Commenters expressed concern over lost fuel tax revenues and the impact that would have on the Highway Trust Fund and Federal highway infrastructure investment (American Highway Users Alliance, Chevron, Departments of Transportation of Idaho, Montana, North Dakota, South Dakota and Wyoming, Office of Wyoming Governor Mark Gordon, U.S. Chamber of Commerce).

Commenters suggested that EPA reflect the effect on fuel prices of the IRA on incentivizing carbon capture and sequestration used for enhanced oil recovery (Donn Viviani). The commenter suggests that such incentives would reduce fuel prices which in turn could slow the transition to BEVs.

Commenters suggested that EPA's use of a 10 percent rebound effect was too high and a value well below that would be more appropriate (Environmental. And Public Health Organizations).

Commenters argued that EPA's fuel savings analysis was unclear and incomplete (NADA). This commenter also argues that EPA appears to have premised its conclusion on the modeling of liquid fuel and electricity consumption levels. This commenter believes that EPA does not explain how it converted modeled fuel consumption levels into monetary values to show actual consumer savings, and that we did not compare fueling costs and electricity rates based on modeled consumption levels. The commenter also believes EPA did not provide information on individual consumer savings. Thus, NADA believes the basis for EPA's consumer fuel savings conclusion is unclear. This commenter also states that, if the average household drives an EV 15,000 miles per year, or 1,250 miles per month, and the EV is charged at home to the tune of 450 kilowatt hours of electricity per month, the household's electricity bill will increase by around 50 percent and electricity prices are likely to rise with increasing demand.

Commenters argued that EPA's fuel savings were incorrect because they did not consider the impact of lower gasoline demand on lower gasoline prices and simultaneously ignoring the impact on electricity prices associated with increased demand (Paul Bonifas and Tim Considine, The Heritage Foundation, Valero). Commenters argued that the BEV refueling times and associated costs are underestimated suggesting that they equate to an additional five minutes of refueling time for recharging once every two weeks (The Heritage Foundation).

<u>Response:</u>

We respond to comments related to the rebound effect in Section 13 of this document, to EVSE charging infrastructure in Section 17 of this document, the grid and infrastructure upgrades in Section 18 of this document.

Regarding fuel savings being included as a benefit of the rule, this is a mischaracterization of EPA's consideration of fuel savings. EPA considers the fuel savings to be a cost of the rule, a cost which happens to be negative and therefore a savings to vehicle drivers. Fuel savings factor into net benefits since net benefits are monetized benefits less costs. The commenter suggests that, if EPA continues to calculate fuel savings and include them in net benefits, that the "costs of a (forced) reduction in fuel consumption in terms of the quality of transportation services must be included in the analysis." EPA disagrees that there are costs associated with a reduction in fuel consumption because there is no reason to believe that there will be an impact on the quality of transportation services. Presumably the commenter believes, without having provided supporting data, that drivers of BEVs will experience less quality in their transportation. This is an unfounded belief given that the literature indicates that BEV drivers to date appear to be happy with their decision to purchase a BEV.[372] Further, studies show that the more consumers are exposed to BEVs the more interested in BEVs they become.[373]

Regarding assertions that the market will provide all the fuel savings customers desire, the issue here is one referred to as the "energy paradox" and EPA has addressed this issue in past rules (see 75 FR 25510 and 77 FR 62914) and again in this rule (Section VIII.K.1 of the preamble).

Regarding comments from Paul Bonifas and Tim Considine concerning fuel prices and those from the American Fuel & Petrochemical Manufacturers regarding electricity prices, our liquid fuel price projections in the final analysis are not EPA's projections, but instead are based on AEO 2023, the best available projections developed by the recognized experts in the Energy Information Administration. Regarding electricity prices, we have updated the electricity prices used for EV charging estimates and the EVSE port costs used in our benefit cost analysis and respond to related comments in Section 17 of this document.

Regarding the impact of lower liquid fuel demand on liquid fuel prices, Paul Bonifas and Tim Considine assert that the significant reduction in liquid fuel demand would lower equilibrium prices for liquid fuels by about 50 percent, assuming an oil supply elasticity of 0.6, thereby reducing EPA's estimated liquid fuel savings from $1.3 trillion to $620 billion. The commenter's source for the suggested oil supply elasticity of 0.6 is the one of the authors of this comment in a study looking at the impacts of increasing supply to the Strategic Petroleum Reserve as opposed to releasing that supply to lower liquid fuel prices.

The impact of lower gasoline demand on gasoline prices is likely two-fold: 1) reduction of crude oil demand, which lowers crude oil prices and then lowers the cost of producing gasoline and other refined products and 2) lower demand for gasoline in refineries would impact the cost of producing gasoline as gasoline production at refineries decreases.

With respect to #1, one would expect that reducing crude oil demand would reduce crude oil prices, however, swing producers such as Saudi Arabia could then turn around and lower crude oil production to send crude oil prices back up again.[374] At the same time, crude oil production is changing with many crude oil wells in decline while new oil fields are being developed. Those which are in decline producing crude oil at, for example, $30/bbl could add tertiary crude oil recovery (carbon dioxide flood) and then their marginal production cost could rise to $70/bbl.

[373] Lundin, Ben, "More BEV Exposure Leads to Higher BEV Purchase Intent," Escalent, December 20, 2022, https://escalent.co/blog/more-bev-exposure-leads-to-higher-bev-purchase-intent/#:~:text=Almost%2070%25%20of%20Heavy%20EV,a%20gas%20or%20diesel%20vehicle., accessed January 30, 2024.

[374] What drives crude oil prices: Supply OPEC; Energy and Financial Markets; Energy Information Administration; last updated 1/9/2024.

Predicting the economics of producing crude oil over the next 30 years is extremely challenging at best.

With respect to #2, reducing gasoline production at refineries would likely lower refining costs. However, as gasoline demand decreases, refineries close and the system returns to the same point of the cost curve for producing gasoline. The refining costs for gasoline would, though, likely change if gasoline demand is decreasing faster than other refined products which is possible.

Because there are so many confounding factors at play when and if liquid fuel demand decreases and how that may or may not impact liquid fuel prices, EPA has chosen not to attempt to reflect such relationships in its analysis using a single elasticity parameter applied to demand as suggested by the commenter. Any attempt at reflecting such relationships are best handled by large scale economic models such as the National Energy Modeling System (NEMS) which considers all such factors simultaneously.

Regarding the comment that EPA used the residential electricity price ($/kWh) in estimating electricity expenditures to charge BEVs, this was true in the proposed rule. For the proposal, EPA used the value reported in the Annual Energy Outlook and used that value to be consistent with the AEO liquid fuel prices used in the EPA analysis. We acknowledge the use of this electricity price as a shortcoming of the NPRM's analysis. In the final rulemaking analysis, we are using estimated electricity prices from the Integrated Planning Model runs done in support of the electric generating unit emission inventory and charge demand estimates. Further, we have added additional factors to reflect the share of BEV charging done at public versus private sources and the different prices projected to be paid at those sources. We respond to comments regarding our electricity charging prices in Section 17 of this document.

Regarding refueling time, we have updated our estimates of refueling time by including a charge rate of 400 miles per hour of charging compared to the 100 miles per hour of charging that was used in the NPRM (see Chapter 4 of the final RIA). We note that the refueling time associated with BEVs is meant to reflect mid-trip charging only, not routine charging done overnight at home, while purchasing groceries or other goods, or while working. We would not expect mid-trip charging to take place once every two weeks. In fact, our OMEGA analysis estimates a mid-trip charging event every 3,600 to 5,200 miles, depending on the vehicle body style (car, van/suv, pickup). This would suggest just 2 to 5 events per year for 10,000 to 15,000 miles of driving in the year.

Regarding comments that the fuel savings analysis was unclear and incomplete, based on the level of detailed observations relayed in this comment, it appears that EPA's analysis was quite clear to the commenter. The commenter also provides an estimate of a 50 percent increase in home electricity consumption associated with in-home BEV charging. Without assessing the accuracy of that estimate, 450 kWh/month of charging at a $0.20/kWh would cost $90/month. A gasoline vehicle driving 1,250 miles/month at 30 miles/gallon and fueled with $3.00/gallon gasoline would be $125/month. Therefore, in this rough back-of-the-envelope calculation that might be typical of a consumer considering a new vehicle purchase, the BEV provides a $35 savings every month or $420/year. If that consumer purchasers a level 2 home charger for $1,280 (see Table 5-12 of the final RIA, single-family home (SFH) L2), that charger would be paid for after 3 years and the $420/year savings would be available for other needs. And this ignores other expected operating savings. Thus, contrary to the implication in this comment, EPA's analysis indicates that ownership costs for BEVs are lower than those for ICE vehicles, on average over time.

8.4 - Social cost of GHGs

Comments by Organizations

Organization: Alliance for Automotive Innovation

Once the agency fixes the modeling of CO2 emissions with and without the new 2027-2032 standards, it should revisit its decision about how to monetize the CO2 emissions benefits. A good case can be made that one set of benefit calculations should make use of a global measure of the social cost of carbon, as use of a global measure may encourage other countries to control CO2 emissions through deployment of BEVs and cleaner electricity systems. EPA has taken this position in the DRIA. However, once again, the agency's analysis should not engage in wishful thinking, as it is well known that most countries are not meeting their pledged commitments under the 2015 Paris accords. It also makes sense to disclose to Congress and the public the climate benefits of the rule, measured with a domestic cost of carbon. This measure would account for the fact that most of the climate benefits of the 2027-2032 rule will occur outside the United States, as greenhouse gases are globally mixing pollutants. Presentation of both global and domestic estimates of climate benefits will ensure that the RIA is seen as an objective analysis. [EPA-HQ-OAR-2022-0829-0701, pp. 291-292]

Overall, Auto Innovators believes that a more modest, measured claim of climate-control benefits in the final rule would make the rule more defensible. As the DRIA stands now, the climate-benefits analysis could be vulnerable to technical criticism. [EPA-HQ-OAR-2022-0829-0701, pp. 291-292]

Organization: American Enterprise Institute

II. The Purported Climate Benefits of the Proposed Rule Are Illusory and the Social Cost of Carbon Parameters Are Fundamentally Flawed

EPA asserts in the proposed rule that it would yield cumulative reductions in greenhouse gas (GHG) emissions of between 7.3 billion and 8.0 billion metric tons through 2055.5 Using the higher figure, that is an annual average reduction of about 276 million metric tons. U.S. emissions of GHG in 2021 were about 6.3 billion metric tons on a CO2-equivalent basis.6 The Biden administration policy goal is net-zero emissions by 2050.7 If we use the EPA climate model in order to estimate the prospective temperature effect of the entire Biden administration policy, under a set of assumptions that exaggerate the temperature effects of reduced emissions, that policy would yield a global temperature reduction of 0.062°C by 2050, and 0.173°C by 2100.8 [EPA-HQ-OAR-2022-0829-0571, pp. 4-5]

5 See the proposed rule at Table 3.

6 See https://www.epa.gov/ghgemissions/inventory-us-greenhouse-gas-emissions-and-sinks#:~:text=In%202021%2C%20U.S.%20greenhouse%20gas,sequestration%20from%20the%20land%20sector. U.S. GHG emissions in 2005 on a CO2-equivalent basis were about 7.5 billion metric tons; see

Table ES-2 at https://www.epa.gov/system/files/documents/2023-04/US-GHG-Inventory-2023-Chapter-Executive-Summary.pdf.

7 See https://www.whitehouse.gov/briefing-room/statements-releases/2023/04/20/fact-sheet-president-biden-to- catalyze-global-climate-action-through-the-major-economies-forum-on-energy-and-climate/#:~:text=President%20Biden%20has%20set%20an,by%20no%20later%20than%202050.

8 Author computations using Model for the Assessment of Greenhouse Gas Induced Climate Change (MAGICC), version 7.0, at https://magicc.org/. Assumes equilibrium sensitivity of the climate system at 4.5°, with global baseline emissions path A1B from the IPCC 4th Assessment Report.

The cumulative reduction in U.S. emissions under the net-zero policy, from 6.3 billion metric tons in 2021 to net zero by 2050, would total about 88.2 billion metric tons. For the 2027- 2050 time period relevant in the proposed rule, the cumulative reduction would be about 60 billion tons. Accordingly, the cumulative emissions reduction of 8.0 billion metric tons asserted in the proposed rule would be about 13.3 percent of the total envisioned in the Biden net-zero policy, which as just noted, would yield a reduction in global temperatures of 0.173°C by 2100. A linearity assumption is not strictly correct, but it is wholly appropriate for purposes of close approximation. The “climate benefit” of the proposed rule, under the explicit EPA assumptions and estimates, would be about 0.023°C by 2100. Because the standard deviation of the surface temperature record is 0.11°C, that effect would not be detectable.9 Accordingly, the monetized climate benefits of the proposed rule asserted by EPA are an illusion. [EPA-HQ-OAR-2022-0829-0571, pp. 4-5]

9 See https://agupubs.onlinelibrary.wiley.com/doi/pdf/10.1029/1999JD900835.

EPA attempts to circumvent this obvious problem by substituting in place of any such analysis an application of the “social cost of carbon” (SC-GHG) to the asserted reductions in GHG emissions attendant upon implementation of the proposed rule, as estimated on an interim basis by the Biden Administration Interagency Working Group.10 [EPA-HQ-OAR-2022-0829-0571, pp. 4-5]

10 The interim estimates are at https://www.whitehouse.gov/wp-content/uploads/2021/02/TechnicalSupportDocument_SocialCostofCarbonMethaneNitrousOxide.pdf.

EPA estimated the climate benefits for the final standards using measures of the social cost of three GHGs: Carbon, methane, and nitrous oxide. The social cost of each gas (i.e., the social cost of carbon (SC–CO2), methane (SC– CH4), and nitrous oxide (SC–N2O)) is the monetary value of the net harm to society associated with a marginal increase in emissions in a given year, or the benefit of avoiding that increase. Collectively, these values are referenced as the ‘‘social cost of greenhouse gases’’ (SC–GHG).11 [EPA-HQ-OAR-2022-0829-0571, pp. 4-5]

11 See the proposed rule at 29371.

The interim IWG estimates are deeply flawed, in that they (1) distort the actual economic growth predictions produced by the integrated assessment models, (2) base predictions of future climate phenomena on climate models that cannot predict the past or the present, (3) incorporate “co-benefits” in the form of a reduction in the emissions of other criteria and hazardous air pollutants already regulated under different provisions of the Clean Air Act, (4) incorporate the asserted benefits of GHG reductions on a global basis, and (5) employ discount rates that are inconsistent and inappropriate.12 [EPA-HQ-OAR-2022-0829-0571, pp. 5-8]

12 See Benjamin Zycher at https://scholarship.law.tamu.edu/cgi/viewcontent.cgi?article=1154&context=lawreview. The issue of discount rates is addressed in section III.

The available analysis suggests that the prospective economic growth risks of anthropogenic climate change, at least in the aggregate, are much smaller than many assert. Consider the predictions from the integrated assessment models, a central one of which is the Dynamic Integrated Climate and Economy Model, for which William D. Nordhaus won the Nobel Prize in Economics in 2018.13 Under DICE, global gross domestic product (GDP) in 2100 varies by about 3 percent across policy scenarios, including no climate policies at all, a figure that is both very small and almost certainly not statistically significant given the vagaries of economic forecasting and the number of years remaining before the end of this century. (I exclude here Nordhaus' "Stern discounting" policy scenario, as it assumes a discount rate effectively equal to zero, a fundamental analytic error.14) Per capita consumption varies only by about 1.3 percent across policy scenarios, also a very small number and almost certain not to be statistically significant. [EPA-HQ-OAR-2022-0829-0571, pp. 5-8]

13 See William Nordhaus and Paul Sztorc, "DICE 2013R: Introduction and User's Manual," Yale University, Department of Economics, October 2013, Figure 4 and Table 1, http://www.econ.yale.edu/~nordhaus/homepage/homepage/documents/DICE_Manual_100413r1.pdf. See also Benjamin Zycher, "The Climate Left Attacks Nobel Laureate Willian D. Nordhaus," monograph, American Enterprise Institute, July 2020, at https://www.aei.org/wp-content/uploads/2020/07/The-Climate-Left-Attacks- Nobel-Laureate-William-D.-Nordhaus.pdf.

14 See Nicholas Stern, The Economics of Climate Change: The Stern Review (Cambridge, UK: Cambridge University Press, January 2007), https://www.cambridge.org/us/academic/subjects/earth-and-environmental- science/climatology-and-climate-change/economics-climate-change-stern-review?format=PB. On the contrast between the climate predictions made by the Stern model and the actual record, see https://rogerpielkejr.substack.com/p/off-target-an-evaluation-of-the-stern?utm_source=substack&publication_id=119454&post_id=104480671&utm_medium=email&utm_content=sha re&triggerShare=true&isFreemail=true. See also David Kreutzer, "Discounting Climate Costs," Heritage Foundation, June 16, 2016, at https://www.heritage.org/environment/report/discounting-climate-costs.

The IPCC — even in its most alarmist analyses — arrives at a conclusion very close to that reported in the DICE analysis. In its "1.5 Degree C" report, it finds that the damage from anthropogenic climate change unmitigated by policy initiatives will reduce global GDP by 2.6 percent by 2100.15 By that year, IPCC projects that individual incomes on average will be at least 400 percent greater than is the case today.16 [EPA-HQ-OAR-2022-0829-0571, pp. 5-8]

15 See Marco Bindi, et. al., "Impacts of 1.5°C of Global Warming on Natural and Human Systems," at https://www.ipcc.ch/site/assets/uploads/sites/2/2019/06/SR15_Chapter3_Low_Res.pdf, Chapter 3 of Valerie Masson-Delmotte, et. al., eds., IPCC Special Report, Global Warming of 1.5°C, at https://www.ipcc.ch/site/assets/uploads/sites/2/2019/06/SR15_Full_Report_High_Res.pdf.

16 This implies average annual growth in per capita GDP of less than 1.5 percent for the rest of this century.

The interim estimates of the SCC are driven by damage functions predicted by the various climate models — the EPA model in particular — the track records of which are poor.17 McKitrick and Christy summarize the contrast between their predictions and the actual satellite record as follows: [EPA-HQ-OAR-2022-0829-0571, pp. 5-8]

17 The specifics of the CMIP5 and CMIP6 models, respectively, can be found at https://pcmdi.llnl.gov/mips/cmip5/ and https://pcmdi.llnl.gov/CMIP6/.

The tendency of climate models to overstate warming in the tropical troposphere has long been noted. Here we examine individual runs from 38 newly released Coupled Model Intercomparison Project Version 6 (CMIP6) models and show that the warm bias is now observable globally as well. We compare CMIP6 runs against observational series drawn from satellites, weather balloons, and reanalysis products. We focus on the 1979–2014 interval, the maximum span for which all observational products are available and for which models were run using historically observed forcings. For lower-troposphere and midtroposphere layers both globally and in the tropics, all 38 models overpredict warming in every target observational analog, in most cases significantly so, and the average differences between models and observations are statistically significant. We present evidence that consistency with observed warming would require lower model Equilibrium Climate Sensitivity (ECS) values.18 [EPA-HQ-OAR-2022-0829-0571, pp. 5-8]

18 See https://agupubs.onlinelibrary.wiley.com/doi/full/10.1029/2020EA001281.

OMB Circular A-4 directs federal agencies conducting benefit/cost analysis of regulatory measures as follows: “Your analysis should focus on benefits and costs that accrue to citizens and residents of the United States. Where you choose to evaluate a regulation that is likely to have effects beyond the borders of the United States, these effects should be reported separately.”23 The IWG analysis incorporates explicitly in its benefit/cost calculation the purported global climate benefits from reductions in U.S. GHG emissions, presumably on the grounds that the assumed GHG externality is global in nature. [EPA-HQ-OAR-2022-0829-0571, p. 8]

23 See OMB Circular A-4, “Regulatory Analysis,” September 17, 2003, at https://obamawhitehouse.archives.gov/omb/circulars_a004_a-4/.

This argument is fundamentally flawed, in substantial part because the global climate effect of all U.S. GHG emissions is very close to zero, as discussed above. Accordingly, the global “benefits” of U.S. GHG emissions reductions would be effectively zero. Neither the IWG nor EPA can dispute this because it is the EPA climate model used directly or indirectly through the IAMs applied to the analysis of the SCC. More generally, it is the EPA climate model that is used throughout the federal government for analysis of climate and energy policies.24 [EPA-HQ-OAR-2022-0829-0571, p. 8]

24 See, e.g., Environmental Protection Agency and Department of Transportation, National Highway Traffic Safety Administration proposed rule, “Greenhouse Gas Emissions and Fuel Efficiency Standards for Medium- and Heavy- Duty Engines and Vehicles — Phase 2,” July 12, 2015, at https://www.regulations.gov/document/EPA-HQ-OAR- 2014-0827-0002.

Furthermore, the inclusion of purported global benefits in the benefit/cost analysis of U.S. GHG policies would create a very large distortion in terms of an efficient international adoption of climate policies. An efficient promulgation of climate policies internationally would attempt to achieve both an equation of the global marginal benefits and costs of GHG emission reductions, and an allocation of emissions reductions that equates the marginal cost of such reductions across economies. If the U.S. is to promulgate domestic policies that equate domestic marginal costs with global marginal benefits, then other countries would have powerful incentives to obtain free rides on U.S. efforts. Given that the marginal cost function for reductions in GHG emissions almost certainly is upward sloping — the marginal cost of GHG reductions rises as such reductions increase — the outcome would be a global effort to reduce GHG emissions more costly than an international effort equating marginal costs across economies.25 That is the central implication of the imperative incorporated in the IWG analysis of the SCC: Under any assumption about the global benefits of reduced GHG emissions, that cannot be an efficient outcome unless the U.S. is the low-cost source of all reductions in GHG emissions, an assumption that simply is not plausible. [EPA-HQ-OAR-2022-0829-0571, p. 8]

25 This is true whether the marginal cost functions across economies are identical or differ, although the latter is far more plausible.

With respect to the issue of the choice among discount rates, “climate policy” by definition is the allocation of resources away from current consumption and from productive activities that yield consumption goods during the current time period, in favor of a reduction in GHG emissions/concentrations that purportedly would increase the production of consumption goods during some series of future time periods. That is why EPA asserts that the proposed rule would yield positive net benefits in present value terms, that is, increase the present value of the consumption stream. Accordingly, that use of resources during the current time period — again, by definition — is an investment, and it must be evaluated in comparison with the social return to alternative investments. [EPA-HQ-OAR-2022-0829-0571, pp. 8-10]

Therefore, it is the opportunity of cost of capital that is the appropriate discount rate to be applied to the evaluation of the proposed rule, because the allocation — the investment — of resources to such endeavors imposes an opportunity cost in the form of other forgone investments. Because the use of scarce resources for reductions in GHG emissions is an investment, whether promising returns low or high, the appropriate discount rate is the opportunity cost of capital for the economy as a whole. For the period 1928-2020, the average annual before-tax return to investment in the Standard and Poor 500, in real (inflation-adjusted) terms was 8.5 percent.26 For the period 1960-2020, the figure was 7.61 percent. Such long-run historical figures are consistent with the directive in OMB Circular A-4 that a discount rate of 7 percent be the baseline parameter applied to regulatory analysis by the federal government. [EPA-HQ-OAR-2022-0829-0571, pp. 8-10]

26 The data on annual returns for several investment alternatives are reported by the Stern School of Management, New York University, at http://www.stern.nyu.edu/~adamodar/pc/datasets/histretSP.xls.

EPA in previous analyses has justified a “consumption rate of interest” defined alternatively at 2.5 percent, 3 percent, or 5 percent, as follows.27 [EPA-HQ-OAR-2022-0829-0571, pp. 8-10]

27 See the regulatory impact analysis for https://www.govinfo.gov/content/pkg/FR-2021-08-10/pdf/2021-16582.pdf.

Second, the IWG found that the use of the social rate of return on capital (7 percent under current OMB Circular A-4 guidance) to discount the future benefits of reducing GHG emissions inappropriately underestimates the impacts of climate change for the purposes of estimating the SC-GHG. Consistent with the findings of the National Academies and the economic literature, the IWG continued to conclude that the consumption rate of interest is the theoretically appropriate discount rate in an intergenerational context… and recommended that discount rate uncertainty and relevant aspects of intergenerational ethical considerations be accounted for in selecting future discount rates. As a member of the IWG involved in the development of the

February 2021 TSD, EPA agrees with this assessment and will continue to follow developments in the literature pertaining to this issue. [EPA-HQ-OAR-2022-0829-0571, pp. 8-10]

That analytic argument is fundamentally flawed. First: The "consumption rate of interest" is not the correct conceptual discount rate for analysis of the proposed rule because the use of resources for purposes of reductions in GHG emissions is obviously an investment, the opportunity cost of which is the marginal social return to investment. Even if we assume that the "consumption rate of interest" conceptually is the correct parameter for discounting purposes, the relevant metric is the real market rate of interest on intertemporal consumption shifts, one crude measure of which is the market rate of interest on unsecured consumer loans. Even given the recent years of low interest rates maintained by the Federal Reserve, that market rate appears to be over 7 percent in real terms.28 For secured loans (new autos), the real interest rate appears to be at least 3 percent,29 but that is not the correct parameter because there is no collateral insuring against the possibility that government policies mandating reductions in GHG emissions will prove uneconomic. The EPA discount rate argument is fundamentally flawed analytically, and is inconsistent with the data for the U.S. credit market. [EPA-HQ-OAR-2022-0829-0571, pp. 8-10]

28 See the data reported by the Federal Reserve Bank of St. Louis at https://fred.stlouisfed.org/series/TERMCBPER24NS.

29 See https://fred.stlouisfed.org/series/RIFLPBCIANM60NM.

Note also that the use of a (low) "consumption rate of interest" for the evaluation of climate policy only would introduce an important bias in the allocation of resources among government policies and between government and private-sector resource use. EPA does not argue that the "consumption rate of interest" should be applied to the benefit/cost analysis of all government investment and regulatory activity; only climate policies are to be so treated, on the grounds of "intergenerational equity," discussed below. Nor would the private sector choose to use an artificially-low discount rate for the evaluation of alternative resource uses. If it is only the climate dimension of investment and consumption choice dynamics that is to be shaped by the use of a low "consumption rate of interest," it is obvious that important distortions would be the central outcome, with a smaller capital stock resulting. [EPA-HQ-OAR-2022-0829-0571, pp. 8-10]

Second: The implicit premise in the EPA discussion of intergenerational analysis and the discount rate is straightforward: Future generations prefer to avoid the damages that they ostensibly will bear because of the climate effects of resource allocation decisions made by the current generation, and because future generations cannot vote during the current time period, it is equitable to force the current generation to bear the costs of anthropogenic climate change that otherwise would be inflicted upon future generations. [EPA-HQ-OAR-2022-0829-0571, pp. 8-10]

However seemingly straightforward, that argument is not correct. Future generations prefer to receive a bequest of an aggregate capital stock more- rather than less valuable, an objective very different from a maximization of the value of one dimension — climate phenomena — of that aggregate capital stock. This requires efficient resource allocation by the current generation, and therefore the application of the correct discount rate. Consider a homo sapiens baby borne in a cave some 50,000 years ago. Despite the fact that at birth that child would have enjoyed environmental quality effectively unaffected by mankind, and a fortiori climate phenomena determined by natural processes only, the baby at birth would have had a life expectancy of only about ten years.30 [EPA-HQ-OAR-2022-0829-0571, pp. 8-10]

30 This life expectancy observation was provided by Professor Gail Kennedy, Department of Anthropology, University of California, Los Angeles, during a telephone interview conducted February 16, 2011.

Accordingly, it is obvious that given the opportunity to choose, that child would opt for less environmental quality and greater climate risk in exchange for a longer life expectancy engendered by a more valuable aggregate capital stock yielding improved shelter, expanded food supplies, a cleaner water supply, better medical care, ad infinitum. Greater wealth is the central objective of any generation, a reality shunted aside by the focus in the RIA upon only the climate dimension of the aggregate capital stock to be bequeathed to future generations. [EPA-HQ-OAR-2022-0829-0571, pp. 8-10]

In short: EPA uses the SCC as a substitute for estimation of the actual prospective climate impacts of its proposed rule because the latter cannot be asserted to be greater than zero operationally or as a matter of statistical significance. But the SCC is fundamentally flawed for the reasons summarized above, and is inconsistent with the evidence on climate phenomena and with the prospective effectives of climate policies in the EPA climate model.31 [EPA-HQ-OAR-2022-0829-0571, pp. 8-10]

Organization: Arizona State Legislature

4. The proposed rule relies on unlawful and faulty calculations for the Social Cost of Greenhouse Gases. The Social Cost of Greenhouse Gases calculations relied upon by EPA in its post-hoc cost-benefit analysis violate the separation of powers and suffer from glaring methodological deficiencies. [EPA-HQ-OAR-2022-0829-0537, p. 2]

IV. EPA’s Calculation of the “Social Cost of Greenhouse Gases” Is Unlawful, Unconstitutional, Arbitrary and Capricious. [EPA-HQ-OAR-2022-0829-0537, pp. 9-10]

As noted above, EPA claims that it need not engage in any cost-benefit analysis to justify the proposed rule. Yet, in Section VIII, to comply with Executive Order 12866, EPA gives a clear indication of what such a cost-benefit analysis would look like if EPA admitted that it were required to conduct one. That cost-benefit analysis rests heavily on the so-called “Social-Cost of Greenhouse Gases.” If adopted by EPA as justification for the proposed rule, it is equally unlawful, unconstitutional, arbitrary, and capricious. [EPA-HQ-OAR-2022-0829-0537, pp. 9-10]

EPA’s calculation of the so-called “Social Cost of Greenhouse Gases” (“SC-GHG”) plays a pivotal role in the analysis conducted in Section VIII. See 88 Fed. Reg. 29,371-379. Avoiding the supposed “social costs” of greenhouse gases is the first and principal benefit of the new emissions standards proposed by EPA. See id. Indeed, it is clear that reducing greenhouse gas emissions is the driving force behind the proposal. See id. But EPA’s approach is baseless. EPA’s continued reliance on the “social cost of greenhouse gases” metric, as calculated by the “Interagency Working Group” convened by Executive Order 13990, to predict future climate damages is unlawful, unconstitutional, arbitrary and capricious. It violates the separation of powers and thPAe Major Questions Doctrine, and suffers from glaring methodological deficiencies. [EPA-HQ-OAR-2022-0829-0537, pp. 9-10]

A. EPA uncritically adopts the Interagency Working Group's values for the SC- GHG, as it was instructed to do by Section 5(b) of E.O. 13990.

In its Section VIII discussion, EPA uncritically adopts the values for the SC-GHG provided by the Interagency Working Group convened by Executive Order 13990. EPA states: "We estimate the global social benefits of CO2, CH4, and N2O emission reductions expected from the proposed rule using the SC-GHG estimates presented in the February 2021 Technical Support Document (TSD): Social Cost of Carbon, Methane, and Nitrous Oxide Interim Estimates under E.O. 13990 (IWG 2021)." 88 Fed. Reg. 29,372 (emphasis added). EPA claims that "[w]e have evaluated the SC-GHG estimates in the TSD and have determined that these estimates are appropriate for use in estimating the global social benefits of CO2, CH4, and N2O emission reductions expected from this proposed rule." Id. However, EPA's substantive discussion of the Interagency Working Group's values includes only statements recognizing their "limitations." See id. For example, EPA states that "these interim SC-GHG estimates have a number of limitations, including that the models used to produce them do not include all of the important physical, ecological, and economic impacts of climate change recognized in the climate-change literature and that several modeling input assumptions are outdated." Id. Further, EPA admits that "more robust methodologies for estimating damages from [greenhouse gas] emissions" are available, and that there is room to "further improve SC-GHG estimation going forward." Id. Nevertheless, with scant analysis, EPA uncritically adopts the Interagency Working Group's values for the "Social Costs" of carbon dioxide, methane, and nitrous oxide: [EPA-HQ-OAR-2022-0829-0537, p. 10]

Table 172 through Table 175 show the benefits of reduced CO2, CH4, N2O and GHG emissions, respectively, and consequently the annual quantified benefits (i.e., total GHG benefits), for each of the four interim social cost of GHG (SC–GHG) values estimated by the interagency working group. [EPA-HQ-OAR-2022-0829-0537, pp. 10-11]

Id. (emphasis added).

Why so? Why does EPA adopt SC-GHG values that it admits are subject to numerous "limitations," are based on "outdated" modeling assumptions, and compare poorly with "more robust methodologies"? Id. Moreover, why does it appear that every other federal agency to quantify the "social costs" of carbon dioxide, methane, and/or nitrous oxide since February 2021 used the Interagency Working Group's "interim estimates"?16 What explains the astonishing, persistent persuasive power of these admittedly flawed numbers? [EPA-HQ-OAR-2022-0829-0537, pp. 10-11]

16 At least twelve agency actions have expressly used the Working Group's "interim estimates" from the 2021 TSD since it was published in February 2021. See, e.g., Doc. 98, Louisiana v. Biden, Case No. 2:21-cv-01074, at 16-18 (W.D. La. Feb. 11, 2022) (citing nine such agency actions, including action by EPA, DOE, BLM, FAR, CEQ, NHTSA, and DOI, addressing issues such as light-duty vehicle emissions standards, general service lamps, oil and gas new and modified sources, fossil fuel leasing, and manufactured housing, among others); see also, e.g., Office of Energy Efficiency and Renewable Energy, Department of Energy, Energy Conservation Program: Energy Conservation Standards for General Service Lamps, Final Rule, 87 Fed. Reg. 27,439 (May 9, 2022), at 27,456/1 ("DOE used the estimates for the SC–GHG from the most recent update of the IWG in its February 2021 TSD."); Office of Energy Efficiency and Renewable Energy, Department of Energy, Energy Conservation Program: Energy Conservation

Standards for Manufactured Housing, Final Rule, 87 Fed. Reg. 32,728 (May 31, 2022), at 32,733/1-2 ("DOE used interim SC-GHG values developed by an Interagency Working Group on the Social Cost of Greenhouse Gases (IWG)."); National Highway Traffic Safety Administration, Department of Transportation, Corporate Average Fuel Economy Standards for Model Years 2024-2026 Passenger Cars and Light Trucks, Final Rule, 87 Fed. Reg. 25,710 (May 2, 2022), id. at 25,724/1 ("In this final rule, NHTSA employed the SC–GHG values from the Interim Revised Estimates developed by the Interagency Working Group on the Social Cost of Greenhouse Gases (IWG), and discounted it at values recommended by the IWG for its main analysis."). By contrast, commenters are not aware of any agencies that are not independent of the President that have declined to adopt the Interagency Working Group's 2021 recommendations on this point.

The answer to this question is obvious: EPA and the other federal agencies use the Interagency Working Group's "Interim Estimates" because they have been ordered to do so by the President. Section 5 of Executive Order 13990 directs that the "Working Group shall …publish an interim SCC, SCN, and SCM within 30 days of the date of this order, which agencies shall use when monetizing the value of changes in greenhouse gas emissions resulting from regulations and other relevant agency actions until final values are published." E.O. 13990, § 5(b)(ii)(A), 86 Fed. Reg. 7040 (emphasis added). The Executive Order is not ambiguous: It provides that "agencies shall use" the Interagency Working Group's values "until final values are published," id. (emphasis added)—which, as EPA concedes, has never happened and is now long overdue. [EPA-HQ-OAR-2022-0829-0537, pp. 10-11]

The meaning of the word "shall" in this context is perfectly plain—it is an auxiliary verb "used to express a command or exhortation." Shall, Merriam-Webster Online, at https://www.merriam-webster.com/dictionary/shall (defining "shall" as "used to express a command or exhortation"); see also, e.g., Kingdomware Technologies, Inc. v. United States, 579 U.S. 162, 171 (2016) ("Unlike the word 'may,' which implies discretion, the word 'shall' usually connotes a requirement."); Lexecon Inc. v. Milberg Weiss Bershad Hynes & Lerach, 523 U.S. 26, 35 (1998) (recognizing that "shall" is "mandatory" and "normally creates an obligation impervious to judicial discretion"). The President "used the word 'shall' in" E.O. 13990, and that functions "as a command." Kingdomware, 579 U.S. at 172. [EPA-HQ-OAR-2022-0829-0537, pp. 11-12]

Thus, in Executive Order 13990, the President gave a command to the agencies—a binding directive that they "shall" use the Interagency Working Group's interim values (and, later, its final values, if they are ever published) in any "regulations and other relevant agency actions" that involve the calculation of SC-GHG. See E.O. 13990, § 5(b)(ii)(A), 86 Fed. Reg. 7040. And every federal agency since then has interpreted it as a command—acting in lockstep with each other in adopting the Interagency Working Group's interim estimates whenever they quantify the benefits of reducing emissions of CO2, CH4, and N2O. [EPA-HQ-OAR-2022-0829-0537, pp. 11-12]

This situation is unlawful, for at least three reasons. First, it involves an unconstitutional arrogation of legislative power to the Working Group, in violation of the separation of powers. Second, it violates the Major Questions Doctrine. Third, the Interagency Working Group's methodology is profoundly flawed, such that any reliance on its numbers is inherently arbitrary and capricious—as EPA all but concedes by recognizing that its numbers are "outdated" and fraught with "limitations." 88 Fed. Reg. 29,372. [EPA-HQ-OAR-2022-0829-0537, pp. 11-12]

B. The Interagency Working Group's promulgation of binding values for the SC- GHG violates the separation of powers and Major Questions Doctrine.

In litigation about the status of the Interagency Working Group, the U.S. Department of Justice admitted: "No statute establishes it, nor delegates it any legislative authority." Doc. 28, Missouri v. Biden, No. 4:21-cv-00287-AGF (E.D. Mo.), at 54. This is undeniably true. There is no statute that either creates or delegates power to an "Interagency Working Group on Social Cost of Greenhouse Gases"—it is purely a creature of E.O. 13990. Yet, pursuant to the plain terms of E.O. 13990, the Working Group purports to exercise legislative authority—the authority to dictate to all federal agencies the specific values that they must use when they monetize the costs of future greenhouse-gas emissions. This is quintessentially legislative power, exercised without any delegation from Congress. [EPA-HQ-OAR-2022-0829-0537, p. 12]

Article I, Section 1 of the Constitution provides: "All legislative Powers herein granted shall be vested in a Congress of the United States, which shall consist of a Senate and House of Representatives." U.S. Const. art. I, § 1. The Interagency Working Group's interim estimates in the 2021 Technical Support Document constitute specific, mandatory numerical values on a policy question of great import, which federal agencies are bound to use in "regulations and other relevant agency actions" under the plain terms of E.O. 13990. E.O. 13990, § 5(b)(ii)(A), 86 Fed. Reg. 7040; see also Interagency Working Group on Social Cost of Greenhouse Gases, United States Government, Technical Support Document: Social Cost of Carbon, Methane, and Nitrous Oxide Interim Estimates Under Executive Order 13990 (Feb. 2021), at https://www.whitehouse.gov/wp-content/uploads/2021/02/TechnicalSupportDocument_SocialCostofCarbonMethaneNitrousOxide.pdf ("2021 TSD"). [EPA-HQ-OAR-2022-0829-0537, p. 12]

This is legislation, plain and simple. "[W]hen an agency wants to state a principle 'in numerical terms,' terms that cannot be derived from a particular record, the agency is legislating and should act through rulemaking." Catholic Health Initiatives v. Sebelius, 617 F.3d 490, 495 (D.C. Cir. 2010) (quoting Henry J. Friendly, Watchman, What of the Night?, BENCHMARKS 144– 45 (1967)). As Judge Posner wrote, adopting "[a] rule that turns on a number" is a "legislative function." Hoctor v. USDA, 82 F.3d 165, 170 (7th Cir. 1996). "Legislators have the democratic legitimacy to make choices among value judgments, choices based on hunch or guesswork or even the toss of a coin, and other arbitrary choices. When agencies base rules on arbitrary choices they are legislating, and so these rules are legislative…." Id. When it adopts specific numbers for the so-called "social costs" of gases, the Interagency Working Group is "legislating." Id. The Working Group adopts specific numbers, set forth in tables, for SC-GHG at four specific discount rates. 2021 TSD, at 4-6. It is unquestionable that the Working Group's adoption of these specific numbers as binding estimates is "legislative." Id. The calculations do not involve the application of simple arithmetic; rather, they involve (as the Working Group admits) "issues of uncertainty and ethics," and "highly contested and exceedingly difficult questions of science, economics, ethics, and law." 2021 TSD, at 17, 21. "[T]he range of discount rates reflects both uncertainty and, at least in part, different policy or value judgments." Id. at 27 (emphasis added). And, as EPA admits here, they involve "outdated" assumptions, inputs with significant "limitations," and the use of a less "robust methodology" than even EPA admits is available. [EPA-HQ-OAR-2022-0829-0537, pp. 12-13]

Thus, the adoption of specific values against a wide range of possibilities, based on assumptions that involve widely disputed scientific methodologies and value judgments at the intersection of "politics" and "ethics," is a legislative action. But no Executive agency may exercise legislative authority without a delegation from Congress. "It is axiomatic that an administrative agency's power to promulgate legislative regulations is limited to the authority delegated by Congress." Bowen v. Georgetown Univ. Hosp., 488 U.S. 204, 208 (1988). So when "there is no statute conferring authority, a federal agency has none." Michigan v. EPA, 268 F.3d 1075, 1081 (D.C. Cir. 2001). Here, the Working Group is purely a creature of Executive authority—it was created solely by Executive Order, not by Congress, and it exercises no delegated authority. The President lacks any independent legislative authority to bestow on the Working Group. See U.S. Const. art. I, § 2 ("The executive Power shall be vested in a President of the United States of America."). Therefore, it has none, and its exercise of legislative power encroaches on the exclusive authority of Congress. [EPA-HQ-OAR-2022-0829-0537, pp. 12-13]

This violates the separation of powers, the most fundamental structural guarantee of liberty. As the Supreme Court has held for decades, "[t]he President's power, if any, to issue [an] order must stem either from an act of Congress or from the Constitution itself." Youngstown Sheet & Tube Co. v. Sawyer, 343 U.S. 579, 585 (1952). Where "[t]here is no statute that expressly authorizes the President to take" an action, "[n]or is there any act of Congress … from which such a power can fairly be implied," the action is not authorized by an act of Congress. Id. In the absence of such an express or implied authorization by act of Congress, "if the President had authority to issue the order he did, it must be found in some provision of the Constitution." Id. at 587. But the vesting Clauses of Article I and Article II reflect a careful separation of the Legislative and Executive Branches into their respective spheres. There is no provision of the Constitution that confers purely legislative authority—of the sort exercised by the Interagency Working Group—on the President. For the Executive Branch to exercise such authority, it must be delegated by Congress. Congress has not done so here. [EPA-HQ-OAR-2022-0829-0537, pp. 12-13]

The separation of powers is the most fundamental and profound feature of our unique structure of government. The vesting clauses of Article I and Article II reflect the Founders' insights that "the legislative, executive, and judiciary departments ought to be separate and distinct," and that this separation is an "essential precaution in favor of liberty." The Federalist No. 47 (Madison) (C. Rossiter ed. 1961), p. 301. As James Madison stated, "[n]o political truth is certainly of greater intrinsic value, or is stamped with the authority of more enlightened patrons of liberty." Id. "The accumulation of all powers, legislative, executive, and judiciary, in the same hands, whether of one, a few, or many, and whether hereditary, selfappointed, or elective, may justly be pronounced the very definition of tyranny." Id. [EPA-HQ-OAR-2022-0829-0537, pp. 13-14]

This principle of separation of powers is the most crucial safeguard of liberty. "It is the proud boast of our democracy that we have 'a government of laws, and not of men.'" Morrison v. Olson, 487 U.S. 654, 697 (1988) (Scalia, J., dissenting). "The Framers of the Federal Constitution . . . viewed the principle of separation of powers as the absolutely central guarantee of a just Government." Id. "Without a secure structure of separated powers, our Bill of Rights would be worthless, as are the bills of rights of many nations of the world that have adopted, or even improved upon, the mere words of ours." Id. "The purpose of the separation and equilibration of powers in general . . . was not merely to assure effective government but to preserve individual freedom." Id. at 727. "While the separation of powers may prevent us from righting every wrong, it does so in order to ensure that we do not lose liberty." Id. at 710. [EPA-HQ-OAR-2022-0829-0537, pp. 13-14]

The Working Group created by EO 13990, therefore, reflects the Executive Branch's naked arrogation of legislative power to itself. "Frequently," a threat to the separation of powers "will come … clad, so to speak, in sheep's clothing…. But this wolf comes as a wolf." Id. at 699. [EPA-HQ-OAR-2022-0829-0537, pp. 13-14]

Furthermore, for similar reasons, the Working Group's promulgation of binding values for the so-called "Social Cost of Greenhouse Gases" violates the Major Questions Doctrine. As noted above, the Major Questions Doctrine requires "clear congressional authorization" for federal agencies to make decisions on questions of major political, social, and economic significance. West Virginia, 142 S. Ct. at 2609. Here, dictating binding values for the "social costs" of gases that apply to all federal agencies making all "regulations and other relevant agency actions," E.O. 13990, § 5(b)(ii)(A), 86 Fed. Reg. 7040, decides a matter of enormous economic and political significance, all at one stroke. Cass Sunstein, one of the architects of the "social cost of carbon" analysis in the Obama Administration, describes the SC-GHG as "the most important number you've never heard of." Cass R. Sunstein, The Arithmetic of Climate Change (Aug. 18, 2021), available at https://papers.ssrn.com/sol3/papers.cfm?abstract_id=3906854. This description is apt because "within the executive branch, the stringency of regulation of greenhouse gases emissions often depends on that number." Id. [EPA-HQ-OAR-2022-0829-0537, p. 14]

In fact, the "social cost of carbon" was cited in regulatory decisions at least eighty-three times during the Obama Administration alone. Howard & Schwartz, Think Global: International Reciprocity as Justification for a Global Social Cost of Carbon, 42:S COLUM. J. ENVT'L LAW 203, 219–20 & appx. A (2017). This included a wide array of agencies—including, but not limited to, EPA, DOE, DOT, DOI, and USDA, see id.—that applied the predecessor Working Group's analysis to formulate federal regulations, policies, and regulatory actions related to vending machines, light trucks, dishwashers, dehumidifiers, microwave ovens, kitchen stoves, clothes washers, small electric motors, residential water heaters, ozone standards, residential refrigerators and freezers, sewage guidelines, medium and heavy-duty vehicles, mercury emissions, industrial boilers, solid waste incineration units, fluorescent lamps, residential clothes dryers, room air conditioners, residential furnaces, residential central air conditioners, battery chargers, dishwashers, petroleum refineries, halide lamps, walk-in coolers and freezers, commercial refrigeration units, commercial clothes washers, commercial ice makers, and heat pumps. See id. [EPA-HQ-OAR-2022-0829-0537, p. 14]

The ability to decide this set of numbers for all federal agencies engaged in all such regulatory actions is a matter of enormous political and economic significance, which requires clear authorization from Congress. West Virginia, 142 S. Ct. at 2609. But here, not only is there no "clear" delegation from Congress, there is no delegation at all—as the U.S. Department of Justice admits, when it comes to the Interagency Working Group, "[n]o statute establishes it, nor delegates it any legislative authority." Doc. 28, Missouri v. Biden, No. 4:21-cv-00287-AGF (E.D. Mo.), at 54. [EPA-HQ-OAR-2022-0829-0537, pp. 14-15]

C. The Interagency Working Group's promulgation of so-called "interim" estimates for SC-GHG violated the APA.

For similar reasons, the Working Group's promulgation of the so-called "interim" estimates—which have served as the definitive values for all federal agencies for two and a half years, with no end in sight—violated the Administrative Procedure Act because it was arbitrary, capricious, contrary to law, unconstitutional, and adopted without agency procedures required by law. See 5 U.S.C. § 706(2)(A)-(D). [EPA-HQ-OAR-2022-0829-0537, p. 15]

First, just as the Interim Estimates constitute a de facto exercise of binding legislative authority, they constitute "legislative rules" under the APA, which can only be promulgated through observance of notice-and-comment procedures. As Judge Posner wrote in Hoctor, "[p]rovided that a rule promulgated pursuant to such a delegation is intended to bind, … the rule would be the clearest possible example of a legislative rule, as to which the notice and comment procedure not followed here is mandatory…." Hoctor, 82 F.3d at 169. "When agencies base rules on arbitrary choices they are legislating, and so these rules are legislative or substantive and require notice and comment rulemaking, a procedure that is analogous to the procedure employed by legislatures in making statutes." Id. at 170-71. [EPA-HQ-OAR-2022-0829-0537, p. 15]

"Notice of a proposed rule must include sufficient detail on its content and basis in law and evidence to allow for meaningful and informed comment." Am. Med. Ass'n v. Reno, 57 F.3d 1129, 1132 (D.C. Cir. 1995). "The purpose of the comment period is to allow interested members of the public to communicate information, concerns, and criticisms to the agency during the rule-making process." Connecticut Light & Power Co. v. Nuclear Regul. Comm'n, 673 F.2d 525, 530 (D.C. Cir. 1982). The Interagency Working Group, however, did not seek any public comment before issuing the 2021 SC-GHG estimates. Instead, it provided notice and comment for not-yet-promulgated SC-GHG estimates for future use—preventing the public from commenting on the 2021 SC-GHG estimates that federal agencies currently use. Thus, the Interim Estimates were adopted "without observance of procedure required by law," 5 U.S.C. § 706(2)(D), and they violate the APA. [EPA-HQ-OAR-2022-0829-0537, p. 15]

Likewise, the Working Group's Interim Estimates are "not in accordance with law," "contrary to constitutional right, power, privilege, or immunity," and "in excess of statutory jurisdiction, authority, or limitations." 5 U.S.C. § 706(2)(A), (B), (C). They are unconstitutional and unlawful because they violate the separation of powers and constitute legislative rules that were adopted without notice and comment. And they are in excess of statutory authority because the Working Group has no statutory authority whatsoever—least of all, authority to promulgate binding legislative rules that apply to all federal agencies on a hotly disputed policy question that has enormous practical consequences. [EPA-HQ-OAR-2022-0829-0537, p. 15]

D. The Interim Estimates are substantively arbitrary and capricious.

The Interagency Working Group's Interim Estimates in the 2021 TSD are also substantively arbitrary and capricious because they ignore important aspects of the problem, they decline to consider relevant data, they violate longstanding principles of statutory interpretation, they suffer from glaring methodological flaws, they lack scientific rigor, and they are irredeemably speculative. See State Farm, 463 U.S. at 43. Moreover, all these errors work in the same direction—to inflate estimated future climate damages. [EPA-HQ-OAR-2022-0829-0537, pp. 15-16]

As an initial matter, the Integrated Assessment Models ("IAMs") employed by the Working Group claim a predictive power that is staggering in scope. They purport to predict the global impact of human migrations, wars, natural disasters, agricultural capacities, technological developments, worldwide mitigation efforts, and other unknowable future developments for the next 300 years—i.e., "the value of all climate change impacts, including (but not limited to) changes in net agricultural productivity, human health effects, property damage from increased flood risk natural disasters, disruption of energy systems, risk of conflict, environmental migration, and the value of ecosystem services," until the year 2300. 2021 TSD, at 2. According to the 2021 TSD, "[e]xamples of affected interests include: direct effects on U.S. citizens and assets located abroad, international trade, tourism, and spillover pathways such as economic and political destabilization and global migration." Id. at 3. The Working Group admits that proper calculations would require predicting "mitigation activities by other countries," and "international mitigation actions." Id. In short, the Working Group's calculations purport to predict the arc of human and ecological history for the next three centuries. [EPA-HQ-OAR-2022-0829-0537, pp. 15-16]

The Interagency Working Group convened by E.O. 13990 lacks adequate tools to make such impossible predictions with anything like scientific rigor. On the contrary, its attempts are hampered by hopelessly outdated assumptions and glaring methodological flaws, as discussed further below. EPA candidly acknowledges that the IAMs suffer from such methodological shortcomings and outdated assumptions. As noted above, EPA admits that the three "Integrated Assessment Models" ("IAMs") on which the 2021 values are based suffer from grievous methodological flaws, including "outdated" assumptions and what EPA euphemistically calls "limitations." 88 Fed. Reg. 29,372. EPA does not bother to elucidate these flaws and limitations, but an analysis of the IAMs and their application reveals that they are inherently speculative, fundamentally non-scientific, lacking in methodological rigor, based on false assumptions, and subject to virtually limitless user manipulation. Five examples illustrate these shortcomings: (1) the selection of the discount rate, (2) the selection of the time horizon over which damages are calculated, (3) the estimate of the Equilibrium Climate Sensitivity factor, (4) the treatment of anticipated benefits of moderate warming, and (5) the geographic scope of anticipated damages. [EPA-HQ-OAR-2022-0829-0537, p. 16]

Dr. Kevin Dayaratna aptly summarizes these shortcomings: "[L]ike its predecessors, the 2021 TSD is predicated on faulty models that are prone to user-selected manipulation. Each model is highly sensitive, or produces a vastly disparate range of results, based on the user assumptions. Essentially the assumptions, and not quantifiable data, drive the results—garbage in, garbage out." Statement of Kevin D. Dayartna 15 ("Ex. A") (attached as Exhibit A). [EPA-HQ-OAR-2022-0829-0537, p. 16]

Selection of the discount rate. First, the selection of the discount rate plays an outsized role in the IAMs' damage calculations. The Interagency Working Group describes the "discount rate" as follows: "[I]n calculating the SC-GHG, the stream of future damages to agriculture, human health, and other market and non-market sectors from an additional unit of emissions are estimated in terms of reduced consumption (or consumption equivalents). Then that stream of future damages is discounted to its present value in the year when the additional unit of emissions was released." 2021 TSD, at 17. Dr. Dayaratna describes this process as follows: "Discounting future benefits of averting climate damage compares the rate of return from CO2 reduction to the rate of return that could be expected from other investments. In principle, discounting runs the compound rate of return exercise backwards, calculating how much would need to be invested at a reasonably expected interest rate today to result in the value of the averted future climate damage." Ex. A, [EPA-HQ-OAR-2022-0829-0537, pp. 16-17]

18. A lower discount rate entails a higher calculation of anticipated damages from climate change, and thus a higher "social cost" for each greenhouse gas. "The present value of a future benefit or cost is the amount you would have to invest today that would grow in value to match that benefit or cost at the specified time in the future. The discount rate represents the rate of return of this investment and should reflect the real rates of return to capital." Id. 19. [EPA-HQ-OAR-2022-0829-0537, pp. 16-17]

As the Working Group admits, the selection of a discount rate "has a large influence on the present value of future damages." 2021 TSD, at 17. As the analysis of Dr. Dayaratna demonstrates, this is an understatement—the selection of discount rate has an enormous influence on outcomes. But, as the Working Group also admits, the selection of the discount rate is an exercise in value judgment, not scientific calculation: "the choice of a discount rate … raises highly contested and exceedingly difficult questions of science, economics, ethics, and law." 2021 TSD, at 17. As the Working Group admits, the selection of a discount rate ultimately rests on "different policy or value judgments." Id. at 27 [EPA-HQ-OAR-2022-0829-0537, p. 17]

Before the 2021 TSD, the discount rate was calculated using OMB's peer-reviewed Circular A-4, which provided for a 7 percent discount rate based on the long-term return on investment capital to be used in cost-benefit analyses. Dayaratna Statement 20. The 2021 TSD abandons the longstanding, peer-reviewed approach to the discount rate in favor of a range of much lower discount rates, which yield much higher "social cost" calculations: 2.5 percent, 3 percent, 5 percent, and the 95th percentile probability distribution at the 3 percent discount rate. 2021 TSD, at 5-8. [EPA-HQ-OAR-2022-0829-0537, p. 17]

The Working Group admits that there are "disagreements in the literature on the appropriate discount rate to use in this context, and uncertainty about how rates may change over time." Id. at 17. Rather than grappling with this uncertainty and disagreement, the Working Group simply selects a range of low values that (it states) "span a plausible range of certainty-equivalent constant consumption discount rates." Id. The Working Group rejects OMB Circular A-4's peer-reviewed approach, concluding that "the social rate of return to capital, estimated to be 7 percent in OMB's Circular A-4, is not appropriate for use in calculating the SC-GHG," and opts for a range of much lower discount rates based on consumption equivalents instead of investment equivalents instead—yielding much higher "social costs" for each gas. Id. Thus, "the IWG is returning to the approach of calculating the SC-GHG based on the consumption rate of interest," which is much lower than the expected rate of return on investment. Id. at 18. [EPA-HQ-OAR-2022-0829-0537, pp. 17-18]

As Dr. Dayaratna discussed, this decision—which purports to resolve "exceedingly difficult questions of science, economics, ethics, and law," id. at 17—results in a dramatic inflation of the "social cost" values on all three of the IAMs—DICE, FUND, and PAGE. Ex. A, 21-27. [EPA-HQ-OAR-2022-0829-0537, pp. 17-18]

For example, using the FUND model, "the choice in the discount rate can cause the social cost of carbon to drop by as much as 80 percent or more." Id. 24. The other models yield similar results. "These figures show that the discount rate an agency picks have a drastic effect on the cost estimates, and the lower the discount rate, the greater the damages." Id. 27. [EPA-HQ-OAR-2022-0829-0537, pp. 17-18]

Time horizon selected. The time horizon selected for expected damages is another arbitrary choice that has a strong influence on the IAMs' results. "Closely related to the choice of discount rate, the time horizon that the agencies choose to use to calculate damages has an outsized impact on the social cost of greenhouse gases." Ex. A, 28. [EPA-HQ-OAR-2022-0829-0537, p. 18]

Quite obviously, purporting to predict climate damages centuries into the future is an irreducibly speculative task. "It is essentially impossible to forecast technological changes decades, let alone centuries, into the future. In particular, many commonplace technological innovations such as internet, smartphones and GPS technology were mere science fiction 300 years ago." Id. 29. "Yet, in every TSD to date, including the 2021 TSD, the IAMs have calculated damages based on projections ending in 2300—nearly 300 years into the future." Id. Asking the models to predict technological changes and other developments for 300 years is speculative to the point of absurdity. [EPA-HQ-OAR-2022-0829-0537, p. 18]

Suggesting that the IAMs can make reliable predictions across a 300-year time frame for all of global economic and technological history is pure speculation. It is akin to asking the soldiers of the First Crusade to predict Columbus's discovery of America, Queen Anne of England to predict the election of Donald Trump, the signers of the Peace of Westphalia to predict the invention of nuclear weapons, and the court of King Louis XIV to predict the invention of smartphones and the internet—all rolled into one, and compounded thousands of times over. This is not science. It is naked speculation. [EPA-HQ-OAR-2022-0829-0537, p. 18]

Yet this naked speculation is an important driver of the Working Group's calculations— and it drives uniformly them in one direction: upward. "Extending the time horizon in such a manner increases the SCC estimates, thus enabling the IWG to claim larger economic damages associated with CO2 emissions." Ex. A, 29. As Dr. Dayaratna recounts, the IAMs leverage the wild uncertainty inherent in 300-year projections of global history by concealing key assumptions. "[T]he IWG's estimates of the SCC are based on climate scenarios 'that are not just badly out of date, but reflecting a set of fictional worlds.'" Ex. A, 31 (quoting Roger Pielke Jr., The Biden Administration Just Failed its First Science Integrity Test (Feb. 28, 2021), at https://rogerpielkejr.substack.com/p/the-biden-administration-just-failed). "The IWG originally estimated the SCC in 2010 based on eight different scenarios of the future of the climate, developed over a decade ago. Four of these scenarios were to represent different trajectories of the future, sans climate policies and thus referred to as 'business as usual'…." Id. (emphasis added). "Four others were combined into a single scenario to reflect a future with climate policy. These five scenarios initially projected out to 2100, and the IWG extended the scenarios to 2300 using a range of assumptions." Id. [EPA-HQ-OAR-2022-0829-0537, p. 18]

"[T]hese BAU scenarios are over a decade old and thus badly outdated and unrealistic." Id. 33. "In fact, they fail to take into account recent transitions toward less CO2 intensive forms of energy such as natural gas—assuming instead [that] … the 'world would have to make it a policy goal to burn as much coal as possible over the coming centuries.'" Id. (quoting Pielke, supra). "If fossil fuels are not burned at the levels described in the scenarios above, then the IWG's estimates of the SCC that they constitute the basis for are therefore wrong, unfounded, and nonsensical." Id. Thus, the IAMs take an implausible worst-case scenario—in fact, one that is not just implausible, but has already been falsified by recent events—and project that worst-case scenario 300 years into the future. Needless to say, this approach "continues to unrealistically increase damages" calculated using the "social cost" rubric. Id. 37. [EPA-HQ-OAR-2022-0829-0537, pp. 18-19]

Equilibrium Climate Sensitivity assumptions. Each IAM includes assumptions about "Equilibrium Climate Sensitivity" ("ECS") in its calculation of future climate damages. See 2021 TSD, at 2 ("The three IAMs were run suing a common set of input assumptions in each model for… equilibrium climate sensitivity (ECS) – a measure of globally averaged temperature response to increased atmospheric CO2 concentrations."). "The ECS is a distribution that probabilistically quantifies the earth's temperature response to a doubling of carbon dioxide concentrations. Simply put, it is one of the most fundamental measures within an IAM of CO2 impacts on climate. Other effects, such as sea-level rise, all depend on a reliable ECS." Ex. A, 39. [EPA-HQ-OAR-2022-0829-0537, pp. 18-19]

The IAMs used by the Working Group employ outdated ECS assumptions that date to 2007 and have been rendered obsolete by subsequent research. "All the TSDs … since … 2013," including the 2021 TSD, "have relied on the Roe & Baker article 'Why is Climate Sensitivity So Unpredictable' published in Science in October 2007." Id. 40. "[T]his [2007] distribution vastly overstates the probability of high-end global warming compared to more recent distributions." Id. [EPA-HQ-OAR-2022-0829-0537, pp. 18-19]

The Working Group, like EPA itself, admits that its assumptions are outdated on this point. It admits that "the versions of the three models used in the 2013 and 2016 TSDs," which the 2021 TSD nevertheless adopts, "do not reflect the tremendous increase in the scientific and economic understanding of climate-related damages that has occurred in the past decade." 2021 TSD, at 22. In fact, "[t]here are several newer and more up-to-date distributions suggested in the peer-reviewed literature, and many of those suggest lower probabilities of extreme global warming in response to CO2 concentrations." Ex. A, 41. In fact, using ECS assumptions current based on peer- reviewed research in 2015—which is "preferable to Roe Baker (2007) because its estimation controlled for observed ocean heat uptake efficiency, thus yielding an empirically constrained sensitivity distribution, id. 42—yields "a reduction of over 45% with respect to the IWG's estimates" for the DICE model, id. 44. Updating the ECS factor likewise yields "a reduction of over 80% with respect to the IWG's estimates" for the FUND model. Id. 45. [EPA-HQ-OAR-2022-0829-0537, pp. 18-19]

Agricultural benefits of warming. "Another policy assumption that is made by the IWG in its modeling choices is that it does not fairly account for agricultural benefits by increased CO2 concentration." Id. 47. "For example, it is a well-established fact that increases in CO2 concentration enhance plant growth by increasing their internal water use efficiency as well as raising the rate of net photosynthesis." Id. Thus, increasing temperature results in an increase in net agricultural productivity—a benefit of warming. Id. [EPA-HQ-OAR-2022-0829-0537, pp. 19-20]

Some models used by the Working Group, such as the DICE model, simply ignore the potential benefits of warming and do not include them in their calculations. "[T]he DICE model as utilized by the IWG explicitly presumes that only damages will result from more CO2 in the atmosphere." Id. 52. By contrast, "[t]he FUND model attempts to quantify these benefits, and when the benefits of CO2 emissions outweigh costs, the SCC is negative." Id. 48. For example, if one corrects the admittedly "outdated" ECS assumption with more current 2015 figures under the FUND model, accounting for the benefits of warming results in negative mean estimates for social costs in 2020, 2030, 2040, and 2050: "Using the empirically estimated Lewis and Curry distribution (2015), the mean estimate of the SCC is negative $1.10 in 2020, negative $1.01 in 2030, negative $0.82 in 2040, and negative $0.53 in 2050 in 2007 dollars." Id. So also, under the other models, "under reasonable updates to the agricultural productivity component, the mean SCC estimate may be zero or negative and that there are substantial probabilities of negative SCC under very reasonable assumptions." Id. 53. [EPA-HQ-OAR-2022-0829-0537, pp. 19-20]

A negative "social cost" means that emitting a metric ton of carbon dioxide is beneficial to society, and thus should be encouraged. See id. 54 ("One policy implication of a negative SCC is that the emission of an additional ton of a greenhouse gas should be encouraged, rather than avoided."). This result effectively discredits the IAMs as tools of rational policymaking: "The fact that, under very reasonable assumptions, the model can elicit SCC estimates of either sign [positive or negative] suggests that it is highly prone to user manipulation, and thus … the model is unreliable and should not be used by lawmakers and regulators." Id. 55. [EPA-HQ-OAR-2022-0829-0537, p. 20]

Global damages. The 2021 Working Group departed from recent practice by considering not just domestic harms, but global anticipated climate damages in its analysis. 2021 TSD, at 3. The decision to consider not just damages to the United States of America, but all other countries potentially impacted by climate change, is not a scientific decision—it is a political decision. In fact, the Working Group did not make this decision—in E.O. 13990, the President commanded it to consider global damages. See E.O. 13990, 86 Fed. Reg. 7040; 2021 TSD, at 3 (acknowledging that "[t]he IWG was tasked with" publishing estimates that "tak[e] global damages into account"). The Working Group concedes that this is a policy decision, involving considerations of "climate risk, environmental justice, and intergenerational equity." 2021 TSD, at 3. [EPA-HQ-OAR-2022-0829-0537, p. 20]

In doing so, the Working Group departed from black-letter Supreme Court law, without lawful justification. Unlike the Working Group—which claims to be constrained by no statute—the federal agencies that must rely on the Working Group's calculations in "regulations and other relevant agency actions," E.O. 13990, § 5(b)(ii)(A), 86 Fed. Reg. 7040, are exercising delegated authority from Congress, pursuant to statutory delegations of authority. There is a black-letter presumption applicable to each of those statutes, that they do not authorize the federal agency to consider global effects when calculating "social costs." When interpreting federal statutes, the Supreme Court has long recognized "the presumption against extraterritorial application," which provides that "when a statute gives no clear indication of an extraterritorial application, it has none." Kiobel v. Royal Dutch Petroleum Co., 569 U.S. 108, 115 (2013) (quoting Morrison v. National Australia Bank Ltd., 130 S.Ct. 2869, 2878 (2010)). This presumption reflects the "presumption that United States law governs domestically but does not rule the world." Id. (quoting Microsoft Corp. v. AT & T Corp., 550 U.S. 437, 454 (2007)). [EPA-HQ-OAR-2022-0829-0537, pp. 20-21]

The Working Group justified its decision to consider global damages, instead of domestic impacts, by arguing that "climate impacts occurring outside U.S. borders can directly and indirectly affect the welfare of U.S. citizens" through "spillover pathways." 2021 TSD, at 3. But that argument, if true, merely calls for the calculation of additional harms to domestic citizens and the domestic economy—it does not argue that “social costs” include harms to foreign citizens and nations. Arguing that domestic actors are harmed through foreign pathways is not the same as arguing that domestic cost-benefit analysis should consider harms to foreign actors. Absent a “clear indication” from Congress in the statute—and none is identified here—there is no statutory authorization to consider such effects. Kiobel, 569 U.S. at 115. [EPA-HQ-OAR-2022-0829-0537, pp. 20-21]

The 2021 TSD does not “likely underestimate” climate damages. Parroting the Interagency Working Group, see 2021 TSD, at 4, 31, 35, EPA suggests with scant analysis that the 2021 TSD’s “limitations suggest that these SCGHG estimates likely underestimate the damages from GHG emissions.” 88 Fed. Reg. 29,372. This ipse dixit is unsupportable. As discussed above, virtually every error in the Working Group’s analysis points in the same direction—toward overstating likely damages, not “underestimating” them. The selection of discount rates well below 7 percent massively inflates damage calculations. The adoption of a 300-year time horizon massively inflates damage calculations. The continued use of the obsolete 2007 ECS values massively inflates damage calculations. The complete disregard of countervailing benefits massively inflates damage calculations. The unlawful expansion of damages to include foreign as well as domestic anticipated harms massively inflates damage calculations. These errors are not randomly distributed. They all point in the same direction: jacking the calculation of costs upward. [EPA-HQ-OAR-2022-0829-0537, p. 21]

For all these reasons, the IAMs and their “social cost” calculations are inherently arbitrary, capricious, and unreliable. For very similar reasons, a federal agency has previously declined “to use ‘social cost of carbon’ analysis or a similar analytical tool to analyze the environmental impacts of greenhouse gas emissions from the construction and operation of the converted [natural gas] facilities.” EarthReports, Inc. v. Fed. Energy Regul. Comm’n, 828 F.3d 949, 956 (D.C. Cir. 2016). In that instance, the Federal Energy Regulatory Commission (FERC) rejected “social cost” calculations because of three factors: (1) “the lack of consensus on the appropriate discount rate leads to significant variation in output,” (2) the SCC “tool does not measure the actual incremental impacts of a project on the environment,” and (3) “there are no established criteria identifying the monetized values that are to be considered significant for NEPA purposes.” Id. (internal quotation marks omitted). FERC noted that “there is no standard methodology to determine how a project’s incremental contribution to [greenhouse gas emissions] would result in physical effects on the environment, either locally or globally.” Id. All these concerns remain true today. [EPA-HQ-OAR-2022-0829-0537, pp. 21-22]

Robert Pindyck, the MIT economist, writes that “an IAM-based analysis suggests a level of knowledge and precision that is nonexistent, and allows the modeler to obtain almost any desired result because key inputs can be chosen arbitrarily.” Robert S. Pindyck, Climate Change Policy: What do the Models Tell Us?, National Bureau of Economic Research Working Paper 19244, at 16 (2013), at https://www.nber.org/system/files/working_papers/w19244/w19244.pdf (emphasis added). The IAMs “have crucial flaws that make them close to useless as tools for policy analysis: certain inputs (e.g. the discount rate) are arbitrary, but have huge effects on the SCC estimates the models produce; the models’ descriptions of the impact of climate change are completely ad hoc, with no theoretical or empirical foundation; and the models can tell us nothing about the most important driver of the SCC, the possibility of a catastrophic climate outcome.” Id. at ii. “IAM-based analyses of climate policy create a perception of knowledge and precision, but that perception is illusory and misleading." Id. [EPA-HQ-OAR-2022-0829-0537, pp. 21-22]

The EPA should jettison its serial reliance on the so-called "interim estimates" for the "Social Cost of Greenhouse Gases" adopted by the unconstitutional Interagency Working Group in the 2021 TSD, as unlawful, unconstitutional, arbitrary, and capricious. [EPA-HQ-OAR-2022-0829-0537, pp. 21-22]

VIII. The proposed rule is arbitrary and capricious because it relies on non-final reports.

On at least two occasions, EPA identifies reports that are not yet final because they are undergoing peer review. [EPA-HQ-OAR-2022-0829-0537, p. 26]

First, EPA reports that it "commissioned a new full-vehicle teardown study" to compare manufacturing cost and assembly requirements between gas-powered and electric-powered vehicles. 88 Fed. Reg. 29,303. "The report was delivered to EPA in February 2023 and will undergo a contractor-managed peer review process to be completed by mid-2023." Id. EPA even plans to rely on the report for the final rule: "The results of this study will be used to inform the analysis for the final rulemaking where appropriate." Id. EPA later admits, "We hope to use this information in additional analytical discussions in the final rule." Id. at 29,391. [EPA-HQ-OAR-2022-0829-0537, p. 26]

Second, as discussed in Section IV, significant issues exist with EPA's current social cost of greenhouse gas methodology. However, EPA apparently is working on an update: "Most recently, EPA has developed a draft updated SC-GHG methodology within a sensitivity analysis in the regulatory impact analysis of EPA's November 2022 supplemental proposal for oil and gas standards that is currently undergoing external peer review and a public comment process." After it published the proposed rule, on May 11, 2023, EPA announced that it had received the peer review and was "taking the peer reviewers' recommendations under advisement."38 [EPA-HQ-OAR-2022-0829-0537, p. 26]

38 U.S. EPA, Peer Review of EPA's Draft 'Report on the Social Cost of Greenhouse Gases: Estimates Incorporating Recent Scientific Advances' Concludes, May 11, 2023, available at https://www.epa.gov/environmental- economics/scghg-tsd-peer-review.

Organization: California Air Resources Board (CARB) (Part 1 of 5)

Social Cost of Carbon

As noted in the DRIA, there has been considerable progress in the state of science in valuation of the Social Cost of Carbon (SCC) since the Interim SCC values were developed based on the Interagency Working Group report in 2007. To better reflect this progress in its analysis, CARB recommends that U.S. EPA include a sensitivity analysis with the draft updated SC-GHG methodology that follows what was provided in U.S. EPA's November 2022 supplemental proposal for oil and gas standards. 78 The estimates from the draft updated SC-GHG methodology of the climate benefits of reducing emissions predict that the benefit per metric ton of CO2 (MTCO2) reduced is over 50 percent greater by 2030 ($51/MTCO2) and over 70 percent greater by 2050 ($84/MTCO2) than the interim values. 79 This shows the estimated net benefits of the proposal may be substantially more than the DRIA estimates. [EPA-HQ-OAR-2022-0829-0780, pp. 48-49]

78 U.S. EPA. Supplementary Material for the Regulatory Impact Analysis for the Supplemental Proposed Rulemaking. Standards of Performance for New, Reconstructed, and Modified Sources and Emissions Guidelines for Existing sources: Oil and Natural Gas Sector Climate Review. September 2022. https://www.epa.gov/system/files/documents/2022-11/epa_scghg_report_draft_0.pdf

79 At a 2.5 percent discount rate.

Organization: California Attorney General's Office, et al.

Third, although the projected benefits through 2055 already outweigh the costs by an impressive degree, even these benefits are understated. As EPA recognizes, the social cost of greenhouse gases ("SC-GHG") metric does not fully capture the harms from climate change. 88 Fed. Reg. at 29,372. In recent comments on EPA's proposed GHG standards for heavy-duty vehicles, a group of states and cities (many of whom are signatories to this comment) set out several ways in which the SC-GHG metric significantly underestimates the climate benefits of reducing GHG emissions, particularly in terms of unquantified climate damages (such as wildfires and loss of cultural and historical resources) and its utilization of overly high discount rates. We attach those comments here for reference.190 Moreover, as EPA states, monetized benefits for reduced criteria and air toxics pollution are only a fraction of the total benefits, representing only the value attributable to reducing PM2.5. 88 Fed. Reg. at 29,372, 29,379-83. Although the Administrator did not rely on the exact size of the proposed standards' projected benefits or the amount by which they exceed projected costs, id. at 29,198, the public's understanding of the Proposal will benefit from EPA underscoring the degree to which projected benefits are underestimated, and projected costs overestimated. See CARB Comment at 69-74. [EPA-HQ-OAR-2022-0829-0746, p. 37]

190 Comments Of States and Cities Supporting EPA's Proposed Greenhouse Gas Emissions Standards For Heavy-Duty Vehicles—Phase 3 (Jun. 16, 2023), at 39-44, EPA-HQ-OAR-2022-0985-1423.

Organization: Clean Fuels Development Coalition et al.

D. The calculations of the social cost of carbon are incorrect.

The calculations of the social cost of carbon are incorrect or highly variable. See DRIA 10-14, 15, 16 ("The distribution of the SC-CO2 estimate reflects uncertainty in key model parameters such as the equilibrium climate sensitivity, as well as uncertainty in other parameters."). Social cost of carbon estimates are nothing new, but those used here are illegal. Relying on such estimates in the proposal exceeds EPA's statutory authority. [EPA-HQ-OAR-2022-0829-0712, p. 36]

Executive Order 13990 directs that agencies "shall use" the SC-GHG Esti mates "when monetizing the value of changes in greenhouse gas emissions resulting from regulations and other relevant agency actions." 86 Fed. Reg. 7,037, 7,040 (Jan. 25, 2021). Consistent with this order, the Biden Administration has been applying the SC-GHG estimates throughout its rulemakings, often to large effect. But the proposal—or indeed any other action undertaken by the Biden Administration—provides no statutory authority for its estimates. Further, these estimates, which are made binding through the dozens of rulemakings and adjudications they are incorporated in, have never undergone notice and comment rulemaking procedure. Because such estimates were made without statutory authority and in violation of the Administrative Procedure

Act, their incorporation into the proposal would be unlawful. [EPA-HQ-OAR-2022-0829-0712, p. 36]

Organization: Delek US Holdings, Inc.

IV. The Proposed Rule Overstates the Benefits of Transitioning to BEVs

The economic benefits of EPA's proposal are based on the flawed, inflated interim social cost of three greenhouse gas estimates (carbon, methane, and nitrous oxide) or "SC- GHGs," including estimates of the "social cost of carbon" or "SCC."24 EPA should refrain from relying on the Interagency Working Group's ("IWG") SC-GHGs Interim Estimates, which suffer from major procedural defects.25 The interim estimates are not the product of a full and legally adequate administrative process, including a robust and independent peer review. While the administration provided an opportunity for public comment on the SC-GHGs in 2021, the interim estimates EPA relies upon in the Proposed Rule were released without any prior notice or public comment period.26 [EPA-HQ-OAR-2022-0829-0527, p. 6]

24 Proposed Rule at 29,371–72 (citing the February 2021 Technical Support Document (TSD): Social Cost of Carbon, Methane, and Nitrous Oxide Interim Estimates under E.O. 13990 (Interagency Working Group on the Social Cost of Greenhouse Gases ("IWG"))).

25 Id.

26 Off. of Mgmt. & Budget, Notice of Availability and Request for Comment on the "Technical Support Document: Social Cost of Carbon, Methane, and Nitrous Oxide Interim Estimates Under Executive Order 13990," 86 Fed. Reg. 24,669 (May 7, 2021).

Further, the interim estimates failed to account for the recommendations of the National Academies of Sciences, Engineering, and Medicine ("NAS"), which called for a new IWG framework and changes to the methodologies used to calculate the underlying SCC estimates.27 Consideration of the recommendations of the NAS is critical for any robust social cost analysis—and is in fact mandated by President Biden's Executive Order 13990 that directed the IWG to develop interim SC-GHG estimates.28 [EPA-HQ-OAR-2022-0829-0527, p. 6]

27 National Academies of Sciences, Engineering, and Medicine. 2017. Valuing Climate Damages: Updating Estimation of the Social Cost of Carbon Dioxide. Washington, DC: The National Academies Press.

28 Exec. Order 13990 of Jan. 20, 2021, Protecting Public Health and the Environment and Restoring Science to Tackle the Climate Crisis, 86 Fed. Reg. 7,037, 7,041 (Jan. 25, 2021) (Sec. 5 (iii) Methodology states: "In carrying out its activities, the Working Group shall consider the recommendations of the National Academies of Science, Engineering, and Medicine as reported in Valuing Climate Damages: Updating Estimation of the Social Cost of Carbon Dioxide (2017)."

The interim estimates also conflict with longstanding White House Office of Management and Budget ("OMB") guidance on information quality, which requires rigorous independent peer review and heightened transparency for such "influential scientific information" as the SC-GHG estimates.29 For these and other reasons, EPA should not rely upon the interim SC-GHG estimates in this rulemaking. [EPA-HQ-OAR-2022-0829-0527, p. 6]

29 Off. of Mgmt. & Budget, Guidelines for Ensuring and Maximizing the Quality, Objectivity, Utility, and Integrity of Information Disseminated by Federal Agencies, 67 Fed. Reg. 8,452 (Feb. 22, 2002); Section 515 of the Treasury and General Government Appropriations Act for Fiscal Year 2001, Pub. L. No. 106-554.

Here, EPA's reliance on these SC-GHG estimates result in overstated benefits in terms of potential GHG emissions reductions achieved domestically while ignoring the increased GHG emissions elsewhere and how those global GHG emissions are distributed amongst a domestic ZEV fleet. [EPA-HQ-OAR-2022-0829-0527, pp. 6-7]

Organization: Energy Innovation

I. The U.S. must transition LDVs and MDVs to zero-emission technologies [i] quickly to reduce their emissions, which contribute to climate change and air pollution—both of which endanger public health and welfare. Adoption of the most stringent tailpipe standards for new vehicles is the most effective tool to achieve this goal. [EPA-HQ-OAR-2022-0829-0561, pp. 1-2]

i This includes technologies that eliminate tailpipe GHG emissions and other pollutants, namely battery electric vehicles for LDVs and MDVs.

Organization: Institute for Policy Integrity at NYU School of Law et al.

The Proposed Rule appropriately applies the climate-damage estimates from the Interagency Working Group on the Social Cost of Greenhouse Gases (Working Group) and rejects the faulty numbers that EPA applied from 2017 until early 2021. The Working Group developed its climate-damage estimates through a rigorous and transparent process incorporating the best available science available at the time. Those values—though widely agreed to underestimate the full social costs of greenhouse gas emissions4—are appropriate to use for now as conservative underestimates. They have been applied in dozens of previous rulemakings5 and upheld in federal court.6 In contrast, the estimates that EPA applied during the Trump administration disregarded the best available science and their use was deemed arbitrary and capricious by a federal court.7 [EPA-HQ-OAR-2022-0829-0743, p. 1]

4 Interagency Working Group on the Social Cost of Greenhouse Gases, Technical Support Document: Social Cost of Carbon, Methane, and Nitrous Oxide – Interim Estimates Under Executive Order 13,990 at 4 (2021) [hereinafter "2021 TSD"] (acknowledging that current social cost valuations "likely underestimate societal damages from [greenhouse gas] emissions"). Richard L. Revesz et al., Global Warming: Improve Economic Models of Climate Change, 508 NATURE 173 (2014) (explaining that the Working Group's values, though methodically rigorous and highly useful, are very likely underestimates) (co-authored with Nobel Prize-winning economist Kenneth Arrow).

5 Peter Howard & Jason A. Schwartz, Think Global: International Reciprocity as Justification for a Global Social Cost of Carbon, 42 COLUM. J. ENV'T L. 203, 270–84 (2017) (listing all uses through mid-2016).

6 Zero Zone v. Dept. of Energy, 832 F.3d 654, 679 (7th Cir. 2016).

7 California v. Bernhardt, 472 F. Supp. 3d 573, 613 (N.D. Cal. 2020).

EPA provides compelling justifications for readopting the Working Group's climate-damage estimates,8 and in fact many additional justifications support this choice. In particular, further justifications support EPA's decision to adopt a global damages valuation and the range of discount rates it applies to climate effects. As detailed herein, there are many additional legal, economic, and policy justifications for such methodological decisions that further bolster EPA's support for these choices. [EPA-HQ-OAR-2022-0829-0743, pp. 1-2]

8 Proposed Rule, 88 Fed. Reg. at 29,371–72; RIA at 10-8 to 10-13.

While the Working Group's climate-damage valuations represent a marked improvement over the arbitrary values that EPA adopted during the Trump administration, they remain underestimates. In November 2022, EPA released a draft update to the social cost of greenhouse gases that faithfully implements the roadmap laid out in 2017 by the National Academies of Sciences and applies recent advances in the science and economics on the costs of climate change (Draft SC-GHG Update).9 These updated valuations more robustly capture the incremental benefits of reducing greenhouse gas emissions and further confirm that the Working Group's climate-damage values represent conservative underestimates. [EPA-HQ-OAR-2022-0829-0743, pp. 1-2]

9 EPA External Review Draft of Report on the Social Cost of Greenhouse Gases (Sept. 2022) (Docket No. EPA- HQ-OAR-2021-0317) ("Draft SC-GHG Update").

These comments are organized into four sections. Section I offers additional justification for adopting a global framework for valuing climate impacts. These include legal justifications based on the Clean Air Act, the National Environmental Policy Act's broad government-wide policy mandates, the Administrative Procedure Act's requirement to consider all important factors, and executive orders and international agreements. This section also provides extensive regulatory precedent outside the climate context supporting EPA's global approach, including the Office of Management and Budget's (OMB) draft update to Circular A-4 (Draft Circular A-4 Update).10 [EPA-HQ-OAR-2022-0829-0743, p. 2]

10 OFF. OF MGMT. & BUDGET, CIRCULAR A-4: DRAFT FOR PUBLIC REVIEW 9–11 (Apr. 6, 2023) ("Draft Circular A-4 Update").

Section II offers additional justification for adopting the range of discount rates endorsed by the Working Group and for declining to apply a 7% capital-based discount rate for climate impacts. In particular, this section provides additional justification for combining climate effects discounted at an appropriate consumption-based rate with other costs and benefits discounted at a capital-based rate. Besides climate effects presenting special legal, economic, and policy considerations for the discount rate, it is appropriate generally for EPA to focus its analysis of this rule on consumption-based rates given that most costs and benefits are projected to fall to consumption rather than to capital investments. This is also confirmed by the Draft Circular A-4 Update.11 [EPA-HQ-OAR-2022-0829-0743, p. 2]

11 Id. at 78–80.

Section III offers extensive justification for relying on the Working Group's other methodological choices, including the fact that the Working Group applied a transparent and rigorous process that relied upon the best-available and most widely-cited models for monetizing climate damages that existed at the time of their development. This section also provides detailed rebuttals to criticisms of the Working Group's methodology from opponents of climate regulation. [EPA-HQ-OAR-2022-0829-0743, pp. 2-3]

Finally, Section IV recommends that EPA apply the revised climate-damage valuations from the Draft SC-GHG Update—either in sensitivity analysis or as part of the main analysis if this regulation is finalized after the Draft SC-GHG Update is finalized. This section also suggests that EPA conduct additional analysis using the updated approach to discounting in the Draft Circular A-4 Update. The section provides modeling results showing a substantial increase under this approach in net benefits for the proposed program and its alternatives. [EPA-HQ-OAR-2022-0829-0743, pp. 2-3]

I. Extensive Justification Supports EPA's Reliance on Global Climate Damage Valuations

In the Proposed Rule, EPA appropriately focuses on a global estimate of climate benefits, continuing its historical approach and once again rejecting its temporary and arbitrary practice during the Trump administration of disregarding all climate effects that occur outside the physical borders of the United States. While EPA offers persuasive justifications for this decision, many additional justifications—some of which EPA itself provides in the Draft SC-GHG Update12—further support this approach.13 In particular, EPA could emphasize the concern for the impacts of U.S. pollution on foreign welfare in the Clean Air Act and other sources of law, further highlight the significance of U.S. strategic interests and reciprocity, further emphasize the importance of extraterritorial impacts and spillovers, and highlight the inconsistency that would occur if the agency considered only domestic benefits while focusing on global costs. [EPA-HQ-OAR-2022-0829-0743, p. 3]

12 Draft SC-GHG Update, supra note 9, at 10–15.

13 See generally Jason A. Schwartz, Inst. for Pol'y Integrity, Strategically Estimating Climate Pollution Costs in a Global Environment (2021), https://policyintegrity.org/files/publications/Strategically_Estimating_Climate_Pollution_Costs_in_a_Global_Envir onment.pdf.

A. Relevant Statutes and Executive Orders Compel, and Certainly Permit, a Global Perspective on Climate Damages

The Clean Air Act, National Environmental Policy Act, Administrative Procedure Act, and other key sources of law not only permit, but in fact require, EPA to consider international effects. EPA should highlight these legal requirements as justification for its focus on global climate impacts. [EPA-HQ-OAR-2022-0829-0743, pp. 3-4]

Section 202 of the Clean Air Act, under which EPA issues the Proposed Rule, charges EPA with regulating "air pollutant[s] which may be reasonably anticipated to endanger public health or welfare,"14 where "welfare" is defined to include "effects on . . . weather . . . and climate."15 When interpreting Section 202, the Supreme Court found "there is nothing counterintuitive to the notion that EPA can curtail the emission of substances that are putting the global climate out of kilter."16 And when industry challenged another EPA climate program under Title I of the Clean Air Act by arguing that the statute "was concerned about local, not global effects," the U.S. Court of Appeals for the D.C. Circuit had "little trouble disposing of Industry Petitioners' argument that the [Clean Air Act's prevention of significant deterioration] program is specifically focused solely on localized air pollution," finding instead that the statute was "meant to address a much broader range of harms," including "precisely the types of harms caused by greenhouse gases."17 [EPA-HQ-OAR-2022-0829-0743, pp. 3-4]

14 42 U.S.C. § 7521(a)(1).

15 42 U.S.C. § 7602(h); Massachusetts v. EPA, 127 S. Ct. 1438, 1447 (2007).

16 Massachusetts, 127 S. Ct. at 1461 (emphasis added). This case concerned Section 202 of the Clean Air Act, which similarly permits EPA to regulate "any air pollutant . . . which may reasonably be anticipated to endanger public health or welfare." Id. at 1454 (quoting 42 U.S.C. § 7521(a)(1)).

17 Coalition for Responsible Regulation v. EPA, 684 F.3d 102, 137-38 (D.C. Cir. 2012), aff'd in part, rev'd in part sub nom. Util. Air Regulatory Grp. v. EPA, 134 S. Ct. 2427 (2014).

And under the Administrative Procedure Act, it is arbitrary and capricious for agencies to "entirely fail[] to consider an important aspect of the problem"30—an obligation that a federal court held requires federal agencies to consider transboundary climate impacts. Specifically, a recent ruling from the U.S. Court for the Northern District of California struck down as arbitrary the Bureau of Land Management's (BLM) rescission of the Waste Prevention Rule in part because the agency had abandoned the Working Group's peer-reviewed, global estimates of the social cost of greenhouse gases in favor of flawed estimates (the same estimates that EPA applied under the Trump administration) that looked narrowly at effects within the U.S. borders.31 The court found that the global values developed by the Working Group reflected "the best available science about monetizing the impacts of greenhouse gas emissions,"32 whereas "focusing solely on domestic effects has been soundly rejected by economists as improper and unsupported by science."33 The court reminded BLM that relevant executive orders, including Executive Order 12,866, require consideration of "all" costs and benefits, based on the "best reasonably obtainable scientific, technical, economic, and other information," and concluded that "no[] . . . regulatory rules or orders require exclusion of global impacts."34 [EPA-HQ-OAR-2022-0829-0743, pp. 5-6]

30 Motor Vehicle Manufacturers Ass'n v. State Farm Mutual Auto. Ins. Co., 463 U.S. 29, 41–43 (1983).

31 Bernhardt, 472 F. Supp. 3d at 613.

32 Id. at 611.

33 Id. at 613.

34 Id. at 611–12 (internal quotation marks omitted).

More recently, Executive Order 13,990 instructs agencies to "tak[e] global damages into account," because "[d]oing so facilitates sound decision-making, recognizes the breadth of climate impacts, and support the international leadership of the United States on climate issues."35 This language again reinforces the instructions from NEPA that, whenever not precluded by statute from doing so, agencies should account for the environmental impacts of their actions on foreign nations and global commons. [EPA-HQ-OAR-2022-0829-0743, p. 6]

35 Exec. Order No. 13,990 § 5(a), 86 Fed. Reg. 7037, 7040 (Jan. 20, 2021).

EPA should draw upon these legal authorities in justifying its reliance on global climate-damage valuations. [EPA-HQ-OAR-2022-0829-0743, p. 6]

The Biden Administration has made such a strategic choice, to adopt a global valuation of climate damages as part of its diplomatic strategy. Executive Order 13,990 unequivocally states that "[i]t is essential that agencies capture the full costs of greenhouse gas emissions as accurately as possible, including by taking global damages into account . . . [to] support the international leadership of the United States on climate issues."41 The Order later elaborates: "Our domestic efforts must go hand in hand with U.S. diplomatic engagement. Because most greenhouse gas emissions originate beyond our borders, such engagement is more necessary and urgent than ever. The United States must be in a position to exercise vigorous climate leadership to achieve a significant increase in global climate action and put the world on a sustainable climate pathway."42 [EPA-HQ-OAR-2022-0829-0743, p. 7]

41 Exec. Order No 13,990 § 5(a).

42 Id. § 6(d). Though this subsection takes action on the Keystone XL Pipeline permit, its statement of diplomatic goals has much broader relevance.

The current Circular A-4 requires agencies to count all significant costs and benefits, including "use" values as well as "non-use" values like bequest and existence values.74 Circular A-4 cautions that "ignoring these values" may cause analyses to "significantly understate the benefits and/or costs" involved.75 Similarly, Circular A-4 recognizes that U.S. citizens may have "altruism for the health and welfare of others," and instructs agencies that when "there is evidence of selective altruism, it needs to be considered specifically in both benefits and costs."76 U.S. citizens will experience costs because of their use values, non-use values, and altruistic values attached to climate effects occurring outside the U.S. borders. [EPA-HQ-OAR-2022-0829-0743, p. 12]

74 A bequest value captures willingness to pay to preserve a resource for a future generation. Existence value captures willingness to pay to preserve a resource even with no intention to ever use or bequeath the resource. Off. of Mgmt. & Budget, Circular A-4: Regulatory Analysis 22 (2003).

75 Id.

76 Id.

Such non-use and altruistic values take many forms. For one, the United States and its citizens have a willingness to pay—as well as a legal obligation—to protect the global commons of the oceans and Antarctica from climate damage. Furthermore, a quarter of the U.S. population consists of either foreign-born immigrants or second-generation residents,77 and subsequent generations of Americans retain significant familial, cultural, economic, and religious ties to their ancestors' home nations across the world.78 U.S. citizens and residents have a significant willingness to pay to protect their relatives, ancestral homes, and cultural and religious sites located abroad.79 Similarly, U.S. citizens value natural resources and plant and animal lives abroad—even if they never see or use those resources—and care about the health and welfare of unrelated foreign citizens80 and cultural and world heritage sites threatened by climate change.81 This altruism is "selective altruism," consistent with Circular A-4, because the United States is directly responsible for a huge amount of the historic emissions contributing to climate change.82 [EPA-HQ-OAR-2022-0829-0743, pp. 12-13]

77 U.S. Census Bureau, Characteristics of the U.S. Population by Generational Status: 2013 at 3 (2016), https://perma.cc/AS3H-BCWK; see also Pew Res. Ctr., First- and second-generation share of the population, 1900- 2017, June 3, 2019, https://perma.cc/Y9WT-75R4 (showing a growing percentage in recent years); see also Pew Res. Ctr., Key Findings About U.S. Immigration, Aug. 20, 2020, https://perma.cc/8JEK-Y88S (showing that 77% of the U.S. foreign-born population are naturalized U.S. citizens or permanent/temporary U.S. residents).

78 Over $100 billion is sent from the United States to other countries in remittances every year. See Pew Res. Ctr., Remittance Flows Worldwide in 2017, Apr. 3, 2019, https://perma.cc/D684-7ZA8.

79 Many cultural sites are located near water because of how civilization developed, Yu Fang & James W. Jawitz, The evolution of human population distance to water in the USA from 1790 to 2010, 10 NATURE COMMUNICATIONS 1 (2019), and so such sites may be especially vulnerable to climate change, see Lee

Bosher et al., Dealing with multiple hazards and threats on cultural heritage sites: an assessment of 80 case studies, 29 DISASTER PREVENTION AND MANAGEMENT: AN INTERNATIONAL JOURNAL 109 (2019). More broadly, there are clear cultural costs of climate change, W. Neil Adger et al., Cultural dimensions of climate change impacts and adaptation, 3 NATURE CLIMATE CHANGE 112 (2013), and a willingness to pay to protect culture, Ali Ardeshiri et al., Conservation or Deterioration in Heritage Sites? Estimating Willingness To Pay for Preservation (Working Paper, 2019).

80 See Arden Rowell, Foreign Impacts and Climate Change, 39 HARV. ENV'T L. REV. 371 (2015); Dana, supra note 71 (discussing U.S. charitable giving abroad and foreign aid, and how those metrics likely severely underestimate true U.S. willingness to pay to protect foreign welfare).

81 See UNESCO, Climate Change Now Top Threat to Natural World Heritage, Dec. 2, 2020, https://perma.cc/K9SW-XQDM.

82 Datablog, A History of CO2 Emissions, THE GUARDIAN (Sept. 2, 2009) (from 1900-2004, the United States emitted 314,772.1 million metric tons of carbon dioxide; Russia and China follow, with only around 89,000 million metric tons each).

Indeed, OMB's Draft Circular A-4 Update is even more explicit than the current guidance on the need to consider direct and indirect transboundary impacts on U.S. citizens. As the Draft Circular A-4 Update explains, effects that occur entirely outside the United States are relevant to consider in a regulatory impact analysis "when they affect U.S. citizens and residents, such as effects experienced by citizens residing abroad"; when "assessing effects on noncitizens residing abroad provides a useful proxy for effects on U.S. citizens and residents that are difficult to otherwise estimate"; and when "assessing effects on noncitizens residing abroad provides a useful proxy for effects on U.S. national interests that are not otherwise fully captured by effects experienced by particular U.S. citizens and residents."83 [EPA-HQ-OAR-2022-0829-0743, p. 13]

83 Draft Circular A-4 Update, supra note 10, at 9–10.

C. Focusing on Global Climate Damages Is Consistent With EPA's Consideration of Global Costs

EPA can further justify its focus on global climate benefits as necessary for consistency with the rest of its analysis. To begin, EPA treated monopsony impacts as an international transfer payment, rather than as potential benefits to U.S. consumers at the expense of foreign oil producers.84 As Circular A-4 suggests, an analysis adopts a global rather than U.S.-centered perspective when it treats such international flows as transfers rather than as costs or benefits.85 EPA's global perspective on monopsony effects is consistent with it adopting a global perspective on climate effects. [EPA-HQ-OAR-2022-0829-0743, pp. 13-14]

84 RIA at 11-27; 86 Fed. Reg. at 43,792.

85 Circular A-4 at 38 (stating that if "the analysis is conducted from the United States perspective," then "transfers from the United States to other nations should be included as costs, and transfers from other nations to the United States as benefits").

More broadly, EPA's analysis implicitly takes a global perspective on compliance costs, and so—as OMB's Draft Circular A-4 Update emphasizes86—it would be arbitrary not to similarly take a global perspective on climate effects. All industry compliance costs ultimately fall on the owners, employees, or customers of regulated and affected firms. Whether the Proposed Rule's compliance costs are passed to consumers or investors, or some combination thereof, a significant portion of the Proposed Rule's alleged compliance costs will ultimately accrue to foreign customers or foreign investors. Regulated manufacturers include major corporations that are headquartered abroad: In fact, many of the country's largest automakers— Toyota, BMW, Nissan, Mercedes, Stellantis (Fiat Chrysler), Volkswagen, and others—are headquartered abroad. The rule's compliance costs will therefore fall partly on foreign actors, but EPA did not break out these "global" costs separately from "domestic" costs. [EPA-HQ-OAR-2022-0829-0743, pp. 13-14]

86 Id. at 10 ("You should be consistent in your treatment of noncitizens residing abroad in your benefit and cost estimates. If you include some effects experienced by such noncitizens in your primary analysis, consistency generally requires also including countervailing effects on similar noncitizens in your primary analysis. For example, if benefits that are experienced by noncitizens residing abroad are included in your analysis, compliance costs borne by noncitizens residing abroad should generally be included in your analysis as well, and vice versa.").

Furthermore, even the domestically-based automakers regulated under this rule are publicly traded with investors across the globe. In general, about 29% of U.S. corporate debt and 14% of equities are foreign-owned,87 and adding foreign direct investment to portfolio stock ownership suggests that foreigners own about 40% of U.S. corporate equity.88 Thus, a significant share of the Proposed Rule's compliance costs are likely to fall on foreign entities, but EPA never distinguishes between those costs that would accrue to foreign entities as opposed to U.S. citizens or U.S. entities. Thus, the agency's calculations of cost implicitly include all global effects. Considering global climate benefits is consistent with that approach. [EPA-HQ-OAR-2022-0829-0743, p. 14]

87 Dept. of Treasury et al., Foreign Portfolio Holdings of U.S. Securities at B-3 (2020), https://perma.cc/6VP6- PPG6.

88 Steve Rosenthal & Theo Burke, Who's Left to Tax? U.S. Taxation of Corporations and Their Shareholders at 2 (Urban-Brookings Tax Policy Center Working Paper, 2020), https://perma.cc/YMR2-XREM.

In a few recent analyses, agencies including EPA have admitted that some portion of the costs or cost savings calculated for publicly-traded corporations will "accru[e] to entities outside U.S. borders" through foreign ownership, employment, or consumption.89 Yet much like in the Proposed Rule, these analyses do not attempt to separate such effects to foreign interests, nor attempt to exclude such effects from consideration altogether. Indeed, splitting corporate effects into subparts based on ultimate ownership—much like separating climate benefits geographically—could be extremely complicated.90 Thus, as a practical matter, agencies typically count all costs or benefits to corporations, no matter how those effects may be passed through to foreign owners, foreign employees, or foreign customers. As the Draft Circular A-4 Update explains, this practice requires consistent treatment for benefits.91 [EPA-HQ-OAR-2022-0829-0743, p. 14]

89 See, e.g., EPA, Regulatory Impact Analysis for the Proposed Reconsideration of the Oil and Natural Gas Sector Emission Standards for New, Reconstructed, and Modified Sources at 3-13 (2018); EPA, Regulatory Impact Analysis for the Proposed Revised Cross-State Air Pollution Rule (CSAPR) Update for the 2008 Ozone NAAQS at 5-5 (2020).

90 See, e.g., EPA, Draft Guidelines for Preparing Economic Analyses: Review Copy prepare for EPA's Science Advisory Board at 5-2 (2020), https://perma.cc/3K86-M7AH ("Limiting standing to citizens and residents of the United States can be complicated to operationalize in practical terms (e.g., how should multi-national firms with plants in the United States but shareholders elsewhere be treated?).").

91 Draft Circular A-4 Update, supra note 10, at 10.

Since EPA analyzes the Proposed Rule's costs globally—without distinguishing between U.S. and foreign effects—it would be inconsistent and arbitrary for the agency to attempt to separate and disregard climate benefits that occur abroad, as doing so would "put a thumb on the scale" by treating costs globally but benefits domestically.92 EPA can therefore highlight its consistent treatment of costs and benefits as further justification for assessing climate damages from a global perspective. [EPA-HQ-OAR-2022-0829-0743, pp. 14-15]

92 Ctr. for Biological Diversity, 538 F.3d at 1198.

D. Considering Extraterritorial Climate Effects Is Consistent With Administrative Precedent Outside the Climate Context

While EPA offers extensive justification for its focus on global damage estimates, it can provide additional regulatory precedent supporting that approach. Agencies often consider the extraterritorial effects of their actions—including effects on international reciprocity, international cooperation, and transboundary spillovers—when administering their statutory authority. And on numerous occasions, courts have endorsed this practice. Indeed, as the Supreme Court has acknowledged, agency decisions "are routinely informed by . . . foreign relations and national security concerns."93 [EPA-HQ-OAR-2022-0829-0743, p. 15]

93 Dep't of Com. v. New York, 139 S. Ct. 2551, 2573 (2019).

For one, as noted above, the National Environmental Policy Act (NEPA) requires agencies to administer and interpret the nation's law to "recognize the worldwide and long-range character of environmental problems" and to "lend appropriate support" to help "maximize international cooperation."94 Numerous court decisions—including one from the U.S. Court of Appeals for the D.C. Circuit—have held that reasonably foreseeable transboundary effects must appear in NEPA analyses.95 And consistent with those decisions, agencies have assessed transboundary impacts under NEPA for over 40 years under Executive Order 12,114, which instructs agencies to "take into consideration in making decisions" effects of their actions on the "environment of a foreign nation" and "the global commons."96 EPA's consideration of extraterritorial environmental impacts is thus consistent with decades of agency practice. [EPA-HQ-OAR-2022-0829-0743, p. 15]

94 42 U.S.C. § 4332(2)(I) (cited at Draft SC-GHG Update, supra note 9, at 15 n.37, as § 4332(2)(F)).

95 E.g. Env't Def. Fund, Inc. v. Massey, 986 F.2d 528 (D.C. Cir. 1993); Gov't of Man. v. Salazar, 691 F. Supp. 2d 37, 51 (D.D.C. 2010).

96 See Exec. Order No. 12,114 § 2–3, 44 Fed. Reg. 1957 (Jan. 4, 1979).

Executive Order 13,990 instructs agencies to ensure that the social cost of greenhouse gas values adequately account for "intergenerational equity."138 A 7% rate ignores much of future generations' welfare and so would be inconsistent with that mandate. Notably, even when using high discount rates for climate damages in 2020, EPA explained that the 7% capital rate did not adequately account for "tradeoffs between improving the welfare of current and future generations."139 Accordingly, EPA's decision not to apply that discount rate for assessing climate damages is entirely justified. [EPA-HQ-OAR-2022-0829-0743, p. 20]

138 Exec. Order § 13,990 5(b)(ii)(E).

139 85 Fed. Reg. at 24,735 (explaining that the central analysis focused on a 3% rate, and the 7% rate was used only for sensitivity analysis).

B. Focusing on Global Climate Damages Furthers U.S. Strategic Interests by Facilitating Reciprocity, Mitigating International Spillover Effects, and Protecting U.S. Extraterritorial Interests

EPA explains in both the regulatory impact analysis36 and the Draft SC-GHG Update37 that it is appropriate to value climate damages on a global scale because climate impacts occurring outside U.S. borders can directly and indirectly affect U.S. welfare through spillovers and foreign reciprocity. Indeed, the theory and evidence for reciprocity on their own justify a focus on the full global values, and additional strategic and practical justifications provide further support for EPA's approach. [EPA-HQ-OAR-2022-0829-0743, p. 6]

36 RIA at 10-11.

37 Draft SC-GHG Update, supra note 9, at 10–15.

1. Use of the Global Values Facilitates International Reciprocity

Because the world's climate is a single interconnected system, the United States benefits greatly when foreign countries consider the global externalities of their greenhouse gas pollution and cut emissions accordingly. It therefore promotes the strategic interests of the United States to encourage all other countries to think globally in setting their climate policies. The United States can advance this objective by itself adopting the full global social cost of greenhouse gases—as numerous leading climate economists and experts have explained.38 Indeed, basic economic principles demonstrate that the United States stands to benefit greatly if all countries apply global social cost of greenhouse gas values in their regulatory decisions and project reviews39—likely trillions of dollars in direct benefits from foreign action to combat climate change.40 [EPA-HQ-OAR-2022-0829-0743, pp. 6-7]

38 Most generally, it is individually rational for a country to fully internalize the global social cost of greenhouse gases "if a country expects a decrease in its own emissions to decrease that of all others in proportion to the ratio of its external cost of emissions to its internal costs." Matthew J. Kotchen, Which Social Cost of Carbon? A Theoretical Perspective, 5 J. ASSOC. ENV'T & RES. ECON. 673, 683 (2017). Other economists have justified use of the global social cost estimates on more intuitive grounds. See, e.g., Tamma Carleton & Michael Greenstone, Updating the United States Government's Social Cost of Carbon at 26-27 (Becker Friedman Institute Working Paper 2021-04, Jan. 2021), https://perma.cc/H9EU-XWBX ("The global SCC . . . is an ingredient in efforts to procure the necessary international action. . . . Even if policymakers decide that the effects of regulations on U.S. citizens are what matter (in terms of both law and policy), it would make sense to use the global measure, as it would protect U.S. citizens against a range of adverse effects from unmitigated climate change."); William Pizer et al., Using and Improving the Social Cost of Carbon, 346 SCIENCE 1189, 1190 (2014) (explaining that the "potential to leverage foreign mitigation," combined with moral, ethical, and security issues, provide "compelling reasons to focus on a global SCC but, more important, to make a strategic choice."); Robert S. Pindyck, Comments on Proposed Rule and Regulatory Impact Analysis on the Delay and Suspension of Certain Requirements for Waste Prevention and Resource Conservation, Nov. 6, 2017, https://perma.cc/HG8Q-MT6H ("[W]hat treatment of international damages is in the United States' self-interest? . . . The simplest answer is to find the value of the [social cost of carbon] that maximizes global welfare. I continue to think that the global value is the appropriate provisional value for use as research on this topic continues.").

39 See Kotchen, supra note 38, at 678 (providing formulas for the "efficiency argument in support of all countries internalizing the GSCC [global social cost of carbon] for domestic policy").

40 Inst. for Pol'y Integrity, Foreign Action, Domestic Windfall: The U.S. Economy Stands to Gain Trillions from Foreign Climate Action (2015), https://perma.cc/T3WN-H42U.

The Biden Administration has made such a strategic choice, to adopt a global valuation of climate damages as part of its diplomatic strategy. Executive Order 13,990 unequivocally states that "[i]t is essential that agencies capture the full costs of greenhouse gas emissions as accurately as possible, including by taking global damages into account . . . [to] support the international leadership of the United States on climate issues."41 The Order later elaborates: "Our domestic efforts must go hand in hand with U.S. diplomatic engagement. Because most greenhouse gas emissions originate beyond our borders, such engagement is more necessary and urgent than ever. The United States must be in a position to exercise vigorous climate leadership to achieve a significant increase in global climate action and put the world on a sustainable climate pathway."42 [EPA-HQ-OAR-2022-0829-0743, p. 7]

41 Exec. Order No 13,990 § 5(a).

42 Id. § 6(d). Though this subsection takes action on the Keystone XL Pipeline permit, its statement of diplomatic goals has much broader relevance.

There is already evidence that the U.S. strategy of combining its domestic efforts— including the global valuation of climate damages—with its diplomatic engagement is spurring foreign reciprocity. As EPA explained in the Draft SC-GHG Update, "[m]any countries and international institutions have either already explicitly adapted the IWG's estimates of global damages in their domestic analyses . . . [or] developed their own estimates of global damages" following the U.S. approach.43 Earlier this year, in fact, Canada adopted the climate-damage valuations from EPA's Draft SC-GHG Update as its official estimates.44 [EPA-HQ-OAR-2022-0829-0743, p. 7]

43 Draft SC-GHG Update, supra note 9, at 14.

44 Social Cost of Greenhouse Gas Emissions, Government of Canada (last modified Apr. 20, 2023), https://www.canada.ca/en/environment-climate-change/services/climate-change/science-research-data/social-cost- ghg.html.

In January 2021, Trevor Houser and Kate Larsen published a conservative estimate of the number of tons of greenhouse gases that the rest of the world had committed to reduce for each ton that the United States has pledged to reduce: a figure they call the "Climate Reciprocity Ratio."49 Using only the quantifiable, unconditional pledges that 51 countries had made since 2014 to cut emissions through 2030, Houser and Larsen conservatively estimate that for every ton the United States pledged to reduce, these other countries had collectively pledged to reduce 6.1–6.8 tons in return.50 While implementation of all these foreign policies is not guaranteed, and while these estimates reflect pledges that may now be outdated, Houser and Larsen cite evidence that several large emitters are on track to meet their goals, and that the ratio should grow over time as the U.S. share of global emissions falls.51 [EPA-HQ-OAR-2022-0829-0743, pp. 8-9]

49 Trevor Houser & Kate Larsen, Rhodium Grp., Calculating the Climate Reciprocity Ratio for the U.S. (2021), https://perma.cc/7MJ8-DN23 (calling their estimate "deliberately conservative").

50 The estimate is conservative because it omits any conditional pledges, any pledges that are not readily quantified into specific reductions, any actions from countries that have not formally submitted Nationally Determined Contributions to the United Nations, any reductions occurring after 2030, and any foreign actions already achieved before 2014 that may have motivated U.S. pledges in the first place. Id.

51 Id.

In short, both empirical evidence and economic theory strongly support a strategic choice for U.S. agencies to adopt the full global estimates of the social cost of greenhouse gases, as this facilitates international reductions in greenhouse gas pollution that directly benefits the United States. Notably, OMB's Draft Circular A-4 Update specifically recognizes that "the potential for inducing strategic reciprocity or other policy changes from actors abroad" offers a basis for considering regulatory impacts on a global basis.52 Accordingly, EPA should provide evidence of foreign reciprocity to further support its focus on the full global valuations of the social cost of greenhouse gases. [EPA-HQ-OAR-2022-0829-0743, pp. 8-9]

52 Draft Circular A-4 Update, supra note 10, at 9.

Experts on the social cost of greenhouse gases have therefore concluded that, because the integrated assessment models that underlie the Working Group's social cost valuations currently do not capture many of these key inter-regional costs, the use of the global values can be further justified as a proxy for capturing all spillover effects.67 Though not all climate damages will spill back to affect the United States, many will, and together with other justifications, the likelihood of significant spillovers makes a global valuation the better, more transparent accounting of the full range of costs and benefits that matter to U.S. policymakers and the public. EPA can therefore highlight spillover impacts as further justification for relying on global social cost valuations. In addition to the spillover effects that EPA already mentions,68 EPA should further argue that transboundary spillovers, feedback loops, information spillovers, and other effects justify a focus on the full global values, either independently or in combination with other strategic and ethical considerations.69 [EPA-HQ-OAR-2022-0829-0743, pp. 10-11]

67 Robert E. Kopp & Bryan K. Mignone, Circumspection, Reciprocity, and Optimal Carbon Prices, 120 CLIMATE CHANGE 831, 833 (2013) (2013) (explaining that the principle of "circumspection" can account for spillover effects and can then be used to justify a global SC-GHG value).

Globalization and the many avenues by which the fortunes of countries are linked mean that a high CSCC in one place may result in costs as the global climate changes even in places where the CSCC is nominally negative. For many countries, the effects of climate change may be felt more greatly through transboundary effects, such as trade disruptions, large-scale migration, or liability exposure than through local climate damage…These considerations suggest that country-level interests may be more closely aligned to global interests than indicated by contemporary country-level contributions to the SCC…[A] host of other strategic and ethical considerations factor into the international relations of climate change mitigation…We make no claim here regarding the utility of the CSCC in setting climate policies. CO2 emissions are a global externality. [EPA-HQ-OAR-2022-0829-0743, p. 11]

69 See Schwartz, supra note 13, at 26; id. at 12 (on information spillovers).

3. Use of the Global Values Preserves Extraterritorial Interests

The RIA highlights direct and indirect impacts on U.S. citizens and assets located abroad as a justification for a global valuation,70 but U.S. extraterritorial interests are even more extensive and significant. A domestic-only estimate of the social cost of greenhouse gases based on some rigid conception of geographic borders or U.S. share of world GDP will fail to capture all the climate-related costs and benefits that matter to U.S. citizens, including impacts to significant U.S. ownership interests in foreign businesses, properties, and other assets, as well as U.S. consumption abroad including tourism,71 and even effects to the millions of Americans living abroad.72 The United States also has military personnel and assets located in almost every nation across the globe, and many if not all installations abroad—including those with high replacement costs or irreplaceable strategic value—face imminent climate risks.73 Because no methodology for estimating a "domestic-only" value would capture these impacts to extra- territorial interests, focusing on the global values can be further justified in part as a proxy for these important considerations. [EPA-HQ-OAR-2022-0829-0743, p. 11]

70 RIA at 10-11.

71 "U.S. residents spend millions each year on foreign travel, including travel to places that are at substantial risk from climate change, such as European cities like Venice and tropical destinations like the Caribbean islands." David A. Dana, Valuing Foreign Lives and Civilizations in Cost-Benefit Analysis: The Case of the United States and Climate Change Policy 10 (Northwestern Faculty Working Paper 196, 2009), https://perma.cc/EW3B-NKYC.

72 2021 TSD, supra note 4, at 15 (citing a 2016 figure from Bureau of Consular Affairs, Dept. of State); see also Dept. of State, Consular Affairs by the Numbers (2020), https://perma.cc/F3M8-EFSJ.

73 Ctr. for Climate & Sec., Military Expert Panel Report: Sea Level Rise and the U.S. Military's Mission 7 (2d ed. 2018), https://perma.cc/ZM4R-ED89.

Both strategic considerations and the need to account for spillovers already provide independent justifications for focusing on the full global social cost of greenhouse gas estimates. But the global values can also be at least partly justified as a proxy for these extra-territorial interests that otherwise would be overlooked using a domestic-only damage estimate. EPA can therefore further highlight U.S. extraterritorial interests as additional justification for relying on global social cost valuations, and can specifically call attention to climate-vulnerable U.S. military installations abroad with high replacement costs or irreplaceable strategic value, U.S. willingness to pay to protect relatives, ancestral homes, cultural and religious sites, and natural resources located abroad, and U.S. altruism toward the people, animals, and natural habitats across the globe. [EPA-HQ-OAR-2022-0829-0743, p. 13]

Beyond NEPA, and outside the climate context, agencies have considered key effects on international reciprocity in their regulatory cost-benefit analyses and decision making. Perhaps the best antecedent on this front is EPA's 1988 regulations to protect stratospheric ozone—another problem that, like greenhouse gases, requires international cooperation to effectively mitigate. In issuing those regulations, EPA recognized that it could "consider other countries' willingness to take regulatory action" in "deciding whether and how to regulate."97 EPA also took "[c]onsideration of the international ramifications of United States action" into account when "analyzing the cost and feasibility of controls."98 And in its regulatory impact analysis, EPA modeled alternative regulatory stringency levels based on potential international participation rates and the influence that EPA regulation would have on reciprocal international actions.99 By adopting a global approach to the social cost of greenhouse gases, EPA therefore draws upon the approach that it took for stratospheric ozone under the Reagan administration. [EPA-HQ-OAR-2022-0829-0743, p. 15]

97 Protection of Stratospheric Ozone, 53 Fed. Reg. 30,566, 30,569 (Aug. 12, 1988).

98 Id. ("Certainly other nations' ozone-depleting emissions or control of emissions affect the cost of United States' controls, and the need for other nations to limit their emissions may make appropriate United States action that encourages, or does not discourage, other nations to agree to such limits.").

99 Env't Prot. Agency, Regulatory Impact Analysis for the Protection of Stratospheric Ozone (1988).

In addition to EPA's consideration of international reciprocity and cooperation in prior rulemakings, agencies have also considered transboundary spillover effects in making key decisions. As one example, when considering the "public interest" in the certification of natural gas exports under the Natural Gas Act,102 the Department of Energy routinely "consider[s] international trade policy, foreign policy, and national security interests."103 As another example, the Food and Drug Administration also frequently considers international effects as part of its regulatory decision making, and has recognized that such costs are particularly relevant because "a portion of foreign costs could be passed on to domestic consumers."104 [EPA-HQ-OAR-2022-0829-0743, pp. 16-17]

102 15 U.S.C. § 717b(a).

103 New Policy Guidelines and Delegation Orders from Secretary of Energy to Economic Regulatory Administration and Federal Energy Regulatory Commission Relating to the Regulation of Imported Natural Gas, 49 Fed. Reg. 6684, 6688 (Feb. 22, 1984).

104 Requirements for Additional Traceability Records for Certain Foods, 87 Fed. Reg. 70,910, 71,071 tbl.2 (Nov. 21, 2022).

Courts have confirmed that agencies may—and, in some cases, must—take into account international spillover effects. In 2020, the U.S. Court of Appeals for the Ninth Circuit rejected a Bureau of Ocean Energy Management approval of an offshore oil drilling and production facility after the agency concluded that domestic extraction would not affect international fossil-fuel supply and consumption.105 As the court explained, because domestic production causes "foreign consumers [to] buy and consume more oil"—and because that consumption "can be translated into estimates of greenhouse gas emissions" that harms the United States—the agency had an obligation to consider those increased foreign emissions resulting from domestic action.106 Two subsequent district court opinions similarly faulted Department of Interior analyses for omitting the effects of domestic production on foreign demand and consumption.107 The fact that courts have required agencies to consider the spillover impacts from foreign greenhouse gas emissions provides strong support for EPA's consideration of spillovers from domestic emissions. [EPA-HQ-OAR-2022-0829-0743, pp. 16-17]

105 Ctr. for Biological Diversity v. Bernhardt, 982 F.3d 723, 738 (9th Cir. 2020).

107 Sovereign Iñupiat for a Living Arctic v. Bureau of Land Mgmt., 555 F. Supp. 3d 739, 764–67 (D. Alaska 2021); citing Friends of the Earth v. Haaland, No. CV 21-2317 (RC), 2022 WL 254526, at [Star]14–15 (D.D.C. Jan. 27, 2022).

Consistent with these examples, the Draft Circular A-4 Update recognizes that relevant benefits and costs to consider in regulatory impact analysis include both effects that "result directly from a regulation's domestic applicability" and those that result "indirectly from a regulation's impact on foreign entities."108 With regard to the latter category, the Draft Circular A-4 Update explains that relevant impacts "include the effects of a regulation on U.S. strategic interests, including the potential for inducing strategic reciprocity or other policy changes from actors abroad or effects on U.S. government assets located abroad," which "are particularly likely to occur when [a] regulation bears on a global commons or a public good."109 Additionally, the Draft Circular A-4 Update states that relevant impacts include "those that occur entirely outside the United States when they affect U.S. citizens and residents."110 [EPA-HQ-OAR-2022-0829-0743, pp. 16-17]

108 Draft Circular A-4 Update, supra note 10, at 9.

109 Id.

110 Id.

As all of these examples illustrate, EPA's consideration of climate damages on a global scale is consistent with how EPA and other agencies have exercised regulatory authority in numerous contexts. [EPA-HQ-OAR-2022-0829-0743, pp. 16-17]

II. Extensive Justification Supports EPA's Decisions to Omit a 7% Discount Rate and To Discount Long-Term Climate Impacts at a Lower Range of Discount Rates than the Proposed Rule's Shorter-Term Impacts

EPA applies the social cost of greenhouse gases estimates calculated at discount rates of 2.5%, 3%, and 5%,111 consistent with the Working Group's current recommendations, and justifies its decision to return to its prior conclusion that a 7% capital-based discount rate is inappropriate for climate effects. EPA's return to a reasonable range of discount rates to assess climate impacts is well supported—in fact, as recognized by both the Working Group in its 2021 update112 and EPA in the Draft SC-GHG Update,113 discount rates of 2% or lower are appropriate for valuing climate damages. [EPA-HQ-OAR-2022-0829-0743, p. 17]

111 Note that just as there is growing evidence that the discount rate should be below 2%, there is growing evidence that 5% is much too high a discount rate. The values at 5% should be considered a very conservative lower bound.

112 2021 TSD, supra note 4, at 16–22 (offering extensive evidence for the use of lower discount rates and recommending that agencies "consider discount rates below 2.5 percent" for valuing the social cost of greenhouse gases); see also id. at 4 ("Consistent with the guidance in E.O. 13990 for the IWG to ensure that the SC-GHG reflect the interests of future generations, the latest scientific and economic understanding of discount rates discussed in this TSD, and the recommendation from OMB's Circular A-4 to include sensitivity analysis with lower discount rates when a rule has important intergenerational benefits or costs, agencies may consider conducting additional sensitivity analysis using discount rates below 2.5 percent.").

113 In the Draft SC-GHG Update, EPA applies a central near-term discount rate of 2%, with additional valuations using near-term discount rates of 1.5% and 2.5%. The discount rates in the Draft SC-GHG Update also decline over time. See Draft SC-GHG Update, supra note 9, at 3 tbl.ES-1; id. at 52–61 (explaining discounting module).

The RIA cites the Working Group's arguments that, for long-term policies with intergenerational effects, uncertainty and ethical considerations make a 7% capital-based discount rate inappropriate.114 These arguments provide sufficient reason for EPA's approach to discount rates. Moreover, additional justifications support EPA's discounting choices. [EPA-HQ-OAR-2022-0829-0743, p. 17]

114 RIA at 10-11 to 10-12.

A. For Numerous Reasons, the 7% Discount Rate Is Inappropriate for Climate Effects

There is no support in the economics literature for applying a 7% discount rate to long- term impacts such as climate damage. The suggestion that EPA must apply a 7% discount rate to climate impacts—which is based exclusively on a narrow reading of two pages of the current Circular A-4 that OMB has proposed to substantially revise—is utterly inconsistent with economic practice and theory.115 There are in fact numerous reasons why applying a 7% discount rate to climate effects that occur over a 300-year time horizon would be unjustifiable—and that discount rates of 2% or lower are appropriate. [EPA-HQ-OAR-2022-0829-0743, pp. 17-18]

115 Although the current Circular A-4 provides discount rates of 3% and 7% as a default assumption, it also requires agency analysts to do more than rigidly apply default assumptions. Circular A-4, supra note 74, at 3 ("You cannot conduct a good regulatory analysis according to a formula. Conducting high-quality analysis requires competent professional judgment."). As such, analysis must be "based on the best reasonably obtainable scientific, technical, and economic information available," id. at 17, and agencies must "[u]se sound and defensible values or procedures to monetize benefits and costs, and ensure that key analytical assumptions are defensible," id. at 27.

Fifth, several standard justifications for capital-based discount rates break down given the particular threats of climate change. For example, one argument for capital-based discount rates is that spending capital on climate-abatement policies has opportunity costs and so, in policy analysis, future costs and benefits should be discounted at the rate of return to capital. However, the irreversible, uncertain, and catastrophic risks of climate change may disrupt this "opportunity cost" rationale: while it may seem, for instance, that future, wealthier generations might have better opportunities to address climate change for themselves, irreversible or catastrophic damages could arise that make future mitigation efforts more expensive or impossible.130 Similarly, if climate damages are "non-marginal," such that climate change significantly affects the very natural resources needed to drive economic growth, then growth could plummet or even turn negative.131 [EPA-HQ-OAR-2022-0829-0743, pp. 19-20]

130 Richard L. Revesz & Matthew R. Shahabian, Climate Change and Future Generations, 84 S. CAL. L. REV. 1097, 1149-52 (2011).

131 Id. at 1153 & n.246 (citing Heal's observation that estimates of productivity growth based on historical records omit depletion of natural resources, and thus bias discount rates upwards).

Executive Order 13,990 instructs agencies to ensure that the social cost of greenhouse gas values adequately account for "intergenerational equity."138 A 7% rate ignores much of future generations' welfare and so would be inconsistent with that mandate. Notably, even when using high discount rates for climate damages in 2020, EPA explained that the 7% capital rate did not adequately account for "tradeoffs between improving the welfare of current and future generations."139 Accordingly, EPA's decision not to apply that discount rate for assessing climate damages is entirely justified. [EPA-HQ-OAR-2022-0829-0743, p. 20]

138 Exec. Order § 13,990 5(b)(ii)(E).

139 85 Fed. Reg. at 24,735 (explaining that the central analysis focused on a 3% rate, and the 7% rate was used only for sensitivity analysis).

B. Extensive Justification Supports EPA's Distinct Approach to Discounting Climate Effects Relative to Other Costs and Benefits

As explained above, EPA's choice to use the social cost of greenhouse gases values calculated with consumption-based discount rates is fully justified. But this choice also means EPA is calculating the present value of reduced greenhouse gas emissions differently than the present value of other costs and benefits (which, per Circular A-4's default recommendations, it calculates using 3%and 7% discount rates). Extensive justification supports this distinct treatment of climate impacts relative to other costs and benefits. [EPA-HQ-OAR-2022-0829-0743, p. 21]

For one, given the nature of the Proposed Rule's costs and benefits and in light of the Draft Circular A-4 Update, it is more appropriate to discount all effects using consumption-based rates, and so the present value calculations that include some costs and benefits discounted at a 7% rate can be viewed as lower-bound sensitivity analyses. The capital-based discount rate theoretically assesses whether the net benefits from government action will exceed the returns that society could earn by instead investing the same resources in the private sector. But this framework for discounting and comparing benefits and costs makes sense only under the "extreme" assumption that all the costs of government action would "fully displace" (i.e., crowd out) private investment.140 In this way, the capital-based rate "at best creat[es] a lower bound on the estimate of net benefits," by applying a maximum discount rate that reflects an extreme case not likely to apply to many government actions.141 As Li and Pizer explain, a capital-based approach does not provide "a suitable discount rate" for regulatory cost-benefit analysis, in large part because the benefits of regulation—and not just the costs—may fall on capital as well.142 [EPA-HQ-OAR-2022-0829-0743, p. 21]

140 2021 TSD, supra note 4, at 18-19.

141 Id.

142 Qingran Li & William A. Pizer, Discounting for Public Benefit-Cost Analysis, RES. FOR THE FUTURE 3 (July 2021), https://www.rff.org/publications/issue-briefs/discounting-for-public-benefit-cost-analysis/.

Moreover, apart from the widespread support for consumption- over capital-based rates,143 special legal, economic, and policy considerations justify a distinct approach to discounting climate effects. While effects like compliance costs will play out over the next several decades, the climate effects of this rule are much longer term, affecting the welfare of future generations over centuries. Therefore, the arguments in favor of lower consumption-based discount rates—based on long-term uncertainty, ethics, declining economic growth, inapplicable market data, and other considerations—apply much more strongly to climate effects than to other costs and benefits. And because a high capital-based rate, like 7%, will effectively ignore the welfare of future generations (e.g., over the course of just 80 years, a 7% rate discounts away 99.5% of a future effect's value144) legal requirements to consider the welfare of future generations caution much more strongly against the application of a 7% rate to long-term climate effects than to other costs and benefits. [EPA-HQ-OAR-2022-0829-0743, p. 21]

143 See Howard et al., supra note 134 ("Recent economic literature strongly supports the use of a consumption discount rate over a capital rate of return over longer time horizons").

144 The discount factor is 1/(1+r)t; 1/(1+0.07)80 = 0.0045 = 0.45%.

Consequently, as the National Academies of Sciences has recognized, differences in the application of discount rates may be warranted "when only some categories [of costs and benefits] have an intergenerational component."145 The National Academies has offered recommendations for how agencies can best apply different annualized discount rates to climate impacts versus other costs and benefits,146 and EPA can rely on the National Academies' guidance to support its approach to discounting here. Likewise, as noted above, both the current Circular A-4147 and Draft Circular A-4 Update also recognize that intergenerational effects merit lower discount rates than intragenerational costs and benefits.148 [EPA-HQ-OAR-2022-0829-0743, p. 21]

145 NAS 2017 Report, supra note 122, at 182.

146 Id.

147 Circular A-4, supra note 74, at 35–36.

148 Draft Circular A-4 Update, supra note 10, at 80–82.

Case law on the social cost of greenhouse gases also offers support for EPA's discounting approach. Specifically, in Zero Zone v. Department of Energy, the plaintiffs argued that the Department of Energy had arbitrarily considered hundreds of years of climate benefits while limiting its assessment of employment impacts and other effects to just a thirty-year time horizon. The court upheld the regulatory analysis, concluding that the difference in time horizons was justified because the rule "would have long-term effects on the environment but . . . would not have long-term effects on employment."149 The choice of time horizons is related to the choice of discount rate: any cost or benefit occurring beyond the end of the analytical time horizon is effectively discounted at a 100 percent rate.150 Analogizing from this precedent, a court may similarly defer to an agency's finding that the long time horizon of climate change justifies a lower discount rate than the rate applied to shorter-term costs and benefits. [EPA-HQ-OAR-2022-0829-0743, p. 22]

149 Zero Zone, 832 F.3d at 679.

150 See Arden Rowell, Time in Cost-Benefit Analysis, 4 U.C. IRVINE L. REV. 1215, 1237-38 (2014) (noting time inconsistencies in different regulatory analyses and advising agencies to identify a temporal break-even point by which a proposed policy will pay for itself).

III. Common Criticisms of the Working Group's Methodology from Opponents of Climate Regulation Lack Merit

While the Working Group developed its social cost valuations through a rigorous process that incorporated the best scientific and economic modeling available at the time, its assumptions have sometimes been criticized by opponents of climate regulation. Such objections lack merit and do not supply bases for EPA to reject the Working Group's expert valuations. This section offers responses to criticisms from opponents of sensible climate policy. [EPA-HQ-OAR-2022-0829-0743, p. 22]

1. EPA Must Monetize Climate Impacts as Part of Its Analysis

It is widely established that federal agencies may—and often must—consider effects on climate change when those effects flow from the agency's actions. With EPA, this is especially well-established. In Massachusetts v. EPA, the Supreme Court held that greenhouse gas emissions qualify as an "air pollutant" for regulation under the Clean Air Act.151 Because one of the Proposed Rule's aims is to regulate greenhouse gas pollution as an "air pollutant" under Section 202 of the Clean Air Act—following the Massachusetts precedent—EPA should obviously consider impacts on climate when deciding upon the stringency of its regulation. [EPA-HQ-OAR-2022-0829-0743, pp. 22-23]

151 Massachusetts v. EPA, 127 S. Ct. 1438 (2007).

Monetizing climate impacts is a natural and rational option to account for those impacts. [EPA-HQ-OAR-2022-0829-0743, pp. 22-23]

Indeed, it is well accepted in regulatory practice and precedent that agencies should monetize regulatory impacts to the extent feasible, to compare costs and benefits along a common metric.152 EPA has long monetized climate damages in vehicles regulations promulgated under the Obama, Trump, and Biden administrations. [EPA-HQ-OAR-2022-0829-0743, pp. 22-23]

152 Circular A-4, supra note 74, at 2 ("Benefit-cost analysis is a primary tool used for regulatory analysis.2 Where all benefits and costs can be quantified and expressed in monetary units, benefit-cost analysis provides decision makers with a clear indication of the most efficient alternative, that is, the alternative that generates the largest net benefits to society (ignoring distributional effects).").

Monetizing climate impacts may also be legally required. In 2007, the U.S. Court of Appeals for the Ninth Circuit held that the federal government must monetize climate impacts when it conducts a cost-benefit analysis. In Center for Biological Diversity v. National Highway Traffic Safety Administration, the Ninth Circuit remanded a fuel economy rule to the Department of Transportation (DOT) for failing to monetize the benefits of carbon dioxide reductions in its regulatory analysis.153 The Court recognized the presence of uncertainty in the valuation of climate damages, but explained that "the value of carbon emissions reduction is certainly not zero."154 By failing to value the benefit of greenhouse gas emission reductions in its analysis, the Court continued, DOT effectively ignored the adverse impacts of greenhouse gas emissions and thus "put a thumb on the scale by undervaluing the benefits . . . of more stringent standards."155 [EPA-HQ-OAR-2022-0829-0743, p. 23]

153 Ctr. for Biological Diversity, 538 F.3d at 1198–1203 (9th Cir. 2008).

154 Id. at 1200.

155 Id. at 1198.

2. Monetizing Climate Benefits Does Not Skew the Analysis, but Rather Provides Balance Since EPA Also Monetizes Costs

Another objection to the use of the social cost of greenhouse gases from critics of climate action is that these valuations account only for the damages from climate change, but do not take account of the alleged economic benefits from fossil-fuel production and usage. But this argument is unpersuasive for two key reasons. [EPA-HQ-OAR-2022-0829-0743, pp. 23-24]

First, the economic benefits of fossil-fuel extraction are far more limited than its proponents suggest, since the broader benefits that society derives from power and electricity are attributable to energy production in general and are not unique to fossil fuels.156 Accordingly, controls on fossil fuels will have limited net economic impacts.157 Second, while there are of course some economic impacts from reductions in fossil-fuel production and usage, those impacts should not be included in any calculation of climate damages, but rather considered separately by regulators on the costs side of the ledger in individual determinations. [EPA-HQ-OAR-2022-0829-0743, pp. 23-24]

156 Renewable energy, like fossil fuels, generates revenue, supports jobs, and vitalizes local economies. See, e.g., Katie Siegner et al., Rocky Mtn. Inst., Seeds of Opportunity: How Rural America Is Reaping Economic Development Benefits from the Growth of Renewables 6–16 (2021), https://perma.cc/DWH9-D4L7.

157 Environmental regulation typically has limited impacts on total employment or other macroeconomic indicators, but rather shifts production from one sector to another. See Inst. for Pol'y Integrity, Does Environmental Regulation Kill or Create Jobs (2017), https://policyintegrity.org/files/media/Jobs_and_Regulation_Factsheet.pdf. Meanwhile, the sharp decline in the cost renewable energy is already expected to crowd out the demand for gas-fuel electricity in the coming years and decades. See, e.g. Energy Info. Admin., Annual Energy Outlook 2021 Narrative 18 tbl. 11 (projecting doubling of renewables as a share of domestic energy consumption—from 21% to 42%—by 2050 under reference case, while share of coal and natural gas declines); Charles Teplin et al., ROCKY MTN. INST., The Growing Market for Clean Energy Portfolios 8 fig. ES-2 (2019), https://perma.cc/P5YJ-WARJ (showing precipitous decline in cost of clean energy to being cheaper than fossil fuels).

In the Proposed Rule, EPA monetizes not only the expected benefits of the proposal but also the expected compliance costs from industry. EPA then compares quantified cost and benefit estimates in determining whether and how to regulate, as instructed by federal guidance and executive order.158 Capturing climate benefits is thus essential to ensuring a balanced analysis. As the Ninth Circuit has recognized, "failure to monetize the most significant benefit of more stringent standards: reduction in carbon emissions"—while continuing to value estimated compliance costs—would "put a thumb on the scale by undervaluing the benefits and overvaluing the costs of more stringent standards."159 [EPA-HQ-OAR-2022-0829-0743, p. 24]

158 Exec. Order No. 12,866 § 1(a), 58 Fed. Reg. 51,735 (Oct. 4, 1993) (directing that "in choosing among alternative regulatory approaches, agencies should select those approaches that maximize net benefits").

B. Other Common Criticisms of the Working Group's Methodology from Opponents of Climate Policy Lack Merit

EPA should also provide responses to any objections to the Working Group's methodology and valuations raised during this comment period. The Working Group, of course, has already responded to criticisms of its methodology that were offered during the public comment period that it held in 2013,160 and EPA should draw from that document where relevant in responding to objections offered through this notice-and-comment process. But some objections are now being raised that were not offered during the 2013 comment period, while some of the responses that the Working Group provided can be supplemented with more recent information. Below, we provide brief responses to common objections that are now being presented by opponents of climate reforms. [EPA-HQ-OAR-2022-0829-0743, p. 24]

160 Response to Comments, supra note 118.

1. The Social Cost Valuations Are Not Too Uncertain to Apply

While critics sometimes argue that there is too much uncertainty to rely on the Working Group's social cost valuations, this argument is incorrect on multiple levels. As a legal matter, the presence of some uncertainty in the social cost valuations should not preclude agencies from using available valuations. And as a factual matter, the Working Group rigorously considered uncertainty and accounted for it in numerous ways. Moreover, the presence of continued uncertainty suggests that the social cost valuations should be higher than presently valued—not that climate damages should be ignored. This is confirmed by EPA's Draft SC-GHG Update, which incorporates the latest available research and produces substantially higher climate-damage valuations than those the Working Group previously developed. [EPA-HQ-OAR-2022-0829-0743, pp. 24-25]

Federal courts have repeatedly recognized that agency analysis necessitates making predictive judgments under uncertain conditions, explaining that "[r]egulators by nature work under conditions of serious uncertainty" 161 and "are often called upon to confront difficult administrative problems armed with imperfect data."162 As the Ninth Circuit has explained, "the proper response" to the problem of uncertain information is not for the agency to ignore the issue but rather "for the [agency] to do the best it can with the data it has."163 Courts generally grant broad deference to agencies' analytical methodologies and predictive judgments so long as they are reasonable and do not require agencies to act with complete certainty.164 [EPA-HQ-OAR-2022-0829-0743, pp. 24-25]

164 See Wis. Pub. Power, Inc. v. FERC, 493 F.3d 239, 260 (D.C.Cir.2007) ("It is well established that an agency's predictive judgments about areas that are within the agency's field of discretion and expertise are entitled to particularly deferential review, so long as they are reasonable.").

The Working Group rigorously considered various sources of long-term uncertainty "through a combination of a multi-model ensemble, probabilistic analysis, and scenario analysis."165 As the Working Group explained, the three reduced-form integrated assessment models (IAMs) account for uncertainty themselves by spanning a range of economic and ecological outcomes.166 Additionally, the use of three separate models—all developed by different experts spanning a range of views—accounts for uncertainty by integrating a diversity of viewpoints and structural and analytical considerations.167 [EPA-HQ-OAR-2022-0829-0743, p. 25]

165 2021 TSD, supra note 4, at 26.

166 See id.

167 See id.

In addition to the use of three distinct damage models with different inputs and assumptions, the Working Group integrated various sources of uncertainty into its damage valuations. For instance, the Working Group applied an equilibrium climate sensitivity—that is, an estimate of how much an increase in atmospheric greenhouse gas concentrations affects global temperatures—that reflects a broad distribution of possible outcomes.168 The Working Group also applied five different socioeconomic and emissions trajectories from the published literature reflecting a range of possible outcomes for future population growth, global gross domestic product, and greenhouse gas emission baselines—all important inputs that affect long- term climate damage estimates.169 The Working Group ran each integrated assessment model 10,000 times per scenario (and per greenhouse gas) for a total of 150,000 draws per greenhouse gas and then averaged across those results to develop its recommended estimates.170 In addition to reporting the average valuations, the Working Group published the results of each model run under each scenario.171 [EPA-HQ-OAR-2022-0829-0743, p. 25]

Moreover, experts broadly agree—and EPA's Draft SC-GHG Update confirms—that the presence of uncertainty in the social cost valuations counsels for more stringent climate regulation, not less.172 This is due to various factors including risk aversion, the informational value of delaying climate change impacts, and the possibility of irreversible climate tipping points that cause catastrophic damage.173 In fact, as discussed above and emphasized in EPA's Draft SC-GHG Update, uncertainty is a factor justifying lowering the discount rate, particularly in intergenerational settings.174 Furthermore, the current omission of key effects of climate change—such as catastrophic damages, wildfires and certain cross-regional spillover effects—also suggests that the true social cost values are likely higher than the Working Group's current estimates.175 [EPA-HQ-OAR-2022-0829-0743, pp. 25-26]

172 See, e.g., Alexander Golub et al., Uncertainty in Integrated Assessment Models of Climate Change: Alternative Analytical Approaches, 19 ENV'T MODELING & ASSESSMENT 99 (2014) ("The most important general policy implication from the literature is that despite a wide variety of analytical approaches addressing different types of climate change uncertainty, none of those studies supports the argument that no action against climate change should be taken until uncertainty is resolved. On the contrary, uncertainty despite its resolution in the future is often found to favor a stricter policy.").

173 The undersigned organizations have filed comments in numerous regulatory proceedings highlighting the various forms of uncertainty that increase the social cost of greenhouse gases, and providing numerous references. See, e.g., Environmental Defense Fund et al., Improper Valuation of Climate Effects in the Proposed Revised Cross- State Air Pollution Rule Update for the 2008 Ozone NAAQS, Technical App'x: Uncertainty (Dec. 14, 2020), https://policyintegrity.org/documents/Joint_SCC_comments_EPA_revised_CSAPR_Ozone_NAAQS_2020.12.14.p df.

175 Interagency Working Group, Technical Support Document: Social Cost of Carbon for Regulatory Impact Analysis 21 (2016) ["2016 TSD"] (recognizing that "these limitations suggest that the [social cost of greenhouse gases] estimates are likely conservative").

2. The Working Group Did Not Bias Its Estimates by Ignoring Positive Impacts of Climate Change

Critics sometimes claim that the Working Group's social cost values ignore important positive impacts of a warming climate. Examples that have been offered to support this argument include alleged agricultural benefits from higher temperatures and decreased wintertime mortality. But these arguments are legally and factually dubious, and miss the forest for the trees. [EPA-HQ-OAR-2022-0829-0743, pp. 26-27]

Mere omission of some impacts does not counsel for abandoning the social cost estimates, particularly since independent experts—and EPA's Draft SC-GHG Update—widely agree that those estimates likely undervalue true climate damages because they omit far more negative effects than positive ones. For instance, the Working Group has explained that several of the underlying economic models omit certain major damage categories such as catastrophic damages and certain cross-regional spillover effects.176 These effects can be massive: One paper, for instance, finds that the inclusion of tipping points doubles the social cost estimates,177 with another paper concluding that the effect is even greater and thus the Working Group's existing values "may be significantly underestimating the needs for controlling climate change."178 The current consensus of experts puts damages for a 3°C increase at roughly 5% to 10% of gross domestic product,179 which is substantially higher than the damages estimated by the IAMs.180 And as the Ninth Circuit has explained, the presence of some omitted damages does not provide a legal basis to ignore established methodologies to monetize climate damages, since while "there is a range of [plausible] values, the value of carbon emissions reduction is certainly not zero."181 [EPA-HQ-OAR-2022-0829-0743, pp. 26-27]

179 See, e.g., Peter Howard & Derek Sylvan, Inst. for Pol'y Integrity, Gauging Economic Consensus on Climate Change 25 (2021) (reporting mean estimate of 8.5% GPD loss and median estimate of 5% loss, based on elicitation of over 700 climate-policy experts).

180 2010 TSD, supra note 171, at 9 fig.1A (showing range of GDP loss below 5% for 3°C temperature increase).

181 Ctr. for Biological Diversity, 38 F.3d at 1200.

In addition to its legal shortcomings, arguments about the impact of positive externalities are also factually suspect. For instance, while agricultural benefits have become a flashpoint in this debate, the IAMs in fact do account for the potential agricultural benefits of carbon dioxide fertilization from a warming planet.182 And evidence suggests that, if anything, these models likely overvalue agricultural benefits from a warming planet—and thus undervalue the social cost of greenhouse gases.183 One paper, for instance, concludes that estimates of net agricultural impacts produced an undervaluation of the social cost values by more than 50%, explaining that "new damage functions reveal far more adverse agricultural impacts than currently represented" in the IAMs used by the Working Group.184 And a comprehensive investigation of the impacts of climate change on agriculture has rejected the hypothesis "that agricultural damages over the next century will be minimal and indeed that a few degrees Celsius of global warming would be beneficial for world agriculture," concluding that climate change "will have at least a modest negative impact on global agriculture in the aggregate."185 This conclusion is confirmed by the Draft SC-GHG Update, which finds that climate change on net will harm, not benefit, the agricultural sector.186 [EPA-HQ-OAR-2022-0829-0743, p. 27]

182 See Peter Howard, Omitted Damages: What's Missing from the Social Cost of Carbon 6 (2014), https://policyintegrity.org/files/publications/Omitted_Damages_Whats_Missing_From_the_Social_Cost_of_Carbon. pdf. See also Inst. for Pol'y Integrity, A Lower Bound: Why the Social Cost of Carbon Does Not Capture Critical Climate Damages and What That Means for Policymakers 5 (2019), https://policyintegrity.org/files/publications/Lower_Bound_Issue_Brief.pdf; Climate Impacts Reflected in the SCC Estimates, Cost of Carbon Project, https://costofcarbon.org/scc-climate-impacts.

186 Draft SC-GHG Update, supra note 9, at 70 tbl.3.1.4 (breaking down damage estimates by sector/category).

Other arguments focusing on omitted positive impacts are equally misguided. For example, while some critics of the Working Group's methodology misleadingly point out that one of the models, DICE, focuses on increased heat-related mortality and does not account for reductions in wintertime mortality, consideration of the many damages omitted from the IAMs (such as particulate matter from wildfires, deaths from flooding, Lyme and other tick-based diseases), including certain mortality effects, consistently point toward a higher social cost value.187 One recent study concludes that the IAMs, on net, undervalue mortality from climate change.188 Focusing on the omission of reductions in wintertime mortality thus misses the forest for the trees, and does not supply a basis to disregard the Working Group's valuations. [EPA-HQ-OAR-2022-0829-0743, p. 27]

187 See, e.g., Howard, supra note 182; see also 2016 TSD, supra note 175, at 21.

188 See Tamma A. Carleton et al., Valuing the Global Mortality Consequences of Climate Change Accounting for Adaptation Costs and Benefits (U. Chicago, Becker Friedman Inst. for Econ. Working Paper No. 2018-51) (Jul. 31, 2019), https://papers.ssrn.com/sol3/papers.cfm?abstract_id=3224365 (finding that new empirical estimates suggest that the increase in morality risk from climate change is valued at approximately 3.2% of global GDP in 2100).

3. The Working Group Did Not Overstate the Pace of Climate Change

Critics sometimes allege that the chosen Equilibrium Climate Sensitivity (ECS) distribution—that is, the amount of warming that is expected to result from a doubling of the atmospheric carbon dioxide concentration—is outdated and fails to account for recent evidence showing that sensitivity to be lower than previously believed. But these arguments rely on cherry-picked data and ignore the scientific consensus. [EPA-HQ-OAR-2022-0829-0743, p. 28]

In 2016, the National Academies of Sciences dedicated an entire report to whether the Working Group should update the social cost metrics to reflect more recent science on the ECS. The National Academies decided that such an update was unnecessary, "recommend[ing] against a near-term change in the distributional form of the ECS" and explaining that any reasonable revisions on this front would "have a minimal impact on estimates of the [social cost of greenhouse gases]."189 [EPA-HQ-OAR-2022-0829-0743, p. 28]

189 Nat'l Acad. Scis., Eng'g & Med., Assessment of Approaches to Updating the Social Cost of Carbon: Phase 1 Report on a Near-Term Update 34, 46 (2016), https://perma.cc/TJM6-XE65 [hereinafter "NAS 2016 Report"].

On top of the National Academies' rejection of this argument, there is little support for the claim that the Working Group overstated the pace of climate change. The most recent estimate from the Intergovernmental Panel on Climate Change (IPCC)—which reflects consensus estimates from the worldwide scientific community—projects an ECS range from 2.5°C to 4°C, with 3°C as a "best estimate."190 This is consistent with the range applied by the Working Group—based off of Roe & Baker—which uses 3°C as its median and 3.5 °C as its mean ECS value.191 In evaluating the ECS, the Working Group assessed estimates from a wide range of experts and selected consensus values. In fact, as the Working Group acknowledged, some ECS estimate ranges go as high as 10º C, making its selected ECS distribution substantially lower than these high-end estimates and a reasonable middle range.192 The Draft SC-GHG Update confirms this approach by applying a similar ECS value using the FaIR model.193 [EPA-HQ-OAR-2022-0829-0743, p. 28]

190 IPCC, AR6 Synthesis Report SPM-14 (2021).

191 2010 TSD, supra note 171, at 13 tbl.1.

192 Id. at 14 fig.2.

193 Draft SC-GHG Update, supra note 9, at 28–29 & 29 tbl.2.2.1.

In previous dockets, opponents of the Working Group's estimates have cited Lewis & Curry (2015)—which estimates a median ECS of 1.64 ºC with an uncertainty range (5–95%) of 1.05–4.05 ºC—to suggest that the Working Group applied an inappropriately high ECS range.194 But in light of the consensus estimates discussed above, that paper is a severe outlier. Since its publication, Lewis & Curry (2015) has been criticized by other climate scientists for methodological deficiencies that may cause it to underestimate the ECS.195 And as noted above, the National Academies did not think that Lewis & Curry (2015) merited an update to the Working Group's valuations to revise the ECS estimates.196 [EPA-HQ-OAR-2022-0829-0743, pp. 28-29]

194 Nicholas Lewis & Judith A. Curry, The Implications for Climate Sensitivity of AR5 Forcing and Heat Uptake Estimates, 45 Climate Dynamics 1009 (2015).

195 See, e.g., Kate Marvel et al., Internal Variability and Disequilibrium Confound Estimates of Climate Sensitivity from Observations, 45 GEOPHYS. RES. LTRS. 1595 (2018) ("[A] range of recent work … suggests that [Lewis & Curry (2015)] may underestimate equilibrium warming."); Timothy Andrews et al., Accounting for Temperature Patterns Increases Historical Estimates of Climate Sensitivity, 45 GEOPHYS. RES. LTRS. 8490 (2018) (explaining that Lewis and Curry disregard "the impact from non?CO2 forcings and unforced climate variability that could have had a significant impact on the pattern of historical temperature change").

196 NAS 2016 Report, supra note 189.

Critics further argue that the ECS distribution applied by the Working Group inappropriately skews rightward, meaning that its mean ECS value exceeds the median value of 3º C that the IPCC has indicated. But that decision is a feature, not a bug. As the National Academies explained, the IPCC has found that there is a "positively skewed distributional form for [the ECS] parameter" similar to the ECS distribution applied by the Working Group.197 (This too is confirmed in EPA's Draft SC-GHG Update.198) In other words, the mean ECS value should be higher than the median ECS value, and the Working Group applied an appropriate distribution. Criticisms to the contrary are meritless. [EPA-HQ-OAR-2022-0829-0743, pp. 28-29]

197 Id. at 25.

198 Draft SC-GHG Update, supra note 9, at 29 tbl.2.2.1 (reporting mean ECS of 3.18 °C and median of 2.95 °C).

4. The Working Group Applied a Reasonable Range of Emission Baselines

Critics sometimes argue that the Working Group's valuations are an overestimate because they apply outdated emission scenarios that exaggerate the baseline level of atmospheric greenhouse gas levels. Using a higher baseline level of emissions raises the social cost estimates because the harm from an additional unit of emissions increases with the baseline atmospheric emissions level. However, the Working Group used a reasonable emissions baseline that reflects different possible mitigation scenarios. [EPA-HQ-OAR-2022-0829-0743, p. 29]

While the Working Group assumed a baseline emissions range of 13–118 gigatons of carbon dioxide emitted per year by 2100,199 recent projections from the Climate Action Tracker indicate that baseline emissions will reach between 14–175 gigatons of carbon dioxide by 2100 under a range of scenarios reflecting different levels of mitigation.200 Thus, the baselines used by the Working Group potentially understate baseline emissions rather than overvalue them as opponents argue. Several of the Working Group's supposedly "business-as-usual" scenarios are actually more consistent with baseline estimates reflecting policy projections.201 Accordingly, the criticism that the Working Group overestimated future greenhouse gas concentrations in the atmosphere falls flat. [EPA-HQ-OAR-2022-0829-0743, p. 29]

199 2010 TSD, supra note 171, at 16 tbl.2.

200 Climate Action Tracker, Global Emissions Time Series (Dec. 1, 2020), https://perma.cc/B4X2- RAWA.

201 Compare id. (projecting 35-48 gigatons of emissions in 2100 under "current policy projections" scenarios and 83-175 gigatons under business-as-usual scenario) with 2010 TSD, supra note 171, at 16 tbl.2 (incorporating supposedly business-as-usual scenarios of 42.7 and 60.1 gigatons in 2100).

Moreover, this choice does not particularly affect the social cost valuations. In comparison to the Working Group's central social cost of carbon estimate in 2020 of $51 per ton, the average social cost of carbon under the Working Group's supposed business-as-usual emissions scenarios is $53 per ton and $41 per ton under the emissions scenario that is consistent with sustained and widespread mitigatory action.202 While relying less on the Working Group's supposed business-as-usual scenarios would therefore modestly decrease the interim social cost valuations in a vacuum, more holistic updates to the metrics as recommended by the National Academies of Sciences would very likely increase the social cost valuations overall—as confirmed by EPA's Draft SC-GHG Update—due to the omitted damages discussed above and recent evidence regarding intergenerational discount rates.203 At best, therefore, this argument makes a mountain out of a molehill. [EPA-HQ-OAR-2022-0829-0743, pp. 29-30]

202 See Peter Howard et al., Option Value and the Social Cost of Carbon: What Are We Waiting For? (Inst. for Pol'y Integrity Working Paper No. 2020/1) at 16 tbl.1 (2020), https://policyintegrity.org/files/publications/Working_paper_06.22.20.pdf.

203 See 2021 TSD, supra note 4, at 4 (Working Group acknowledging that its current social cost valuations "likely underestimate societal damages from [greenhouse gas] emissions").

5. The Working Group Applied Scientifically-Based Damage Models

Critics sometimes claim that the IAMs—the damage functions for translating climate impacts into economic losses—are flawed and arbitrary. While newer data has enabled the development of updated damage models that EPA applies in the Draft SC-GHG Update, the Working Group's damage functions nonetheless are based on reasonable assumptions made by a range of experts.204 They have also withstood scientific scrutiny, and while opponents of climate reform frequently highlight criticism of the damage functions by a notable economist, they take this criticism out of context. [EPA-HQ-OAR-2022-0829-0743, p. 30]

204 Response to Comments, supra note 118, at 8 ("While the development of the DICE, FUND and PAGE models necessarily involved assumptions and judgments on the part of the modelers, the damage functions are not simply arbitrary representations of the modelers' opinions about climate damages.").

The Working Group selected three models of climate damages that, when the Working Group selected them in 2010, were the most widely used and cited models in the economics literature linking physical climate impacts to economic damages205: the DICE, FUND, and PAGE models.206 These models were developed by outside experts, published in peer-reviewed economic literature,207 and the product of extensive scholarship and expertise. One of the models, DICE, was developed by William Nordhaus, an economics professor and former provost of Yale University who won a Nobel Memorial Prize in Economic Sciences for developing the model. And PAGE's developer, Chris Hope, was a lead author and review editor for the Third and Fourth Assessment Reports of the IPCC, which shared the Nobel Peace Prize in 2007 with former U.S. Vice President Al Gore.208 [EPA-HQ-OAR-2022-0829-0743, p. 30]

205 Response to Comments, supra note 118, at 4 (stating the models "remain the most widely cited"), 8 (quoting the National Academies of Sciences for recognizing that the chosen models represent "the most widely used impact assessment models" available).

206 2010 TSD, supra note 171, at 5.

207 Response to Comments, supra note supra note 118, at 4.

208 See Chris Hope faculty bio page, University of Cambridge Judge Business School, https://www.jbs.cam.ac.uk/faculty-research/research-teaching-staff/chris-hope/.

The three models reflect a wide diversity of methodological assumptions about a range of key parameters and inputs.209 This reflects, in part, different judgments about the experts who developed the models. For instance, Richard Tol, who developed the FUND model, has stated that "[t]he impact of climate change is relatively small," and dismissed much of the research behind climate change as "scaremongering" rather than "sound science."210 Unsurprisingly, his model produces the lowest damage estimates of the three models incorporated by the Working Group.211 William Nordhaus, who developed the DICE model, is widely credited with popularizing the goal that global temperatures increase no more than 2° Celsius (or 3.6° Fahrenheit) above pre-industrial levels212—a goal now considered conservative by the global community.213 His model produces higher damage estimates that are close to the Working Group's average damage valuations.214 [EPA-HQ-OAR-2022-0829-0743, pp. 30-31]

209 See 2010 TSD, supra note 171, at 6 (discussing how "[t]he parameters and assumptions embedded in the three models vary widely").

210 Richard S.J. Tol, Why Worry About Climate Change?, ESRI Research Bulletin 2009/1/1, at 3, 5 (2009).

211 See 2010 TSD, supra note 171, at 50 tbl.A5 (reporting that FUND model has the lowest mean estimate of the three models at all discount rates, including a negative social cost of carbon estimate at a 5% discount rate).

212 The 2° C Limit on Global Warming, The Economist (Dec. 6, 2015), https://www.economist.com/the-economist-explains/2015/12/06/the-2degc-limit-on-global-warming.

213 For instance, the Paris Agreement calls for governments to "hold[] the increase in the global average temperature to well below 2°C above pre-industrial levels and pursu[e] efforts to limit the temperature increase to 1.5°C above pre-industrial levels, recognizing that this would significantly reduce the risks and impacts of climate change." Paris Agreement to the United Nations Framework Convention on Climate Change, Art. 2(1)(a), Dec. 12, 2015, T.I.A.S. No. 16-1104.

214 Compare 2010 TSD, supra note 171, at 50 tbl.A5 with id. at 1.

Opponents of climate mitigation policy sometimes point to criticisms from Robert S. Pindyck, a noted climate economist who has been critical of the Working Group's choice of damage functions. But as Professor Pindyck has himself stated, his "writings continue to be taken out of context by some to unfairly attack the Interagency Working Group's methodology and its interim estimates."215 While Professor Pindyck has questioned the shape of the models' damage functions,216 he has acknowledged that the damage functions reflect "common beliefs" about the effects of two or three degrees of warming. [EPA-HQ-OAR-2022-0829-0743, p. 31]

215 Robert S. Pindyck, Comments on "Technical Support Document: Social Cost of Carbon, Methane, and Nitrous Oxide Interim Estimates Under Executive Order 13990" at 1 (June 15, 2021), https://www.regulations.gov/comment/OMB-2021-0006-0012.

216 Robert S. Pindyck, Climate Change Policy: What do the Models Tell Us? (Nat'l Bureau of Econ. Research, Working Paper No. 19244) 16 (2013), https://perma.cc/G25M-MA7W.

And Pindyck states that uncertainty about the social cost estimates, including the damage functions, "does not imply that [their] value should be set to zero until the uncertainty is resolved."217 In fact, he actually advocates for an even higher social cost value than that produced by the Working Group218 and declared in 2017 (prior to the release of the Draft SC-GHG Update) that "the federal government should continue to use the [Working Group's] interim estimates . . . as lower bound estimates."219 [EPA-HQ-OAR-2022-0829-0743, p. 31]

217 Robert S. Pindyck, Comments to Ms. Catherine Cook, Bureau of Land Management, on Proposed Rule and Regulatory Impact Analysis on Delay and Suspension of Certain Requirements for Waste Prevention and Resource Conservation 3 (Nov. 6, 2017), https://perma.cc/8MY5-58P5; see also Pindyck, supra note 216, at 16 (My criticism of IAMs should not be taken to imply that because we know so little, nothing should be done about climate change right now, and instead we should wait until we learn more. Quite the contrary.").

218 Pindyck, supra note 215, at 1 ("My work instead strongly suggests that the estimates of the social cost of greenhouse gases should be higher than the February 2021 interim estimates[.]") In 2019, Pindyck's own estimate of the average social cost of carbon dioxide was between $80 to $100, with plausible values going up to $200. Robert S. Pindyck, The Social Cost of Carbon Revisited, 94 J. ENV'T ECON. & MGMT. 140, 140, 154–55 (2019). This is far higher than the Working Group's current central estimate of $51.

219 Pindyck, supra note 215, at 1.

In other words, the best critic of the Working Group's methodology that opponents could find supports the continued use of the Working Group's estimates and considers them to be conservative underestimates of the true cost to society of greenhouse gas emissions. His conclusion is supported by EPA's Draft SC-GHG Update, which provides conclusive evidence that the Working Group's climate-damage valuations are underestimates. Accordingly, criticisms of the Working Group's valuations from opponents of sensible climate policy are groundless. [EPA-HQ-OAR-2022-0829-0743, p. 31]

IV. EPA Should Conduct Additional Analysis Using the Climate-Damage Estimates from the Draft SC-GHG Update and the Discounting Approach from the Draft Circular A-4 Update

While EPA's application of the Working Group's climate-damage valuations as conservative underestimates is legally justified, the agency should conduct additional analysis using the draft climate-damage valuations that EPA recently published.220 EPA's draft valuations faithfully implement the roadmap laid out in 2017 by the National Academies of Sciences for updating the social cost of greenhouse gases221 and apply recent advances in the science and economics on the costs of climate change. EPA's methodology and valuations are consistent with those applied by a range of expert independent researchers. And while EPA's draft valuations remain underestimates,222 they more fully account for the costs of climate change by incorporating the latest available research on climate science, damages, and discount rates. While EPA should apply the Draft SC-GHG Update in sensitivity analysis if it finalizes this regulation prior to its finalization of that update, it should consider applying those valuations in its primary analysis (with the Working Group's estimates in sensitivity analysis) should it finalize the SC- GHG Update before this rule. [EPA-HQ-OAR-2022-0829-0743, p. 32]

220 Draft SC-GHG Update, supra note 9.

221 Nat'l Acads. Sci., Engineering & Med., Valuing Climate Damages: Updating Estimation of the Social Cost of Carbon Dioxide (2017).

222 Draft SC-GHG Update, supra note 9, at 4 ("[B]ecause of data and modeling limitations . . . estimates of the SC- GHG are a partial accounting of climate change impacts and, as such, lead to underestimates of the marginal benefits of abatement."); id. at 72.

Likewise, EPA should also conduct additional analysis using the discounting approach from the Draft Circular A-4 Update. The Draft Circular A-4 Update would ensure that long-term benefits and costs receive proper consideration in regulatory impact analysis. Specifically, the Draft Circular A-4 Update proposes to lower the default, risk-free consumption discount rate used in regulatory impact analysis from the current 3% to 1.7%, based on updated data and extensive economic scholarship.223 Also reflecting current economic literature, the update would eliminate the use of the opportunity cost of capital discount rate (i.e., the 7% rate in the current Circular A-4) and replace it with the shadow price of capital approach.224 These updates are consistent with the best available evidence and widely supported by the leading experts in the field.225 Once again, EPA should apply the discounting approach from the Draft Circular A-4 Update in sensitivity analysis if it finalizes this regulation prior to OMB's finalization of that update, and consider applying that approach in its primary analysis should OMB finalize the Circular A-4 Update before this rule is finalized. [EPA-HQ-OAR-2022-0829-0743, p. 32]

223 Draft Circular A-4 Update, supra note 10, at 75–76.

224 Id. at 78–80.

225 Howard et al., supra note 134.

Table 1 shows the climate benefits of the Proposed Rule and Alternative 1 (the proposal's more stringent alternative) using EPA's "central" certainty-equivalent near-term discount rate of

2%.226 For comparison, the table presents those estimates alongside the four estimates from the Working Group that EPA provides in the Proposed Rule. [EPA-HQ-OAR-2022-0829-0743, p. 32]

226 Id. at 9 (describing 2% as the "central" rate).

Table 1: Climate Benefits Using Draft SC-GHG Update (2020$ Billion)

Working Group 5% Average: Proposed Program: 82; Alternative 1: 91

Working Group 3% Average: Proposed Program: 330; Alternative 1: 360

Working Group 2.5% Average: Proposed Program: 500; Alternative 1: 560

Working Group 3% 95th percentile: Proposed Program: 1000; Alternative 1: 1100

Draft Update (2% discount)227: Proposed Program: 1200; Alternative 1: 1300 [EPA-HQ-OAR-2022-0829-0743, p. 32]

227 Emissions in future years are discounted back to present value using a 3% discount rate. This is consistent with EPA's approach to the climate-damage valuations using non-standard discount rates of 2.5% and 5%.

Table 2 shows the net benefits of the Proposed Rule and Alternative 1 using the 1.7% discount rate from the Draft Circular A-4 Update (except for climate benefits, which are discounted starting at a near-term rate of 2% per the Draft SC-GHG Update).

Table 2: Net Benefits Using 1.7% Social Discount Rate (2020$ Billion)

3% discount rate, 3% average SC-GHG from Interagency Working Group: Proposed Program: 1600; Alternative 1: 1800

3% discount rate, 2% average SC-GHG from EPA's 2022 Draft Update: Proposed Program: 2500; Alternative 1: 2800

1.7% discount rate, 2% average SC-GHG from EPA's 2022 Draft Update: Proposed Program: 3200; Alternative 1: 3500 [EPA-HQ-OAR-2022-0829-0743, p. 33]

As Table 2 illustrates, the net benefits of both of the proposed program and Alternative 1 increase when a 1.7% social discount rate is applied (with a 2% near-term discount rate applied to climate impacts consistent with the Draft SC-GHG update). As these updated discount rates are used, the net benefits of Alternative 1 relative to the proposed program also increase. [EPA-HQ-OAR-2022-0829-0743, p. 33]

By applying the latest available science and evidence on both discounting and valuing climate damages, EPA will ensure a more complete presentation and analysis of the benefits and costs of the Proposed Rule and any alternatives that it considers. [EPA-HQ-OAR-2022-0829-0743, p. 33]

Conclusion

For the foregoing reasons, it is appropriate for EPA to continue to apply the Working Group's valuations of the social cost of greenhouse gases in the Proposed Rule as conservatives underestimates. Nonetheless, to bolster its assessment of the costs and benefits of the Proposed Rule and potential alternatives, EPA should conduct additional analysis using the climate-damage estimates from the Draft SC-GHG Update and the discounting approach from the Draft Circular A-4 Update. [EPA-HQ-OAR-2022-0829-0743, p. 33]

Organization: Kentucky Office of the Attorney General et al.

B. The cost-benefit analysis supporting the Proposed Rule is flawed.

The Agency relies on the flawed social cost of carbon metric to measure the alleged benefits of the Proposed Rule. U.S. Environmental Protection Agency, Draft Regulatory Impact Analysis: Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles (April, 2022) at 560 ("DRIA") (EPA "estimate[s] the social benefits of GHG reductions expected to occur as a result of the proposed and alternative standards using estimates of the social cost of greenhouse gases (SC-GHG)."). The SC-GHG allegedly represents "the monetary value of the net harm to society associated with a marginal increase in emissions . . . in a given year." Id. EPA asserts that "the SC-GHG includes the value of all climate change impacts (both negative and positive), including (but not limited to) changes in net agricultural productivity, human health effects, property damage from increased flood risk and natural disasters, disruption of energy systems, risk of conflict, environmental migration, and the value of ecosystem services." Id. [EPA-HQ-OAR-2022-0829-0649, pp. 9-10]

This cost-benefit analysis suffers from serious flaws. And when an agency relies "on a cost benefit analysis as part of its rule-making, a serious flaw undermining that analysis can render the rule unreasonable." National Ass'n of Home Builders v. EPA, 682 F.3d 1032, 1040 (D.C. Cir. 2012). Specifically, EPA's SC-GHG analysis dramatically and unjustifiably inflates the alleged benefits of the Proposed Rule in relation to its costs. [EPA-HQ-OAR-2022-0829-0649, pp. 9-10]

For example, the Proposed Rule uses a discount rate much lower than the normal 7%. A lower discount rate ensures that the putative benefits of regulation always outweigh the costs. Longstanding guidance from the Office of Management and Budget's Circular A-4 stipulates a 7% discount rate for rules that primarily affect capital investment. Here, EPA specifically rejects that guidance. "EPA concludes that a 7 percent discount rate is not appropriate to apply to value the social cost of greenhouse gases . . . ." DRIA at 564. Instead, the Proposed Rule utilizes a 3% discount rate—a decrease of 57%. The Proposed Rule settles on the 3% discount rate "for simplicity in presentation" and because 3% "is the rate used in past GHG rules[.]" 88 Fed. Reg. 29,199. But mere convenience has never been recognized as a reason to short-circuit adequate cost-benefit analysis. [EPA-HQ-OAR-2022-0829-0649, pp. 9-10]

The Agency argues that "to discount the future benefits of reducing GHG emissions inappropriately underestimates the impacts of climate change for the purposes of estimating the SC-GHG." DRIA at 563. EPA is wrong, and its conclusory, normative statement appears to misunderstand the basic economic function of a discount rate. Its lower discount rate is simply a ruse to help the Agency arrive at its preferred, but not accurate, cost-benefit analysis. Though the Office of Management and Budget ("OMB") is in the process of amending Circular A-4—a proposal that has its own flaws—OMB specifically indicated that the version requiring utilization of a 7% discount rate "remains in effect." Draft OMB Circular A-4 (April 6, 2023), https://www.whitehouse.gov/wp-content/uploads/2023/04/DraftCircularA-4.pdf. [EPA-HQ-OAR-2022-0829-0649, pp. 9-10]

Additionally, the Proposed Rule considers global climate impacts instead of focusing on domestic impacts. DRIA at 563. According to EPA, "[t]he only way to achieve an efficient allocation of resources for emissions reductions on a global basis … is for all countries to base their policies on global estimates of damages." Id. But Congress did not authorize the Agency to address international pollution through tailpipe emissions regulation. And under the presumption against extra-territoriality, courts generally limit the application of statutes to domestic applications. RJR Nabisco, Inc. v. Eur. Cmty, 579 U.S. 325, 335, 136 S. Ct. 2090, 2100 (2016) ("When a statute gives no clear indication of an extraterritorial application, it has none." (citation omitted)). [EPA-HQ-OAR-2022-0829-0649, pp. 9-10]

The effect of these errors is significant. EPA estimates the value of the Proposed Rule's benefit at between "$83 billion and $1.0 trillion across a range of discount rates and values for the social cost of carbon." 88 Fed. Reg. at 29,344. The range of these supposed benefits illustrates their arbitrary and capricious nature. When EPA irrationally and arbitrarily stacks the benefit side of the cost-benefit deck, it negates the usefulness of that analysis. [EPA-HQ-OAR-2022-0829-0649, pp. 9-10]

Organization: Landmark Legal Foundation

When performing the legally required analysis to calculate the costs and benefits of the Proposed Rule, the Environmental Protection Agency ("EPA") uses a metric calculated by an entity with no statutory or constitutional authority. Costs and benefits in the Proposed Rule are calculated based on values called the "social cost" of carbon, methane, and nitrous oxide emissions, collectively known as Social Cost of Greenhouse Gases ("SC-GHGs"). These metrics measure the predicted cost of each ton of greenhouse gas released into the atmosphere. An SC-GHG valuation "in principle includes the value of all climate change impacts." 88 Fed. Reg. 29199n130 (May 5, 2023). The valuations generally are used to estimate the benefit of imposing policy that regulates sources of greenhouse gas production, or the climate cost of permitting projects that increase greenhouse gas emissions. Since 2008, the federal government has used Social Cost of Carbon valuations when considering regulatory actions. Jane A. Leggett, Federal Citations to the Social Cost of Greenhouse Gases, Congressional Research Service, March 21, 2017, available at https://sgp.fas.org/crs/misc/R44657.pdf (Accessed June 20, 2023). By 2017, there were at least 160 regulatory actions that cited SC-GHG valuations in their calculations. Id. [EPA-HQ-OAR-2022-0829-0547, pp. 2-3]

SC-GHG valuations, however, may be used to manipulate regulatory cost-benefit analyses to support otherwise unjustifiable proposed rules. For example, this Proposed Rule purports that its benefits come from the greenhouse gases it will prevent from being emitted. According to the proposed rule and its SC-GHG estimates, the benefits of the new standards would equate to "$83 billion to $1.0 trillion across a range of discount rates and values for the social cost of carbon..." 88 Fed Reg 29344 (May 5, 2023). [EPA-HQ-OAR-2022-0829-0547, pp. 2-3]

As rosy as these outcomes appear, the Proposed Rule is illegitimate because its cost benefit analysis is based on improperly established SC-GHG valuation standards. Shortly after entering office, President Biden issued Executive Order 13990 ("EO 13990" or "the Order"), creating the IWG. The IWG was formed with the express purpose of issuing a monetary valuation to be used by every government agency in calculating the costs of emitting certain greenhouse gases. The SC-GHGs that underlie the justification for the proposed rule are based upon valuations promulgated by this group. The IWG, however, is not vested with any constitutional or statutory authority to institute such a policy. Thus, the creation of the IWG and the use of its published SC-GHG valuations violate the federal rulemaking process and the Constitution's separation of powers. For this reason, the proposed rule is unlawful. [EPA-HQ-OAR-2022-0829-0547, p. 3]

The IWG is not vested with any statutory authority to act as an agency. Lacking a clear statement of congressional intent, the President did not have the authority to implement the IWG in the first place. [EPA-HQ-OAR-2022-0829-0547, pp. 3-4]

No statute vests the IWG with any authority and President Biden's Order establishing it does not cite any statutes. He claims that "the authority vested in [him] as President by the Constitution and the laws of the United States of America" allows him to issue the Order. Exec. Order 13990 (January 20, 2021). But this purported authority resides neither in the law nor in the Constitution. [EPA-HQ-OAR-2022-0829-0547, pp. 3-4]

The IWG provisions of EO 13990 differ significantly from other Executive Orders issued around the same time. For example, contrast the vague assertion of statutory authority in EO 13990 with the operative language in EO 14054. In EO 14054, President Biden states that his authority to terminate a declaration of an emergency comes from "the International Emergency Economic Powers Act....the National Emergencies Act. section 212 (f) of the Immigration and Nationality Act of 1952. , and section 301 of title 3, United States Code." Exec. Order No. 14054 (Nov. 18, 2021). Similarly, Section 3 of EO 13990 specifically cites "the Antiquities Act, 54 U.S.C. 320301, et seq." to establish the statutory authority to direct the Secretary of the Interior to review monument boundaries and conditions. 86 Fed. Reg. 7039 (Jan. 25, 2021). [EPA-HQ-OAR-2022-0829-0547, pp. 3-4]

The Presidential power that underpins executive orders "must stem either from an act of Congress or from the Constitution itself." Youngstown Sheet & Tube Co. v. Sawyer, 343 U.S. 579 (1952). This requirement for clear statutory authorizations is essential to maintain the separation of powers and to prevent overreach of executive power. In this case, EO 13990 creates a body with quasi-legislative authority without a Congressional grant to do so. This EO therefore violates the Constitution. [EPA-HQ-OAR-2022-0829-0547, pp. 3-4]

For the IWG to legally behave like an agency, as it has by creating the SC-GHG rules, Congress must enact a statute granting that power. The President does not have, nor has he even claimed to have, specific statutory or constitutional authority to create such an agency. Only the legislature retains such privileges. And because the legislature has not exercised that power here, the President may not vest the IWG with the authority to issue regulatory actions carrying the full force of law. [EPA-HQ-OAR-2022-0829-0547, pp. 3-4]

Organization: Landmark Legal Foundation

The Proposed Rule uses a metric established by an entity with no constitutional or statutory authority. The Interagency-Working Group ("IWG") is not vested with any statutory authority to act as an executive agency. Therefore, the President did not have the authority to implement the IWG in the first place. [EPA-HQ-OAR-2022-0829-0547, pp. 1-2]

2. The IWG nonetheless acts as an agency and is therefore subject to the Administrative Procedures Act ("APA"). [EPA-HQ-OAR-2022-0829-0547, pp. 1-2]

3. The APA requires agencies to follow a proscribed rulemaking process that provides opportunities for the public to comment on agency actions. The IWG bypassed this process when it established new metrics for the Social Costs of Greenhouse Gas ("SC- GHG"). [EPA-HQ-OAR-2022-0829-0547, pp. 1-2]

As rosy as these outcomes appear, the Proposed Rule is illegitimate because its cost benefit analysis is based on improperly established SC-GHG valuation standards. Shortly after entering office, President Biden issued Executive Order 13990 ("EO 13990" or "the Order"), creating the IWG. The IWG was formed with the express purpose of issuing a monetary valuation to be used by every government agency in calculating the costs of emitting certain greenhouse gases. The SC-GHGs that underlie the justification for the proposed rule are based upon valuations promulgated by this group. The IWG, however, is not vested with any constitutional or statutory authority to institute such a policy. Thus, the creation of the IWG and the use of its published SC-GHG valuations violate the federal rulemaking process and the Constitution's separation of powers. For this reason, the proposed rule is unlawful. [EPA-HQ-OAR-2022-0829-0547, p. 3]

The IWG is not vested with any statutory authority to act as an agency. Lacking a clear statement of congressional intent, the President did not have the authority to implement the IWG in the first place. [EPA-HQ-OAR-2022-0829-0547, pp. 3-4]

No statute vests the IWG with any authority and President Biden's Order establishing it does not cite any statutes. He claims that "the authority vested in [him] as President by the Constitution and the laws of the United States of America" allows him to issue the Order. Exec. Order 13990 (January 20, 2021). But this purported authority resides neither in the law nor in the Constitution. [EPA-HQ-OAR-2022-0829-0547, pp. 3-4]

The IWG provisions of EO 13990 differ significantly from other Executive Orders issued around the same time. For example, contrast the vague assertion of statutory authority in EO 13990 with the operative language in EO 14054. In EO 14054, President Biden states that his authority to terminate a declaration of an emergency comes from "the International Emergency Economic Powers Act....the National Emergencies Act. section 212 (f) of the Immigration and Nationality Act of 1952. , and section 301 of title 3, United States Code." Exec. Order No. 14054 (Nov. 18, 2021). Similarly, Section 3 of EO 13990 specifically cites "the Antiquities Act, 54 U.S.C. 320301, et seq." to establish the statutory authority to direct the Secretary of the Interior to review monument boundaries and conditions. 86 Fed. Reg. 7039 (Jan. 25, 2021). [EPA-HQ-OAR-2022-0829-0547, pp. 3-4]

The Presidential power that underpins executive orders "must stem either from an act of Congress or from the Constitution itself." Youngstown Sheet & Tube Co. v. Sawyer, 343 U.S. 579 (1952). This requirement for clear statutory authorizations is essential to maintain the separation of powers and to prevent overreach of executive power. In this case, EO 13990 creates a body with quasi-legislative authority without a Congressional grant to do so. This EO therefore violates the Constitution. [EPA-HQ-OAR-2022-0829-0547, pp. 3-4]

For the IWG to legally behave like an agency, as it has by creating the SC-GHG rules, Congress must enact a statute granting that power. The President does not have, nor has he even claimed to have, specific statutory or constitutional authority to create such an agency. Only the legislature retains such privileges. And because the legislature has not exercised that power here, the President may not vest the IWG with the authority to issue regulatory actions carrying the full force of law. [EPA-HQ-OAR-2022-0829-0547, pp. 3-4]

The IWG acts as an agency and is therefore subject to the APA. [EPA-HQ-OAR-2022-0829-0547, pp. 5-6]

The President is within his power to create advisory boards to advise him on policy recommendations. Congress, however, "under its legislative power is given the establishment of offices [read: agencies], the determination of their functions and jurisdiction..." Myers v. United States, 272 U.S. 52 (1926). [EPA-HQ-OAR-2022-0829-0547, pp. 5-6]

The IWG's role as a promulgator of binding SC-GHG valuations goes beyond a legal advisory role, and instead makes it an agency. In EO 13990 § 5(b)(ii), which describes the "Mission and Work" of the IWG, the Order charges the IWG with the duties of an agency. The Order states that the Working Group will publish their binding valuations of SC-GHGs "as appropriate and consistent with applicable law." 86 Fed. Reg. 7040 (Jan. 25, 2021). The Order also tasks the IWG to "publish an interim SCC, SCN, and SCM." 86 Fed. Reg. 7040 (Jan. 25, 2021). Moreover, the Order tasks the IWG with publishing a final valuation of SC-GHGs "by no later than January 2022." Id. Those numbers are what "agencies shall use when monetizing the value of changes in greenhouse gas emissions..." (emphasis added). Id. In other words, the valuations published by the IWG are binding to other government agencies and are not simply figures produced to advise the President on relevant climate issues. The SC-GHG valuations the working group produces therefore constitute technical guidelines that are implemented in further governmental policy and action. [EPA-HQ-OAR-2022-0829-0547, pp. 5-6]

Given these substantial agency activities, the IWG is subject to the requirements of the APA. [EPA-HQ-OAR-2022-0829-0547, pp. 5-6]

The APA dictates a stringent rulemaking process, which is essential for public input. Nonetheless, the IWG bypassed this process completely. [EPA-HQ-OAR-2022-0829-0547, pp. 6-7]

The APA defines a regulation as "the whole or part of an agency statement of general or particular applicability and future effect designed to implement, interpret, or prescribe law or policy." 5 U.S.C. § 551. According to this statue, the binding prescriptive and implementary nature of the valuations used in the Proposed Rule makes them regulations. Regulations encompassed by the APA, but which have not been implemented according to the APA rulemaking process, are built upon unauthorized and improper legal grounds. The Proposed Rule, derived from such unlawful regulations in EO 13990 and the subsequent IWG valuation, is also unauthorized and improper under the APA. [EPA-HQ-OAR-2022-0829-0547, pp. 6-7]

The APA requires that, for an agency to create a new rule, an agency must follow the steps of the rulemaking process, which consists of posting a proposed rule, receiving and responding to public comments, and then posting the final rule. This all takes place on the public Federal Register website, ensuring that the American public, and all other interested parties, can provide meaningful input before a rule takes on the full force and effect of law. EO 13990 circumvents this process by skipping notice and comment altogether and implementing the SC- GHG valuations directly. This end-run of the rulemaking process violates the APA. [EPA-HQ-OAR-2022-0829-0547, pp. 6-7]

The very purpose of the APA is to allow notice-and-comment, public discourse, open criticism, and abridgements to be part of the regulatory process. It is especially critical when certain regulations will have prominent effects on individual Americans or vast swaths of the American economy. The APA was not passed by Congress simply as a procedural formality, but rather as a direct response to the actions of President Roosevelt, who massively increased the size and centralization of the executive branch. Hall, D: Administrative Law Bureaucracy in a Democracy 4th Ed., page 2. Pearson, 2009. [EPA-HQ-OAR-2022-0829-0547, pp. 6-7]

The APA is meant to protect the separation of powers in our government. It is unacceptable for the Biden administration to circumvent this check on power through the fiat of Executive Order. This intrusion must be rectified. [EPA-HQ-OAR-2022-0829-0547, pp. 6-7]

The federal rulemaking process is supposed to create regulations that allow federal agencies to effectively enforce congressional statutes. Without adherence to Notice and Comment, the administrative state could legislate on its own, without oversight from the public. Circumvention of Notice and Comment is antithetical to Article I, Section I of the US Constitution, which vests the legislative power solely in the people's immediate representatives. [EPA-HQ-OAR-2022-0829-0547, p. 8]

With this EPA tailpipe regulation, based on the inclusion of unlawful SC-GHG metrics produced by the IWG, the public has not been afforded the proper Notice and Comment period. Since this method was created without going through the formal rulemaking process, the valuations are invalid, and the Proposed Rule itself is unlawful. [EPA-HQ-OAR-2022-0829-0547, p. 8]

Organization: Our Children's Trust (OCT)

As an example, transitioning Montana to 100% wind-water-solar for all energy purposes reduces Montana's 2050 annual energy costs by 69.6% or $6.3 billion per year, saves another $1.7 billion per year in health costs and an additional $21.1 billion per year in avoided global climate damages. Electric transportation uses less energy than ICE engine transportation, with the Ford F150 EV 3.9 times more efficient than the gas/E85 F150. The efficiencies in EVs and cost savings are true across all states. See Expert Report of Dr. Jacobson and Trial Testimony and Demonstratives in Held v. Montana. [EPA-HQ-OAR-2022-0829-0542, p. 2]

Organization: Paul Bonifas and Tim Considine

Climate Benefit: The EPA bases their climate benefit on an $80 per ton price of carbon, which reflects the global cost of carbon instead of the domestic cost. When correcting for that error, the domestic social cost of carbon for the United States is between $3 and $8 dollars per ton according to the Institute for Energy Research4. This results in a more realistic climate benefit of $22 billion, a $308 billion benefit decrease from the EPA's calculations. [EPA-HQ-OAR-2022-0829-0551, p. 3]

4 Institute for Energy Analysis (2017) "Explaining IERs position on the social cost of carbon," https://instituteforenergyresearch.org/analysis/clarifying-iers-position-social-cost-carbon/

Climate Benefit

EPA Claimed Benefit: $330 billion

Realistic Benefit: $22 billion [EPA-HQ-OAR-2022-0829-0551, pp. 7-8]

EPA estimates $330 billion in climate benefits. Most of these benefits, however, accrue to the global community. The social cost of carbon used in the EPA Regulatory Impact Analysis reflects this global focus but not the domestic social cost of carbon, which is far lower, in contrast to the $80 per ton estimate used by EPA. [EPA-HQ-OAR-2022-0829-0551, pp. 7-8]

For a 3% discount rate, the domestic social cost of carbon for the United States is between $3 and $8 dollars per ton according to the Institute for Energy Research26. The Office of Management and Budget provides guidelines for project evaluation and states: “Your analysis should focus on benefits and costs that accrue to citizens and residents of the United States,”27. Hence, US domestic consumers would realize only $22 billion in net climate benefits with the remaining benefits accruing to consumers outside the US. [EPA-HQ-OAR-2022-0829-0551, pp. 7-8]

26 Institute for Energy Analysis (2017) “Explaining IERs position on the social cost of carbon,” https://instituteforenergyresearch.org/analysis/clarifying-iers-position-social-cost-carbon/

27 Office of Management and Budget (2003) “Circular A4,” https://www.whitehouse.gov/sites/whitehouse.gov/files/omb/circulars/A4/a-4.pdf

The social cost of carbon is estimated from integrated assessment models (IAM). These models project future emissions and atmospheric concentrations of CO2, average global temperatures, the economic impacts from these temperature changes, the costs of abating greenhouse gas emissions, and the trade- offs from cutting pollution today to avoid environmental damages in the future. Each IAM is different depending on assumptions made about abatement costs, damage costs, and many other parameters. As a result, various IAM studies have strikingly different estimates for the social cost of carbon so that Pindyck28 notes: [EPA-HQ-OAR-2022-0829-0551, p. 8]

28 Pindyck, Robert S. (2013) “Climate change policy: What do the models tell us?” Journal of Economic Literature, 51, 3, 860– 872. (Robert Pindyck is the Bank of Tokyo-Mitsubishi Professor of Economics and Finance at Sloan School of Management at Massachusetts Institute of Technology)

“And here we see a major problem with IAM-based climate policy analysis: the modeler has a great deal of freedom in choosing functional forms, parameter values, and other inputs, and different choices can give wildly different estimates of the SCC and the optimal amount of abatement. You might think that some input choices are more reasonable or defensible than others, but no, “reasonable” is very much in the eye of the modeler. Thus, these models can be used to obtain almost any result one desires.” [EPA-HQ-OAR-2022-0829-0551, p. 8]

Organization: Reginald Modlin and B. Reid Detchon

1. Valuing the social cost of those avoided emissions at $25 per ton would imply a benefit of more than $3 billion per year. Using the “interim” rate of $51 per ton put forward by the Biden administration in 2021, the benefits would come to more than $6 billion per year. At the rate of $76 per ton used in the administration’s proposed Corporate Average Fuel Economy Standards, the benefits exceed $9 billion per year. [EPA-HQ-OAR-2022-0829-0570, pp. 39-40]

Organization: Senator Shelley Moore Capito et al.

Lastly, both rules rely on a questionable cost metric, known as the Social Cost of Greenhouse Gases (SC-GHG), to inflate the rules' projected benefits and skew its overall cost-benefit analysis. The EPA's use of SC-GHG in its cost estimate relies upon an economic modeling sleight of hand in the form of "discount rates" to exaggerate potential costs associated with the status quo and the benefits of transitioning to BEV s. The estimate also emphasizes theoretical future costs in foreign countries to justify imposing the rules' real costs and job losses on American families today. [EPA-HQ-OAR-2022-0829-5083, p. 5]

Organization: Steven G. Bradbury

Regrettably, the EPA is not likely to adjust its “social cost of carbon” benefits esti- mates downward at all. In fact, the Agency may be planning to dial them way up—perhaps to as high as $3 trillion to $5 trillion—when it finalizes these rules. The proposals rely on the usual discount rates of 3 and 7 percent traditionally used by the Office of Management and Budget (OMB) when estimating the present value of benefits expected to accrue in the distant future. But the Biden OMB has recently proposed to amend its Circular A-4 (gov- erning such calculations) to encourage agencies to use lower discount rates (such as the 1.7 percent rate generally applicable to interest on long-term Treasury bonds) in assessing the value of long-term or so-called “intergenerational” benefits.66 The use of the lower rate will increase the monetized present value of claimed benefits considerably. In these pro- posed rules, EPA has labeled its benefits calculations “interim,” signaling that it may choose to recalculate the benefits using a lower discount rate, should OMB finalize the proposed amendments to A-4. Doing so would only exacerbate the arbitrary nature of the Agency’s inflated benefit estimates for the proposed rules. [EPA-HQ-OAR-2022-0829-0647, p. 23]

Organization: The Heritage Foundation (Kevin Dayaratna and Diana Furchtgott-Roth)

Rule is Predicated on Flawed Modeling of the Social Cost of Carbon

The proposed rule claims purported climate benefits in terms of carbon dioxide emissions. Specifically, p. 29344 of the proposed rule states: "The present value of climate benefits attributable to the proposed standards are estimated at $83 billion to $1.0 trillion across a range of discount rates and values for the social cost of carbon (present values in 2027 for GHG reductions through 2055)" In engaging in this type of cost/benefit analysis one must assess the robustness of the social cost of carbon. [EPA-HQ-OAR-2022-0829-0674, p. 15]

The tremendous uncertainty associated with the SCC is relevant for this question.40 The SCC is an estimate in dollars of the cumulative long-term damage caused by one CO2 emitted in a specific year. That number also represents an estimate of the benefit of avoiding or reducing one ton of CO2 emissions. The SCC is estimated by Integrated Assessment Models (IAMs), which have been used in the past by the federal government as a basis for regulatory policy. For example, the Obama administration's Interagency Working Group (IWG) had drawn upon three models – abbreviated as DICE, FUND, and PAGE—to estimate the SCC.41,42 The Biden administration appears to be using other models as well.43 [EPA-HQ-OAR-2022-0829-0674, p. 15]

43 Interagency Working Group, "Technical Support Document: Social Cost of Carbon, Methane, and Nitrous Oxide Interim Estimates under Executive Order 13990" https://www.whitehouse.gov/wp-content/uploads/2021/02/TechnicalSupportDocument_SocialCostofCarbonMethaneNitrousOxide.pdf (hereafter IWG, TSD 2021) and United States Environmental Protection Agency, "EPA External Review Draft of "Report on the Social Cost of Greenhouse Gases: Estimates Incorporating Recent Scientific Advances," November 11, 2022, https://www.epa.gov/environmental-economics/scghg

As any model is as good as the assumptions from which it is composed, we took these IAMs in house at The Heritage Foundation and tested their sensitivity to a variety of important and reasonable assumptions. We have found that under very reasonable assumptions they can offer a plethora of different estimates of the SCC, ranging from extreme damages to overall benefits. Therefore, the vast potential estimates of the SCC suggest that the economic impact of climate change is highly questionable, and therefore understanding of climate-related risks is quite uncertain. [EPA-HQ-OAR-2022-0829-0674, pp. 15-16]

Among others, SCC estimates are highly sensitive to:

- Discount rates chosen to calculate the present value of future emissions and reductions. [EPA-HQ-OAR-2022-0829-0674, pp. 15-16]

- Estimated climate sensitivities chosen to estimate the warming impact of projected increases in atmospheric GHG concentration. [EPA-HQ-OAR-2022-0829-0674, pp. 15-16]

- Timespan chosen to estimate cumulative damages from rising GHG concentration. [EPA-HQ-OAR-2022-0829-0674, pp. 15-16]

- Assumptions regarding agricultural benefits [EPA-HQ-OAR-2022-0829-0674, pp. 15-16]

We find the economic impact of climate change (even if it exists) is quite uncertain depending on assumptions made and that the EPA should take note accordingly. [EPA-HQ-OAR-2022-0829-0674, pp. 15-16]

How Discount Rates Affect the SCC44 [EPA-HQ-OAR-2022-0829-0674, pp. 16-17]

44 Sections 3-6 draw upon Kevin Dayaratna's testimony on "Climate Change, Part IV: Moving Toward a Sustainable Future," before the House Oversight and Reform Subcommittee on the Environment, September 24,
2020, https://oversight.house.gov/sites/democrats.oversight.house.gov/files/Dayaratna%20Testimony%2C%20updated%2 0for%20Sept%2024%20hearing.pdf.

Models used to estimate the SCC rely on the specification of a discount rate. Discounting is essential in benefit-cost analysis because compliance costs are best viewed as investments intended to yield benefits in the future. Applying discount rates enables agencies to compare the projected rate of return from CO2-reduction expenditures to the rates of return from other potential investments in the economy. [EPA-HQ-OAR-2022-0829-0674, pp. 16-17]

Office of Management and Budget (OMB) guidance in Circular A-4 specifically stipulates that agencies discount the future costs and benefits of regulations using both 3.0% and 7.0% discount rates.45 The Obama and Biden administrations have suggested that a 7% discount rate is an affront to intergenerational equity, apparently on the theory that discount rates higher than 1% to 2% imply that people living today are more valuable than people living decades or centuries from now.46 [EPA-HQ-OAR-2022-0829-0674, pp. 16-17]

45 Office of Management and Budget, "Circular A-4," Obama White House, February 22, 2017, https://obamawhitehouse.archives.gov/omb/circulars_a004_a-4/ (accessed September 27, 2021).

46 IWG, TSD 2021, pp. 17-19.

We respectfully disagree. The point of discounting is not to rank the worth of different generations but to have a consistent basis for comparing alternate investments. Only then can policymakers determine which investments are most likely to transmit the most valuable capital stock to future generations. In other words, discounting clarifies the opportunity cost of investing in climate mitigation, for example, rather than medical research, national defense, or trade liberalization. [EPA-HQ-OAR-2022-0829-0674, pp. 16-17]

Not only is it reasonable to include a 7% discount rate in SCC estimation, it is arguably the best option because 7% is the rate of return of the New York Stock Exchange over the last hundred and twenty-five years and thus particularly pertinent to the financial institutions impacted by this rule.47 Only by using a 7% discount rate can policymakers assess the wealth foregone when government spends funds on GHG reduction rather than other policy objectives or simply allows companies and households to invest more of their dollars as they see fit. [EPA-HQ-OAR-2022-0829-0674, p. 17]

47 D. W. Kreutzer, "Discounting Climate Costs," Heritage Foundation Issue Brief No. 4575, June 16, 2016, https://www.heritage.org/environment/report/discounting-climate-costs; Kevin Dayaratna, Rachel Greszler and Patrick Tyrrell, "Is Social Security Worth Its Cost?" Heritage Foundation Backgrounder No. 3324, July 10, 2018, https://www.heritage.org/budget-and-spending/report/social-security-worth-its-cost.

It is hard to shake the suspicion that the IWG declines to use a 7% discount rate, even as a sensitivity case analysis, because doing so would spotlight the comparatively low rates of return of GHG-reduction policies. [EPA-HQ-OAR-2022-0829-0674, p. 17]

If any government agency is going to use SCC analysis, it should include SCC discounted at 7% as part of its benefit-cost analysis, because only on that basis can the public compare climate policy “investments” to other capital expenditures. And only through such comparisons can policymakers reasonably assess which investments will best position future generations to inherit the most productive capital stock. Furthermore, as the above analysis illustrates, under a 7% discount rate, the SCC is essentially zero and might even be negative at times, suggesting overall net benefits to climate change [EPA-HQ-OAR-2022-0829-0674, p. 18]

Substitution of gas-fired combustion for coal firing reduces net greenhouse gas emissions by nearly 60%. Supercritical natural-gas fired turbine technology can actually reduce net emissions to zero in an experimental plant,51 though a much-anticipated commercial-grade upscaling has yet to be achieved. These developments only serve to emphasize how foolhardy it is to use, as the IWG does, a 300-year period (2000-2300). Dayaratna and his former Heritage Foundation colleague David Kreutzer ran the DICE model with a significantly shorter, albeit still unrealistic, time horizon of 150 years into the future.52 [EPA-HQ-OAR-2022-0829-0674, pp. 19-20]

51 See for example Sonia Patel, "Breakthrough: NET Power’s Allam Cycle Test Facility Delivers First Power to ERCOT Grid," Power, November 18, 2021, https://www.powermag.com/breakthrough-net-powers-allam-cycle-test- facility-delivers-first-power-to-ercot-grid/

52 Dayaratna and Kreutzer, Loaded DICE: An EPA Model Not Ready for the Big Game, Backgrounder No. 2860, The Heritage Foundation, November 21, 2013, https://www.heritage.org/environment/report/loaded-dice-epa-model-not- ready-the-big-game.

Here are the DICE-estimated SCC values with a baseline ending in 2300:

SEE ORIGINAL COMMENT FOR Average SCC Baseline, End Year 2300 [EPA-HQ-OAR-2022-0829-0674, pp. 19-20]

Here are the results with a baseline ending in 2150:

SEE ORIGINAL CMMENT FOR TABLE Average SCC, End Year 2150 [EPA-HQ-OAR-2022-0829-0674, pp. 19-20]

The SCC estimates drop substantially—in some cases by more than 25%—as a result of ending the SCC estimation period in 2150. [EPA-HQ-OAR-2022-0829-0674, pp. 19-20]

How the Equilibrium Climate Sensitivity (ECS) Distribution Affects the SCC

The key climate specification used in estimating the SCC is the equilibrium climate sensitivity (ECS) distribution. Such distributions probabilistically quantify the earth’s temperature response to a doubling of CO2 concentrations. [EPA-HQ-OAR-2022-0829-0674, pp. 20-21]

ECS distributions are derived from general circulation models (GCMs) or more comprehensive earth system models (ESMs), which attempt to represent physical processes in the atmosphere, ocean, cryosphere and land surface. The IWG used the ECS distribution from a study by Gerard Roe and Marcia Baker published 15 years ago in the journal Science.53 This non-empirical distribution, calibrated by the IWG based on assumptions it selected in conjunction with past Intergovernmental Panel on Climate Changes (IPCC) recommendations,54 is no longer scientifically defensible.55 In particular, since 2011, a variety of newer and empirically-constrained distributions have been published in the peer-reviewed literature. Many of those distributions suggest lower probabilities of extreme global warming in response to CO2 concentrations. Figure 1 are three such distributions:56 [EPA-HQ-OAR-2022-0829-0674, pp. 20-21]

Curry, "The Implications for Climate Sensitivity of AR5 Forcing and Heat Uptake Estimates," Climate Dynamics, Vol. 45, No. 3, pp. 1009–1923, http://link.springer.com/article/10.1007/s00382-014-2342-y.

SEE ORIGINAL COMMENT FOR Outdated Roe Baker (2007) and More Recent ECS Distributions. Figure 1: A variety of equilibrium climate sensitivity (ECS) distributions

The areas under the curves between two temperature points represent the probability that the earth's temperature will increase between those amounts in response to a doubling of CO2 concentration. For example, the area under the curve from 4°C onwards (known as right-hand "tail probability") represents the probability that the earth's temperature will warm by more than 4°C in response to a doubling of CO2 concentrations. Note that the more up-to-date ECS distributions (Otto et al., 2013; Lewis, 2013; Lewis and Curry, 2015) have significantly lower tail probabilities than the outdated Roe-Baker (2007) distribution used by the IWG.

Here, again, is the IWG's 2016 SCC estimates for 2020-2050:

SEE ORIGINAL COMMENT FOR Table ES—1: Social Cost of CO2, 2010-2050(in 2007 dollars per metric ton of CO2) [EPA-HQ-OAR-2022-0829-0674, pp. 21-22]

In Climate Change Economics, Dayaratna and colleagues re-estimated the DICE and FUND models' SCC values using the more up-to-date ECS distributions and obtained the following results:57 [EPA-HQ-OAR-2022-0829-0674, pp. 21-22]

Using the more up-to-date ECS distributions dramatically lowers SCC estimates. The IWG's outdated assumptions overstate the probabilities of extreme global warming, which artificially inflates their SCC estimates. In its Fifth Assessment Report (AR5), the IPCC used the Coupled Model Intercomparison Project Phase 5 (CMIP5) models to project future warming and the associated climate impacts.58 Figure 2 compares predicted and observed average tropospheric temperature over the tropics.59 The observations come from satellites, weather balloons, and reanalyses.60 A careful look analysis reveals that only one of the 102 model runs correctly simulates what has been observed. This is the Russian climate model INM-CM4, which also has the least prospective warming of all of them, with an ECS of 2.05°C, compared to the CMIP5 average of 3.2°C. [EPA-HQ-OAR-2022-0829-0674, pp. 21-22]

58 Program for Climate Model Diagnosis and Intercomparison, CMIP5 – Coupled Model Intercomparison Project Phase 5 – Overview, https://pcmdi.llnl.gov/mips/cmip5/.

59 The CMIP5 predictions are available at https://climexp.knmi.nl/start.cgi.

60 Climate reanalyses produces synthetic histories of recent climate and weather using all available observations, a consistent data assimilation system, and mathematical modeling to fill in data gaps. See National Center for Atmospheric Research, Atmospheric Reanalysis: Overview & Comparison, https://climatedataguide.ucar.edu/climate-data/atmospheric-reanalysis-overview-comparison-tables and ECMWF, Climate Reanalysis, https://www.ecmwf.int/en/research/climate-reanalysis

Altogether, faulty assumptions regarding climate sensitivity have been manifested in the SCC and associated regulatory policy, and more realistic assumptions inject significant uncertainty into the potential long-term impact of climate change. [EPA-HQ-OAR-2022-0829-0674, p. 25]

-Negative SCC Values

Policymakers and the media often assume carbon dioxide emissions have only harmful impacts on society. However, CO2 emissions have enormous direct agricultural67 and ecological benefits,68 global warming lengthens growing seasons,69 and warming potentially also alleviates cold-related mortality, which may exceed heat-related mortality by 20 to 1.70 [EPA-HQ-OAR-2022-0829-0674, p. 25]

67 Literally hundreds of peer-reviewed studies document significant%age increases in food crop photosynthesis, dry- weight biomass, and water-use efficiency due to elevated CO2 concentrations. See the Center for the Study of Carbon Dioxide and Global Change's Plant-Growth Database: http://co2science.org/data/plant_growth/plantgrowth.php

68 See, for example, Randall J. Donahue et al. 2013. Impact of CO2 fertilization on maximum foliage cover across the globe's warm, arid environments. Geophysical Research Letters Vol. 40, 1–5, https://friendsofscience.org/assets/documents/CO2_Fertilization_grl_Donohue.pdf; Zaichun Zhu et al. The Greening of the Earth and Its Drivers. 2016. Nature 544, 84-87, https://www.nature.com/articles/nature22030.

69 EPA, Climate Change Indicators: Length of Growing Season, https://www.epa.gov/climate-indicators/climate- change-indicators-length-growing-season.

70 Antonio Gasparrini et al. 2015. Mortality risk attributable to high and low ambient temperature: a multicountry observational study, The Lancet, Volume 386, Issue 9991, https://www.thelancet.com/journals/lancet/article/PIIS0140-6736(14)62114-0/fulltext.

Of the three IAMs used by the IWG, only the FUND model estimates CO2 fertilization benefits. Dayaratna and colleagues investigated whether a model with CO2 fertilization benefits could produce negative SCC estimates. A negative SCC means that each incremental ton of CO2 emissions produces a net benefit. [EPA-HQ-OAR-2022-0829-0674, p. 25]

The researchers calculated the probability of a negative SCC under a variety of assumptions. Below are some of the results published both at the Heritage Foundation as well as in the peer-reviewed journal Climate Change Economics:71 [EPA-HQ-OAR-2022-0829-0674, pp. 25-27]

As the above statistics illustrate, under a variety of reasonable assumptions, the SCC has a substantial probability of being negative. In fact, in some cases, the SCC is more likely to be negative than positive, which implies—if one adopts the perspective of a central planner—that the EPA should, in fact, subsidize (not limit) CO2 emissions. We, of course, oppose such interventionism. Our purpose here is to illustrate the extreme sensitivity of these models to reasonable changes in assumptions as well as to point out that the probabilities of negative SCC value are non-trivial and potentially quite substantial. [EPA-HQ-OAR-2022-0829-0674, pp. 25-27]

Updated Agricultural Benefits and Benefit-Cost Analysis

It is a well-established fact that increases in CO2 concentration enhance plant growth by increasing their internal water use efficiency as well as raising the rate of net photosynthesis.72 As discussed in the previous section, the FUND model attempts to incorporate those benefits; however, this aspect of the model is grounded on research that is one-to-two decades old. Even so, as discussed in the preceding section, Dayaratna et al. (2017) found substantial probabilities of negative SCC using the outdated assumptions in FUND. Dayaratna et al. (2020) summarized more recent CO2 fertilization research in a peer-reviewed study published in Environmental Economics and Policy Studies and re-estimated the FUND model's SCC values upon updating those assumptions.73 To facilitate the EPA's review of that research, we excerpt several paragraphs from Dayaratna et al. (2020): [EPA-HQ-OAR-2022-0829-0674, pp. 27-28]

72 K.E. Idso and S.B. Idso. 1994. Plant responses to atmospheric CO2 enrichment in the face of environmental constraints: A review of the past 10 years' research. Agricultural and Forest Meteorology, 69, 153-203, https://www.sciencedirect.com/science/article/abs/pii/0168192394900256; Jennifer Cuniff et al. 2008. Response of wild C4 crop progenitors to subambient CO2 highlights a possible role in the origin of agriculture. Global Change Biology 14: 576-587, https://onlinelibrary.wiley.com/doi/abs/10.1111/j.1365-2486.2007.01515.x.

73 Kevin Dayaratna, Ross McKitrick, and Patrick Michaels. 2020. Climate sensitivity, agricultural productivity and the social cost of carbon in FUND. Environmental Economics and Policy Studies 22: 433-448, https://link.springer.com/article/10.1007/s10018-020-00263-w.

Three forms of evidence gained since then indicates that the CO2 fertilization effects in FUND may be too low. First, rice yields have been shown to exhibit strong positive responses to enhanced ambient CO2 levels. Kimball (2016) surveyed results from Free-Air CO2 Enrichment (FACE) experiments, and drew particular attention to the large yield responses (about 34%) of hybrid rice in CO2 doubling experiments, describing these as “the most exciting and important advances” in the field. FACE experiments in both Japan and China showed that available cultivars respond very favorably to elevated ambient CO2. Furthermore, Challinor et al. (2014), Zhu et al. (2015) and Wu et al. (2018) all report evidence that hybrid rice varietals exist that are more heat-tolerant and therefore able to take advantage of CO2 enrichment even under warming conditions. Collectively, this research thus indicates that the rice parameterization in FUND is overly pessimistic. [EPA-HQ-OAR-2022-0829-0674, pp. 27-28]

Second, satellite-based studies have yielded compelling evidence of stronger general growth effects than were anticipated in the 1990s. Zhu et al. (2016) published a comprehensive study on greening and human activity from 1982 to 2009. The ratio of land areas that became greener, as opposed to browner, was approximately 9 to 1. The increase in atmospheric CO2 was just under 15% over the interval but was found to be responsible for approximately 70% of the observed greening, followed by the deposition of airborne nitrogen compounds (9%) from the combustion of coal and deflation of nitrate-containing agricultural fertilizers, lengthening growing seasons (8%) and land cover changes (4%), mainly reforestation of regions such as southeastern North America. [EPA-HQ-OAR-2022-0829-0674, pp. 27-28]

Munier et al. (2018) likewise found a remarkable increase in the yield of grasslands. In a 17-year (1999-2015) analysis of satellite-sensed LAI, during which time the atmospheric CO2 level rose by about 10%, there was an average LAI increase of 85%. A full 31% of earth’s continental land outside of Antarctica is covered by grassland, the largest of the three agricultural land types they classified. Also, for summer crops, such as maize (corn) and soybeans, greening increased an average of 52%, while for winter crops, whose area is relatively small compared to those for summer, the increase was 31%. If 70% of the yield gain is attributable to increased CO2, the results from Zhu et al (2016) imply gains of 60%, 36%, and 22% over the 17-year period for, respectively, grasslands, summer crops and winter crops, associated with only a 10% increase in CO2, compared to parameterized yield gains in the range of 20% to 30% for CO2 doubling in FUND. [EPA-HQ-OAR-2022-0829-0674, pp. 27-28]

Third, there has been an extensive amount of research since Tsingas et al. (1997) on adaptive agricultural practices under simultaneous warming and CO2 enrichment. Challinor et al. (2014) surveyed a large number of studies that examined responses to combinations of increased temperature, CO2 and precipitation, with and without adaptation. In their metanalysis, average yield gains increased 0.06% per ppm increase in CO2 and 0.5% per percentage point increase in precipitation, and adaptation added a further 7.2% yield gain, but warming decreased it by 4.9% per degree C. In FUND, 3°C warming negates the yield gains due to CO2 enrichment. However, based on Challinor et al.’s (2014) regression analysis, doubling CO2 from 400 to 800 pm, while allowing temperatures to rise by 3°C and precipitation to increase by 2%, would imply an average% yield increase ranging from 2.1 to 12.1% increase, indicating the productivity increase in FUND is likely too small. [EPA-HQ-OAR-2022-0829-0674, pp. 27-28]

<u>EPA Summary and Response</u>

<u>Summary:</u>

We have grouped the comments related to the SC-GHG into four distinct themes, the use of discount rates, global versus domestic calculations, fundamental modeling of the SC-GHG, and process level comments related to the SC-GHG. Below is a summary of each theme and EPA's response.

A few commenters expressed concern with how discount rates are applied within the proposed regulation's analyses. For example, the *Kentucky Office of the Attorney General* expressed concern that the proposed rule uses a discount rate much lower than what they characterize as the normal 7%, which they assert ensures that the putative benefits always outweigh the costs. *The Heritage Foundation* also expressed concern over the discount rates used within this rule, "It is hard to shake the suspicion that the IWG declines to use a 7% discount rate, even as a sensitivity case analysis, because doing so would spotlight the comparatively low rates of return of GHG-reduction policies." However, the *Institute for Policy Integrity* wrote at length supporting EPA's choice of discount rate, including support for omitting the 7% discount rate and EPA's choice to use the SC-GHG values calculated with consumption-based discount rates.

American Enterprise Institute, Arizona State Legislature, Kentucky Office of the Attorney General, Paul Bonifas and Tim Considine, and *Senator Shelley Moore Capito* all express concerns with the use of global SC-GHG values, arguing that future damages in foreign countries should not justify domestic costs to Americans today and citing OMB guidance regarding focusing on domestic benefits and costs. However, the *Institute for Policy Integrity* supports EPA's use of global values within the proposed rule, arguing that this global approach is justified because the impacts of GHGs are global, because there are spillover effects from global impacts to the U.S., because of extraterritorial interests of the U.S., because of administrative precedent, because relevant statutes and Executive Orders compel or at least permit it, and in order to facilitate international reciprocity, among other arguments. The *Alliance for Automotive Innovation* supports the presentation of both global and domestic estimates of climate benefits will ensure that the RIA is seen as an objective analysis.

American Enterprise Institute, *Arizona State Legislature, Kentucky Office of the Attorney General*, *Paul Bonifas and Tim Considine and The Heritage Foundation* all criticized the EPA's approach to calculating the SC-GHG. The main comments were related to criticizing the Integrated Assessment Models (IAMs) used for estimating climate damages as incapable of projecting conditions 300 years into the future, the use of purported unrealistic Business as Usual (BAU) scenarios, the use of purported outdated estimates of climate sensitivity, and not including sufficient benefits to agriculture resulting from higher CO2 concentrations. The *Clean Fuels Development Coalition* stated that the calculations of the social cost of carbon are incorrect, and that relying on such estimates in the proposal exceeds EPA's statutory authority.

In contrast, the *Institute for Policy Integrity* defended EPA's process and results against many common criticisms, such as too much uncertainty, ignoring positive climate impacts, too high climate sensitivities, too high emission baselines, or flawed IAMs. *The Institute for Policy Integrity* urged EPA to update the SC-GHG approach to include advances consistent with the draft SC-GHG update from the Oil and Gas rule (2023). They argued that the interim SC-GHG underestimates climate damages by omitting key damage sectors.

Lastly, a few commenters (The Arizona State Legislature, the Clean Fuels Development Coalition, Delek US Holdings, Kentucky Office of the Attorney General and *Landmark Legal Foundation)* criticized the use of the interim SC-GHG for what they claim are violations of administrative process requirements. *Arizona* claims that the adoption of the IWG estimate for the SC-GHG was based solely on the instruction from EO 13990, that it violates the major questions doctrine and the separation of powers, that it never was subject to public comment, and that it is therefore unlawful, unconstitutional, arbitrary, and capricious. Moreover, they claim that it suffers from glaring methodological deficiencies. *The Clean Fuels Development Coalition (et al.)* similarly argues that the SC-GHG estimates have never undergone notice and comment rulemaking procedure, that there is no statutory authority for the IWG interim estimates, and that they are in violation of the APA. Finally, *Delek US Holdings, Inc*. also highlight a claimed lack of public comment, and also criticize the SC-GHG for not incorporating the recommendations of the NAS to update the SC-GHG.

In contrast, *California Air Resources Board* and *Institute for Policy Integrity at NYU School of Law* support the use of the "draft updated SC-GHG methodology that follows what was provided in U.S. EPA's November 2022 supplemental proposal for oil and gas standards".

Response:

Regarding the discount rate used within the SC-GHG, consistent with the recent scientific literature, the recommendations of the National Academies, and the recent update of OMB Circular A-4, the SC-GHG now relies on the use of a dynamic discount rate. This discount rate is calibrated to observed market interest rates in the near term and uses a Ramsey approach to dynamically update the discount rate over the long-term. See the preamble of this rule and the 2023 Final Oil and Gas NSPS RIA for more details. Within the RIA for this final rule, EPA uses updated SC-GHG estimates that EPA believes represents the latest available science and follows the recommendations of the National Academies of Science, Engineering, and Medicine. Please refer to the supplementary material to the Final RIA for the Oil and Gas NSPS, "Report on the Social Cost of Greenhouse Gases: Estimates Incorporating Recent Scientific Advances," and the Response to Comments document for the Oil and Gas NSPS for detailed responses pertaining to the rigor of the updated methodology, including the discounting approach.

Note that the EPA presented these updated discount rate estimates in a sensitivity analysis in the December 2022 Supplemental RIA for the Oil and Gas Rulemaking that address recommendations of the National Academies of Sciences, Engineering, and Medicine (2017), and invited public comment on the sensitivity analysis and on the technical report, titled "External Review Draft: Report on the Social Cost of Greenhouse Gases: Estimates Incorporating Recent Scientific Advances," explaining the methodological updates that was included as Supplementary Material to the Oil and Gas Supplemental Proposal RIA. The EPA published and used these estimates in the main analysis of the RIA for the December 2023 Final Oil and Gas NSPS/EG Rulemaking, "Standards of Performance for New, Reconstructed, and Modified Sources and Emissions Guidelines for Existing Sources: Oil and Natural Gas Sector Climate Review" and responded to public comments received on the new estimates in the Response to Comments document for the Final Oil and Gas Rulemaking.

As also discussed in preamble Section VIII, we monetize benefits of the final CO_2 standards and evaluate other costs in part to better enable a comparison of costs and benefits pursuant to E.O. 12866, but we recognize that there are benefits we are unable to fully quantify. EPA's consistent practice has been to set standards to achieve improved air quality consistent with CAA section 202 and not to rely on cost-benefit calculations, with their uncertainties and limitations, in identifying the appropriate standards. Regarding commenters' assertions that EPA has improperly inflated the climate benefits of the rule, and one commenter's (Steven Bradbury) assertion that the SC-GHG "effectively approaches zero," EPA disagrees with these commenters' contentions. As we explain in preamble Section VIII.E and RIA Chapter 6.2, the SC-GHG is based on a voluminous record, significant public process, and an external expert peer review. EPA's use of SC-GHG for purposes of assessing the monetized climate benefits of this rulemaking is clearly reasonable. While we strongly disagree with commenter Steven Bradbury about monetized climate benefits, solely for purposes of this argument we note that even without the monetized benefits from the SC-GHG the rule would be net beneficial. As further explained in Section VIII.E of the preamble, to the extent that EPA considers the positive monetized net benefits as supportive of the final standards (regardless of magnitude of the net benefits), this illustrative hypothetical shows that the positive monetized net benefits do not depend on either the final rule's SC-GHG estimates or the IWG SC-GHG estimates (see RIA Appendix to Chapter 9 for the latter in the final rule); EPA would still find the emissions reductions, in light of the cost of compliance, available lead time and other factors, justify adoption of these standards. In sum, while the positive net benefits figure supports EPA's final standards, we do not consider it necessary to the justification. EPA finds that this approach, of placing weight on judging the appropriate level of emissions reductions, in light of the costs of compliance and lead time, while still evaluating and considering total social costs and benefits, is consistent with both the Supreme Court's decision in Michigan v EPA, 576 US 743 (2015) and with section 202 of the CAA.

EPA follows applicable guidance and best practices when conducting its benefit-cost analyses, including OMB Circular A-4 and EPA's Guidelines for Preparing Economic Analyses. We therefore consider our analysis methodologically rigorous, and a best estimate of the projected benefits and costs associated with the final rule.

With respect to the social cost of greenhouse gases (SC-GHG), as more fully discussed in preamble Section VIII.E and RIA Chapter 6.2, EPA has updated its approach in the final rule and the final approach uses updated estimates of the SC-GHG that reflect recent advances in the scientific literature on climate change and its economic impacts and incorporate recommendations made by the National Academies of Science, Engineering, and Medicine[375]. The EPA published and used these estimates in the RIA for the December 2023 Final Oil and Gas NSPS/EG Rulemaking, "Standards of Performance for New, Reconstructed, and Modified Sources and Emissions Guidelines for Existing Sources: Oil and Natural Gas Sector Climate Review." As we explain in preamble Section VIII.E and RIA Chapter 6.2, EPA's updated SC-GHG estimates are based on a voluminous record, significant public process, and expert peer review. EPA's use of SC-GHG for purposes of assessing the climate benefits of this rulemaking is clearly reasonable.

[375] National Academies of Sciences, Engineering, and Medicine (National Academies). 2017. Valuing Climate Damages: Updating Estimation of the Social Cost of Carbon Dioxide. National Academies Press.

An updated discussion of the reasons for focusing on the global impacts of GHGs when calculating the SC-GHG can be found in the preamble for this final rule, as well as the RIA and RTC for the December 2023 Final Oil and Gas NSPS/EG Rulemaking, "Standards of Performance for New, Reconstructed, and Modified Sources and Emissions Guidelines for Existing Sources: Oil and Natural Gas Sector Climate Review." We incorporate and rely on those reasons for this rulemaking as well. Within the RIA for this final rule, EPA used updated SC-GHG estimates that EPA believes represents the latest available science and follows the recommendations of the National Academies of Science, Engineering, and Medicine. Please refer to the supplement to the 2023 Final Oil and Gas RIA, "Report on the Social Cost of Greenhouse Gases: Estimates Incorporating Recent Scientific Advances" for detailed responses pertaining to the rigor of the updated methodology and responses pertaining to the global focus of the SC-GHG estimates. EPA notes that when the Agency is directed to consider costs under the CAA, it does not consider costs on a nationality basis but rather, typically, cost is considered at the facility or firm level without respect to which entity owns or operates the facility(s) or firm(s). Further, EPA's cost estimates in RIAs, including the cost estimates contained in the Final RIA for this rule, regularly do not differentiate between compliance costs expected to accrue to U.S. firms versus foreign interests.[376]

Note that the EPA presented these updated estimates in a sensitivity analysis in the December 2022 Oil and Gas Supplemental RIA that address recommendations of the National Academies of Sciences, Engineering, and Medicine (2017), and invited public comment on the sensitivity analysis and on the technical report, titled External Review Draft: Report on the Social Cost of Greenhouse Gases: Estimates Incorporating Recent Scientific Advances, explaining the methodological updates that was included as Supplementary Material to the Oil and Gas Supplemental Proposal RIA. The EPA published and used these estimates in the main analysis of the RIA for the December 2023 Final Oil and Gas NSPS/EG Rulemaking, "Standards of Performance for New, Reconstructed, and Modified Sources and Emissions Guidelines for Existing Sources: Oil and Natural Gas Sector Climate Review" and responded to public comments received on the new estimates in the Response to Comments document for the Final Oil and Gas Rulemaking.

As discussed in preamble Section VIII.E and RIA Chapter 6.2, EPA has updated its approach and now uses estimates of the SC-GHG that reflect recent advances in the scientific literature on climate change and its economic impacts and incorporate recommendations made by the National Academies of Science, Engineering, and Medicine[377]. The EPA presented these updated estimates in a sensitivity analysis in the December 2022 Oil and Gas Supplemental RIA that address recommendations of the National Academies of Sciences, Engineering, and Medicine (2017), and invited public comment on the sensitivity analysis and on the technical report, titled

[376] For example, in the RIA for the 2018 Proposed Reconsideration of the Oil and Natural Gas Sector Emission Standards for New, Reconstructed, and Modified Sources, the EPA acknowledged that some portion of regulatory costs will likely "accru[e] to entities outside U.S. borders" through foreign ownership, employment, or consumption (https://www.epa.gov/sites/default/files/2018-09/documents/oil_and_natural_gas_nsps_reconsideration_proposal_ria.pdf, p. 3-13, accessed 03/05/2024). Similarly, some portion of the regulatory costs of this rule will fall on foreign vehicle manufacturers and on companies who import components or entire vehicles made in other countries for sale in the U.S. In general, a significant share of U.S. corporate debt and equities are foreign-owned.

[377] National Academies of Sciences, Engineering, and Medicine (National Academies). 2017. Valuing Climate Damages: Updating Estimation of the Social Cost of Carbon Dioxide. National Academies Press.

External Review Draft: Report on the Social Cost of Greenhouse Gases: Estimates Incorporating Recent Scientific Advances, explaining the methodological updates that was included as Supplementary Material to the Oil and Gas Supplemental Proposal RIA. The EPA published and used these estimates in the main analysis of the RIA for the December 2023 Final Oil and Gas NSPS/EG Rulemaking, “Standards of Performance for New, Reconstructed, and Modified Sources and Emissions Guidelines for Existing Sources: Oil and Natural Gas Sector Climate Review” and responded to public comments received on the new estimates in the Response to Comments document for the Final Oil and Gas Rulemaking. These estimates have taken on the latest and most up to date science, including updates to the climate model, the socioeconomic, and the damage estimation components. With respect to climate sensitivity, EPA’s updated modeling approach includes representation of climate sensitivity uncertainty consistent with the most recent IPCC assessment, addressing that concern from *Arizona*. Regarding the comments about emissions projections and time horizon of analysis, EPA’s updated modeling is now relying on socioeconomic and emissions projections developed under the Resources for the Future (RFF) Social Cost of Carbon Initiative (referred to as the RFF-SPs). As described in the “Report on the Social Cost of Greenhouse Gases: Estimates Incorporating Recent Scientific Advances” (included as a supplement to the 2023 Final Oil and Gas rule) the RFF-SPs are a set of probabilistic projections of population, GDP, and GHG emissions (CO_2, CH_4, and N_2O) to 2300. Consistent with the National Academies’ recommendation, the RFF-SPs were developed using a mix of statistical and expert elicitation techniques to capture uncertainty in a single probabilistic approach, taking into account the likelihood of future emissions mitigation policies and technological developments, and unlike other sources of projections, they provide inputs for estimation out to 2300 without further extrapolation assumptions. This is a suitable time horizon consistent with the National Academies’ recommendation[378] and OMB Circular A-4 (2003) guidance[379], since in the modeling conducted for this report 2300 is far enough in the future to capture the majority of discounted climate damages. See Section 2.1 and 3 of the “Report on the Social Cost of Greenhouse Gases” from the Final Oil and Gas rule for more discussion. The approach to estimating damages has also advanced – see the “Report on the Social Cost of Greenhouse Gases” for more discussion on the damage modules and the approach to accounting for carbon fertilization.

As we explain in preamble Section VIII.E and RIA Chapter 6.2, the SC-GHG estimates are based on a voluminous record, significant public process, an external expert peer review, as well as being responsive to the recommendation from the National Academy of Sciences, Engineering, and Medicine (NAS, 2017). EPA’s use of SC-GHG for purposes of assessing the climate benefits of this rulemaking is clearly reasonable.

We disagree with commenters, such as *Arizona*, *Clean Fuels Development Coalition, and Delek US Holdings* that the Interagency Working Group (IWG) was required to undertake notice and comment rulemaking in order to recommend values for SC-GHG to EPA. The IWG is not

[378] The National Academies (2017) recommended that socioeconomic scenarios used to estimate the SC-GHG should: “extend far enough in the future to provide inputs for estimation of the vast majority of discounted climate damages”.

[379] Regarding the analytic time horizon for regulatory benefit-cost analysis, OMB Circular A-4 (2003) advises “The ending point should be far enough in the future to encompass all the significant benefits and costs likely to result from the rule” (OMB 2003). OMB Circular A-4 (2023) similarly advises “The ending point for your analysis should be far enough in the future to encompass, to the extent feasible, all the important benefits and costs likely to result from all regulatory alternatives being assessed” (OMB 2023).

an “agency” for purposes of the APA, and it does not violate the separation of powers for the President to provide guidance to agencies on how to perform benefit-cost analyses when appropriate and consistent with applicable law. Commenters are free, as demonstrated by the docket for this rulemaking, to comment on EPA’s approach to estimating SC-GHG and the role those estimates should play in EPA’s decisionmaking about the final standards adopted in this rule. However, EPA notes that it did not primarily use the IWG estimates in this final rule (though they are included as an appendix to RIA Chapter 9), because EPA concluded it would be more appropriate to use estimates of the SC-GHG that reflect recent advances in the scientific literature on climate change and its economic impacts and incorporate recommendations made by the National Academies of Science, Engineering, and Medicine. EPA also notes, as explained above, that the benefit-cost analysis for this rule played a very limited role in decision-making for the standards. EPA did not rely on benefit-cost analysis to *identify* the appropriate standards. That is, EPA did not seek to select standards that would maximize net benefits as calculated by the benefit-cost analysis. Based on the RIA and the range of scenarios we evaluated, we anticipate such an approach would have required significantly more stringent standards, which would, in EPA’s judgment, be inconsistent with the statutory requirement to give appropriate consideration to costs of compliance and lead time. As described in section V of the preamble, and explained above in responding to Stephen Bradbury’s comment, the selection of the final standards was made based on judgments about the feasibility of further emissions reductions, in light of the cost of compliance, available lead time and other factors, and not specifically on estimates of the SC-GHG [380]

EPA considers its use of estimates of the SC-GHG entirely consistent with its authority under the CAA 202(a) to establish standards, and has fully complied with applicable requirements, including Section 307(d) of the Clean Air Act in this rulemaking. Unless a statute requires a different approach, it is entirely permissible for agencies to consider costs and benefits when deciding whether or how to regulate. See, e.g., *Entergy Corp. v. Riverkeeper*, 556 U.S. 208, 226 (2009). The costs and benefits of these final standards plainly include the effects of the standards on emissions of GHG. Any attempt to consider monetized net benefits of this rulemaking must at least attempt to monetize the effect of GHG emissions such as through estimates of SC-GHG. Indeed, courts have held that it may be arbitrary and capricious for agencies not to use SC-GHG in their benefit-cost analyses (see the 2023 Final Oil and Gas NSPS RIA for a more complete history of government use of the SC-GHG).

As discussed in preamble Section VIII.E and RIA Chapter 6.2, EPA has updated its approach and now uses estimates of the SC-GHG that reflect recent advances in the scientific literature on climate change and its economic impacts and incorporate recommendations made by the National Academies of Science, Engineering, and Medicine[381]. The EPA published and used these estimates in the RIA for the December 2023 Final Oil and Gas NSPS/EG Rulemaking, “Standards of Performance for New, Reconstructed, and Modified Sources and Emissions Guidelines for Existing Sources: Oil and Natural Gas Sector Climate Review.” This directly addressed the comment by *Delek US Holdings* suggesting that the EPA follow the NAS

[380] For example, EPA would have adopted the same standards had it considered the IWG estimates to be more appropriate. EPA presents IWG estimates of the SC-GHG for the final standards in an appendix to the RIA. Indeed, as explained above, the rule would be net beneficial even if no monetized climate benefits were included.
[381] National Academies of Sciences, Engineering, and Medicine (National Academies). 2017. Valuing Climate Damages: Updating Estimation of the Social Cost of Carbon Dioxide. National Academies Press.

recommendations and makes a number of the comments by *Arizona and the Clean Fuels Development Coalition* moot, as there was an opportunity to provide comment on these new values during the Oil and Gas NSPS/EG Rulemaking process. The EPA gave notice in the proposal for this rule that these updated SC-GHG values were under consideration.

In this section, Auto Innovators comments on the major categories of estimated social benefits for the CO2 performance standards for model years 2027-2032. [EPA-HQ-OAR-2022-0829-0701, pp. 285-288]

1. Local/Regional Air Quality benefits from Control of Criteria Air Pollutants

The DRIA estimates that the present value of the quantified health benefits from criteria air pollution control range from $64 billion to $290 billion, depending on the discount rate and the dose-response study used for PM2.5 and mortality. This range is so large that it overlaps the lower agency estimate of the Proposed Rule's climate benefits ($83 billion to $1 trillion). Auto Innovators believes that the agency's estimates are not consistent with the findings in the peer-reviewed scientific literature and are exaggerated. [EPA-HQ-OAR-2022-0829-0701, pp. 285-288]

In any event, any net reductions in PM2.5 emissions (primary or PM2.5 precursors) accomplished by the revised CO2 standards will not provide public health benefits that are additive to the emissions reductions accomplished by EPA's other mobile-source and stationary-source programs for criteria air pollutants. The public health benefits are not additive, as we explain below, because of the way Congress designed the Clean Air Act, structured state implementation plans, and the way EPA defined emissions limits and nonattainment on a community-by-community basis. [EPA-HQ-OAR-2022-0829-0701, pp. 285-288]

Specifically, reductions in vehicle emissions do not provide additive benefits to public health because the structure of the Clean Air Act allows the states to include national changes in mobile source emissions in their state emissions inventories and implementation plans for attainment of the National Ambient Air Quality Standards. In nonattainment areas and areas close to nonattainment, states and localities are disinclined to impose any more limits on stationary source emissions than is necessary to meet EPA's air-quality standards. If state and local limits are unduly strict, new factories may be built in other states and localities where the state implementation plans are not as strict on new stationary sources. (In attainment areas, where PM2.5 health benefits might also be considered, there is the complication of the Prevention of significant Deterioration (PSD) doctrine that needs to be evaluated). Thus, the practical impact of diminished mobile source emissions, at the margin, is somewhat less pressure on stationary sources to meet the requirements described in state implementation plans. Thus, there are benefits from further reductions in mobile source emissions under the Proposed Rule, but they are likely to be realized in reduced compliance costs for stationary sources rather than as public health benefits from reduced overall exposures to PM2.5. The magnitude of the compliance cost savings is likely to be a small fraction of the estimated public health benefits that the agency has claimed, given EPA estimates that the benefits of PM control vastly exceed costs in the stationary source arena. At a minimum, Auto Innovators suggests presentation of two alternative approaches for calculating the benefits of PM2.5 control: one where the benefits are expressed as compliance-cost savings for stationary sources and one – as developed in the DRIA – where the benefits of PM2.5 control are expressed as public health gains. [EPA-HQ-OAR-2022-0829-0701, pp. 285-288]

Auto Innovators made a similar public comment on the DRIA supporting the 2023-2026 rules. In the final rule, Auto Innovators' comment was ignored in the agency's "Response to Comment" document. (This was unusual, as many of the other Auto Innovators comments were handled very carefully in the Response to Comment document). [EPA-HQ-OAR-2022-0829-0701, pp. 285-288]

In this rulemaking alone, new criteria pollutant controls are expected to reduce direct PM2.5 emissions from gasoline vehicles by roughly 90%, so those same PM2.5 control benefits should not also be counted as benefits of the CO2 standards and BEVs. Auto Innovators suggests the EPA focus on the potential benefits of a successful transformation to electric vehicles rather than incremental benefits of adding additional PM control beyond the California ACC II requirements. [EPA-HQ-OAR-2022-0829-0701, pp. 285-288]

The final regulatory impact analysis should acknowledge that the peer-reviewed scientific literature does not generally support the agency's claim that a shift from ICEs to BEVs in the light-duty sector will reduce criteria air pollution across the country. In 2021, Burnham et al. of Argonne National Laboratory (DOE) presented a regional U.S. lifecycle analysis of the impact of BEVs through 2050, accounting for upstream emissions of criteria air pollutants at the powerplant. The abstract of their paper concludes as follows: [EPA-HQ-OAR-2022-0829-0701, pp. 285-288]

We generated state-level emission factors using a projection from 2020 to 2050 for three light-duty vehicle types. We found that BEVs currently provide GHG benefits in nearly every state, with the median state's benefit being between approximately 50% to 60% lower than gasoline counterparts. However, gasoline vehicles currently have lower total NOx, urban NOx, total PM2.5, and urban PM2.5 in 33%; 15%; 70%; and 10% of states, respectively. BEV emissions will decrease in 2050 due to a cleaner grid, but the relative benefits when compared to gasoline vehicles do not change significantly, as gasoline vehicles are also improving over this time. [EPA-HQ-OAR-2022-0829-0701, pp. 285-288]

The results of this study concerning total PM2.5 are especially concerning because the agency's quantified criteria-pollutant benefits in this rulemaking are dominated by an alleged advantage of BEVs with respect to PM2.5 control. Moreover, the lifecycle analysis by Burnham et al. (2021) is published in the peer-reviewed literature, while the agency's lifecycle inputs and analysis have not been peer reviewed by qualified experts. For the final rule, Auto Innovators believes it is unwise for the agency to rely on its lifecycle analysis of criteria air pollutant control as a primary rationale for the final rule. [EPA-HQ-OAR-2022-0829-0701, pp. 285-288]

Insofar as criteria air pollution control is considered a primary rationale for a rule that regulates CO2 emissions, we recommend that the agency go beyond an analysis of average ICE emissions and consider "best-in-class" vehicle emissions in the baseline. For example, in a peer-reviewed contribution, Winker et al. (2018) compared HEVs and BEVs in terms of criteria air pollution emissions. When the upstream emissions from BEVs are included, they find that BEV emissions are 0.06 grams per mile (NOx) while average HEV emissions are 0.004 grams per mile (NOx and HC). The results of Winkler et al. are consistent with an earlier paper by Michalek et al. (2011), which found that HEVs and PHEVs, with small battery packs, are environmentally and economically superior to BEVs. Thus, HEVs may be a superior technological option for criteria air pollution control than BEVs, at least in some regions of the country and until the upstream and manufacturing emissions of BEVs are controlled. [EPA-HQ-OAR-2022-0829-0701, pp. 285-288]

Organization: American Enterprise Institute

Because no policy to reduce GHG emissions can satisfy any plausible benefit/cost test — their attendant future climate effects for the most part would approach zero — federal agencies often have included purported "co-benefits," that is, the benefits of reductions in other pollutants, as factors to be considered in the evaluation of proposed regulations and projects. This is particularly the case for the asserted health benefits of reductions in the emissions of fine particulates (PM2.5).19 Like many of the other pollutants included in the co-benefits methodology, fine particulates are a "criteria" pollutant,20 as distinct from "hazardous air pollutants (HAP)." EPA already limits ambient levels of PM2.5 in a separate regulation, and is required under the CAA to determine every five years whether that standard "accurately reflects the latest scientific knowledge" on the health effects of exposure to particulates.21 [EPA-HQ-OAR-2022-0829-0571, pp. 5-8]

19 The EPA discussion of particulate matter regulatory actions is at https://www.epa.gov/pm-pollution/particulate- matter-pm-implementation-regulatory-actions. For sharp critiques of the EPA analysis of the mortality and morbidity effects of fine particulate matter, see https://www.regulations.gov/document/EPA-HQ-OAR-2015-0072- 0260 and https://www.sciencedirect.com/science/article/abs/pii/S0273230017301538. See also https://junkscience.com/2023/06/milloy-sets-off-greens-responds-to-politifact-inquiry-on-wildfire-smoke/#more- 108474.

20 See the EPA summary discussion at https://www.epa.gov/criteria-air-pollutants.

21 See the EPA requirements for fine particulates at https://www.epa.gov/pm-pollution/implementation-national- ambient-air-quality-standards-naaqs-fine-particulate-matter. The CAA sections are at https://www.epa.gov/clean-air- act-overview/clean-air-act-title-i-air-pollution-prevention-and-control-parts-through-d#ia.

The Clean Air Act explicitly requires the EPA, upon finding that a given criteria pollutant endangers the public health, to promulgate a "national ambient air quality standard" (NAAQS) that "protects the public health" with "an adequate margin of safety."22 The CAA also empowers the EPA to regulate emissions of HAP. The law mandates that costs not be considered in the establishment of the NAAQS; this means that those standards are likely to be too stringent in a benefit/cost sense. Lowering the emissions of those pollutants even more through insertion of a co-benefits calculation in a new regulation aimed at an entirely different type of emission means that the excess net costs of the regulation are likely to be driven up even more. [EPA-HQ-OAR-2022-0829-0571, pp. 5-8]

Organization: American Fuel & Petrochemical Manufacturers

In another example of EPA's biased analysis, EPA estimated the value of health benefits from reductions in PM2.5 emissions by multiplying PM2.5-related benefit- per-ton ("BPT") values by the annual reduction in tons of directly emitted PM2.5 and PM2.5 precursor emissions (NOx and SO2) from displaced ICEVs.206 However, EPA ignored the fleet turnover benefit that would result from replacing older ICEVs with new, more efficient, ICEVs.

Health Impact Analysis

Morbidity Health Endpoints and Ozone Impacts

U.S. EPA's health analysis of the proposed rule focused solely on evaluating mortality, excluding other morbidity health effects associated with fine particulate matter (PM2.5) emission reductions. Reporting morbidity endpoints such as asthma would highlight the importance of this proposed rule, particularly on children and other vulnerable populations. For instance, CARB suggests including additional studies, such as those that show the increased susceptibility of the development of asthma in children due to air pollution. 87, 88 Also, the analysis of the proposed rule only provides the total valuation and does not report the number of health outcomes themselves (e.g., mortality cases). While the economic assessment is important, providing the quantification of the health effects would be valuable in informing the public about the wide range of health implications. Additionally, adding a quantification of ozone impacts would strengthen this analysis and provide a more comprehensive quantitative assessment of the effects of criteria pollutants on health. CARB recommends that U.S. EPA report the number of health cases and quantify the morbidity health effects, providing a more comprehensive understanding of the potential benefits of reducing PM2.5 exposure. Also, we recommend that U.S. EPA similarly include the quantified health impacts of ozone. [EPA-HQ-OAR-2022-0829-0780, p. 52]

Health Impacts at Low Levels of PM2.5 and Ozone

CARB recommends that U.S. EPA also include a discussion of the research showing health impacts at low levels of air pollution, particularly PM2.5 and ozone. Strong associations have been found between PM2.5 levels below the current NAAQS (12 µg/m3) 89 and premature mortality in key multi-city epidemiological studies in the U.S. and Canada. For instance, as included in U.S. EPA's 2022 Supplement to the 2019 Integrated Science Assessment (ISA) for PM, 90 a study by Bennett et al. (2019) found that long-term exposure in excess of very low PM2.5 levels (3 µg/m3) may still lead to lower life expectancy for both men and women. 91 This study is representative of the research studies that show that mortality and morbidity impacts still occur at PM2.5 levels below the current standard. [EPA-HQ-OAR-2022-0829-0780, pp. 52-53]

89 As finalized in the Federal Register 78 No. 10. January 15, 2013. https://www.govinfo.gov/content/pkg/FR- 2013-01-15/pdf/2012-30946.pdf

90 U.S. EPA. Supplement to the 2019 Integrated Science Assessment for Particulate Matter (Final Report, 2022). U.S. Environmental Protection Agency, Washington, DC, EPA/635/R–22/028, 2022.

91 Bennett JE, Tamura-Wicks H, Parks RM, Burnett RT, Pope CA 3rd, Bechle MJ, Marshall JD, Danaei G, Ezzati M. Particulate matter air pollution and national and county life expectancy loss in the USA: A spatiotemporal analysis. PLoS Med. 2019 Jul 23;16(7):e1002856. doi: 10.1371/journal.pmed.1002856. PMID: 31335874; PMCID: PMC6650052.

Similarly, research has demonstrated significant adverse health impacts at ozone levels below the current NAAQS (70 ppb). 92 As described in U.S. EPA's 2020 Ozone ISA, 93 multiple epidemiological studies showed that both short- and long-term exposures to ozone with median or average levels near or below the current 8-hour NAAQS were associated with adverse health outcomes, including lung function decline, increases in childhood asthma onset, preterm births, increased emergency room visits, and premature mortality. CARB therefore recommends that U.S. EPA include and discuss the evidence showing that health impacts still occur at low air pollution levels, as described in U.S. EPA's 2019 PM ISA, 94 2020 Ozone ISAs, and the 2022 Supplement to the PM ISA. [EPA-HQ-OAR-2022-0829-0780, pp. 52-53]

F. Comparison of Criteria Emissions and Possible Health Benefits

For this part of the analysis, ERM utilized EPA's COBRA model to estimate the public health benefits associated with all the policy scenarios. ERM's analysis shows that stricter standards and increased deployment of clean L/MD vehicles results in greater gains in terms of consumer savings and avoided public health impacts (such as premature death, hospital admissions and emergency room visits, respiratory symptoms, and reduced activity and lost workdays). The policy scenario reflective of our Alternative 1+ recommended approach achieves the most reductions: nearly an 80% reduction in NOx and a 60% reduction in PM in 2040 compared to 2026 levels. An Alternative 1+ approach is also projected to achieve almost $42 billion in monetized value of reductions: nearly $8.5 billion more in monetized value than would occur under EPA's Main Proposal and preferred approach (as shown in Figure V.F-1). [EPA-HQ-OAR-2022-0829-0759, pp. 31-32]

SEE ORIGINAL COMMENT FOR Table V.F-1: Comparison of Possible Health Benefits114 [EPA-HQ-OAR-2022-0829-0759, p. 31]

SEE ORIGINAL COMMENT FOR Figure V.F-1: Comparison of Possible Health Benefits112 [EPA-HQ-OAR-2022-0829-0759, p. 32]

112 Id. at 12

ERM's analysis incorporates: EPA's assumed changes in tailpipe emission reductions, EPA's upstream assumptions that rely upon the Integrated Planning Model (IPM) for electricity generated units, and ERM assumptions on changes from reduced demand on refining of finished products for diesel (and gasoline) based on the use of Argonne National Laboratory's Greenhouse Gases, Regulated Emissions, and Energy Use in Technologies (GREET) model. [EPA-HQ-OAR-2022-0829-0759, p. 32]

The benefits associated with the Alternative 1+ approach are further depicted in Table V.F-1, which shows the various scenario criteria emissions (NOx and PM) aggregated from 2026-2040 for each of the policy scenarios, as well as possible reduced health incidents, and the monetized value of these reductions (if realized) compared to EPA's No Action scenario.113 [EPA-HQ-OAR-2022-0829-0759, p. 32]

113 ERM's analysis results in slightly lower cumulative reductions of NOx and PM compared with EPA's net air pollutant impacts for the EPA Main Proposal, Alternative 1, and Alternative 3 policy scenarios (Tables 9-37, 9-38 and 9-40 of the DRIA). However, despite the difference, Alternative 1+ would correspond with approximately a 25% increase in benefits relative to the EPA Main Proposal and a similar increase would be expected under EPA's methodology.

114 ERM, Impacts Report at 12.

1. Comparison of Overall Societal Benefits

The results from ERM's analysis (depicted in Figure V.I-1) show that on a net societal basis––inclusive of the costs to fleets as well as air quality benefits, climate benefits, and reduced utility bills—the greatest benefits are seen with Alternative 1+ at about $125.7 billion through the 2040 timeframe. [EPA-HQ-OAR-2022-0829-0759, p. 35]

SEE ORIGINAL COMMENT FOR Figure V.I-1: Comparison of Possible Annual Net Societal Benefits119 [EPA-HQ-OAR-2022-0829-0759, p. 36]

119 Id. at 15.

This figure depicts net annual societal benefits (which incorporates net incremental fleet cost savings, climate benefits, air quality benefits, and reduced utility bills). [EPA-HQ-OAR-2022-0829-0759, p. 36]

Organization: Northeast States for Coordinated Air Use Management (NESCAUM) and the Ozone Transport Commission (OTC)

EPA's technical analysis finds that 15,000 tons of PM2.5 would be reduced in 2055 as a result of the proposed LDV and MDV standards. EPA estimates the cumulative monetized benefits of the standards through 2055 to be between $63 and $280 billion (2020 $US) depending on the selected discount rate.27 Other analyses have also demonstrated the substantial health and air quality benefits that can be expected from stringent particulate emission standards. For example, the Manufactures of Emission Controls Association (MECA) conducted a study to model the benefits of a national 0.5 mg/mi PM standard. The study found that implementation of a national 0.5 mg/mi PM standard would result in health cost savings ranging from $18 to $163 billion (2020 $US) depending on the pace of electrification and selected discount rate.28 NESCAUM and the OTC urge EPA to finalize the standards as proposed for all three test cycles. [EPA-HQ-OAR-2022-0829-0584, pp. 10-11]

27 See EPA, DRIA, EPA-420-D-23-003 (Apr. 14, 2023), https://www.regulations.gov/document/EPA-HQ-OAR- 2022-0829-0360. As EPA notes in the DRIA, these monetized benefits do not reflect benefits associated with reducing ambient concentrations of ozone, direct exposure to nitrogen dioxide, or exposure to mobile source air toxics, nor do they account for improved ecosystem effects or visibility. The estimated benefits of the proposal would be larger if these unquantified benefits were monetized.

28 MECA, Impacts Analysis of a Revised Federal Light-Duty On-Road Particulate Matter Standard (June 2023), LDV_PM_Standard_Final_Report_06272023.pdf (meca.org).

Organization: Paul Bonifas and Tim Considine

The air pollutant benefit calculations have serious limitations, including lacking direct measures of individual lifetime pollution exposures and facing the potential for the confounding of effects from the omission of unknown, unmeasured, or inadequately-controlled-for mortality risk factors. With improved pollution controls on internal combustion engines, exposure rates are much lower than in the past and continue to decline as new vehicles replace older models. This suggests that EPAs estimated benefits from reduced criteria air pollutants also may be over-estimated. [EPA-HQ-OAR-2022-0829-0551, p. 4]

The EPA's "benefits" for both Energy Security & Air Pollutant are unchanged in this realistic analysis because it would require a thorough quantitative investigation. However, even with these likely overstated benefits staying consistent, the overall cost of the EPA's rule is still overwhelmingly negative. [EPA-HQ-OAR-2022-0829-0551, p. 4]

Air Pollutant Benefits

The EPA also estimates that their proposed rule could generate between $140 and $280 billion in benefits from reduced criteria air pollutants citing two studies.52 Like the modeling-based social cost of carbon, which is not observable, these studies also have serious limitations, lacking direct measures of individual lifetime pollution exposures and facing the potential for the confounding of effects from the omission of unknown, unmeasured, or inadequately-controlled-for mortality risk factors. With improved pollution controls on internal combustion engines, exposure rates are much lower than in the past and continue to decline as new vehicles replace older models. This suggests that EPAs estimated benefits from reduced criteria air pollutants also may be over-estimated. Even if keeping the EPA's estimate of air pollution benefits untouched, the overall economic impact of this rule is still overwhelmingly negative. [EPA-HQ-OAR-2022-0829-0551, p. 12]

EPA Summary and Response

Summary:

One commenter stated that the benefits of controlling emissions from light- and medium-duty vehicles far outweigh the costs. Another commenter provided a benefits analysis of different and more stringent standards.

Another commenter claimed that the criteria pollutant benefits analysis was flawed, suggesting that the criteria pollutant benefits of the proposal: (1) are exaggerated; (2) are not additive to the benefits attributable to emissions reductions accomplished by EPA's other mobile-source and stationary-source programs for criteria air pollutants ("because of the way Congress designed the Clean Air Act, structured state implementation plans, and the way EPA defined emissions limits and nonattainment on a community-by-community basis"); and, (3) should be estimated using alternative approaches for calculating the benefits of $PM_{2.5}$ control. The same commenter suggested that direct $PM_{2.5}$ emission reductions from new criteria pollutant controls should not be counted as benefits of the CO_2 standards and BEVs. We also received comment that EPA overestimated $PM_{2.5}$-related benefits due to "the inherent unsupported assumption that the derived C-R relationships continue to hold fully, well below the ranges of exposure observations on which those C-R relationships were based." This commenter suggested benefits from reduced air pollution may be overestimated because exposure rates will be lower in the future and asserted that the benefit calculations have limitations because they lack direct measures of individual lifetime exposures and face potential confounding of effects from the omission of various mortality risk factors.

EPA also received comment that, "The interim IWG estimates are deeply flawed, in that they … incorporate 'co-benefits' in the form of a reduction in the emissions of other criteria and hazardous air pollutants already regulated under different provisions of the Clean Air Act."

One commenter claimed that, when applying the BPT approach to monetizing PM-related health benefits, EPA ignored the fleet turnover benefit that would result from replacing older ICEVs with new, more efficient, ICEVs.

EPA also received comment suggesting we did not monetize non-fatal illnesses in the proposal and that EPA should include a discussion of the research showing health impacts at low levels of air pollution, particularly $PM_{2.5}$ and ozone.

Response:

In this RTC section's response, EPA is focusing on addressing comments related to the health benefits associated with the criteria pollutant impacts of the rule. To the extent that these commenters raise other issues, those issues are addressed elsewhere in this RTC or in the final rule's preamble for this action.

EPA notes that, consistent with CAA section 202, in evaluating potential standards we carefully weighed the statutory factors, including the emissions impacts of the standards, and the feasibility of the standards (including cost of compliance in light of available lead time). We monetize benefits of the standards and evaluate other costs in part to enable a comparison of costs and benefits pursuant to E.O. 12866, but we recognize there are benefits that we are currently unable to fully quantify. EPA's practice has been to set standards to achieve improved air quality consistent with CAA section 202, and not to rely on cost-benefit calculations, with their uncertainties and limitations, as identifying the appropriate standards. Nonetheless, our conclusion that the estimated benefits exceed the estimated costs of the final program reinforces our view that the standards are appropriate under section 202(a). More specifically, for this rule our benefits assessment indicates that the rule has positive net monetized benefits under any of the alternative discount rates. To the extent that EPA considers the positive monetized net benefits as supportive of the final standards (regardless of the magnitude of those positive benefits), net benefits are positive regardless of which stream of $PM_{2.5}$ health benefits are used; EPA would still find the emissions reductions, in light of the cost of compliance, available lead time and other factors, justify adoption of these standards.

After consideration of comments, for the final rule we did not fundamentally alter our approach to estimating criteria air pollutant benefits from that used in the proposal. However, we did conduct air quality modeling of the regulatory program's impacts in 2055 and used the ambient $PM_{2.5}$ and ozone concentration data as inputs to a full analysis of the health benefits (including avoided deaths and avoided non-fatal illnesses) attributable to the rule in 2055. This additional analysis is responsive to comments suggesting EPA include in its analysis ozone-related benefits and quantified estimates of specific health endpoint incidence. We also estimated the present and annualized value of costs and benefits using a 2 percent discount rate, in addition to a 3 and 7 percent discount rate, and we used updated Social Cost of Greenhouse Gas (SC-GHG) values to monetize climate benefits. Both of these updates are responsive to comments requesting the EPA to use a lower range of discount rates than those used in the proposal. Responses to comments related to the SC-GHGs and benefits related to reductions of GHG emissions can be found in Section 8.4 of the RTC. We expand our response to comments about the discount rate later in this section.

EPA agrees with the commenter who stated that the benefits of controlling emissions from light- and medium-duty vehicles far outweigh the costs. Another commenter provided a benefits analysis of different and more stringent standards. To the extent that the information introduced by this commenter was intended to advocate for more stringent standards, we refer the reader to Sections 3.2 and 4 of this RTC document, and Section V of the preamble.

We generally respond to commenters who claimed that the criteria pollutant benefits analysis was flawed by noting that the benefits analyses of the proposed and final rulemakings follow all appropriate best practices, and our methods are described and supported, in detail, in the preamble and RIA that accompany the final rule. EPA's analysis is consistent with applicable guidance and best practices for conducting benefit-cost analyses, including OMB Circular A-4 and EPA's Guidelines for Preparing Economic Analyses. We consider our analysis consistent with the guidance, methodologically rigorous, and a best estimate of the projected societal benefits and costs associated with the final program.

The Agency disagrees with the commenter who claimed that the criteria pollutant benefits of the rule: (1) are exaggerated; (2) are not additive to the benefits attributable to emissions reductions accomplished by EPA's other mobile-source and stationary-source programs for criteria air pollutants ("because of the way Congress designed the Clean Air Act, structured state implementation plans, and the way EPA defined emissions limits and nonattainment on a community-by-community basis"); and, (3) should be estimated using alternative approaches for calculating the benefits of $PM_{2.5}$ control. As noted above, we consider our criteria pollutant benefits a best and credible estimate of those associated with the rule. The improvements in air quality related to the rule are incremental to all other rulemakings that are currently "on the books," and we account for the full suite of already-promulgated rulemakings (for both mobile and stationary sources) in our baseline ("business as usual") scenario to which we compare the changes in air quality once the light- and medium-duty standards are in place. These benefits are also additive to benefits achieved by other regulations, since they will achieve unique emissions reductions attributed specifically to this rulemaking. Furthermore, the regulatory authority under which we promulgate mobile source regulations is distinct from, and independent of, the NAAQS standard-setting process. Regardless of an area's attainment/nonattainment determination status, the light- and medium-duty vehicle standards will apply nationally, and the health benefits associated with the standards will accrue to those who experience reductions in pollution exposure. Any consideration of how these standards might affect decisions related to the NAAQS attainment/nonattainment process is beyond the scope of this rulemaking, and we therefore also reject the suggestion that PM benefits be expressed as compliance-cost savings associated with theoretical (and unsupported) relaxation of stationary source regulations in the future. We further note that state agencies have expressed the view in comments that the emissions reductions of this rule are essential to enabling states to attain and maintain the NAAQS, particularly in light of the CAA's constraints on state regulation of mobile sources. See, e.g., EPA-HQ-OAR-2022-0829-0559, pp. 2-3. Thus, we disagree that these reductions should be treated as displacing other reductions.

The same commenter suggested that direct $PM_{2.5}$ emission reductions from new criteria pollutant controls should not be counted as benefits of the CO_2 standards and BEVs. We respond that we do not double count $PM_{2.5}$ reductions associated with the standards. As discussed above, we are not taking credit for the same $PM_{2.5}$ reductions from the criteria pollutant controls and the GHG standards; the PM reductions from both programs are incremental to each other and additive. We therefore consider it appropriate to assess the benefits of the entire program.

In response to the comment mentioning EPA's monetization of "co-benefits" (benefits related to pollutants other than GHGs such as criteria pollutant benefits), we note that benefits from criteria pollutant reductions are directly related to the criteria pollutant standards being finalized and are a co-controlled pollutant related to the GHG standards. As noted above, the emissions benefits attributable to the GHG and criteria pollutant standards are additive and are not double counted, and their inclusion in the benefit-cost analysis is consistent with OMB Circular A-4 guidance, which states that Agencies should attempt to monetize all of the benefits attributable to a rulemaking in its regulatory impact analyses. Furthermore, we reject the commenter's assertion that somehow the IWG SC-GHG estimates are flawed because they "incorporate 'co-benefits' in the form of a reduction in the emissions of other criteria and hazardous air pollutants already regulated under different provisions of the Clean Air Act." If we interpret this comment to mean that pollution reduction benefits associated with the standards are inflated because they include criteria pollutant benefits that might already be controlled by other regulations, such as the PM NAAQS ($PM_{2.5}$ is the only monetized criteria pollutant benefit in the benefit-cost analysis of the standards; we did not monetize HAP pollutant benefits), this is incorrect. The NAAQS and their associated RIAs illustrate, but do not predict, the benefits and costs of possible emissions control strategies to attain a revised NAAQS; these costs and benefits are illustrative and cannot be added to, nor are they a substitute for, the costs and benefits of policies that prescribe specific emission control measures, such as those associated with the specific mobile source emissions control measures reflected in the benefit-cost analysis of the proposed and final standards.

We respond to comments about fleet turnover in Section 12.1.3 of this RTC document and to the issue of ICE vehicle "backsliding" in Section 12.3 of this document. We respond to the comment regarding criteria pollutants attributable to the shift from ICEs to BEVs in the light-duty sector in Section 19.2 of this RTC document.

In response to the commenter who suggested we did not monetize non-fatal illnesses in the proposal, this is incorrect. For the analysis of both the proposed and final standards, we use a reduced-form "benefit-per-ton" (BPT) approach to estimate the monetized $PM_{2.5}$-related health benefits of the final standards. As described in RIA Chapter 6.5, the BPT approach monetizes avoided premature deaths and illnesses that are expected to occur as a result of reductions in directly-emitted $PM_{2.5}$ and $PM_{2.5}$ precursors attributable to the standards. The commenter was correct in noting that the BPT approach does not monetize ozone (and other air pollutant) benefits, nor does the BPT approach allow us to report on individual health endpoint incidence. The estimated benefits of the standards would be larger if the BPT approach were able to estimate those omitted health benefits. However, as mentioned earlier in this response, EPA conducted full-scale photochemical air quality modeling of the final rule's impacts in 2055. Using the ambient $PM_{2.5}$ and ozone concentration data, we conducted a full benefits analysis that quantifies and monetizes the $PM_{2.5}$- and ozone-related benefits attributable to the rule in 2055. This analysis complements the BPT approach, which we use to monetize $PM_{2.5}$-related benefits in the benefit-cost analysis. See RIA Chapter 7 for more information about the air quality modeling and health benefits analyses.

The same commenter also suggested that EPA include a discussion of the research showing health impacts at low levels of air pollution, particularly $PM_{2.5}$ and ozone, and cited EPA's PM and ozone ISAs as evidence. Drawing from the same robust body of literature, we agree that there are health impacts at low levels of air pollution and that there is no evidence of a threshold below which exposure to $PM_{2.5}$ and ozone yields no health response. In our discussion of criteria pollutant benefits in both the preamble and RIA for this rulemaking, we refer to the health benefits Technical Support Document (Benefits TSD) that accompanied the 2023 PM NAAQS

Proposal, which details the approach used to estimate $PM_{2.5}$- and ozone-related benefits.[382] In that TSD, we summarize some of this research and how it applies to the benefits analysis.

Regarding the comment that EPA has overestimated $PM_{2.5}$-related benefits due to "the inherent unsupported assumption that the derived C-R relationships continue to hold fully, well below the ranges of exposure observations on which those C-R relationships were based," we reject this premise. As detailed in the 2019 PM ISA and previous assessments in support of the PM NAAQS, EPA's review of the science has consistently found no evidence of a threshold below which exposure to $PM_{2.5}$ yields no health response. Specifically, the 2019 PM ISA found that "extensive analyses across health effects continues to support a linear, no-threshold concentration-response (C-R) relationship." This conclusion in the 2019 PM ISA is supported by the more recent evaluation of the health effects evidence detailed in the recently released Supplement to the PM ISA which found "continued evidence of a linear, no-threshold concentration-response (C-R) relationship."

As noted above, based on the evidence and lack of nonlinear relationships between long-term $PM_{2.5}$ exposure and health impacts, we assume a linear, no-threshold relationship and find that health impacts are associated with exposures from low levels of air pollution. The commenter who suggests benefits from reduced air pollution may be overestimated because exposure rates will be lower in the future provides no evidence to support this assertion, which is contrary to the weight of evidence in the literature that supports such impacts. The commenter also asserted that the benefit calculations have limitations because they lack direct measures of individual lifetime exposures and face potential confounding of effects from the omission of various mortality risk factors. EPA agrees that there are uncertainties associated with the estimation and assignment of exposure in epidemiological studies, and that confounding is also a potential source of uncertainty, both of which are discussed in the Benefits TSD cited above. However, we disagree that the potential uncertainty is a limitation. We follow a systematic approach to identifying the studies and risk estimates most appropriate to inform a $PM_{2.5}$ and ozone health benefits analysis for an RIA, and we take into consideration a number of minimum and preferred study attributes that include whether specified models from individual studies are single- or multi-pollutant, among many other factors.[383] Clearly specifying criteria for identifying such studies helps ensure EPA transparently specifies its scientific judgement. These criteria are similar to those applied in previous EPA RIAs with the primary goal of identifying risk estimates that best characterize risk from $PM_{2.5}$ and ozone exposure among the total population located throughout the U.S.

7. Environmental Justice Considerations

We agree with EPA that a reduction in heavy aromatics in gasoline will produce beneficial reductions in PM emissions that will further national environmental justice goals. EPA notes in the NPRM that people living and working near roadways will benefit from fuel improvements that reduce PM formation, that those individuals are more likely to be people of color and/or have a low socioeconomic status (SES), and that lower-SES neighborhoods are likely to have more vehicles with higher emissions than higher-SES neighborhoods.442 A fuel-based regulation to reduce PM emissions would do so for all vehicles in the on-road fleet. Importantly, the greatest absolute emissions reductions will occur in and benefit lower-SES communities, as those communities are more likely to have the highest-emitting vehicles, i.e., a higher proportion of older vehicles with the highest emissions levels (due to their vehicle's age). [EPA-HQ-OAR-2022-0829-0701, pp. 270-271]

442 NPRM at 29393

EPA also uses this same rationale (proximity of low-SES communities to roadways) in support of a proposed lower tailpipe PM emissions limit, but the distribution of ages of vehicles on roadways is not discussed. The emissions reductions from the proposed tailpipe emissions rule will only reduce emissions for the newest vehicles, which in the near-term benefits higher-SES communities more than lower-SES communities. Moreover, these new vehicles will tend to replace vehicles of more recent vintage that already adhere to the newest, most stringent PM emissions limits. A fuel-based regulation targets all vehicles and is the only approach that immediately reduces emissions from older, higher-emitting vehicles more often found in low-SES communities. [EPA-HQ-OAR-2022-0829-0701, pp. 270-271]

Organization: American Council for an Energy-Efficient Economy (ACEEE)

The U.S. needs the strongest vehicle standards

The United States will need to greatly reduce light-duty vehicle (LDV) greenhouse gas emissions if it is to have any chance of meeting the Biden Administration's economy-wide emissions reduction goal of 50% by 2030 and stave off the worst impacts of climate change. Transportation is now the largest source of greenhouse gas emissions in the United States and the light-duty sector makes up 58% of those emissions.1 Reducing carbon emissions is critical to tackling climate change but increasing LDV efficiency will also have significant benefits to air quality and will reduce driver fueling costs. Vehicles are a significant contributor to local air pollution and the associated health impacts, leading to increased rates of asthma, increased risk of heart attacks, strokes, and lung cancer.2 These impacts are particularly bad in low-income communities and communities of color, which bear a disproportionate air pollution burden.3 Greater efficiency can also provide significant cost savings for drivers when they refuel their vehicles. Low-income households are especially burdened by fueling costs, paying three times more than their higher-income counterparts on gasoline, as a percent of their total income.4 [EPA-HQ-OAR-2022-0829-0642, pp. 1-2]

Organization: American Lung Association (ALA) et al.

The American Lung Association's most recent "State of the Air" report noted that approximately 120 million Americans live in communities impacted by unhealthy levels of ozone and/or particle pollution.1 Exposure to air pollution can contribute to asthma attacks, heart attacks and stroke, lung cancer, low birthweight and premature birth, premature death and other health risks. Traffic pollution specifically is associated with premature death due to cardiovascular disease, lung cancer death, asthma onset in children and adults and other negative outcomes.2 The burdens of air pollution are not equally shared: people of color make up the majority of those living in the communities with unhealthy air and a person of color in the United States is 3.7 times more likely to live in a community with the worst air pollution in the nation than a white person. [EPA-HQ-OAR-2022-0829-0745, p. 1]

Organization: California Air Resources Board (CARB) (Part 1 of 5)

Introduction

Reducing emissions from motor vehicles is urgently needed to combat climate change and reduce exposure to harmful air pollution, especially in the nation's most vulnerable communities. The California Air Resources Board (CARB) commends the U.S. Environmental Protection Agency (U.S. EPA) for proposing to adopt multi-pollutant emissions standards for the 2027 and later model years (MY) for light- and medium-duty vehicles. [EPA-HQ-OAR-2022-0829-0780, p. 7]

The science could not be clearer. We must act now to reduce pollution to stabilize the climate and avoid the most serious consequences of climate change. In California and many other states, the changing climate is already increasing the frequency and severity of drought, wildfires, and extreme weather events like heat waves, jeopardizing public health and economic stability. We likewise must continue to urgently pursue efforts to improve air quality and reduce toxic emissions and reduce the disparate impacts that have persisted for decades. In California and across the U.S., many low-income communities and communities of color are exposed to disproportionate levels of pollution from on-road vehicle emissions, which contributes to respiratory illness, cardiovascular disease, cancer, and premature death. These impacts are often compounded by the congregation of nearby industrial sources, including upstream, midstream, and downstream fuel production sources. Furthermore, many of these same communities are especially vulnerable to the effects of climate change, as the most severe harms from climate change fall disproportionately on these underserved communities who are least able to prepare for and recover from associated impacts. U.S. EPA's proposed standards are urgently needed to help address these issues. [EPA-HQ-OAR-2022-0829-0780, p. 7]

Despite significant progress reducing air pollution, California experiences some of the nation's poorest air quality, with more than 21 million Californians living in areas that exceed federal ozone standards. 3 Within these areas, there are many low-income and disadvantaged communities that are exposed to not only ozone, but also to particulate and toxic pollutant levels that are significantly higher than applicable federal standards and which have immediate and detrimental health effects. With new research demonstrating adverse health impacts even below NAAQS levels, it remains critically important to continue to reduce emissions wherever feasible. [EPA-HQ-OAR-2022-0829-0780, p. 8]

4 CARB. 2022 Scoping Plan for Achieving Carbon Neutrality. December 2022. https://ww2.arb.ca.gov/sites/default/files/2023-04/2022-sp.pdf.

The above impacts especially apply to tribal communities. Due to land dispossession and forced migration, tribal communities are more exposed to extreme heat and more likely to rely on local water sources that are less resilient to drought and more contaminated.69 Beyond those impacts, tribal communities also suffer cultural harms from the decimation or harm to local ecosystems and species of particular meaning to cultural practices.70 These cultural resources have intrinsic value, and they are also critical to tribal community identity and group cohesion, which translates into direct health benefits.71 Moreover, degradation of these cultural resources threatens traditional ecological knowledge, such as particularized understanding of local ecosystems, agriculture, and sustainable practices, that can help limit the impacts of climate change.72 Tribal communities with sovereign land holdings are also more vulnerable to climate impacts because they are unable to relocate.73 [EPA-HQ-OAR-2022-0829-0746, pp. 10-11]

73 Farnell et al., supra n. 69.

Furthermore, environmental justice communities, including tribal communities, are environmentally overburdened due to greater existing pollution exposure.74 This disadvantage manifests in higher rates of chronic disease, premature death, and other adverse public health outcomes.75 Compounding these disparities, residents of environmental justice communities also have less access to health care—they are less likely to have health insurance and less likely to be able to afford necessary tests and procedures, and health care facilities are poorly staffed and equipped.76 Consequently, residents of environmental justice communities are less able to withstand climate impacts that further damage their health, such as increased local smog conditions.77 [EPA-HQ-OAR-2022-0829-0746, pp. 10-11]

77 California Climate Justice Report, supra n.61, at 40-43.

In addition to being more vulnerable to the impacts of climate change, environmental justice communities endure structural disadvantages that blunt their ability to adapt to a changing climate. Environmental justice communities have less access to financial resources, such as income and wealth, that are critical to climate resilience.78 More financial resources equate to more mobility, more ability to spend (on utilities, health care, home adaptation, etc.) to reduce climate harms, and more safeguards (such as insurance) in the event of extreme climate events.79 Environmental justice communities have higher rates of limited English proficiency, which can reduce access to climate resilience programs and increase vulnerability in extreme climate events due to an inability to understand public health information.80 Social capital in the political process is critical to ensure environmental justice communities receive resources to increase climate resilience and to prevent further entrenching existing inequities. Environmental Health Equity and Environmental Justice

Scientific Evidence on Environmental Health Equity

CARB commends U.S. EPA for its thorough review of the environmental justice literature on the effects of GHG and criteria pollutants and air toxics across different populations. The documentation for the proposed rule highlights the disproportionate climate impacts and exposure to traffic-related air pollution (TRAP) among vulnerable groups, such as people of color, low-income populations, children, and outdoor workers. However, this analysis could be strengthened by additional discussions on cumulative impacts and climate change, health co-benefits of climate actions, and additional research on disproportionate exposure to TRAP. Inclusion of these topics would enhance the description of the evidence base for persistent health disparities affecting marginalized populations, which further illustrates why the proposed standards are so urgently needed to advance and attain health equity. [EPA-HQ-OAR-2022-0829-0780, p. 54]

Disproportionate impact of exposure to Traffic-Related Air Pollution (TRAP)

While U.S. EPA conducted an extensive literature review on disparities in exposure to TRAP across U.S. populations, CARB has identified several national studies and a series of California studies that enrich the existing literature already documented by U.S. EPA for the proposed standards. [EPA-HQ-OAR-2022-0829-0780, pp. 56-57]

A recent nationwide study reported that people of color experience disproportionate exposures to PM2.5. 103 The study found that the systemic PM2.5 exposure disparity experienced by people of color is related to emission sources from almost all major emission categories. The largest sources of the disparities are industry, light-duty gasoline vehicles, construction, and heavy-duty diesel vehicles. Moreover, the disproportionate exposures have been seen in individual U.S. states, in individual urban and rural areas, across incomes, and across exposure levels. Another national study showed that zip codes with more White and Native American populations have lower average PM2.5 levels than ZIP codes with more Black, Asian, and Hispanic or Latino populations. 104 The disparities in PM2.5 exposure is also shown in zip codes with low-income populations compared to zip codes with high-income populations. Moreover, people of color in the U.S. not only face longer-term PM2.5 exposure but also short-term PM2.5 exposure (e.g., more days with PM2.5 concentrations above the thresholds) than non-Hispanic Whites. 105 [EPA-HQ-OAR-2022-0829-0780, pp. 56-57]

Environmental pollutants affect children more than adults, and children in low-income and urban areas near industrial, rail, and traffic sources face particularly high health risks. Results from CARB's groundbreaking, long-term children's health study in Southern California demonstrated that particle pollution may significantly reduce lung function growth in children 106, 107, 108 and indicates these effects are likely permanent. 109 Additionally, increased exposure to vehicular traffic pollution was associated with adverse childhood health impacts, including slower lung development, 110 increased symptoms and medication use in asthmatic children, 111, 112 and increases in the development of asthma in children. 113 Compared with non-Hispanic White children, the cohort's Hispanic White children, especially those with more Native American ancestry, tended to live closer to a freeway or a major nonfreeway road. Furthermore, a higher percentage of asthma was observed among the Hispanic White children with more than 50 percent Native American ancestry who lived near a major nonfreeway road compared to those who lived farther away. 114 CARB is submitting these studies to U.S. EPA to further demonstrate the increased impacts on vulnerable populations from TRAP, pointing to the urgent need to adopt more stringent emission standards to protect these groups. Disproportionate Exposure to Air Pollution at the Community Scale

In addition to research studies documenting disparate health impacts from exposure to air pollution, CARB illustrates these disproportionate impacts for one California community. This example points to the urgent need to address these emission sources for communities that face similar exposures. [EPA-HQ-OAR-2022-0829-0780, pp. 57-59]

The benefits of U.S. EPA's proposal for on-road vehicles are especially critical from a community perspective in disadvantaged communities along heavily traveled roads. In these communities, the pollution and public health impacts from on-road vehicle emissions are especially significant and greater than in other communities. In California, East Los Angles, Boyle Heights, and West Commerce is one such community. Selected under CARB's Community Air Protection Program to develop a community air monitoring plan and a community emissions reduction program, this community has more than 30 miles of freeways within its approximately 26 square mile emissions study boundary area (Figure 4). 115 Emissions from on-road vehicles are a significant contributor to the community's air pollution exposure, and its population shows a greater degree of health impacts from air pollution. [EPA-HQ-OAR-2022-0829-0780, pp. 57-59]

The community has a high cumulative air pollution exposure burden, a significant number of sensitive receptors, and includes census tracts that have been designated as disadvantaged communities by California law. 116 [EPA-HQ-OAR-2022-0829-0780, pp. 57-59]

115 For more information on this community and CARB's Community Air Protection Program, see: https://ww2.arb.ca.gov/our-work/programs/community-air-protection-program/communities/east-los-angeles- boyle-heights-west.

116 Disadvantaged community designations per Senate Bill 535 (De León, Chapter 830, Statutes of 2012).

[See original for graphic titled "Figure 4. East LA/Boyle Heights/West Commerce Community Boundary"] [EPA-HQ-OAR-2022-0829-0780, pp. 57-59]

Based on the 2019 American Community Survey (ACS) data from the Census Bureau, 117 more than 227,000 people live within the East LA/Boyle Heights/West Commerce community.

Major freeways bisecting the community include Highways 101 and 60, and Interstates 5, 10, and 710, resulting in four freeway junctions and increased pollution exposures for the populations living and working in this community as compared to Los Angeles County as a whole. [EPA-HQ-OAR-2022-0829-0780, pp. 57-59]

117 U.S. Census Bureau, 2015-2019 American Community Survey 5-year Estimates. https://data.census.gov/cedsci/

Approximately 95 percent of the population in this community is Latino, nearly 14 percent are children under the age of 10 years, and 11 percent of the population is elderly (over the age of 65 years). These population characteristics are important indicators of disparities in existing pollution burden, exposure to air pollution, and health vulnerabilities—especially for children and the elderly. 118 [EPA-HQ-OAR-2022-0829-0780, pp. 57-59]

118 The metrics presented here are the same as the data presented in the 2019 Community Emissions Reduction Plan for East Los Angeles, Boyle Heights, West Commerce, but have been updated to include the latest Census ACS 5-year estimates (2015-2019) for the community boundary. South Coast Air Quality Management District, Assembly Bill (AB) 617 Community Air Initiatives, Community Emissions Reduction Plan for East Los Angeles, Boyle Heights, West Commerce, September 2019, http://www.aqmd.gov/docs/default-source/ab-617-ab- 134/steering-committees/east-la/cerp/carb-submittal/final-cerp.pdf?sfvrsn=8

Certain groups of the general population are more vulnerable to air pollution by virtue of their age and health, including children, elderly, pregnant women, and health compromised individuals. Places where these sensitive populations gather, called sensitive receptor locations, can include schools, day-care providers, hospitals, nursing homes, and senior care facilities. There are numerous sensitive receptor locations in the East LA/Boyle Heights/West Commerce community, including 80 schools, 79 day-care providers, and 36 health care facilities including hospitals, nursing homes and dialysis clinics (Figure 5). [EPA-HQ-OAR-2022-0829-0780, pp. 57-59]

[See original for graphic titled “Figure 5. Sensitive Receptors in East LA/Boyle Heights/West Commerce Community”] 119 [EPA-HQ-OAR-2022-0829-0780, pp. 57-59]

119 The metrics presented here are the same as the data presented in the 2019 Community Emissions Reduction Plan for East Los Angeles, Boyle Heights, West Commerce, but have been updated to include the latest Census ACS 5-year estimates (2015-2019) for the community boundary. South Coast Air Quality Management District, Assembly Bill (AB) 617 Community Air Initiatives, Community Emissions Reduction Plan for East Los Angeles, Boyle Heights, West Commerce, September 2019, http://www.aqmd.gov/docs/default-source/ab-617-ab- 134/steering-committees/east-la/cerp/carb-submittal/final-cerp.pdf?sfvrsn=8

CalEnviroScreen 4.0 is a screening tool developed by the California Office of Environmental Health Hazard Assessment to help identify California communities that are disproportionately burdened by multiple sources of pollution and socioeconomic indicators. Approximately 95 percent of the census tracts in this community are in the top 25 percent (75-100th percentile) of the CalEnviroScreen 4.0 120 (CES) scores within the State. The maximum overall CES score for any census tract in the community is the 99th percentile, which means that people living in that census tract are in the top 1 percent of the most impacted census tracts in the State. Most of the census tracts in this community are considered disadvantaged under California law. 121 [EPA-HQ-OAR-2022-0829-0780, pp. 57-59]

120 The Office of Environmental Health Hazard Assessment (OEHHA) released the California Communities Environmental Health Screening Tool: CalEnviroScreen 4.0 in October 2021. https://oehha.ca.gov/media/downloads/calenviroscreen/report/calenviroscreen40reportf2021.pdf

121 Disadvantaged community designations per Senate Bill (SB) 535 (De León, Chapter 830, Statutes of 2012).

Table 4 and Table 5 present the number of census tracts in the community that are in the top 25 percent (75-100th percentile) of impacted tracts in the State, as well as the maximum percentile for exposure (e.g., ozone, PM2.5, diesel PM, traffic impacts), health status (asthma, cardiovascular disease, low birth weight), and socio-economic (education, linguistic isolation, poverty, unemployment, and housing burden) indicators for the census tracts in this community. [EPA-HQ-OAR-2022-0829-0780, pp. 57-59]

Table 4. CalEnviroScreen (CES) 4.0 Overall Score in the East LA/Boyle Heights/West Commerce Community [EPA-HQ-OAR-2022-0829-0780, pp. 60-64]

CES 4.0 Overall Score: CES Score

Number of Census Tracts with Highest CES Scores (Top 25%, 75-100th Percentile): 51

Percent of Census Tracts with Highest CES Scores (Top 25%, 75-100th Percentile) 122: 91%

Maximum Percentile in Community: 99.9 [EPA-HQ-OAR-2022-0829-0780, pp. 60-64]

122 The percentages for the overall CES 4.0 score represent the number of census tracts in this community that are considered "disadvantaged" per SB 535 (75th percentile or top 25% of all census tracts in the State)

[See original for table titled "Table 5. CalEnviroScreen (CES) 4.0 Scores for Key Exposure, Health, and Socio-Economic Indicators in the East LA/Boyle Heights/West Commerce Community"]123 [EPA-HQ-OAR-2022-0829-0780, pp. 60-64]

123 The percentages for the individual CES 4.0 metrics present the number of census tracts in the community that are in the top 25 percent of census tracts for a given indicator.

Figure 6 compares the average scores for exposure (e.g., ozone, PM2.5 concentrations, diesel PM emissions, traffic impacts), health status (asthma, cardiovascular disease, low birth weight), and socio-economic (education, linguistic isolation, poverty, unemployment, and housing burden) indicators in the community against statewide averages—the community scores for these key indicators are generally higher compared to the statewide averages. [EPA-HQ-OAR-2022-0829-0780, pp. 60-64]

[See original for graph titled "Figure 6. CalEnviroScreen 4.0 Scores for Key Indicators in the East LA/Boyle Heights/West Commerce Community Relative to Statewide Averages"] [EPA-HQ-OAR-2022-0829-0780, pp. 60-64]

The indicators discussed above also explain the disparate effects of air pollution faced by other communities in California, which extends to numerous other communities across the nation. Figure 7 presents the average scores for PM2.5 concentrations and diesel PM emissions relative to statewide averages for a few communities across the State; vehicle emissions contribute predominantly to the particulate matter and diesel PM impacts in these communities. The chart includes asthma-related emergency room visits and linguistic isolation (i.e., limited

English speaking) as proxies for demographic and socio-economic disadvantages faced by these communities. [EPA-HQ-OAR-2022-0829-0780, pp. 60-64]

[See original for graph titled “Figure 7. CalEnviroScreen 4.0 Scores for PM2.5 Concentration, Diesel PM Emissions, and Socio-economic Indicators in California Communities”] [EPA-HQ-OAR-2022-0829-0780, pp. 60-64]

Many California communities experience significantly higher levels of both regional and near-source air pollution, and the demographic and socio-economic characteristics of these communities exacerbate their susceptibility and vulnerability to the adverse effects of air pollution. A 2019 CARB research study revealed on-road vehicles and industrial activity to be the top two sources of exposure in California, each contributing to 24 percent of the total PM2.5 exposure, and disproportionately impacting non-white and low-income populations. 124 Existing scientific literature conclusively links air pollution to adverse health outcomes, including pre-mature mortality, and the disproportionate pollution and health burden on poor and socially disadvantaged communities. OEHHA’s CES 4.0 report provides an exhaustive review of existing literature connecting each of the indicators used in the CES method to pollution burden and population sensitivities. 125 [EPA-HQ-OAR-2022-0829-0780, pp. 60-64]

124 Apte J. et al (2019). A Method to Prioritize Sources for Reducing High PM2.5 Exposures in Environmental Justice Communities in California. CARB Research Contract Number 17RD006. https://ww2.arb.ca.gov/sites/default/files/classic//research/apr/past/17rd006.pdf

125 OEHHA CES 4.0 Report. October 2021. pp. 29-197. https://oehha.ca.gov/media/downloads/calenviroscreen/report/calenviroscreen40reportf2021.pdf

The East LA, Boyle Heights, West Commerce community is just one example of many such communities across the nation that bear the consequences of near-roadway emissions, in addition to impacts from other sources of air pollution in their neighborhoods. For these communities, reducing emissions from on-road vehicles is a priority. [EPA-HQ-OAR-2022-0829-0780, pp. 60-64]

Organization: California Attorney General's Office, et al.

Strong emissions standards are necessary now to stave off the worst impacts of human-induced climate change and to confront inequitably distributed threats to public health and the environment from climate change as well as other forms of pollution. From extreme heat to wildfires to drought, our States and Cities are already experiencing the devastating impacts of climate change, which will continue to mount and compound with rising concentrations of GHGs in the atmosphere. Moreover, vehicle emissions of oxides of nitrogen (NOx), particulate matter (PM), and other criteria pollutants continue to endanger the health and welfare of our residents. [EPA-HQ-OAR-2022-0829-0746, p. 1]

4. Environmental Justice Communities Disproportionately Bear the Burden of Climate Change Impacts

Climate change’s impacts will continue to disproportionately fall on environmental justice communities.55 Environmental justice communities experience more severe climate impacts and are more vulnerable as the climate crisis worsens. [EPA-HQ-OAR-2022-0829-0746, pp. 8-10]

55 “Environmental justice” is defined by EPA as the “fair treatment and meaningful involvement of all people regardless of race, color, national origin or income with respect to development, implementation, and enforcement of environmental laws, regulations and policies.” EPA, EJ 2020 Action Agenda: The U.S. EPA’s Environmental Justice Strategic Plan for 2016-2020, EPA-300-B-1-6004, at 1 (Oct. 2016). For the purpose of this comment, the term “environmental justice community” refers to a community of color or community experiencing high rates of poverty that, due to past and/or current unfair and inequitable treatment, is overburdened by environmental pollution, and the accompanying harms and risks from exposure to that pollution because of past or current unfair treatment.

Severe climate harms are already a reality for many environmental justice communities. Globally, the last nine years have been the nine hottest on record, and that trend is expected to continue.56 Members of environmental justice communities tend to work in occupations with increased exposure to extreme heat, such as the agricultural, construction, and delivery industries.57 Farmworkers die of heat-related causes at 20 times the rate of the rest of the U.S. civilian workforce.58 Since 2005, the first year California began tracking the number of heat-related fatalities, 36% of California’s heat-related worker deaths have been of farmworkers.59 Similarly, although construction workers comprise only 6% of the national workforce, they account for 36% of heat-related deaths.60 [EPA-HQ-OAR-2022-0829-0746, pp. 8-10]

60 Xiuwen Sue Dong et al., Heat-Related Deaths Among Construction Workers in the United States, 62 AM. J. INDUS. MED. (2019), at 1047-57.

At home, environmental justice communities suffer disproportionate impacts from extreme heat because they are more likely to lack air conditioning, tree canopy, and greenspace. Environmental justice communities have less access to air conditioning to cool down, and are less able to pay the utility bills required to run air conditioning units or fans.61 In urbanized environments, pavement, cement, and other non-vegetated areas contribute to the heat island effect, in which built environments retain heat, causing daytime temperatures to be from 1 °F to 6 °F hotter than suburban and rural areas and nighttime temperatures to be as much as 22 °F hotter.62 The heat island effect is inequitably distributed—it is most extreme in lower-income communities and communities of color.63 Contributing to this effect is the lack of tree canopy and greenspace in environmental justice communities, often due to lower historical and ongoing investment. Indeed, tree canopy and greenspace is highly correlated with historical redlining practices, in which federal housing policy directed investment away from lower-income communities, and especially communities of color, characterized as “risky” for loan servicing.64 Moreover, an EPA report found that individuals with lower incomes and individuals of color are respectively 11% to 16% and 8% to 14% more likely to live in areas with the highest projected increases in premature mortality from extreme heat.65 [EPA-HQ-OAR-2022-0829-0746, pp. 8-10]

In addition, flooding and drought from extreme weather events disproportionately affect environmental justice communities, and the inequity will grow as climate impacts worsen. Due to disinvestment, environmental justice communities often lack sufficient infrastructure to control flooding or ensure steady water supplies.66 They also suffer from more severe impacts, such as contaminated water from pollutant flows during floods and increased concentration of contaminants during droughts.67 EPA has also determined that individuals with lower incomes are more likely to live in areas with the highest projected land losses from sea level rise inundation and are more likely to face substantial traffic delays due to climate-driven changes in high-tide flooding.68 [EPA-HQ-OAR-2022-0829-0746, pp. 8-10]

3. Criteria Pollutant and Air Toxics Emissions from Light- and Medium-Duty Vehicles Disproportionately Impact Environmental Justice Communities

Criteria pollutant emissions from light- and medium-duty vehicles disproportionately endanger residents of environmental justice communities by exposing them to harmful air pollution that causes significant health impacts. Light- and medium-duty vehicles' emissions are concentrated along transportation corridors. 88 Fed. Reg. at 29,396. Aggravating historical injustices, decision-makers disproportionately site highways and other transportation infrastructure in lower-income communities and communities of color. The burden of vehicle emissions therefore falls inequitably on environmental justice communities, which also face industrial pollution cumulatively with vehicle emissions.91 [EPA-HQ-OAR-2022-0829-0746, pp. 13-15]

91 See, e.g., EPA, Estimation of Population Size and Demographic Characteristics among People Living Near Truck Routes in the Coterminous United States (Feb. 16, 2022), EPA-HQ-OAR-2019-0055-0982, at 11-12, Fig. 3, 17-19, Fig. 9 (finding that individuals living near major truck routes are more likely to be people of color and lower-income); see also Michelle Meyer and Tim Dallmann, The Real Urban Emissions Initiative, Air quality and health impacts of diesel truck emissions in New York City and policy implications (2022), at 7 Fig. 5 (concluding that Black and Latino individuals in New York City are disproportionately exposed to PM2.5 along freight corridors); Gaige Hunter Kerr, et al., COVID-19 Pandemic Reveals Persistent Disparities in Nitrogen Dioxide Pollution, 118 PROC. NAT'L ACAD. SCIENCES 30 (2021); Mary Angelique G. Demetillo, et al. Space-Based Observational Constraints on NO2 Air Pollution Inequality from Diesel Traffic in Major US Cities, GEOPHYSICAL RESEARCH LETTERS 48 (2021); Paul Allen, et al., Newark Community Impacts of Mobile Source Emissions: A Community- Based Participatory Research Analysis (2020); Maria Cecilia Pinto de Moura, et al., Union of Concerned Scientists, Inequitable Exposure to Air Pollution from Vehicles in Massachusetts (2019); Iyad Kheirbek, et al., The Contribution of Motor Vehicle Emissions to Ambient Fine Particulate Matter Public Health Impacts in New York City: a Health Burden Assessment, 15 ENV'T HEALTH 89 (2016).

For example, EPA modeling has shown that race and income are significantly associated with living near major roadways nationally, even when controlling for other factors.92 EPA research has also indicated that people of color are more likely to live within 300 feet of major transportation facilities and go to school within 200 meters of the largest roadways.93 Environmental justice communities bear the effects of these land use patterns. In the Northeast and Mid-Atlantic Region, average concentrations of exposures to PM2.5 are 75%, 73%, and 61% higher for Latinx residents, Asian-American residents, and African American residents, respectively, than they are for white residents.94 PM2.5 and NO2 concentrations are also highest for Black and Latinx communities in Massachusetts, in part because of their proximity to industrial facilities and highways, and these concentrations have increased over time even though overall exposure to those pollutants has decreased in the Commonwealth.95 [EPA-HQ-OAR-2022-0829-0746, pp. 13-15]

More granular data from California fully illustrate this phenomenon. The census tracts in California with the highest levels of exposure to ozone, PM2.5, and air toxics like diesel particulate matter are communities of color bordering major transportation corridors—Highway 99 in the San Joaquin Valley and Highways 10 and 60 in the Inland Empire: [EPA-HQ-OAR-2022-0829-0746, pp. 13-15]

Census Tracts in California with Highest Levels of Ozone, PM2.5, and Diesel PM Exposure96

Census Tract	Location	People of Color	Ozone	PM2.5	Diesel PM
6065041408	Riverside	78.1%	91st	92nd	97th
6071002109	Ontario	73.2%	91st	96th	93rd
6071003301	Fontana	91.6%	97th	93rd	94th
6065040303	Jurupa Valley	79.3%	95th	94th	97th
6029003113	Bakersfield	80.4%	94th	100th	96th
6029001801	Bakersfield	57.3%	94th	100th	95th
6029002812	Bakersfield	72.5%	94th	100th	96th
6029002813	Bakersfield	76.6%	94th	100th	95th

[EPA-HQ-OAR-2022-0829-0746, pp. 13-15]

96 Data from CalEnviroScreen 4.0, California Office of Environmental Health Hazard Assessment, available at https://oehha.ca.gov/calenviroscreen/report/calenviroscreen-40. Metrics for ozone, PM2.5, and diesel particulate matter exposure are the census tract's percentile ranking as compared to all census tracts in California, demonstrating that these census tracts are among those with the greatest pollution exposure statewide. The raw data for these percentile rankings are available on the CalEnviroScreen 4.0 website. The eight census tracts shown here are examples of the 29 census tracts in California that rank above the 90th percentile statewide for exposure to ozone, fine particulate matter, and diesel particulate matter, all of which are communities in Bakersfield or the Inland Empire near major transportation thoroughfares.

Refineries, drilling sites, and other upstream sources of emissions are also disproportionately located in or near environmental justice communities.97 These facilities routinely emit dozens of toxic air contaminants, such as formaldehyde and benzene, and can cause accidental releases of air toxics that require emergency response. 98 Many of these upstream emissions sources also release other pollution, such as water contaminants.99 Residents of communities near these sites tend to have higher rates of health problems, such as cancers, chronic disease, and adverse birth outcomes, even after accounting for other demographic factors.100 As with transportation corridors, census tract-level data from California demonstrate these concerns. For example, the census tracts near the California refinery with the largest output (the Marathon Refinery in Carson)101 are overwhelmingly communities of color with high cumulative pollution burdens and adverse health outcomes: [EPA-HQ-OAR-2022-0829-0746, pp. 15-16]

101 California Energy Commission, California's Oil Refineries, available at https://www.energy.ca.gov/data-reports/energy-almanac/californias-petroleum-market/californias-oil-refineries (data as of Feb. 7, 2023).

Census Tracts near the Marathon Refinery in Carson, California 102

Census Tract	People of Color	Pollution	Toxic Releases	Asthma	Heart Disease
6037294120	98.0%	93rd	99th	83rd	93rd
6037543306	92.4%	96th	99th	57th	52nd
6037543905	97.2%	84th	99th	72nd	77th
6037294110	90.5%	88th	99th	75th	83rd

[EPA-HQ-OAR-2022-0829-0746, pp. 15-16]

102 Data from CalEnviroScreen 4.0, supra n.96. Metrics for overall pollution burden, toxic releases, asthma, and heart disease are the census tract's percentile ranking as compared to all census tracts in California, demonstrating that these census tracts are among those with the greatest pollution exposure and detrimental health impacts statewide.

Accordingly, achieving emissions reductions from light- and medium-duty vehicles is a critical step to begin dismantling historical patterns of environmental injustice burdening communities near transportation infrastructure and upstream emissions sources. See CARB's Comment at 84- 96. [EPA-HQ-OAR-2022-0829-0746, pp. 15-16]

b. More stringent standards will reduce the air pollution dangers faced by communities near refineries and roadways

Our States and Cities agree with EPA that reducing air toxics—including known carcinogens like formaldehyde and benzene—and criteria pollutants from vehicle exhaust and refining will significantly benefit our residents, especially those in communities proximate to major roadways and refineries. 88 Fed. Reg. at 29,395-97. [EPA-HQ-OAR-2022-0829-0746, pp. 31-32]

PM2.5 and air toxics pollution from refineries significantly impact neighboring communities due to localized concentrations of these pollutants. Nearly 700,000 people live within three miles of the 17 refineries that reported actual annual benzene fenceline concentrations in 2020 above the level set by EPA that requires the refinery to take action to clean up emissions. Of these 700,000 people, 62% are African-American, Hispanic, Asian/Pacific Islander, or American

Indian residents, and nearly 45% have incomes below the poverty level.182 [EPA-HQ-OAR-2022-0829-0746, pp. 31-32]

182 Environmental Integrity Project, Environmental Justice and Refinery Pollution: Benzene Monitoring Around Oil Refineries Showed More Communities at Risk in 2020 (Apr. 28, 2021), at 7, n. 6, available at https://environmentalintegrity.org/wp-content/uploads/2021/04/Benzene-report-4.28.21.pdf.

Communities near major roadways will also benefit greatly from any improvements in air quality. EPA has long acknowledged that people living, working, and attending school near major roadways face greater air pollution exposure. 88 Fed. Reg. at 29,221; 77 Fed. Reg. 62,624, 62,907 (Oct. 15, 2012); 75 Fed. Reg. 25,324, 25,504 (May 7, 2010). The pollution and public health impacts from on-road vehicle emissions are especially significant and greater in disadvantaged communities.183 For example, the community of Wilmington, Carson, and West Long Beach in Los Angeles, California is affected by six major freeway junctions, as well as freight, port, and rail operations, oil and gas production, and five petroleum refineries. A majority of this community is considered disadvantaged under California law, scoring higher than the state average on key indicators of vulnerability, including criteria pollutant exposure, health status, and socio-economic criteria. See CARB Comment at 88-90. Measures that reduce pollution in these communities are urgently needed, and addressing that need (and others described above) is mandatory under Section 202(a). Our States and Cities strongly agree with EPA's assessment that the proposed standards will significantly benefit public health and welfare, especially in areas next to major roadways. 88 Fed. Reg. at 29,395-97. [EPA-HQ-OAR-2022-0829-0746, pp. 31-32]

183 CARB, Benefits of California's Zero-Emission Vehicle Standards on Community-Scale Emission Impacts (Jul. 6, 2021), App. B to Comments of States and Cities in Support of EPA Reversing Its SAFE 1 Actions.

While the proposed standards are expected to moderately increase criteria pollutant and air toxics emissions from power plants due to some increase in electricity demand from more electric vehicles, id. at 29,353, 29,397, EPA's other regulatory actions to control power plant emissions, and emissions from related infrastructure, and our States and Cities' efforts to promote renewable generation should reduce these impacts to the communities adjacent to these plants. Nevertheless, EPA should further develop its understanding of the distributive impacts for communities proximate to power plants and refineries. [EPA-HQ-OAR-2022-0829-0746, pp. 31-32]

Organization: Center for American Progress (CAP)

Automobile emissions and their effects on health are not distributed equally. People of color are exposed to 24 percent more automobile emissions.5 and the ALA finds that people of color are 3.7 times as likely as White Americans to live in a county with 3 failing grades for air pollution.6 Strong standards must be finalized quickly in order to protect all Americans, especially those disproportionately affected, from the harmful effects of automotive air pollution.7 [EPA-HQ-OAR-2022-0829-0658, pp. 1-2]

5 Tessum et al. More than one-third of Americans live in areas with failing grades for ozone or particulate pollution, and people of color are 3.7 times more likely than white people to live in a county with failing air quality.1 Already at a disadvantage, these communities have the most to lose from emissions standards that do little to attack pollution from gas-powered cars and trucks. EPA should act in accordance with President Biden’s recent recommitment to environmental justice and treat pollution from gas-powered vehicles as an urgent environmental justice issue. [EPA-HQ-OAR-2022-0829-0671, p. 1]

Organization: Ceres BICEP (Business for Innovative Climate and Energy Policy) Network

Finally, on-road vehicles are largely responsible for the harmful pollutant emissions that disproportionally impact historically low-income and BIPOC16 communities located near fleet depots, major transportation corridors, distribution centers, and ports. 36% of Americans live in communities with unhealthy air pollution, and a person of color is 64% more likely than a white person to live in such a community.17 Further, the American Lung Association predicts that the U.S. could see $978 billion in public health benefits from cleaner air by 2050 as the nation shifts to 100% zero-emission new passenger vehicle sales and clean electricity generation.18 EPA’s decision to reduce multipollutant vehicle emissions is positive, and we urge EPA to finalize LMDV emission standards at least as strong as those proposed as soon as possible to protect the health of those in these vulnerable communities and realize these significant economic benefits. [EPA-HQ-OAR-2022-0829-0600, pp. 2-3]

Organization: Ceres Corporate Electric Vehicle Alliance (CEVA)

While medium- and heavy-duty trucks represent only 5% of vehicles on the road, their GHG emissions represent 23% of the transportation sector’s carbon footprint, which grew 75% over the last three decades.9 They are also largely responsible for the harmful pollutant emissions that disproportionally impact historically low-income and BIPOC communities located near fleet depots, major transportation corridors, distribution centers, and ports.10
In fact, the American Lung Association found that one in three Americans live in places with

unhealthy air pollution, largely due to transportation sector emissions. As such, vehicle emissions standards serve as a crucial mechanism to protect public health and advance environmental justice.11 Further, with many major companies aiming to deploy 50-100% zero-emission trucks by 2030, EPA's proposed standards fail to stimulate the rate of commercial electric truck production that commercial fleet operators seek.12 By strengthening the proposed Phase 3 standards to ensure at least 50% ZEV sales across all market segments by 2032, EPA will accelerate the industry's necessary investments in heavy-duty ZEV manufacturing and the accompanying investments in charging infrastructure. Organization: Colorado Energy Office, Colorado Department of Transportation, and Colorado Department of Public Health and Environment

Environmental impacts from the transportation sector—and the resulting health and economic consequences—are a major concern. Vehicles are the top source of greenhouse gas (GHG) emissions in Colorado, and are also a top source of particulate matter, NOx, and other criteria air pollutants that have disproportionate impacts on communities living near highways and freight routes. Transportation is one of the two largest sources of ozone precursors in Colorado along with oil and gas production, largely due to NOx emissions from vehicles, and reducing transportation emissions is a critical strategy to meet federal health-based air quality standards. [EPA-HQ-OAR-2022-0829-0694, p. 1]

Organization: District of Columbia Department of Energy and Environment (DOEE)

Environmental Justice Implications

DOEE acknowledges that the District's metropolitan and natural environments are constructed and managed in ways that have not benefitted the District's communities equally. District residents who continue to suffer the effects of environmental hazards—and their compounding impacts—are disproportionately people of color and people experiencing poverty. These hazards manifest as air pollution, inequities in access to clean water and nutritious food, lack of proximate green space, proximity to industrial toxins, racial disparities in life expectancy, and increased vulnerability to extreme weather events and climate change. Most germane to this rulemaking, many of these residents have had highways and major arterials constructed through their communities, increasing the burdens from air pollution emitted by motor vehicles. By addressing racial inequity in the systems we manage and influence, we create opportunities for more communities to benefit from, and participate in, the process of identifying and implementing environmental solutions. [EPA-HQ-OAR-2022-0829-0550, pp. 3-4]

People of color and people with lower incomes are more likely to live near high-volume or high-traffic density roads than their white, wealthier counterparts. About 19% of the US population lives near highly trafficked roads, whereas 27% of people of color live near high-volume roads (Census of the US near- roadway population, Rowangould). According to the Union of Concerned Scientists, “Nearly one half of everyone living in the United States—an estimated 150 million—live in areas that don’t meet federal air quality standards. Passenger vehicles and heavy-duty trucks are a major source of this pollution, which includes ozone, particulate matter, and other smog-forming emissions.” [EPA-HQ-OAR-2022-0829-0550, pp. 3-4]

The Union of Concerned Scientists further confirms the hazards of vehicle emissions and living near roads through modeling of vehicle air pollution in California as well as the Northeast and Mid-Atlantic region. The study indicated similar results as the Census of the US near-roadway population by Rowangould, finding that people near roads are burdened by the prevalent and harmful PM2.5. UCS modeling shows that Asian Americans are, on average, exposed to 34 percent higher levels of PM2.5 from vehicles than the average for the total US population. Other groups also have higher than average exposure: African Americans are burdened with 24 percent higher than average exposure, and Latinos have 23 percent higher exposure. On the other hand, exposure of whites to PM2.5 from vehicles is, on average, 14 percent lower than the average exposure for everyone.10 [EPA-HQ-OAR-2022-0829-0550, pp. 4]

10 David Reichmuth. Air Pollution from Cars, Trucks, and Buses in the US: Everyone is Exposed, But the Burdens are not Equally Shared. In addition, data from the Centers for Disease Control and Prevention shows that, nationally, Black and Indigenous people statistically have significantly higher asthma rates than their counterparts in other races.11 In the District, children who live in predominately Black communities have 20 to 25 times more asthma-related emergency room visits than their counterparts in majority White communities.12 [EPA-HQ-OAR-2022-0829-0550, pp. 4-5]

11 Center for Disease Control. Most Recent National Asthma Data. https://www.cdc.gov/asthma/most_recent_national_asthma_data.htm.

Studies also illustrate links between increased school absenteeism and ozone exposure.13 This is a District-wide concern as disparities already exist in the education system between students of color and White students. In particular, the literacy disparities have grown since the Covid-19 pandemic: 28% of Black and 30% of Hispanic students were proficient on a fall 2021 test, while 70% of White students were proficient. In the fall of 2019, 44% of Black students and 42% of Hispanic students hit these benchmarks, compared with 73% of White students.14 [EPA-HQ-OAR-2022-0829-0550, pp. 4-5]

13 Daniel L Mendoza et al 2020 Environ. Res. Lett. in press https://doi.org/10.1088/1748-9326/abbf7a

14 Perry Stein. 2022 The Washington Post. “Literacy scores show widening achievement gap in D.C. during pandemic.” https://www.washingtonpost.com/education/2022/03/17/dc-schools-achievement-gap-pandemic-reading/

According to DC Kids Count, White students achieve third-grade literacy at a rate 2-3 times more than Black and Latinx students. This gap continues into high school, where 19% of Black students and 41% of Latinx students who enroll in an Advanced Placement (AP) class pass at least one of the AP or International Baccalaureate (IB) exams. Meanwhile, 83% of White students pass at least one of the exams.15 Often, students experiencing greater education inequality are also living in areas of the District that are exposed to higher levels of air pollution and noxious emissions, which ultimately leads to more health issues and a higher likelihood of more missed school days and further education loss.16 [EPA-HQ-OAR-2022-0829-0550, p. 5]

15 DC Kids Count Powered by DC Action. 2021. “DC Students’ Educational Outcomes Gaps are Massive.” https://dckidscount.org/education/

16 DC Kids Count Powered By DC Action. 2021. “How Many DC Kids Live in Poverty in Ward 5? Are Homeless?” https://dckidscount.org/ward-snapshots/ward5/

On-road vehicle emissions constitute one of the most significant individual contributors to local air pollution-related health burdens, making up 23% of all pollution-related premature deaths in the District. On-road vehicle emissions are estimated to contribute to 51% of NO2-attributable new asthma cases and 13% of pollution-attributable premature deaths in the District. Regional emissions from all sectors, which originate outside of the District’s jurisdiction, contribute disproportionately to the District's air pollution- related new asthma cases and premature deaths (89% and 57%, respectively). [EPA-HQ-OAR-2022-0829-0550, p. 5]

These studies illustrate that air quality is an issue connected to all aspects of people’s lives. The pollution from vehicle emissions affects District residents, creating poor air quality and living conditions and with it, a myriad of health, wellness, and educational discrepancies. The District strives to reduce pollution as much as possible; however, pollution from light-duty and medium-duty vehicles must be solved at a larger scale as light-duty and medium-duty vehicles from states across the United States travel into the District. Therefore, the District cannot solve all its pollution problems without action from EPA. EPA needs to set stronger light-duty and medium-duty vehicle emission standards to relieve overburdened and bystander communities experiencing the adverse impacts of vehicle emissions. [EPA-HQ-OAR-2022-0829-0550, p. 5]

Organization: Donna Jackson

[*From Hearing Testimony, May 10, 2023*] This new proposed rule has the distinction of harming black people on two continents, in the African nation of Congo as well as here in the United States. In the Congo where 75 percent of the world's cobalt needed for rechargeable EV batteries is located, black slave and child labor is readily being used to mine these minerals. It is well documented that their conditions are deplorable. The need for cobalt and thus the extent of the suffering will increase exponentially as a result of the EPA's proposed rule and if that wasn't bad enough, this new proposed rule will create an economic hardship and serious decline in the standard of living for all Americans but especially black Americans. Blacks have more single parent households, lower medium household income and higher poverty rates than the overall population. According to the 2021 U.S. Census Bureau, the median household income for black Americans was $45,000 compared to $71,000 for white Americans and $101,000 for Asian Americans. As such, they can't afford more expensive EV vehicles nor the higher prices for limited supply of gasoline powered vehicles and as it is, many Blacks have already been priced out of the new vehicles markets and can only afford used ones. Overall the consequences of this rule will remove private car ownership from many if not most black Americans. Even if the EVs weren't so expensive, they still don't fit the lives of many Blacks Americans, for example, more

Blacks are renters, so fewer have the chance to charge their vehicles at home. Many black Americans live in apartments where street and parking lots is the norm with no ability to charge. In addition, many black households can only afford one vehicle but the reality is EVs are practical only for multi car households and the list goes on. Suffice to say it is that no EV supporter ever bothered to ask the black community if this is what they want or fits the needs of their family. And for those Blacks who want EV vehicle, they are free to choose one with or without an EPA mandate. The proposed rule here only serves to force more expensive vehicles on everyone whether they like it or not. The truth is that black people like most Americans want to make these choices for themselves. For this reason, I urge the EPA to withdraw the proposed rule and instead start thinking of ways to make personal transportation more accessible. [From Hearing Testimony, EPA-HQ-OAR-2022-0829-5115, Day 2]

Organization: Elders Climate Action

Action requested:

Elders Climate Action requests that EPA revise the standards for HDVs to set a zero emission standard for nitrogen oxides (NOx), PM2.5 and CO2 for the classes of L/MDVs or types of L/MDVs that operate in duty cycles for which zero emission power trains are currently in use or which EPA expects will be available by 2027 [EPA-HQ-OAR-2022-0829-0737, pp. 1-2].

ECA requests that EPA use its authority to set emission standards to –

1) respond meaningfully to the urgency of the climate crisis that threatens to destroy the future for our children and grandchildren by destroying or disrupting the natural systems upon which all life, including human civilization, relies to thrive and survive, to avoid turning the planet into an unsustainable Hell on Earth;

2) optimize the emission reductions needed from L/MD on-road vehicles to ensure attainment of the ozone and PM2.5 NAAQS within the deadlines established by the CAA rather than delaying attainment until 2045 for some areas, and not attaining at all in the New York/Connecticut?New Jersey, Houston, South Coast and San Joaquin Valley nonattainment areas; and

3) to end the inequitable and unlawful disparate impact on BIPOC and low income frontline communities who are most exposed to emissions from L/MDVs in violation of Title VI of the Civil Rights Act and thereby suffer "disproportionately high and adverse human health or environmental effects on minority populations and low-income populations" in violation of EO 12,898. [EPA-HQ-OAR-2022-0829-0737, pp. 1-2]

3. Public Health Urgency.

Diesel trucks and buses are also major sources of other deadly air pollutants. Medium and heavy-duty diesel engines emit more than 60% percent of the deadly particle pollution from vehicles. Particle pollution cuts short tens of thousands of US lives per year and contributes to the heavy burden of asthma on our nation's children. Diesels are the primary source of particles in communities near heavily-trafficked highways where 65 million Americans are exposed to harmful concentrations. [EPA-HQ-OAR-2022-0829-0737, pp. 4-5]

Vehicle pollution inequitably harms Black and Latinex communities that are much more likely compared to whites to reside near heavy truck traffic on highways, and at truck terminals, ports and distribution centers. [EPA-HQ-OAR-2022-0829-0737, pp. 4-5]

NOx from diesels combines with heat and sunlight in the atmosphere to form ground level ozone, or smog, a lung irritant and asthma trigger. Heavy duty vehicle emissions are a major contributor to urban smog in the 230 urban counties where pollution concentrations violate national air quality standards. [EPA-HQ-OAR-2022-0829-0737, pp. 4-5]

The need for national zero emission standards is greatest in the urban areas that EPA has designated “extreme” (South Coast AQMD) and “severe” (San Joaquin Valley AQMD), or recently bumped-up to “serious” for ozone. NOx emissions from L/MDVs are a primary contributor to their numerous elevated violations of the ozone NAAQS. These areas are not able to achieve sufficient emissions reductions to attain the NAAQS without significant NOx reductions from L/MDVs. [EPA-HQ-OAR-2022-0829-0737, pp. 4-5]

2. Impacts of Climate Warming on Public Health are Significant and Widespread.

Fire smoke and unprecedented hot temperatures are having a significant impact on human health as an example of the regional impact of heat waves, drought and wildfires. [EPA-HQ-OAR-2022-0829-0737, pp. 4-5]

The heat dome that raised temperatures above 110 F for three days in the Pacific NW in June 2021 caused over 200 heat-related deaths in Oregon and Washington. [EPA-HQ-OAR-2022-0829-0737, pp. 4-5]

Recent research demonstrates that emissions from wildfire are the largest source of fine particle pollution in large regions of the U.S., and contributed to thousands of pre-mature deaths. Wildfire in the western U.S. now accounts for half of all fine particle pollution in some areas of the West, doubling the exposure to PM2.5 [18] from non-fire sources including motor vehicles, power plants and industrial operations.19 [EPA-HQ-OAR-2022-0829-0737, pp. 4-5]

18 PM2.5 are particles smaller than 2.5 micrometers in diameter.

19 Burke, M. et al., The changing risk and burden of wildfire in the United States | PNAS (Jan 11, 2021).

A warming climate is responsible for roughly half of the increase in burned area in the United States (4), and future climate change could lead to up to an additional doubling of wildfire-related particulate emissions in fireprone areas (36) or a many-fold increase in burned area (37, 38). Costs from these increases include both the downstream economic and health costs of smoke exposure, as well as the cost of suppression activities, direct loss of life and property, and other adaptive measure (e.g., power shutoffs) that have widespread economic consequences.20 [EPA-HQ-OAR-2022-0829-0737, pp. 4-5]

20 Id.

Using satellite measurements of smoke plumes integrated with ground level monitored PM2.5 (fine particle) concentration data, Burke et al. estimate that between 7,000 and 14,500 deaths per year (depending on the dose/response curve used to estimate mortality from observed exposures) are attributable to fire smoke in the contiguous U.S. [EPA-HQ-OAR-2022-0829-0737, pp. 4-5]

Mortality and other health impacts such as asthma attacks and exacerbating COPD will be experienced most severely by communities already burdened by the adverse health effects of daily exposure to fine particle pollution emitted from tailpipes, power plants and industrial sources. Exposure to fire smoke in the American West during the 2020 fire season was universal. No communities were spared. But fire smoke at least doubled the annual exposure routinely suffered by BIPOC and low income communities living near major highways and industrial sources. [EPA-HQ-OAR-2022-0829-0737, pp. 4-5]

In Oregon, mortality attributed to fire includes many hundreds more deaths than the lives lost directly to fires. Statewide smoke pollution during the 2020 fires threatened lives and well- being with extreme hazard concentrations of particles known to cause pre-mature death and cancer, exacerbate asthma, COPD and other respiratory conditions, and cardio-vascular diseases. [EPA-HQ-OAR-2022-0829-0737, pp. 4-5]

The Oregon Health Authority (OHA) reports that "[t]he most severe recent air quality events in Oregon are due to wildfire smoke…"21 OHA cited a study finding that fire smoke in 2012 "caused hundreds of premature deaths, nearly 2,000 emergency room visits and more than $2 billion in health costs."22 OHA points to the longer fire season as increasing the harm from exposure to smoke. "Fire seasons in Oregon are roughly 100 days longer than they were in the 1970s. Longer seasons mean more smoke in Oregon communities."23 The greater density of smoke and longer duration of smoke exposure in 2020 likely at least doubled the mortality caused by smoke exposure compared to 2012. [EPA-HQ-OAR-2022-0829-0737, pp. 4-5]

21 Oregon Climate and Health Report, 40 (Oregon Health Authority, 2020).

22 Id., 33.

23 Id.,

In addition, low income families without air conditioning are much less able to escape smoke pollution by closing doors and windows during the summer heat to keep themselves safe. [EPA-HQ-OAR-2022-0829-0737, pp. 4-5]

Workers cannot avoid exposure to smoke pollution if required to work outdoors. [EPA-HQ-OAR-2022-0829-0737, pp. 4-5]

Beyond the economic and environmental damage, social disruption, and harm to health that will result from a longer fire season and expanded fire zones, more deadly air quality will likely make parts of the American West uninhabitable during the fire season for the most vulnerable populations such as the elderly, children and those with existing respiratory and cardiovascular conditions. [EPA-HQ-OAR-2022-0829-0737, pp. 4-5]

These recent data and other sources published since 2009, including the data discussed at length in the Administrator's 2009 Endangerment Finding, 74 Fed. Reg. 66,496 (December 15, 2009), confirm the finding that EPA made 12 years ago: "The Administrator finds that the elevated atmospheric concentrations of the well-mixed greenhouse gases may reasonably be anticipated to endanger the public health and welfare of current and future generations." Id., at 66,523. [EPA-HQ-OAR-2022-0829-0737, pp. 15-17]

Organization: Energy Innovation

In addition to improvements to public health and welfare that the EPA's proposed tailpipe GHG standards would achieve, the proposed multi-pollutant standards will help reduce criteria pollutants and air toxics from remaining internal combustion engine (ICE) vehicles. As LDVs and MDVs transition away from combustion and tailpipes that cause harmful air pollution, these multi-pollutant standards are critical to saving the lives and improving the health of the people and children harmed by transportation pollution.15 Although we do not provide detailed comments on this aspect of the proposed rule, we encourage the EPA to adopt the most stringent standards feasible to mitigate the harmful effects of these pollutants. The EPA aptly points out that "reducing human exposure to these pollutants results in significant and measurable health benefits,"16 especially to frontline communities, communities of color, and low-income communities and individuals that bear the burden of bad air quality from tailpipe emissions.17 Adopting more stringent multi-pollutant standards will also help states meet National Ambient Air Quality Standards18 and improve air quality in all communities. [EPA-HQ-OAR-2022-0829-0561, p. 7]

Organization: Environmental and Public Health Organizations

EPA should set strong emissions standards to meet its obligations under presidential directives on environmental justice. Under Executive Order 12,898, EPA "shall make achieving environmental justice part of its mission by identifying and addressing, as appropriate, disproportionately high and adverse human health or environmental effects of its programs, policies, and activities on minority populations and low-income populations." 59 Fed. Reg. 7629 (Feb. 11, 1994). And Executive Order 14,008 directs EPA to develop "programs, policies, and activities to address the disproportionately high and adverse human health, environmental, climate-related and other cumulative impacts on disadvantaged communities, as well as the accompanying economic challenges of such impacts.'' 86 Fed. Reg. 7619, 7629 (Jan. 27, 2021). It also establishes the Administration's policy ''to secure environmental justice and spur economic opportunity for disadvantaged communities that have been historically marginalized and overburdened by pollution.'' Id. [EPA-HQ-OAR-2022-0829-0759, p. 18]

C. More stringent standards would bring greater benefits to environmental justice communities.

This rulemaking will provide benefits to environmental justice communities by reducing harm from climate change and pollution exposure. And Alternative 1, with a faster ramp rate after

2030, would bring even greater benefits to vulnerable populations that suffer the brunt of pollution and climate change harms. EPA appropriately recognizes that environmental justice communities are disproportionately affected by climate change and pollution impacts related to light- and medium-duty vehicles and upstream emissions. Addressing these harms by providing these communities relief more quickly—a priority for this Administration—is a compelling reason why EPA should adopt Alternative 1 with a faster ramp rate after 2030. [EPA-HQ-OAR-2022-0829-0759, p. 18]

Given the vast history of disproportionate environmental and public health burdens placed on communities of color and low-income communities, EPA appropriately included consideration of environmental justice, energy justice, and equity in its Proposal.74 Communities that are overburdened with pollution from sources such as major roadways, industrial sites, and agriculture are predominantly low-income, and a large percentage of residents of these communities are people of color and non-English speakers.75 With the improvements described in this comment letter, this rulemaking could bring about significant air quality and health improvements in communities that are disproportionately burdened with air pollution from motor vehicles and overburdened from pollution more broadly.76 [EPA-HQ-OAR-2022-0829-0759, p. 18]

74 For more information on the history and definition of the environmental justice movement, see Initiative for Energy Justice, Section 1—Defining Energy Justice: Connections to Environmental Justice, Climate Justice, and the Just Transition (Dec. 23, 2019), https://iejusa.org/section-1-defining-energy-justice/.

75 See Gina M. Solomon et al., Cumulative Environmental Impacts: Science and Policy to Protect Communities, 83 Annual Review of Public Health (Jan. 6, 2016), https://pubmed.ncbi.nlm.nih.gov/26735429/.

76 See EPA, ISA for Particulate Matter at Ch. 12: Populations and Lifestages Potentially at Increased Risk of a Particulate Matter-Related Health Effect; Section 5: Sociodemographic Factors, https://www.epa.gov/isa/integrated-science-assessment-isa-particulate-matter.

1. Reductions in greenhouse gas emissions will bring climate change benefits to environmental justice communities.

Reducing GHG emissions from light- and medium-duty vehicles will help reduce the significant harm that climate change inflicts on environmental justice communities. By 2055, the Proposed Standards would avoid 7,300 million metric tons (MMT) of CO2 emissions, 88 Fed. Reg. at 29198, tbl. 3, and EPA's calculations show the Proposal would produce climate benefits of between $82 and $1,000 billion in 2020 dollars by 2055, depending on the values used for GHG emission reductions. Id. at 29200, tbl. 6 (using a 3% discount rate). As compared to the Proposed Standards, by 2055 Alternative 1 would achieve an additional 800 MMT of CO2 savings, 88 Fed. Reg. at 29203, tbl. 14, and increase climate benefits by between $9 and $100 billion. Id. at 29205, tbl. 17. And adopting Alternative 1 with a faster ramp rate after 2030 would bring even more climate benefits to environmental justice communities. See infra Section V (detailing the societal benefits of more stringent standards). [EPA-HQ-OAR-2022-0829-0759, p. 19]

Reducing climate harm will benefit environmental justice communities because, as EPA has aptly described, climate change disproportionately affects these communities. 88 Fed. Reg. at 29393-95. EPA recognized in the 2009 Endangerment Finding that vulnerable populations, including economically and socially disadvantaged communities and Indigenous or minority populations, are especially vulnerable to climate change. Id. at 29393. Reports from the U.S. and international climate bodies over the last decade add evidence to the conclusion that climate change disproportionately impacts environmental justice communities, including by "altering exposures to heat waves, floods, droughts, and other extreme events; vector-, food- and waterborne infectious diseases; changes in the quality and safety of air, food, and water; and stresses to mental health and well-being.'' Id. at 29394. Notably, the 2016 scientific assessment on the Impacts of Climate Change on Human Health predicts that people of color will suffer a disproportionate impact of climate exacerbations of air pollution. Id. at 29395. It also describes unique vulnerabilities of Native American communities because of expected impacts to their cultural resources, customs, and traditional subsistence lifestyles, including expected declines in food security for Alaskan Indigenous Peoples. Id. [EPA-HQ-OAR-2022-0829-0759, p. 20]

Though EPA has included a significant number of publications in its literature review, it should also include its 2021 analysis of the disproportionate climate impacts on vulnerable populations. The study quantifies the increased risks of climate change on socially vulnerable populations in six categories: Air Quality and Health; Extreme Temperature and Health; Extreme Temperature and Labor; Coastal Flooding and Traffic; Coastal Flooding and Property; and Inland Flooding and Property, using data on where people live as an indicator of exposure.79 The report concludes that Black and African American individuals will likely face higher impacts of climate change for all six impacts analyzed compared to all other demographic groups. Black and African Americans are 40% more likely to live in communities with the highest increase in premature mortality from extreme temperatures, and 34% are more likely to live in areas with the highest increases in PM2.5 childhood asthma diagnoses with 2°C (3.6°F) of global warming.80 Hispanic and Latinos are also significantly more likely to live in areas where impacts are projected to be highest.81 Low-income individuals and those without a high school diploma have 25-26% greater risk of living in areas with the highest extreme temperature labor hours lost.82 [EPA-HQ-OAR-2022-0829-0759, p. 20]

82 Id. at 77.

And as we witness time and again with each unfolding disaster, vulnerable populations suffer the most from climate change-fueled extreme events. Taking recent events in this country as illustrative examples, economically disadvantaged individuals, low-wage outdoor workers, and homeless and elderly people died from heat stroke in the Northwest heat wave in 2021,83 an event that researchers found would have been "virtually impossible without human-caused climate change."84 In New Orleans, the people who could not evacuate before disastrous Hurricanes Katrina and Ida struck land are those who did not have the means or ability to do so.85 In New York City, many people who could only afford to live in illegal basement apartments died as a result of flooding during Ida.86 During western wildfire season, those without homes or means do not have the luxury of filtered air to protect their lungs.87 To help address the urgency of the climate crisis and its impacts on vulnerable populations, EPA must adopt the more stringent Alternative 1 with a faster ramp rate after 2030. [EPA-HQ-OAR-2022-0829-0759, pp. 20-21]

2. Reductions in criteria pollution emissions will bring health benefits to environmental justice communities.

This rulemaking presents a critical opportunity to mitigate the adverse health impacts plaguing communities that are overburdened by air pollution from motor vehicles and other sources. According to the American Lung Association's (ALA) 2023 State of the Air report, which grades counties on daily and long-term measures of particle pollution and daily measures of ozone, more than 119 million Americans live in places that received failing grades for unhealthy levels of ozone or PM in their air.88 The report notes:

88 Am. Lung Ass'n, State of the Air 2023 Report (2023) at 12, https://www.lung.org/getmedia/338b0c3c-6bf8-480f-9e6e-b93868c6c476/SOTA-2023.pdf?ext=.pdf.

Although people of color are 41% of the overall population of the U.S., they are 54% of the nearly 120 million people living in counties with at least one failing grade. And in the counties with the worst air quality that get failing grades for all three pollution measures, 72% of the 18 million residents affected are people of color, compared to the 28% who are white.89

89 Id.

In addition to the disproportionate impact on people of color noted above, ALA outlines other "high-risk" groups that are impacted by the pollution in these regions. For example, low-income communities are particularly vulnerable and at risk of health impacts from pollution. More than 14.6 million people whose incomes meet the federal definition for living in poverty reside in counties that received a failing grade on at least one of the ALA's pollutant indicators, while nearly 2.6 million people living in poverty reside in counties that received failing grades on all three pollutant measures.90 In addition, around 27 million children (under age 18) and 18 million older adults (age 65 or older) live in counties that received a failing grade on at least one pollutant.91 [EPA-HQ-OAR-2022-0829-0759, pp. 21-22]

90 Id. at 20.

91 Id.

In fact, it is well established that communities of color and economically disadvantaged communities are disproportionately exposed to environmental burdens from a variety of sources. The White House Council on Environmental Quality (CEQ) released (and recently updated) a Climate and Economic Justice Screening Tool, which identifies communities around the country that are "marginalized, underserved, and overburdened by pollution"92 and would therefore qualify for Justice4093 investments (President Biden's key environmental justice initiative). The Screening Tool identifies census tracts as "disadvantaged" if they are above the threshold for one or more environmental or climate indicators (e.g., exposure to diesel PM or PM2.5, traffic proximity and volume, or proximity to hazardous waste sites) and above the threshold for socioeconomic indicators related to income and education.94 A recent analysis found that 64% of the population in census tracts the Screening Tool identifies as disadvantaged are Hispanic/Latino, Black or African American, or American Indian or Alaskan Native.95 Overall, 50% of Hispanic/Latino, Black or African American, and American Indian or Alaskan Native individuals in the country reside in disadvantaged communities, compared to just 17% of White, Non-Hispanic/Latino individuals.96 [EPA-HQ-OAR-2022-0829-0759, p. 22]

92 The White House, Biden-Harris Administration Launches Version 1.0 of Climate and Economic Justice Screening Tool, Key Step in Implementing President Biden's Justice40 Initiative (Nov. 22, 2022) https://www.whitehouse.gov/ceq/news-updates/2022/11/22/biden-harris-administration-launches-version-1-0-of-cli mate-and-economic-justice-screening-tool-key-step-in-implementing-president-bidens-justice40-initiative/. 96 Id.

3. Significant decreases in vehicle and upstream non-GHG emissions over time will provide benefits to environmental justice communities.

In addition to securing GHG reductions, the Proposal will reduce non-GHG tailpipe emissions over time as well as upstream emissions from refineries, both of which will benefit environmental justice communities. 88 Fed. Reg. at 29393. Compared to the Proposal, Alternative 1 provides greater reductions in criteria pollutants and air toxics. Compare id. at 29198–99, tbls. 4 and 5, with id. at 29204–05, tbls. 15-16. EPA should adopt Alternative 1 with a faster ramp rate after 2030 to bring more relief more quickly to environmental justice communities. [EPA-HQ-OAR-2022-0829-0759, p. 23]

Notably, the immediate benefits more stringent standards would provide from reductions over time in tailpipe and upstream refining emissions vastly outweigh any potentially small non-GHG emissions increases from upstream electric generation. By one measure, reducing refinery emissions may be more beneficial to environmental justice communities as a whole than reducing emissions from electric generation. EPA has concluded that refineries have far higher health benefits per ton of emission reductions than do electric generating units, due in part to greater proximity to populations.97 [EPA-HQ-OAR-2022-0829-0759, p. 23]

97 EPA, Office of Air and Radiation, Office of Air Quality Planning and Standards, Technical Support Document, Estimating the Benefit per Ton of Reducing PM2.5 Precursors from 17 Sectors, at 6, 16 (Feb. 2018), available at https://www.epa.gov/sites/production/files/2018-02/documents/sourceapportionmentbpttsd_2018.pdf (valuing electricity-generation-unit emissions of particulate matter in 2020 at $150,000–350,000 per ton and corresponding refinery emissions at $360,000–830,000 per ton).

EPA correctly concludes that environmental justice communities are disproportionately harmed by the non-GHG criteria and air toxics emissions associated with vehicles and upstream sources, and therefore these communities will especially benefit from reduced tailpipe emissions. 88 Fed. Reg. at 29395–97. After conducting a literature review and its own analysis, EPA recognizes that higher percentages of communities of color and low-income communities live or attend school near major roadways, suffering the largest share of their emissions and associated adverse health impacts. Id. EPA also recognizes that higher percentages of communities of color and low-income communities live near electric generating units and refineries. Id. at 29397. EPA should, however, strengthen its statement that "[a]nalysis of populations near refineries also indicates there may be potential disparities in pollution-related health risk from that source." Id. (emphasis added). The study of socioeconomic factors near refineries cited by EPA itself concludes that "[m]inority and African American percentages are approximately twice as high as national percentages" for cancer risk as a result of petroleum refinery emissions.98 That study alone is enough evidence to warrant a conclusion that such populations do experience disparities in health risk. For further evidence, please see NGO coalition comments on the Proposed SAFE Vehicles Rule for Model Years 2021-2026.99 Additionally, EPA should recognize here, as it did in its Proposed Rule for MY 2023-2026 Passenger Cars and Light Trucks, that "most anthropogenic sources of PM2.5, including industrial sources, and light- and heavy-duty vehicle sources, disproportionately affect people of color."100 Finalizing strong standards will help mitigate these harms. i. Additional reductions in PM pollution are urgently needed, especially in communities that have long faced elevated pollution burdens. [EPA-HQ-OAR-2022-0829-0786, p. 63]

Continuing to drive criteria pollutant reductions is particularly important for low-income communities and communities of color, which have historically faced significant and elevated harms from health-harming transportation pollution. As a result of housing discrimination and other unjust policies, communities of color and low-income communities constitute a higher percentage of the population near our roads and highways and therefore suffer disproportionately from associated harmful pollution.174 According to the American Lung Association's 2023 State of the Air report, people of color are almost four times more likely to breathe the most polluted air when compared to white people.175 A report by Moving Forward Network also found that, on average, Asian and Black Americans are exposed to PM2.5 pollution that is 56 and 44 percent higher, respectively, than white Americans.176 And an EDF analysis of the Bay Area in California found that neighborhoods with higher percentages of residents of color experienced double the rate of asthma from nitrogen dioxide (NO2) –a pollutant often used as a marker for transportation-related pollution.177 Moreover, as described above, recent studies have found light- duty vehicles, including light-duty trucks are responsible for a significant share of pm- attributable premature mortalities. [EPA-HQ-OAR-2022-0829-0786, p. 63]

Accordingly, finalizing the criteria standards EPA has proposed, including setting the PM standard at a level that will encourage the use of GPFs, is critical to protecting health and combatting environmental injustice. [EPA-HQ-OAR-2022-0829-0786, p. 63]

Organization: Governing for Impact and Evergreen Action (GFI)

In addition to contributing to the climate crisis, light and medium duty passenger vehicles are responsible for emitting harmful pollutants including carbon monoxide, particulate matter, and nitrogen oxides, which can cause or contribute to significant negative public health outcomes such as lung and heart diseases.15 These harmful health outcomes disproportionately affect low income populations and communities of color, who are exposed to greater amounts of vehicle pollution.16 Unfortunately, these same communities are at the greatest risk of harm from the impacts of climate change, and often lack sufficient resources or support to protect themselves from these harmful impacts.17 Strong transportation emissions standards — for both GHGs and criteria pollutants — will limit the present and imminent public health threats that vulnerable populations face due to vehicle pollution. [EPA-HQ-OAR-2022-0829-0621, pp. 2-3]

17 See generally, EPA "Climate Change and Social Vulnerability in the United States: A Focus on Six Impacts," 430-R-21- 003 (2021), available at: https://www.epa.gov/cira/social-vulnerability-report.

Organization: GreenLatinos et al.

On behalf of the undersigned environmental justice groups, locality-based organizations, and other advocacy groups, we urge the U.S. EPA to create the strongest possible standards to mitigate detrimental impacts of heavy duty vehicle (HDV) and light- and medium-duty vehicle (L/MDV) pollution on our communities. The current tailpipe emissions rulemaking can help enable us to achieve a more sustainable, emissions-free future for all communities. [EPA-HQ-OAR-2022-0829-0789, p. 1]

Evidence makes clear how instrumental the swift adoption of stringent HDV and L/MDV standards are for the future of Latino/e communities. The 2023 American Lung Association State of the Air Report (https://www.lung.org/research/sota) finds that more than one-third (36%) of people in the U.S. live in areas with failing grades for ozone or particulate pollution. This is concerning, especially considering the same report found that people of color are 3.7 times more likely than white people to live in a county with failing national air quality standards, putting our communities at even greater risk to severe health impacts and premature death. [EPA-HQ-OAR-2022-0829-0789, p. 1]

Pollution from vehicles makes us sick and kills us. The data shows this over and over again. We need long-term protective regulation now. [EPA-HQ-OAR-2022-0829-0789, p. 2]

For example, Latino/e children are three times more likely (https://www.jpedhc.org/article/S0891-5245(06)00737-1/fulltext) than white children to live in counties with low air quality. About 10% of Latino/e children (https://www.edf.org/blog/2014/04/22/why-latinos-are-disproportionately-affected-asthma-and-what-we-can-do#:~:text=Today%20in%20the%20United%20States,from%20this%20chronic%20respiratory%20illness.) suffer from asthma, and Latino/e children are 40% more likely to die from asthma than non-Latino white children. These disparities have only increased over time relative to the air quality standards set by the U.S. EPA. [EPA-HQ-OAR-2022-0829-0789, p. 2]

Transportation is the largest source of pollution that fuels the climate crisis in the US. Latino/e communities disproportionately suffer harm from tailpipe emissions. While Latino/es are less likely to have access to a car (https://salud-america.org/research-latinos-face-big-public-transportation-challenges/) and Latino/e workers commute by public transit nearly three times (https://www.demos.org/research/move-thrive-public-transit-and-economic-opportunity-people-color) the rate of white commuters, our community can face up to 75% higher rates of exposure (https://www.ucsusa.org/about/news/communities-color-breathe-66-more-air-pollution-vehicles) to harmful pollutants. [EPA-HQ-OAR-2022-0829-0789, p. 2]

Today, we are at a critical nexus for clean transportation policy: We must drastically and permanently reduce air pollution from vehicles and transform our transportation landscape. [EPA-HQ-OAR-2022-0829-0789, p. 2]

It is critical that the Biden administration pass regulations to reduce vehicle pollution and accelerate the shift to EVs. This action is crucial to achieving environmental justice. By implementing stringent HDV and L/MDV standards, the U.S. EPA will act on the Biden Administration's stated commitment to environmental justice, (https://www.whitehouse.gov/omb/briefing-room/2022/05/23/delivering-historic-and-long-overdue-investments-in-disadvantaged-communities/) which the White House reaffirmed in April 2023 with a new Executive Order, Revitalizing Our Nation's Commitment to Environmental Justice for All. (https://www.whitehouse.gov/briefing-room/statements-releases/2023/04/21/fact-sheet-president-biden-signs-executive-order-to-revitalize-our-nations-commitment-to-environmental-justice-for-all/) [EPA-HQ-OAR-2022-0829-0789, p. 2]

The strongest possible HDV and L/MDV standards will help reach the urgent goal to cut greenhouse gas emissions by 60% by 2030 and will put American cars and trucks on a clear path towards achieving 100% zero emission electric vehicle (EV) sales by 2035 or earlier. [EPA-HQ-OAR-2022-0829-0789, p. 2]

The Biden administration's leadership in setting strong HDV and L/MDV standards is instrumental to mitigate the inequitable tailpipe pollution experienced by Latino/e and other frontline communities, which triggers asthma and other sometimes fatal respiratory illnesses. [EPA-HQ-OAR-2022-0829-0789, p. 2]

We need the cleanest possible vehicles now. Our lives literally depend on it. [EPA-HQ-OAR-2022-0829-0789, p. 2]

Organization: Interfaith Power & Light

It is critical to remember that the climate crisis is a challenge of racial, economic, and generational justice, and these rules target air pollution that disproportionately harms marginalized communities of color and low-wealth communities that reside in counties closest to major freeways. Implementing the strongest light-duty vehicle standards is a matter of environmental justice, and these standards would deliver massive emission reductions and life-saving relief to frontline communities. [EPA-HQ-OAR-2022-0829-0530, p. 1]

Organization: International Council on Clean Transportation (ICCT)

Health benefits and environmental justice modeling recommendations

In evaluating the health benefits of the proposed rule, it is critical to consider the evidence of increases in PM from recent model year vehicles. The health benefits assessment included in EPA's proposal uses emission factors from Motor Vehicle Emission Simulator (MOVES), which likely underestimates PM emissions from recent model year vehicles. Figure 15 shows a comparison between EPA MOVES emission factors and remote sensing UV smoke averages by model year, shown as a percent change from each sources respective model year 2005 averages.140 From model years 2006–2015, year-to-year changes, shown in the slopes of the lines, are relatively consistent between EPA MOVES and remote sensing data. However, from model year 2015 on, the trends diverge. For light-duty passenger trucks, the EPA MOVES PM emission factors sharply decline while the remote sensing data show an increase in UV smoke averages.141 Though less significant, a similar trend is observed for passenger cars, with the EPA MOVES PM emission factor continuing to decline after 2015 and remote sensing UV smoke averages showing a slight increase. These findings suggest that the modeled air quality and health benefits of the proposed rule may be underestimated when considering the large benefits of replacing 2015–2020 model year vehicles with future vehicles meeting the proposed PM emission limits. [EPA-HQ-OAR-2022-0829-0569, pp. 53-54]

140 EPA MOVES emission factors are converted from fuel-specific to distance-specific emission factors for this comparison. This is done using real-world fuel economy data from EPA Automotive Trends report, the same source used to convert the remote sensing emissions from fuel-specific to distance-specific.

141 Light-duty passenger truck emission trends from EPA MOVES are compared to light-duty truck (LDT) emission trends from remote sensing data. Similarly, passenger car emission trends from EPA MOVES are compared to light-duty vehicle (LDV) emission trends from remote sensing data.

SEE ORIGINAL COMMENT FOR Figure 15. Percent change in distance-specific PM emission factor from EPA MOVES and remote sensing (RS) UV smoke measurements from Colorado (CO) and Virginia (VA) sources by model year, compared to model year 2005. [EPA-HQ-OAR-2022-0829-0569, pp. 53-54]

Additionally, a full assessment of relative air quality and health benefits across demographics, as done for the heavy-duty multi-pollutant rule, is recommended for this light-duty and medium-duty multi-pollutant rule. It is widely understood that heavy-duty vehicles contribute to racial disparities in exposure to air pollution, and EPA reported the projected air quality impacts across demographics in their finalized heavy-duty multi-pollutant rule. Inequities in air pollution exposure exist for light-duty vehicle emissions as well. One study finds that on a national level, people of color are exposed to 46% more ambient PM2.5 from light-duty gasoline vehicles than White people.142 This is a greater disparity than that of HDVs; the same study finds that people of color exposed to 35% higher ambient PM2.5 levels from heavy-duty diesel vehicles compared to White people. Additionally, the health benefits from the heavy-duty multipollutant rule, as projected by the EPA, are on similar scales to that of the proposed light-duty and medium-duty vehicle rule.143 Thus, as the environmental justice and health implications of the light-duty and medium-duty vehicle rule are significant, a full assessment of the projected distribution of changes in PM2.5 and ozone concentrations by geography, race/ethnicity, and income is recommended for the finalized rule. [EPA-HQ-OAR-2022-0829-0569, pp. 53-54]

142 Tessum, C et al. (2021). PM2.5 Polluters Disproportionately and Systemically Affect People of Color in the United States," Science Advances 7, no. 18: eabf4491, https://doi.org/10.1126/sciadv.abf4491.

143 EPA's proposed light-duty and medium-duty rule is estimated to result in $63 billion and $280 billion (for 7% and 3% discount rates, respectively) in total monetized health benefits from 2027 to 2055. EPA's finalized heavy-duty multipollutant rule is projected to result in $53–150 billion and $91–260 billion (for 7% and 3% discount rates, respectively) in total monetized health benefits from 2027 to 2045.

Benefits and cost-effectiveness of the proposal

The LDV and MDV proposal is projected to reduce 15,000 tons of PM2.5, 66,000 tons of NOx, and 220,000 tons of hydrocarbons from 2027 to 2055.144 These benefits are compared to

2055 levels without the proposal. Based on the previous section on Particulate Matter emission standards, health benefits associated with PM reductions could be greater than EPA's projections. The proposed standards would reduce air pollution near-road where affected populations are often low-income or communities of color. Reducing these emissions will provide cleaner air and are critical to improving public health. [EPA-HQ-OAR-2022-0829-0569, p. 55]

Organization: Mass Comment Campaign sponsored by Arizona Interfaith Power & Light. (web) (216 signatures)

As a person of faith and conscience, I recognize that we have a moral obligation to cut carbon emissions that harm our Shared Home. People of faith and conscience are ready for bold, new transportation solutions, and cleaner cars and light trucks are an integral step towards addressing climate change for our communities, future generations, and our Sacred Earth. [EPA-HQ-OAR-2022-0829-0692]

I am asking EPA to move quickly and finalize the strongest possible light-duty vehicle (LDV) standards. This proposal is a first step and the EPA needs to finish the job by finalizing the strongest possible standards this year. [EPA-HQ-OAR-2022-0829-0692]

In order for the U.S. to meet our Paris Climate Agreement goals we need the strongest possible long-term standards—beyond model year 2026— that will put the country on a path to a 100% zero-emission new vehicle sales target by 2035. Not implementing the strongest possible light-duty vehicle standards would create major negative implications for our country's climate goals. [EPA-HQ-OAR-2022-0829-0692]

We must also keep in mind that these rules target air pollution that disproportionately harms marginalized communities of color and low-wealth communities. For example, "Black and Hispanic Americans are exposed to 56 and 63 percent more particulate matter pollution, respectively, than they produce." This is especially concerning for people of faith, as all religions call on us to treat our neighbors with respect, dignity, and compassion. Implementing the strongest LDV standards is a matter of environmental justice, and these standards would deliver massive emission reductions and life-saving relief to frontline communities. [EPA-HQ-OAR-2022-0829-0692]

In addition, electrifying passenger vehicles will be key to improving air quality and saving lives across the nation. More than 119 million American residents currently live in areas with unhealthy levels of air pollution. In 2020, the national passenger vehicle fleet represented approximately 94% of the nation's on-road vehicles and generated over 33,400 tons of fine particles annually, which are so small that they easily enter our bloodstream and harm our health. It is also critical that standards require tighter limits on internal combustion engine vehicles in order to continually make these cars cleaner as manufacturers transition to zero- emission vehicles. [EPA-HQ-OAR-2022-0829-0692]

So again, on behalf of millions of people of faith and conscience around the country, I urge the EPA to move quickly and finalize the strongest possible light-duty vehicle standards in order to reap the benefits of light-duty vehicle electrification and accelerate the transition to zero-emission vehicles. [EPA-HQ-OAR-2022-0829-0692]

Organization: Mass Comment Campaign sponsoring organization unknown (44,335 signatures)

I am a supporter of the League of Conservation Voters, and I am writing to ask that the EPA set the strongest rules possible to cut dangerous pollution from trucks and passenger vehicles. I urge you to ensure that light-, medium-, and heavy-duty vehicle standards accelerate greater zero-emission vehicle adoption, pushing beyond what is expected from federal clean energy investments. [EPA-HQ-OAR-2022-0829-1704]

Emissions from cars and trucks both contribute to climate change and impact my health and the health of communities across the country. Low-wealth communities and communities of color are often hit hardest, as are any neighborhoods near highways, freight hubs and anywhere with lots of traffic. These communities deserve a chance to live in a society where access to clean air is a fundamental right. [EPA-HQ-OAR-2022-0829-1704]

We encourage you to finalize the strongest standards possible that will open the door to a brighter future for all. Please adopt strong vehicle emissions standards that bring us to 100% clean vehicles sold by 2035. Or else help us all to buy an electric vehicle, because those things are expensive! [EPA-HQ-OAR-2022-0829-1704]

Organization: Mayor Becky Daggett, City of Flagstaff, Arizona et al.

Critical pollution reductions

In 2020, the transportation sector contributed 27 percent of total GHG emissions in the United States—more than any other single sector. Transport also contributes over 55 percent of our nation’s total nitrogen oxide (NOx) emissions. NOx and particulate matter pollution pose serious health risks, leading to devastating human health impacts including asthma, other respiratory issues, and even premature death. [EPA-HQ-OAR-2022-0829-0732, p. 2]

Fast-tracking robust car and truck standards is critical for the United States to meet its GHG targets over the coming decade, meet Clean Air Act requirements and provide long-overdue protections for environmental justice communities. We believe that such standards would be consistent with the U.S. nationally determined contribution to the Paris Agreement, under which the United States committed to cut economy-wide GHG emissions by 50 to 52 percent in 2030, compared to 2005 levels. [EPA-HQ-OAR-2022-0829-0732, p. 2]

Stakeholder involvement

EPA must incorporate a robust and responsive stakeholder engagement process— particularly for frontline communities. Transportation is a leading source of air pollution and disproportionately harms people on lower incomes and people of color. EPA must work with environmental justice communities to ensure they are included in decision-making processes. [EPA-HQ-OAR-2022-0829-0732, p. 2]

Organization: Minnesota Pollution Control Agency (MPCA)

The proposed standards would advance environmental justice by decreasing vehicle emissions of non- greenhouse gas pollutants that contribute to ambient concentrations of ozone, particulate matter, nitrogen dioxide, carbon monoxide, and air toxics. Reducing emissions of these from vehicles through stringent emissions standards is important for protecting the health of communities near busy roadways. MPCA research demonstrates that communities of concern for environmental justice are disproportionately exposed to air pollution from transportation.3 National studies have identified significant disparities in exposure to nitrogen oxides (NOX) based on race: researchers at the University of Minnesota estimate that people of color in America experience 38% more NOX pollution where they live than white Americans.4 People in these communities are also often more vulnerable to air pollution health impacts due to underlying structural inequities, such as limited access to health care, housing insecurity, and systemic racism. [EPA-HQ-OAR-2022-0829-0557, p. 3]

3 Pratt et al. (2015) Traffic, Air Pollution, Minority and Socio-Economic Status: Addressing Inequities in Exposure and Risk. Int. J. Res. Public Health, 12(5): 5355-5372. https://doi.org/10.3390/ijerph120505355

4 Clark LP, Millet DB, Marshall JD (2014) National Patterns in Environmental Injustice and Inequality: Outdoor NO2 Air Pollution in the United States. PLoS ONE 9(4): e94431. doi:10.1371/journal.pone.0094431

Organization: National Association of Mutual Insurance Companies (NAMIC)

Representing two thirds of the providers of America’s homeowners’ insurance, NAMIC is respectfully concerned with and reaching out about statements made by the Environmental Protection Agency regarding potential differential treatment of insurance policyholders or applicants. Specifically, the EPA, in submissions to the Federal Register, appears to assert that individuals within referenced Environmental Justice populations (defined as people of color and low-income populations in at least some EPA Federal Register notices) have less or limited access to homeowner insurance. Examples of such EPA publications follow: [EPA-HQ-OAR-2022-0829-5092, pp. 1-2]

- Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles on 05/05/2023,

- Greenhouse Gas Emissions Standards for Heavy-Duty Vehicles-Phase 3 on 04/27/2023,

- Revised 2023 and Later Model Year Light-Duty Vehicle Greenhouse Gas Emissions Standards on 12/30/2021,

- Revised 2023 and Later Model Year Light-Duty Vehicle Greenhouse Gas Emissions Standards on 08/10/2021, and,

- Standards of Performance for New, Reconstructed, and Modified Sources and Emissions Guidelines for Existing Sources: Oil and Natural Gas Sector Climate Review on 11/15/2021. [EPA-HQ-OAR-2022-0829-5092, pp. 1-2]

In its posted online EJ 2020 Glossary, the EPA defines [https://www.epa.gov/environmentaljustice/ej-2020-glossary] “Environmental Justice” (EJ) as follows: “The fair treatment and meaningful involvement of all people regardless of race, color, culture, national origin, income, and educational levels with respect to the development, implementation, and enforcement of protective environmental laws, regulations, and policies." [EPA-HQ-OAR-2022-0829-5092, pp. 1-2]

By presenting statements about homeowners' insurance in the above referenced publications which feature discussions of Environmental Justice, the EPA seems to imply that potential insurance availability or affordability issues may be linked to EJ. Yet, the EPA does not offer specific references or "scientific assessments" on insurance coverage in such areas to support the implication that homeowner insurance is not being made available in some way based on race, color, culture, national origin. [EPA-HQ-OAR-2022-0829-5092, pp. 1-2]

Respectfully, NAMIC asks the EPA to refrain from such charges regarding homeowners' insurance in its publications moving forward. NAMIC is greatly concerned that an agency of the federal government with minimal expertise in homeowners' insurance would infer such morally repugnant allegations. The Administration's requirement of a "whole of government" focus on climate and equity does not empower federal agencies to broadly impute blame, particularly in the absence of legal authority in an industry that is highly regulated at the state level. [EPA-HQ-OAR-2022-0829-5092, pp. 1-2]

The Information Quality Act passed through Section 515 of the Consolidated Appropriations Act [PLAW-106publ554.pdf (govinfo.gov)], 2001 requires that each federal agency disseminating information ensure and maximize the quality, objectivity, utility, and integrity of information (including statistical information) disseminated by the agency, and to allow affected persons to seek and obtain correction of information disseminated by the agency. [EPA-HQ-OAR-2022-0829-5092, pp. 1-2]

If the EPA has rigorous scientific assessments to support these statements, NAMIC would greatly appreciate the EPA sharing that information with us. However, if the EPA does not have such scientific assessments , we would respectfully request that the EPA discontinue the inclusion of such statements is support of proposed rules of a federal regulatory agency. [EPA-HQ-OAR-2022-0829-5092, p. 2]

Organization: National Corn Growers Association (NCGA)

Bringing high octane fuel to market in the form of midlevel ethanol blends will be significantly less capital-intensive than attempting to increase blend stock octane with hydrocarbon components at refineries. It will also be incredibly cleaner. The avoided production cost and offset emissions lower end-costs to consumers, reducing both economic costs and social costs related to health and environment, key considerations in advancing environmental justice and avoiding adverse impacts from oil refineries on communities that have historically borne them. [EPA-HQ-OAR-2022-0829-0643, p. 7]

Organization: National Parks Conservation Association (NPCA)

Lastly, to the degree through which this proposal could increase the development and permitting of domestic critical mineral mining projects to support LDV and MDV battery production, NPCA asks that EPA and the administration as a whole take necessary steps to mitigate or entirely avoid negative impacts on overburdened populations and sensitive ecosystems. This includes promoting practices such as critical mineral recycling, as well as overseeing the responsible citing of mining projects to limit harms to environmental justice communities, indigenous communities, and ecosystems within our beloved national parks. [EPA-HQ-OAR-2022-0829-0607, pp. 4-5]

Organization: National Tribal Air Association (NTAA)

Climate Change and Greenhouse Gas Mitigation

The acute and continuous impacts of climate change on Native Americans and Alaska Native Villagers are well documented. Unfortunately, new consequences of this global crisis continue to be revealed. For multiple reasons including vulnerability and geographic constraints, Tribal communities are disproportionately suffering from these changes. The U.S. Fourth National Climate Assessment (NCA4)1 noted, in part, that “Climate change increasingly threatens indigenous communities’ livelihoods, economies, health, and cultural identities by disrupting interconnected social, physical, and ecological systems.” A more focused examination of Tribal needs to address the impacts of climate change is presented in 2021 publication The Status of Tribes and Climate Change (STACC)2. [EPA-HQ-OAR-2022-0829-0504, pp. 1-2]

1 USGCRP, 2018: Impacts, Risks, and Adaptation in the United States

2 The Status of Tribes and Climate Change (STACC), Institute for Tribal Environmental Professionals, 2021

The NTAA has a long history of information sharing with EPA and advocacy for reducing emissions of greenhouse gases. Multiple reports, policy statements, and comment letters are compiled and accessible on our organization’s website3. NTAA’s Status of Tribal Air Reports (STAR) including STAR 20224 document climate change impacts on Tribal lands and people. [EPA-HQ-OAR-2022-0829-0504, pp. 1-2]

4 Status of Tribal Air Report, National Tribal Air Association 2022

Criteria Pollutant Emissions Standards

Many residents in Indian country continue to be exposed to concentrations of ozone and particulate matter that exceed current National Ambient Air Quality Standards. With a few exceptions, the sources of this pollution are outside the jurisdiction and control of Tribal governments. It is imperative that the EPA and applicable state and local authorities take all necessary measures to return Tribal communities to healthy air quality. [EPA-HQ-OAR-2022-0829-0504, p. 2]

The proposed emissions standards for new light-duty and medium-duty vehicles for non-methane organic gases plus nitrogen oxides (NMOG+NOx) constitute one key step in reducing the impacts from the largest source of these ozone-precursor pollutants. Concurrently, reduced emissions of NMOG+NOx will reduce ambient air concentrations of particulate matter, and PM2.5 more specifically. The NTAA supports the proposed standards for these pollutants across the applicable vehicle categories and looks forward to healthier air quality in our many impacted communities. [EPA-HQ-OAR-2022-0829-0504, p. 2]

Organization: Our Children's Trust (OCT)

4. Strengthening the GHG emission standards for passenger cars and light trucks is needed in order to protect the fundamental constitutional rights of children and future generations, particularly children within environmental justice communities, including communities of color, low-income communities, and indigenous communities. Executive Order 13990's policy directive clearly states "to listen to the science; to improve public health and protect our environment; to ensure access to clean air and water; . . . to reduce greenhouse gas emissions[.]" The science is clear. The world must stop fossil fuel emissions as soon as possible, every ton matters and causes more danger, 5 and the transportation sector must be an early target for decarbonization. A key tool for EPA to facilitate emission reductions is through strong GHG emission standards for passenger cars and light trucks. [EPA-HQ-OAR-2022-0829-0542, pp. 2-3]

5 IPCC, Summary for Policymakers, in Climate Change 2021: The Physical Science Basis, SPM-37 (2021) ("Every tonne of CO? emissions adds to global warming.").

The Earth's Energy Is Imbalanced and thus the EPA's Must Cease Infringing the Constitutional Rights of Youth. EPA has Public Trust and Constitutional Obligations to use its Authority to Protect the Atmosphere. [EPA-HQ-OAR-2022-0829-0542, p. 3]

Our Children's Trust represents twenty-one youth plaintiffs, including eleven Black, Brown, and Indigenous youth, in the constitutional climate lawsuit, Juliana v. United States, in which the Administrator, in his official capacity, and EPA are defendants. This case asserts, and courts have found, that, through the government's past and ongoing affirmative actions that cause climate change, it has violated the youngest generation's constitutional rights to life, liberty, property, and equal protection of the law, as well as failed to protect essential public trust resources. In this litigation, federal courts have affirmed "that the federal government has long promoted fossil fuel use despite knowing that it can cause catastrophic climate change" 16 and "has long understood the risks of fossil fuel use and increasing carbon dioxide emissions". 17 The Ninth Circuit Court of Appeals found that there was evidence showing that the federal government was a substantial factor in causing the youth's constitutional injuries because "[a] significant portion of [GHG] emissions occur in this country; the United States accounted for over 25% of worldwide emissions from 1850 to 2012, and currently accounts for about 15%." 18 Without immediate effective action, our children and future generations will continue to suffer injury with long-lasting and potentially irreversible consequences. 19 These judicially-recognized facts should guide EPA's policies and practices so they can identify, and alter, those policies that exacerbate American youth's existing climate change injuries. [EPA-HQ-OAR-2022-0829-0542, p. 5]

Chem. & Phys. 3761 (2016); U.S. Global Change Research Program, Fourth National Climate Assessment, Vol. II (2018); David I. Armstrong McKay et al., Exceeding 1.5°C Global Warming Could Trigger Multiple Climate Tipping Points, 377 Science eabn7950

(2022); Nico Wunderling et al., Global Warming Overshoots Increase Risks of Climate Tipping Cascades in a Network Model, 13 Nature Climate Change 75 (2023). Note that many researchers use the temperature targets set during the Paris Accord as a point of reference, not as a sanctioning of those levels of average planetary heating.

Under the 5th Amendment to the U.S. Constitution, the government is restrained from engaging in conduct that infringes upon fundamental rights to life, liberty, and property, and equal protection of the law, all of which includes a climate system that sustains human life and liberty. Under the Public Trust Doctrine, embedded in our Constitution and other founding documents, and in the very sovereignty of our Nation, U.S. residents (both present and future, i.e., Posterity) have a right to access and use crucial natural resources, like air and water. The U.S. government, and its executive agencies, have fiduciary duties as trustees to manage, protect, and prevent substantial impairment to our country's vital natural resources which the government holds in trust for present and future generations. 20 [EPA-HQ-OAR-2022-0829-0542, p. 5]

20 Juliana v. United States, 217 F. Supp. 3d 1224, 1254 (D. Or. 2016).

Our children and future generations are already suffering injury with long-lasting and potentially irreversible consequences at present levels of heating. Moreover, all young people seeking environmental and climate justice, especially youth from frontline and environmental justice communities that have contributed the least to emissions and have long suffered from systemic environmental racism and social and economic injustices, must not only have their voices heard, but have their rights protected. [EPA-HQ-OAR-2022-0829-0542, pp. 5-6]

To learn more about how young people are being harmed, please watch the award-winning, independent feature-length documentary film now streaming on Netflix, YOUTH v GOV. These stories constitute just a small sample of what American children are experiencing due to the climate crisis the federal government continues to exacerbate by and through its national energy system. We request that the EPA incorporates the protection of children's fundamental rights to a safe climate system, defined by the best available science, into future rulemaking, policies, and initiatives. Human laws must respect the laws of nature; our government ignores the natural laws of energy imbalance and climate destabilization at the peril of our children. [EPA-HQ-OAR-2022-0829-0542, p. 6]

Organization: South Coast Air Quality Management District

4. Consider special provisions to increase ZEV adoption in environmental justice communities. Environmental justice (EJ) communities are disproportionately impacted by air pollution due to proximity to goods movement corridors such as ports and railyards as well as freeways. Further, many residents in EJ communities are classified in low- or moderate-income groups, and struggle to afford ZEVs which are still more expensive than conventional engine vehicles. We believe special provisions and incentives should be considered for easier access to ZEVs by these communities. For example, ACC II includes a provision for manufacturers to receive an additional 0.5 credit for each ZEV sold at a discount to qualifying communities. Also, manufacturers can earn an additional 0.1 credit per each sale of lower-priced vehicles that low-income community residents can afford. These incentive provisions in the ACC II regulation not only provide easier access for EJ community members but also lead to accelerated deployment of ZEVs and PHEVs in communities with the highest pollution burden and public health need. [EPA-HQ-OAR-2022-0829-0659, p. 3]

Organization: Southern Environmental Law Center (SELC)

There are also major economic costs to climate change, and studies have found that the future costs will be unequally distributed across the United States.28 Relative to the rest of the nation, the South will face the largest economic losses from climate change, with low-income and minority communities particularly affected.29 Lower income counties in the South may lose between 5 and 20 percent of gross domestic product per year—compared to an average yearly loss of 1.2 percent nationally—for every additional degree of warming by the 2080s.30 [EPA-HQ-OAR-2022-0829-0591, p. 4]

28 See, e.g., Hsiang, et al., supra note 9, at 1363.

N.Y. TIMES (June 29, 2017), https://www.nytimes.com/interactive/2017/06/29/climate/southern-states-worse- climate-effects.html. [EPA-HQ-OAR-2022-0829-0591, p. 4]

Exposure to this type of pollution is not equally distributed across all populations in the United States, and this inequity raises serious environmental justice concerns. Compared to national averages, a higher percentage of low-income and minority communities live along routes that experience high volumes of light- and medium-duty vehicle traffic,48 increasing these communities' exposure to tailpipe pollution and its harmful effects. One study estimated that, even among populations living within 100 meters of major roadways, minorities are exposed to up to 15 percent more PM2.5 pollution and up to 35 percent more nitrogen dioxide (NO2) pollution than their White counterparts.49 This disproportionate burden stems in part from our nation's long history of discriminatory zoning and land use policies and practices, including those implemented in the South, that resulted in redlining and the intentional siting of infrastructure projects through poor, minority neighborhoods.50 [EPA-HQ-OAR-2022-0829-0591, p. 6]

In California, drastic GHG emissions reductions have been estimated to improve air quality and reduce local particulate matter emissions associated with freight transport that disproportionately impact disadvantaged communities").

Organization: The Heritage Foundation (Kevin Dayaratna and Diana Furchtgott-Roth)

NHTSA estimates that the decline in new vehicle sales would result in up to 812 additional deaths on the road each year, 16,206 more injuries, and almost 50,000 more crashes involving property damage.24 This is because fewer people would be able to afford new and later-model used cars, which are safer than old cars. EPA's proposed regulations would make the situation worse. EPA does not account for this in the rule. [EPA-HQ-OAR-2022-0829-0674, pp. 5-6]

This increase in prices caused by successive reductions in emissions contradicts NHTSA's core values,25 namely leading "the Nation by setting the motor vehicle and highway safety agenda," and serving "as the catalyst for addressing critical safety issues that affect the motor vehicle and highway safety communities." Deaths and injuries from the new rules would be concentrated among low-income Americans, disproportionately minorities, who would pay the price of the new rule: due to the price increases, they would buy fewer new cars and fewer later-model used cars. [EPA-HQ-OAR-2022-0829-0674, pp. 5-6]

24 Ibid., pp. 25894-5.

Organization: Valero Energy Corporation

I. EPA fails to adequately consider the environmental justice impacts of the proposed rule.

Disadvantaged communities already face significant access barriers to electric vehicles, such as: higher upfront costs to electric vehicle ownership; a lack of existing charging infrastructure available to them in low-income, minority populated, and rural areas; and costlier and time-intensive charging due to a greater reliance on public charging infrastructure, particularly for individuals living in multi-family housing. [EPA-HQ-OAR-2022-0829-0707, p. 55]

EPA's EJ analysis must be thorough and inclusive of factors that may impact the price of transported goods, such as ZEV affordability, the availability of public charging, reasonable charging practices, and a lifecycle analysis of electric vehicles and power generation emissions. Without doing so, EPA runs the risk of intensifying price disparities and access to transport relative to the baseline for EJ communities. EPA's EJ analysis must be thorough and inclusive of electric vehicle affordability, the availability of public charging, reasonable charging practices, and a lifecycle analysis of electric vehicles and power generation emissions. Without doing so, EPA runs the risk of intensifying price disparities and access to transport relative to the baseline for EJ communities. These impacts can be both quantitively and qualitatively characterized.300 EPA's silence on these disparities is especially worrisome given EPA's prior binding commitments to EJ analysis for the benefit of disadvantaged and low-income communities. [EPA-HQ-OAR-2022-0829-0707, p. 55]

300 See, i.e., supra.

To date, the target electric vehicle customer base for OEMs consists of "mostly male, high-income, highly educated, homeowners, who have multiple vehicles in their household and have access to charging at home."301 Additionally, according to the U.S. Department of Transportation (DOT), "the rate of EV adoption in rural areas is roughly 40% lower than it is in urban areas, and EV charging infrastructure expansion has mostly been concentrated in cities and along major highways".302As a result, electric vehicle ownership remains primarily concentrated in affluent, large metropolitan and urban areas.303 By contrast, the supporting electricity generation necessary to support EPA's proposal is predominantly located in more remote, rural regions that are geographically isolated from urban centers. [EPA-HQ-OAR-2022-0829-0707, pp. 55-56]

301 Scott Hardman*, Kelly L. Fleming, Eesha Khare, and Mahmoud M. Ramadan, A perspective on equity in the transition to electric vehicles, MIT SCIENCE POLICY REVIEW (Aug. 30, 2021) available at https://sciencepolicyreview.org/2021/08/equity-transition-electric-vehicles/.

302 U.S. Department of Transportation, Community Benefits of Rural Vehicle Electrification (last updated February 2, 2022), available at https://www.transportation.gov/rural/ev/toolkit/ev-benefits-and-challenges/community- benefits.

303 See, i.e., Shuocheng Guo, Eleftheria Kontou, Disparities and equity issues in electric vehicles rebate allocation, Energy Policy, Volume 154, 2021, 112291, ISSN 0301-4215, available at https://doi.org/10.1016/j.enpol.2021.112291.

EPA's proposal directly impacts EJ communities by contributing to additional, local emissions to meet electric vehicle charging demand. Consequently, in theory, EJ communities incur an incremental burden in exchange for the subsidization of electric vehicles for more affluent consumers. And this subsidy occurs at expense of our most vulnerable communities burdened by emissions as a direct result of the proposal, with no corresponding benefit, since electric vehicles are likely to remain concentrated in affluent areas. Further, these communities remain unable to afford EPA's chosen mode of transport and are particularly vulnerable to rising electricity costs. [EPA-HQ-OAR-2022-0829-0707, pp. 55-56]

Notwithstanding EPA's hope that its proposal may serve to incentivize the purchases of electric vehicles, these vehicles are significantly more expensive on average than their ICE vehicle counterparts and unaffordable for many households. These are costs are also likely understated as each electric vehicle already enjoys thousands of dollars' worth of Federal and state subsidies, which are ultimately funded by taxpayers. Additionally, an automakers' ability to sell electric vehicles to consumers depends on substantial price subsidies in the form of credit support. EPA ignores the reality that many EJ stakeholders are currently unable to afford the upfront costs of purchasing an electric vehicle in the first place. With the cost of transition minerals expected to escalate exponentially in the coming years as a function of limited supply and increasing demand, the costs to manufacture and purchase electric vehicles will likely rise. [EPA-HQ-OAR-2022-0829-0707, p. 56]

EPA should also consider the effects of the proposal on electricity prices, as low-income populations often spend a larger percentage of their earnings on essential utilities compared to the rest of the United States. Reliance on electric vehicles has been shown to spur increases in load and demand during peak periods, which impact electricity prices. Because EPA lacks expertise in the area of electrical grid management and economics, EPA should consult with other agencies and credible experts in these areas in order to adequately evaluate these impacts.304 EPA should ensure that the proposal meets reliability and affordability criteria and helps EJ communities make informed decisions about their own energy needs. Additionally, EPA's EJ assessment fails to acknowledge the likelihood that many owners will lack access to residential charging, which will substantially increase their operating expenses. Consistent reliance on fast charging also shortens electric vehicle battery life, resulting in a need to replace the battery and/or the vehicle more frequently. [EPA-HQ-OAR-2022-0829-0707, pp. 56-57]

304 See, West Virginia, 142 S.Ct. at 2612-13 (stating that EPA admitted that opining on trends in electricity transmission, distribution, and storage requires technical and policy expertise not traditionally needed in EPA regulatory development and finding that there is little reason to think Congress assigned such decisions to the EPA).

If EJ is truly a commitment for EPA, it should carefully consider criticisms like those leveled by The Two Hundred, which point out the disproportionate impacts to working and minority communities as a result of California's climate approach regarding electrified transport; those impacts and concerns remain true, and indeed are magnified under the proposed standards.305 [EPA-HQ-OAR-2022-0829-0707, pp. 56-57]

305 See Plaintiffs' Complaint, The Two Hundred for Homeownership, et al. v. California Air Resources Board, et al., No. 1:22-CV-01474.

It is critical from the outset to design standards to minimize the potential for price shocks and supply disruptions. As written, the proposal ultimately benefits electric vehicle manufacturers at the expense of disadvantaged communities by subsidizing unaffordable transportation that is not fit for the purposes of commuting to and from EJ communities. At minimum, EPA should perform a thorough EJ assessment specific to its LDV proposal that is comprehensive of both transport challenges and impacts faced by EJ stakeholders and the government-wide Justice40 Initiative. [EPA-HQ-OAR-2022-0829-0707, pp. 56-57]

The average purchase price of EV cars in 2022 was approximately $65,000, which is more than what 46 percent of American households earn in income in a year.306 While the average "used" EV sold for $42,895 in March of 2023.307 While EPA's DRIA anecdotally indicates that "emerging consensus suggests that purchase price parity is likely to occur by the mid-2020's for some vehicle segments and models"308, Ford CEO Jim Farley told attendees at its 2023 Capital Markets Days that EV cost parity may not come until after 2030.309 Moreover US auto makers are focusing their efforts on producing higher priced electric SUVs and trucks, including Fords $100,000 F150 Lightening Platinum310 and GM's announcement that its luxury brands, Cadillac and Buick, will be its first all-electric product lineups.311 While smaller EV's like the Chevy Bolt, touted by the Biden Administration as being affordable alternatives, are being discontinued.312 The reality is that most middle- and lower-income families simply cannot afford to purchase a new or used EV, even when taking into account available tax incentives and rebates. In fact, middle – and lower -income families are more likely to purchase older used vehicle, due to their lower upfront costs, and to hold onto those vehicles for longer periods.313 [EPA-HQ-OAR-2022-0829-0707, pp. 56-57]

Organization: Western Energy Alliance

Affordability/Environmental Justice: EPA is assuming that although the retail price of EVs is typically higher than for comparable ICEVs at this time, the price difference will narrow or disappear as the cost of batteries and other components fall in the coming years. EPA is taking a huge leap of faith in the ability of EV manufacturers to innovate in time for the arbitrary deadlines imposed by the president and EPA through this rule. Market projections six months from now are difficult, much less nine years into the future. [EPA-HQ-OAR-2022-0829-0679, p. 7]

But recent evidence suggests that EPA's assumption is well off the mark. EV battery costs soared in 2022 due to rising raw material and battery component costs. As countries around the world attempt to reach similar arbitrary targets for EVs and renewable energy, the competition for limited supplies of raw materials will likewise grow.13 Prices for rare earth minerals have increased between 60% and 400% while prices for lithium have increased by over 300% since 2020.14 Further, a U.K. study has found that EVs depreciate at a rate of 51% compared to 37% for gasoline cars, losing £15,220 ($18,786) versus £9,901 ($12,400).15 Clearly EPA's estimate that "…the average upfront per-vehicle cost to meet the proposed standards to be approximately $1,200 in MY 2032, as shown in Table 7.131…" is greatly underestimated. EPA mentions but then dismisses the impact on low-income households by just assuming that manufacturers, "will continue to offer a variety of models at different price points…" and that they will save on fuel costs. [EPA-HQ-OAR-2022-0829-0679, p. 7]

Organization: Wisconsin Department of Natural Resources

In this proposal, EPA concludes that people who live or attend school near major roadways are more likely to be non-White, Hispanic, or have a low socioeconomic status. As such, these populations are expected to directly benefit from reduced tailpipe emissions of criteria pollutants and mobile source air toxics that would result from these standards. EPA also notes that poorer or predominantly non-White communities can be especially vulnerable to climate change impacts, which these proposed GHG standards would help address. Reducing greenhouse gases, ozone, and particulate matter pollution from on-road vehicles will improve health outcomes throughout Wisconsin. Most importantly, it will take a critical step toward improving air quality in areas overburdened by pollution. [EPA-HQ-OAR-2022-0829-0507, p. 2]

Organization: Zero Emission Transportation Association (ZETA)

It's also critical to highlight that tailpipe emissions from LMD ICEVs do not affect all communities equally. The intersections of negative health outcomes, their link to transportation-related pollution, and the ties to race are well-documented. In 2017, a national study found that in 2010, people of color experienced 37% more NOX exposure than white populations and had 2.5 times higher concentrations of NOX within their communities.64 Furthermore, had these communities of color been exposed to the same level of NOX as white populations, 5,000 deaths from heart disease could have been prevented. Likewise, the American Lung Association estimates that people of color are 3.2 times more likely to live in a county with at least one pollution-related "failing grade."65 [EPA-HQ-OAR-2022-0829-0638, pp. 15-16]

64 "Changes in Transportation Related Air Pollution Exposures by Race, Ethnicity, and Socioeconomic Status: Outdoor Nitrous Oxide in the US in 2000 and 2010", Lara P. Clark, et. al., (September 14, 2017) https://ehp.niehs.nih.gov/doi/10.1289/EHP959

65 Id. at footnote 62

A study conducted in New York State found that road emissions have a disproportionate impact on both lower-income communities and communities of color.66,67 For example, 74% of New York's African American and Latino populations and 80% of its Asian American population experience higher NOX emissions than the state-wide average. Another study found that the New York City metro area experiences 1,400 premature deaths annually, specifically as a result of road emissions. Within the city, PM2.5 vehicle air pollution causes approximately 320 premature deaths from heart disease and other illnesses each year. The West Bronx in particular—whose population is 70% Latino and 29% African American—is home to the Cross

Bronx Expressway and has the worst air quality in the state. [EPA-HQ-OAR-2022-0829-0638, pp. 15-16]

EPA Summary and Response

Summary:

Many commenters shared concerns and evidence about environmental justice. Commenters shared evidence and examples of how traffic-related air pollution affects the people who are likely to be low-income and also likely to be people of color (ACEEE, ALA, BGA, CARB; CAP; Ceres BICEP, EDF; GFI; Arizona Interfaith Power & Light and League of Conservation Voters; MPCA; SELC, Tesla; WI DNR; ZETA). The commenters also discussed heath disparities associated with race and ethnicity (GreenLatinos et al., CARB, others). Elders Climate Action mentions lack of air conditioning in low-income families and outdoor workers being unable to avoid exposure to smoke from fires. Several commenters also highlighted evidence that populations living near refineries and other industrial facilities are more likely to be people of color or low income, as well as likely to face higher risks from the associated emissions (Environmental and Public Health Organizations, NCGA, CARB, California Attorney General et al.). California Attorney General et al. suggested that EPA further develop EJ research on communities near power plants and refineries. GreenLatinos et al. also shared evidence that Latino/es are less likely to have access to a car and more likely to commute by public transport.

Environmental and Public Health Organizations provide evidence that reducing emissions from refineries has higher benefits per ton than do EGU emission reductions, citing an EPA report. The commenter urges EPA to strengthen statements about evidence of adverse disparities for populations near refineries (in particular, they prefer a more definitive statement than “may be potential disparities”).

In contrast, numerous commenters express concerns about the potential economic impacts of the rule on low-income and/or communities of color (Donna Jackson, Valero Energy Corporation). Also, other commenters pointed to evidence that low-income households face higher expenditures for fueling their vehicles with gasoline (e.g., ACEEE). The Heritage Foundation (Davaratna and Furchtgott-Roth) claim new rules will create death and injuries concentrated among low-income Americans, “disproportionately minorities,” who would purchase fewer new and recent model year used cars. The Hyundai Motor America and SCAQMD suggest EPA should provide incentives to make it easier for EJ or low-moderate income communities to purchase ZEV and/or PHEVs. These comments are summarized and responded to in RTC Section 13.2. By contrast, the Alliance for Automotive Innovation claimed that vehicle standards without fuel-based regulations will disproportionately benefit higher-SES communities, as those locations purchase newer vehicles more rapidly than lower-SES communities.

Valero Energy Corporation comments that EPA's EJ analysis must be thorough and include factors affecting the price of transported goods, including ZEV affordability, the availability of public charging, reasonable charging practices, and lifecycle emissions analysis. The comments claim that charging will cause higher emissions from electrical generation in more remote rural regions that are geographically isolated from urban centers. It claims that these standards will incur burdens on EJ communities that subsidize electric vehicles for more affluent consumers, who remain concentrated in affluent areas. It claims that electric vehicles are unaffordable to these communities, despite higher electricity costs being imposed on them.

Commenters shared how the problems of environmental justice were caused by a long history of discriminatory policies, such as zoning, land use, and infrastructure siting, particularly in poor and/or communities of color (SELC; California Attorney General et al.). NTAA highlighted the problems and disparities faced by Tribes and residents of Indian Country that emission reductions could help address (NTAA).

Several comments suggest that EPA should set new fuel standards to reduce emissions from gasoline-powered motor vehicles (e.g., Alliance for Automotive Innovation, National Corn Growers Association). The Alliance for Automotive Innovation stated that reducing heavy aromatics will reduce PM from all gasoline vehicles on the road and further EJ. The Alliance also suggested that such fuel-based standards would benefit low-SES communities more quickly than tailpipe standards, as higher-SES communities purchase new vehicles more quickly than lower-SES communities.

Two commenters make claims that EPA is bound by legal requirements to reduce emissions in a manner that either removes inequitable exposure to air pollution (Elders Climate Action, citing Title VI of the Civil Rights Act of 1964) or preserves future generations' access to a healthy climate and environment under the Public Trust Doctrine (Our Children's Trust).

Numerous commenters urged EPA to conduct additional analyses of environmental justice. ICCT urged EPA to include a full-scale photochemical modeling analysis of the rule and how it will differentially affect different demographic groups. In the context of how benefits of the rule would be greater with changes to the MOVES model, ICCT also made comments suggesting that EPA's MOVES model understates PM emissions from motor vehicles. Environmental and Public Health Organizations urged EPA to include its 2021 analysis of the adverse and disproportionate impacts of climate change on vulnerable populations.

Reflecting the "meaningful involvement" part of environmental justice, Mayor Becky Daggett of Flagstaff, AZ urged EPA to incorporate strong stakeholder engagement process, particularly involving frontline communities.

NAMIC requested that EPA refrain from stating that people of color or low-income populations have less or limited access to homeowner insurance.

NPCA requested that, to the extent this rule increases the development and permitting of domestic critical mineral projects in support of battery production for vehicles, EPA and the Administration as a whole move to avoid adverse impacts on overburdened populations and sensitive ecosystems. It lists as examples critical mineral recycling as well as responsible siting of mining projects to limit harms to EJ communities, indigenous communities, and natural park ecosystems.

NTAA and CARB provided comments about how Tribal communities face unique and adverse effects of climate change and air pollution. NTAA described how Tribal communities are unique in their vulnerability and limited ability to independently address climate change. NTAA mentions adverse and disproportionate impacts on Tribal communities resulting from climate change, with note of the NCA4's statement that climate change threatens indigenous communities' sociopolitical and ecological systems. NTAA also notes that, despite much air pollution being outside the jurisdiction of Tribal governments, many residents of Indian country live in areas with ozone and PM concentrations that exceed current NAAQS. NTAA urges EPA, in combination with state and local governments, to take all necessary measures to ensure healthful air quality to Tribal communities.

Response:

EPA acknowledges the comments that provided evidence and examples of how communities of color and lower-income or lower-SES communities face higher levels of ambient air pollution, including vehicle-generated air pollution, and higher rates of death and disease than other communities. EPA recognizes comments about how low-income and low-SES families face barriers to managing exposures to temperature changes, such as due to limited access to air conditioning and increased incidence of outdoor work, as well as comments that people of color are more often reliant on public transit. EPA also acknowledges all those comments that refer to historical public policies at federal, state, and local levels that had discriminatory intent and impact, such as discriminatory "redlining" in underwriting criteria for mortgages created by the Home Owners' Loan Corporation (HOLC) and intentional siting of highways and other locally-unwanted infrastructure in poor neighborhoods of color. EPA acknowledges the unique concerns of Tribal and indigenous communities, as expressed by NTAA.

Regarding comments that EPA should strengthen its statement about evidence of adverse and disparate impacts of refinery emissions on nearby populations, EPA has included new references to represent the state of research more fully on this issue.

As regards the comment from Elders Climate Action that LMDV emissions create harmful and disparate exposures that violate Title VI of the Civil Rights Act of 1964, the EPA did not propose, nor is finalizing, any federal financial assistance for any program or activity in this rulemaking, so comments related to Title VI of the Civil Rights Act of 1964 are out of the scope of this rulemaking. EPA is committed to taking decisive action to advance environmental justice and civil rights as part of its FY 2022-2026 Strategic Plan. This rulemaking advances that strategic goal by setting stronger national emission standards for light- and medium-duty vehicles. In general, our discussion of environmental justice and the impacts of this final rule on communities overburdened by pollution is included in preamble Section VIII.J, with additional information in this Section 9 of this RTC document.

Valero Energy Corporation's comments about the impacts of electricity prices are summarized and addressed in Sections 17 and 18 of this RTC. However, here, we disagree with the comments on the environmental justice implications of these rules.

First, the assumption that these standards require electrification of the fleet is not aligned with the final form of the standards. The performance-based standards are technology-neutral. EPA presents multiple example pathways for compliance with these standards, and manufacturers are free to use any combination of vehicle technologies to meet the standards.

Second, Valero Energy Corporation provides no data to support its hypothetical assertions that low-income communities in remote, rural areas will be disproportionately harmed by these standards. Preamble Section VII.B and RIA Chapter 7.4 presents results from EPA's air quality modeling of impacts of this rule in 2055. Preamble Section VII.D and RIA Chapter 7.6 examines the how these air quality changes are expected to affect different demographic groups. Notably, $PM_{2.5}$ and ozone reductions are estimated for the total CONUS, for both metropolitan and non-metropolitan areas, for all racial groups, for all educational levels, and for all levels of life expectancy. The few areas that experience increased PM2.5 concentrations of 0.025 ug/m3 or greater constitute 0.1% of the CONUS population. Areas experiencing ozone increases of 0.1 ppb or greater also constitute 0.1% of the CONUS population.

Finally, Valero Energy Corporation fails to account for changes in power sector emissions. In particular, we note that the agency has broad authority to regulate emissions from the power sector (e.g., the mercury and air toxics standards, and new source performance standards), as do the States and EPA through cooperative federalism programs (e.g., in response to PM NAAQS implementation requirements, interstate transport, emission guidelines, and regional haze),[384] and that EPA reasonably may address air pollution incrementally across multiple rulemakings, particularly across multiple industry sectors. For example, EPA has separately proposed new source performance standards and emission guidelines for greenhouse gas emissions from fossil fuel-fired power plants, which would also reduce emissions of criteria air pollutants such as $PM_{2.5}$ and SO_2 (88 FR 33240, May 23, 2023). Furthermore, while some emission increases are expected associated with higher electrical generation, those impacts decline over time. Furthermore, the net emissions of all criteria pollutants – including onroad emissions, EGUs, and refineries – are also decreasing, as described in Section VII.A of the preamble and Chapter 7.1 of the RIA.

The Alliance for Automotive Innovation's comments in support of reductions of heavy aromatics in gasoline are summarized and addressed in part in Section 11.1 of this RTC. However, its comment that tailpipe emission rules only reduce emissions for the newest vehicles, with near-term benefits accruing more to higher-SES communities than lower-SES communities, is not supported by available evidence. In particular, the Alliance mistakes the location of individual vehicle ownership for the location where emissions of aggregate vehicle traffic occur. In fact, numerous studies cited in Section II of the preamble illustrate that concentrations of traffic-related air pollutants are found to be highest in locations near major roads and other locations of high vehicle activity. Furthermore, simulation studies examining the impact of emission reductions focused on turning over the vehicle fleet starting with making the newest vehicles cleanest have shown similar results. In particular, a recent study by Yu et al. (2023) examining adoption of light-duty ZEV in California demonstrated that, despite simulating higher-SES census tracts adopting ZEVs at higher rates than lower-SES tracts, more rapid reductions in exposures were estimated to occur in low-SES locations.[385]

---

[384] See also CAA 116.

[385] Yu et al. (2023) California's zero-emission adoption brings air quality benefits yet equity gaps persist. Nature Communications 14: 7778. (Online at https://doi.org/10.1038/s41467-023-43309-9)

The ICCT recommended that EPA conduct a full assessment of the air quality and health impacts of this rule on different demographic groups, akin to “the heavy-duty multi-pollutant rule.” As described in RIA Chapter 7.6, EPA did conduct full-scale photochemical modeling and examination of which groups were affected by the rule in a manner consistent with ICCT’s recommendation. ICCT’s comments about MOVES PM emission rate are addressed in RTC Section 12.5.1.

NAMIC’s comment and request that we remove mention of limited access to homeowners’ insurance overlooks considerable evidence. The text in the preamble is intended to indicate that individuals who may be classified as being particularly vulnerable or sensitive to climate impacts, and who frequently comprise communities facing environmental justice concerns, often live in locations that face the greatest risks from climate change effects and have fewer resources available to adapt. As is well documented, areas that experience greater threats of natural hazards, such as wildfires, hurricanes, or coastal inundation, face higher rates for homeowners’ and flood insurances, which may price out individuals from accessing more comprehensive coverage, leave them uninsurable, or may prevent them from being able to rebuild in areas where home values and construction costs have exceeded historic amounts (Gotham 2014; Keenan et al., 2018; Fleming et al., 2018; Wilson et al. 2021; Brown, 2022).[386,387,388,389,390] Low-income and Black, Indigenous, and People of Color (BIPOC) individuals often are more likely to inhabit areas facing greater vulnerability to climate change hazards that can affect home displacement or loss, such as wildfires, sea level rise, or extreme weather events (Gamble et al., 2016; EPA, 2021).[391,392]

There are clear examples of how this is translating into real-time effects. The costs of the National Flood Insurance Program have gone up considerably in recent years, and rates are expected to continue to increase, thus pricing out low-income homeowners (Fleming et al., 2018).[393] We have seen that homeowners’ insurance providers are cancelling coverage or failing

[393] Fleming, E., J. Payne, W. Sweet, M. Craghan, J. Haines, J.F. Hart, H. Stiller, and A. Sutton-Grier, 2018: Coastal Effects. In Impacts, Risks, and Adaptation in the United States: Fourth National Climate Assessment, Volume II

to insure homes at greater risk of wildfire damage, the greatest burdens of which are being, and will be, borne by low-income individuals (Auer & Hexamer, 2022).[394] This all is irrespective of concerns regarding rising housing costs across the United States (Brooks, 2022), let alone the influence of gentrification and general disparities in socioeconomic and racial demographics between renters versus homeownership (Kuebler & Rugh, 2013; Tedesco et al., 2022).[395,396,397] Homeownership in desirable areas that are less at risk of climate hazards increasingly is becoming less available to, or less populated by, low-income or BIPOC households (Keenan et al., 2018; Ruhks-Ahidiana, 2021; Tedesco et al., 2022). [15,398,399]

Comments from NPCA about taking steps to avoid adverse impacts resulting from impacts of future domestic mining of critical minerals are recognized. While EPA acknowledges that mining impacts are a concern, many of these topics, such as siting for mines, are out of scope for this rulemaking which does not regulate the mining sector. Particular issues associated with critical minerals are addressed in RTC Section 15 (recycling and environmental issues from mining; critical minerals and supply chain).

The comments by Our Children's Trust about the Public Trust Doctrine are addressed in RTC Section 2.

Comments about the rule's potential vehicle safety and disparate and adverse impacts on low-income populations are addressed in RTC Section 22.

Comments about the rule's potential disparate and adverse economic impacts on low-income and low-SES communities are addressed in RTC Section 13.

In response to commenters who identify potential environmental justice concerns from the effects of criteria and GHG pollutants from light-duty and medium-duty vehicles, or additional scientific information, views, or analyses that were not specifically addressed in the proposed or final action, the EPA notes that the evidence regarding the environmental justice impacts of the proposed and final rulemakings is adequately described in Section VIII.J of the preamble.

The EPA does not interpret supportive comments related to the environmental justice impacts associated with the proposal as indicating disagreement with the evidence on environmental justice information that was presented in the proposal, but rather understands these comments to suggest that the additional information they provide adds support for finalizing the rulemaking.

To the extent that the information introduced by commenters was intended to advocate for more stringent standards, we refer the reader to Section 3 and 4 of this RTC document. See Sections 8 and 12 of this RTC document for responses relating to our updated cost and technology assessments for the final rule. For responses related to GHGs and the social cost of GHGs, see Sections 8.4 and 10 of the RTC. Comments regarding new fuel standards are responded to in Section 19 of the RTC.

10 - Climate science and GHG emissions

Comments by Organizations

Organization: Advanced Energy United

A large percentage of emissions reductions from the transportation sector will be accomplished by replacing gas- and diesel-powered buses, trucks and vans with EV models. EVs are not only much more energy efficient than gas-powered cars but are also less expensive to fuel and maintain over their lifetimes. Thus, the EPA's proposed rule presents an opportunity to decarbonize the largest source of emissions in the American economy while scaling up an emerging domestic market. Electrified transportation reduces our reliance on fossil fuels, strengthens America's energy independence, and produces economic benefits across the value chain of the automotive industry. [EPA-HQ-OAR-2022-0829-0695, p. 2]

Organization: Alliance for Automotive Innovation

Once the agency fixes the modeling of CO2 emissions with and without the new 2027-2032 standards, it should revisit its decision about how to monetize the CO2 emissions benefits. A good case can be made that one set of benefit calculations should make use of a global measure of the social cost of carbon, as use of a global measure may encourage other countries to control CO2 emissions through deployment of BEVs and cleaner electricity systems. EPA has taken this position in the DRIA. However, once again, the agency's analysis should not engage in wishful thinking, as it is well known that most countries are not meeting their pledged commitments under the 2015 Paris accords. It also makes sense to disclose to Congress and the public the climate benefits of the rule, measured with a domestic cost of carbon. This measure would account for the fact that most of the climate benefits of the 2027-2032 rule will occur outside the United States, as greenhouse gases are globally mixing pollutants. Presentation of both global and domestic estimates of climate benefits will ensure that the RIA is seen as an objective analysis. [EPA-HQ-OAR-2022-0829-0701, pp. 288-289]

Overall, Auto Innovators believes that a more modest, measured claim of climate-control benefits in the final rule would make the rule more defensible. As the DRIA stands now, the climate-benefits analysis could be vulnerable to technical criticism. [EPA-HQ-OAR-2022-0829-0701, pp. 291-292]

Organization: American Council for an Energy-Efficient Economy (ACEEE)

The U.S. needs the strongest vehicle standards

The United States will need to greatly reduce light-duty vehicle (LDV) greenhouse gas emissions if it is to have any chance of meeting the Biden Administration's economy-wide emissions reduction goal of 50% by 2030 and stave off the worst impacts of climate change. Transportation is now the largest source of greenhouse gas emissions in the United States and the light-duty sector makes up 58% of those emissions.1 Reducing carbon emissions is critical to tackling climate change but increasing LDV efficiency will also have significant benefits to air quality and will reduce driver fueling costs. Vehicles are a significant contributor to local air pollution and the associated health impacts, leading to increased rates of asthma, increased risk of heart attacks, strokes, and lung cancer.2 These impacts are particularly bad in low-income communities and communities of color, which bear a disproportionate air pollution burden.3 Greater efficiency can also provide significant cost savings for drivers when they refuel their vehicles. Low-income households are especially burdened by fueling costs, paying three times more than their higher-income counterparts on gasoline, as a percent of their total income.4 [EPA-HQ-OAR-2022-0829-0642, pp. 1-2]

3 https://www.lung.org/clean-air/outdoors/who-is-at-risk/disparities

4 https://www.aceee.org/white-paper/2021/05/understanding-transportation-energy-burdens

The Infrastructure Investment and Jobs Act (IIJA) and the Inflation Reduction Act (IRA) have set aside historic amounts of funding for electric vehicles and will greatly reduce greenhouse gas (GHG) emissions from the transportation sector if that money is invested with climate impacts in mind. EPA's standards must build off of these investments. While we commend EPA for proposing strong standards that help the U.S. achieve President Biden's 2030 goal of 50% zero emission new vehicle sales, these historic investments mean we can go even further.5 Since the IRA was signed into law, $50 billion in investments in EV and battery manufacturing, and supply chain projects have been announced.6 These investments could get the U.S. to over 60% new light-duty EV sales by the early 2030s.7 But more will be needed to adequately address the climate emergency. EPA's MY 2027-2032 standards should fully account for the recent federal activity and build off them to achieve further emissions reductions. [EPA-HQ-OAR-2022-0829-0642, pp. 1-2]

Organization: American Enterprise Institute

IV. Assertions of a Serious Anthropogenic Climate Threat Are Inconsistent with the Evidence

EPA asserts that "there is consensus that the effects of climate change represent a rapidly growing threat to human health and the environment, and are caused by GHG emissions from human activity, including motor vehicle transportation." This is not correct, even apart from the dubious premise that some sort of undefined “consensus” is a proper basis for policy formulation, and even apart from the failure of EPA even to attempt to separate anthropogenic and natural influences on climate phenomena. [EPA-HQ-OAR-2022-0829-0571, p. 12]

There is no evidence in support of the “rapidly growing threat” asserted by EPA. Anthropogenic climate change is “real” — increasing GHG concentrations are having detectable effects — and incontrovertible, but that does not tell us the magnitude of the observable impacts, which must be measured empirically. [EPA-HQ-OAR-2022-0829-0571, p. 12]

Temperatures are rising, but as the Little Ice Age ended no later than 1850, it is not easy to separate natural from anthropogenic effects on temperatures and other climate phenomena, as discussed below in section VII.36 The latest research in the peer-reviewed literature suggests that mankind is responsible for about half of the approximate temperature increase of 1.1 degrees C since 1880.37 [EPA-HQ-OAR-2022-0829-0571, p. 12]

36 On the Little Ice Age, see Michael E. Mann, “Little Ice Age,” in Encyclopedia of Global Environmental Change, Volume 1: The Earth System: Physical and Chemical Dimensions of Global Environmental Change, ed. Michael C. MacCracken, John S. Perry and Ted Munn (Chichester, England: John Wiley & Sons, 2002), http://www.meteo.psu.edu/holocene/public_html/shared/articles/littleiceage.pdf.

37 See, e.g., Nicholas Lewis, “Objectively Combining Climate Sensitivity Evidence,” Climate Dynamics, September 19, 2022, at https://link.springer.com/article/10.1007/s00382-022-06468-x; Ross McKitrick and John Christy, “A Test of the Tropical 200- to 300 hPa Warming Rate in Climate Models”; Nicholas Lewis and Judith Curry, “The Impact of Recent Forcing and Ocean Heat Uptake Data on Estimates of Climate Sensitivity,” Journal of Climate 31 (August 2018): 6051–71, https://journals.ametsoc.org/doi/pdf/10.1175/JCLI-D-17-0667.1; and John R. Christy and Richard McNider, “Satellite Bulk Tropospheric Temperatures as a Metric for Climate Sensitivity,” Asia-Pacific Journal of Atmospheric Sciences 53 (2017): 511–18, https://link.springer.com/article/10.1007/s13143-017-0070-z. For a chart summarizing the recent empirical estimates of equilibrium climate sensitivity as reported in the peer- reviewed literature, see Patrick J. Michaels and Paul C. Knappenberger, “The Collection of Evidence for a Low Climate Sensitivity Continues to Grow,” Cato Institute, September 25, 2014, https://www.cato.org/blog/collection- evidence-low-climate-sensitivity-continues-grow.

There is little trend in the number of “hot” days for 1895–2017; eleven of the 12 years with the highest number of such days occurred before 1960, as shown in the following chart.38 [EPA-HQ-OAR-2022-0829-0571, pp. 12-15]

38 For the reconstruction of the NASA data, see John R. Christy, “Average per Station (1114 USHCN Stations) 1895–2017: Number of Days Daily Maximum Temperature Above 100?F and 105?F,” drroyspencer.com, http://www.drroyspencer.com/wp-content/uploads/US-extreme-high-temperatures-1895-2017.jpg.

SEE ORIGINAL COMMENT FOR Graph of Average per station (1114 USHCN Stations) 1895-2017. Number days of daily Maximum temperature above 100 F degrees and 105 F degrees [EPA-HQ-OAR-2022-0829-0571, pp. 12-15]

NOAA has maintained since 2005 the U.S. Climate Reference Network, comprising 114 meticulously maintained temperature stations spaced more or less uniformly across the lower 48 states, 21 stations in Alaska, and two stations in Hawaii.39 They are placed to avoid heat island effects and other such distortions as much as possible; the reported data show no trend over the available 2005–2023 reporting period, as shown in the following chart.40 [EPA-HQ-OAR-2022-0829-0571, pp. 12-15]

39 For the Climate Reference Network program description, see National Centers for Environmental Information, “U.S. Climate Reference Network,” https://www.ncdc.noaa.gov/crn/.

40 For a visualization of a prototypical station, see Willis Eschenbach, “NOAA’s USCRN Revisited—No Significant Warming in the USA in 12 Years,” Watts Up with That?, November 8, 2017, https://wattsupwiththat.com/2017/11/08/the-uscrn-revisited/. For the monthly data and charts reported by the National Oceanic and Atmospheric Administration (NOAA), see National Oceanic and Atmospheric Administration, “National Temperature Index,” https://www.ncdc.noaa.gov/temp-and-precip/national-temperature- index/time-series?datasets%5B%5D=uscrn¶meter=anom-tavg&time_scale=p12&begyear=2005&endyear=2020&month=8, and the monthly data at https://www.ncei.noaa.gov/access/monitoring/national-temperature-index/time-series/anom-tavg/1/0.

SEE ORIGINAL COMMENT FOR Graph of Average Temperature Anomaly Jan 2005-Feb 2023 [EPA-HQ-OAR-2022-0829-0571, pp. 12-15]

Koonin notes for the U.S. as follows for 1900 through 2019:

… the average coldest temperature of the year has clearly increased since 1900, while the average warmest temperature has hardly changed over the last sixty years and is about the same today as it was in 1900.41 [EPA-HQ-OAR-2022-0829-0571, pp. 12-15]

41 See Steven E. Koonin, Unsettled: What Climate Science Tells Us, What It Doesn’t, and Why It Matters, Dallas: BenBella Books, 2021, at p. 102.

A NOAA reconstruction of global temperatures over the past one million years, using data from ice sheet formations, shows that there is nothing unusual about the current warm period.42 [EPA-HQ-OAR-2022-0829-0571, pp. 12-15]

42 See https://www.instituteforenergyresearch.org/wp-content/uploads/2020/03/temperature-flucturations.png, from R. Bintanja and R. S. W. van de Wal, “North American Ice-Sheet Dynamics and the Onset of 100,000-Year Glacial Cycles,” Nature 454, no. 7206 (August 14, 2008): 869–72, https://www.researchgate.net/publication/23171740_Bintanja_R_van_de_Wal_R_S_W_North_American_ice- sheet_dynamics_and_the_onset_of_100000-year_glacial_cycles_Nature_454_869-872. NOAA published the underlying data at R. Bintanja and R. S. W. van de Wal, “Global 3Ma Temperature, Sea Level, and Ice Volume Reconstructions,” National Oceanic and Atmospheric Administration, August 14, 2008, https://www.ncdc.noaa.gov/paleo-search/study/11933.

SEE ORIGINAL COMMENT FOR Graph of Temperature Fluctuations Over the Past Million Years [EPA-HQ-OAR-2022-0829-0571, pp. 12-15]

Global mean sea level has been increasing at about 3.3 mm per year since satellite measurements began in 1993, as shown in the following chart from NASA.43 That ongoing sea level rise would be about 13 inches over the course of a century, an outcome very unlikely to prove a “crisis,” in particular given the time available for adaptation. [EPA-HQ-OAR-2022-0829-0571, pp. 15-17]

43 NASA reports 96.7 millimeters of sea level rise for the period 1993-2022. See the NASA data at https://climate.nasa.gov/vital-signs/sea-level/.

SEE ORIGINAL COMMENT FOR Graph of Sea Height Variation (mm) 1995-2020

The tidal-gauge data before the altimeter era show annual increases of about 1.8 mm per year, as shown in the following chart.44 [EPA-HQ-OAR-2022-0829-0571, pp. 15-17]

44 Ibid.

SEE ORIGINAL COMMENT FOR Graph of Sea Level Change (mm)

The two datasets are not directly comparable in that the tidal gauges do not measure sea levels per se; they measure the difference between sea levels and "fixed" points on land that in reality might not be fixed due to seismic activity, tectonic shifts, land settlement, precipitation, and other parameters. Accordingly, the data are unclear as to whether there is occurring an acceleration in sea level rise. It is reasonable to hypothesize that there has been such an acceleration simply because temperatures are rising due to both natural and anthropogenic influences, and such increases should result in more melting ice and the thermal expansion of seawater. But because rising temperatures are the result of both natural and anthropogenic causes, as discussed in section VII, we do not know the relative contributions of those causes to any such acceleration.45 [EPA-HQ-OAR-2022-0829-0571, pp. 15-17]

45 See Frederikse et. al. at https://www.nature.com/articles/s41586-020-2591-3. As a crude approximation, the data suggest that about two-thirds of such sea level increases are due to ice melt, and one-third to thermal expansion of seawater. See Judith Curry, "Sea Level and Climate Change," Climate Forecast Applications Network, November 25, 2018, https://curryja.files.wordpress.com/2018/11/special-report-sea-level-rise3.pdf. Curry cites research from Xianyao Chen and colleagues, the central finding of which is that "global mean sea level rise increased from 2.2 ± 0.3 mm/year in 1993 to 3.3 ± 0.3 mm/year in 2014." See Xianyao Chen et al., "The Increasing Rate of Global Mean Sea-Level Rise During 1993–2014," Nature Climate Change 7 (June 26, 2017): 492–95, https://www.nature.com/articles/nclimate3325. Whether the trend from a 21-year period can yield important inferences is a premise problematic at a minimum. For a different empirical conclusion from the tidal gauge record, see J. R. Houston and R. G. Green, "Sea-Level Acceleration Based on U.S. Tide Gauges and Extensions of Previous Global-Gauge Analyses," Journal of Coastal Research 27, no. 3 (May 2011): 409–17, https://meridian.allenpress.com/jcr/article-abstract/27/3/409/28456/Sea-Level-Acceleration-Based-on-U-S-Tide- Gauges?redirectedFrom=fulltext. For an example of temporary rapid sea-level rise in the 18th century, see W. R. Gehrels et al., "A Preindustrial Sea-Level Rise Hotspot Along the Atlantic Coast of North America," Geophysical Research Letters 47 (2020), https://agupubs.onlinelibrary.wiley.com/doi/epdf/10.1029/2019GL085814. For further reported evidence of an acceleration, see Hans-Otto Pörtner et al., Special Report on the Ocean and Cryosphere in a Changing Climate, Intergovernmental Panel on Climate Change, 2019, https://www.ipcc.ch/srocc/.

The inconsistency of the northern and southern hemisphere sea ice changes add to the analytic complexity of anthropogenic climate change. The arctic sea ice has been declining, as shown in the following two charts.46 For the second chart, however, note that the small number of years shown prevents a reliable derivation of inferences. [EPA-HQ-OAR-2022-0829-0571, pp. 17-22]

46 See, respectively, https://www.epa.gov/climate-indicators/climate-change-indicators-arctic-sea-ice and https://nsidc.org/arcticseaicenews/.

The IPCC in the AR6 reports that “The SREX (Seneviratne et al., 2012) assessed low confidence for observed changes in the magnitude or frequency of floods at the global scale. This assessment was confirmed by AR5 (Hartmann et al., 2013).”58 [EPA-HQ-OAR-2022-0829-0571, pp. 25-28]

58 See https://www.ipcc.ch/report/ar6/wg1/downloads/report/IPCC_AR6_WGI_Chapter11.pdf at p. 1568.

The available data do not support the ubiquitous assertions about the dire impacts of declining pH levels in the oceans.59 Goklany reports as follows.60 [EPA-HQ-OAR-2022-0829-0571, pp. 25-28]

59 For a summary discussion, see https://www.mattridley.co.uk/blog/thousands-of-results-on-ocean-acidification/. A comprehensive database is at CO2 Science, “Ocean Acidification Database,” http://www.co2science.org/data/acidification/results.php. See also Alan Longhurst, Doubt and Certainty in Climate Science, pp. 214–25, https://curryja.files.wordpress.com/2015/09/longhurst-print.pdf.

60 See https://www.thegwpf.org/content/uploads/2015/10/benefits1.pdf at p. 16.

There is no likelihood of the ocean’s average pH getting anywhere near as low as 7 (neutral) because of elevated carbon dioxide concentrations during the next three centuries. Ocean pH currently averages about 8 and is forecast to fall by 0.2 pH units or so during the present century. This change is considerably smaller than the difference in pH between different parts of the ocean, different days in the same part of the ocean, and even different times of day in coral reef lagoons. An examination of upper-ocean pH for a wide variety of ecosystems ranging from polar to tropical, open-ocean to coastal, kelp forest to coral reefs, indicates that variations in month-long pH spanned a range of 0.024 –1.430 pH units, and found that many organisms ‘are already experiencing pH regimes that are not predicted until 2100. [EPA-HQ-OAR-2022-0829-0571, pp. 25-28]

The IPCC in the Fifth Assessment Report was deeply dubious about the various severe effects often asserted to be looming as impacts of anthropogenic warming; an example is a collapse of the Antarctic western and Greenland ice sheets. The IPCC analysis in the Sixth Assessment Report is almost identical.61 [EPA-HQ-OAR-2022-0829-0571, pp. 25-28]

61 For the AR5, see Julie M. Arblaster et al., “Long-Term Climate Change: Projections, Commitments and Irreversibility—Final Draft Underlying Scientific-Technical Assessment,” in Working Group I Contribution to the IPCC Fifth Assessment Report (AR5), Climate Change 2013: The Physical Science Basis, September 23–26, 2013, p. 12–78, at http://www.climatechange2013.org/images/uploads/WGIAR5_WGI- 12Doc2b_FinalDraft_Chapter12.pdf. See the analogous analysis in the AR6 at p. 12-115 at https://www.ipcc.ch/report/ar6/wg1/downloads/report/IPCC_AR6_WGI_Full_Report.pdf.

Organization: American Lung Association (ALA) et al.

In addition to being a leading contributor to air pollution challenges, transportation is the leading source of climate pollution in the nation. The life-saving progress made to clean the air under the Clean Air Act is increasingly challenged by climate change impacts. Extreme heat, drought and catastrophic wildfire conditions and enhanced conditions for ozone formation increase pollution burdens and inequities. Climate impacts on health are far reaching beyond degraded air quality, including water quality, vector-borne diseases, mental health impacts, health issues from displacement and other risks.3 EPA must act to set the strongest possible multi-pollutant standards for new passenger vehicles that ensure cleaner combustion engines while spurring the rapid and widespread transition to zero-emission technologies needed to ensure cleaner air and a healthy climate. [EPA-HQ-OAR-2022-0829-0745, pp. 1-2]

Losses from additional energy conversions

Conversion of energy from one form to another is not 100% conservative. With each energy conversion from one form to another, you lose some energy. [EPA-HQ-OAR-2022-0829-0562, p. 1]

In a typical vehicle you have energy conversions of fuel => pistons => forward motion. With an electrical vehicle you have

Power generation => electricity => battery => electricity => electrical motor => forward motion. [EPA-HQ-OAR-2022-0829-0562, p. 1]

An electrical vehicle has at least 5 conversions with associated losses. Requiring vehicles to be battery powered will result in increased energy use with increased energy losses. This comes with a limited benefit, if any. [EPA-HQ-OAR-2022-0829-0562, p. 1]

Any benefit which can be conceived is tied to power plant generation. According to https://afdc.energy.gov/vehicles/electric_emissions.html [EPA-HQ-OAR-2022-0829-0562, p. 1]

In geographic areas that use relatively low-polluting energy sources for electricity generation, all-electric vehicles and PHEVs typically have an especially large life cycle emissions advantage over similar conventional vehicles running on gasoline or diesel. In areas with higher-emissions electricity, all-electric vehicles and PHEVs may not demonstrate as strong a life cycle emissions benefit. [EPA-HQ-OAR-2022-0829-0562, p. 1]

And the amount of any benefit may not be all that great. https://www.fueleconomy.gov/feg/climate.shtml [EPA-HQ-OAR-2022-0829-0562, p. 1]

Highway vehicles release about 1.4 billion tons of greenhouse gases (GHGs) into the atmosphere each year—mostly in the form of carbon dioxide (CO_2) [EPA-HQ-OAR-2022-0829-0562, p. 1]

https://ourworldindata.org/greenhouse-gas-emissions

Today, we collectively emit around 50 billion tonnes of CO_2e each year.

So the maximum we could hope to save would be 1.4 / 50, or 2.8% of that released. And this needs to be put in light of the total CO_2 in the atmosphere. [EPA-HQ-OAR-2022-0829-0562, pp. 1-2]

https://www.climate.gov/news-features/understanding-climate/climate-change-atmospheric-carbon- dioxide

Published May 12, 2023

Based on the annual report from NOAA’s Global Monitoring Lab, global average atmospheric carbon dioxide was 417.06 parts per million (“ppm” for short) in 2022, setting a new record high. [EPA-HQ-OAR-2022-0829-0562, pp. 1-2]

Using 1 ppm = 7.8 Gigatonnes of Carbon Dioxide in the atmosphere. This calculates to

417.06 x 7.8 Gigatonnes / 1 ppm = 3,253 Gigatonnes

1.4 billion tonnes (Gigatonnes) / 3,253 Gigatonnes = 0.000307402120091

The most we could hope to save would be 0.0003 of the total atmosphere carbon dioxide. But that's only if none was produced from vehicles. However, any savings will be less than 0.0003 with the power generation plants which produce carbon dioxide. And there will be additional waste of energy in the energy conversions to the different forms needed for electric vehicles. [EPA-HQ-OAR-2022-0829-0562, pp. 1-2]

Energy conversion from battery to forward movement [EPA-HQ-OAR-2022-0829-0562, pp. 2-3]

According to archive.org, https://www.fueleconomy.gov/feg/evtech.shtml In December, 2019, it stated:

EVs convert about 59%–62% of the electrical energy from the grid to power at the wheels. Conventional gasoline vehicles only convert about 17%–21% of the energy stored in gasoline to power at the wheels.

Then in February, 2020, it stated: [EPA-HQ-OAR-2022-0829-0562, pp. 2-3]

EVs convert over 77% of the electrical energy from the grid to power at the wheels. Conventional gasoline vehicles only convert about 12%–30% of the energy stored in gasoline to power at the wheels.

with a disclaimer stating:

https://www.fueleconomy.gov/feg/atv-ev.shtml

EVs are 60% to 73% efficient, depending upon drive cycle. However, if the energy recaptured from regenerative braking is counted (i.e., recounted when it is re-used), EVs are 77% to 100% efficient. [EPA-HQ-OAR-2022-0829-0562, pp. 2-3]

Regenerative braking would add additional complexity in calculating conversion efficiencies and costs.

The university of Calgary agrees with the 2019 statement, https://energyeducation.ca/encyclopedia/Electric_vehicle

Modern EVs have an efficiency of 59-62% converting electrical energy from the storage system to the wheels.

Energy conversion from electrical grid to battery [EPA-HQ-OAR-2022-0829-0562, pp. 2-3]

Battery efficiency declines with age, temperature, and charging speed and the total state of charge capacity level. This means, range loss.

Charging to 100% at 60 degrees Celsius can reduce capacity to 60% after 3 months. Recommended state of charge capacities is from 30% to 70% which also means, range loss.

https://optiwatt.com/blog/the-comprehensive-guide-to-maximizing-your-teslas-battery-efficiency-and-battery-life [EPA-HQ-OAR-2022-0829-0562, pp. 2-3]

Even if the vehicle is not used for extended periods of time, it is recommended to keep it plugged in. This will result in total waste of energy that only goes for maintaining the battery to prevent degradation.

Battery charging efficiency is dependent upon internal resistance.

Rolls Battery Engineering states: [EPA-HQ-OAR-2022-0829-0562, pp. 2-3]

Charge efficiency for Flooded deep cycle models is typically ~80%. This should be reduced 1% per year after the third (3) year of operation. [EPA-HQ-OAR-2022-0829-0562, p. 2]

Energy power plant to electrical grid

More than 60% of energy used for electricity generation is lost in conversion. https://www.eia.gov/todayinenergy/detail.php?id=44436

Each conversion results in loss to the remaining energy. [EPA-HQ-OAR-2022-0829-0562, pp. 2-3]

More than 60% energy loss from the power plant to the electrical grid. 20% or more energy loss from the electrical grid to battery.

Up to 41% energy loss from battery to forward movement.

There will be a higher demand on our energy grid, leading to increased electrical costs and risks of additional brownouts and blackouts throughout the country. Electric vehicles have increased weight posing safety concerns with increased stopping distances, (including within school zones), increased damage in crashes, and yet more energy needed to move the vehicle forward. It also adds more wear and tear to the roads, adding yet more energy waste. It requires increased structural strength in parking garages with yet more energy waste. [EPA-HQ-OAR-2022-0829-0562, pp. 2-3]

I fear the whole picture has not been presented and that there is going to be a lot of energy wasted in startup construction, people moved over to something new, and then in a few years, charging and use efficiencies will have been reduced, the mistake will be realized, and it will be too late. [EPA-HQ-OAR-2022-0829-0562, p. 3]

I urge the EPA to hold off on requirements moving towards use of Electric Vehicles. The power grid is needed to be stabilized to support the dramatic electrical demand, there is lack of infrastructure to support charging stations, the battery capabilities is not yet up to speed, there are indirect environmental costs that may not yet be realized. There may be such a time for wide scale use of Electric Vehicles, but the time is not yet. [EPA-HQ-OAR-2022-0829-0562, p. 3]

Organization: Arizona State Legislature

3. The proposed rule fails to model its climate change impacts. EPA justifies the proposed rule on the basis that it will avoid climate change impacts, but EPA did not conduct modeling to determine the proposed rule's impact on temperature change or sea-level rise. [EPA-HQ-OAR-2022-0829-0537, p. 2]

Global damages. The 2021 Working Group departed from recent practice by considering not just domestic harms, but global anticipated climate damages in its analysis. 2021 TSD, at 3. The decision to consider not just damages to the United States of America, but all other countries potentially impacted by climate change, is not a scientific decision—it is a political decision. In fact, the Working Group did not make this decision—in E.O. 13990, the President commanded it to consider global damages. See E.O. 13990, 86 Fed. Reg. 7040; 2021 TSD, at 3 (acknowledging that "[t]he IWG was tasked with" publishing estimates that "tak[e] global damages into account"). The Working Group concedes that this is a policy decision, involving considerations of "climate risk, environmental justice, and intergenerational equity." 2021 TSD, at 3. [EPA-HQ-OAR-2022-0829-0537, p. 20]

Organization: BlueGreen Alliance (BGA)

Strong, technology-forcing vehicle standards are essential to meet climate goals, advance environmental justice, and create good jobs in the clean economy. The transportation sector is the single largest contributor to climate-warming greenhouse gas emissions in the U.S., and the local air pollutants emitted by vehicles, including particulate matter (PM), nitrous oxides (NOx), and volatile organic compounds (VOCs) have disproportionate impacts on low-income and non-white communities. Meanwhile, the supply chains for light- and medium-duty vehicles and the manufacturing jobs within them—are critical to the economic health and stability of auto manufacturing communities across the country (See Figure1). [EPA-HQ-OAR-2022-0829-0667, p. 2]

SEE ORIGINAL COMMENT FOR Figure 1: Light- and Medium-Duty Vehicle Assemblers and Component Manufacturers. Light and Medium Duty Vehicle Manufacturing. [EPA-HQ-OAR-2022-0829-0667, p. 2]

Source: BGA [EPA-HQ-OAR-2022-0829-0667, p. 2]

Organization: California Air Resources Board (CARB) (Part 1 of 5)

The science could not be clearer. We must act now to reduce pollution to stabilize the climate and avoid the most serious consequences of climate change. In California and many other states, the changing climate is already increasing the frequency and severity of drought, wildfires, and extreme weather events like heat waves, jeopardizing public health and economic stability. [EPA-HQ-OAR-2022-0829-0780, p. 7]

In addition to ongoing air quality challenges, California is on the front lines of climate change. With the increasing severity and frequency of drought, wildfire, extreme heat, and other impacts, Californians need only look out their windows to know that climate change is real and rapidly getting worse. 4 The impacts we thought we would see in the decades to come are happening now and, as with air pollution, are disproportionately affecting low-income communities and communities of color. [EPA-HQ-OAR-2022-0829-0780, p. 8]

Cumulative impacts of climate change

U.S. EPA acknowledges that climate change can disproportionately affect people of color and low-income communities due to various factors, such as lower resilience to climate impacts. However, the analysis would benefit from an assessment of the cumulative impacts of multiple risk factors to thoroughly estimate climate vulnerability. The proposed rule would lower GHG emissions and mitigate the adverse effects of climate change on health outcomes and inequalities among these groups. [EPA-HQ-OAR-2022-0829-0780, pp. 54-55]

CARB's 2022 Scoping Plan for Achieving Carbon Neutrality 98 also recognizes that communities do not experience exposure to pollution sources and the resulting effects equally. Low-income communities and communities of color consistently experience significantly higher rates of pollution and adverse health conditions than others. Research has demonstrated that the "cumulative impacts" 99 of various social, economic, and environmental factors can worsen health conditions, and the combination of all these factors can compound the health effects of individual exposures. CARB has been working over the past decade to better understand and map cumulative impacts in California, in coordination with the California Office of Environmental Health Hazard Assessment (OEHHA), and to identify communities that are experiencing the highest levels of socioeconomic- and pollution-related vulnerability. CARB notes that U.S. EPA has also conducted research in this area, such as in its report, "Cumulative Impacts Research: Recommendations for EPA's Office of Research and Development." 100 CARB recommends U.S. EPA incorporate information from this report, which further illustrates the need to reduce climate stressors for vulnerable groups and the associated public health benefits of the proposed standards. [EPA-HQ-OAR-2022-0829-0780, pp. 54-55]

Co-benefits of climate action

Reducing GHG emissions can help mitigate climate impacts, as U.S. EPA has addressed. However, many actions to reduce GHG emissions also have health co-benefits that can improve the health and well-being of populations, as well as address climate change. CARB's 2022 Scoping Plan for Achieving Carbon Neutrality: Appendix G (Public Health) 101 included a qualitative analysis that evaluated the broad range of benefits of a dramatic reduction in fossil fuels by 2045 combined with healthier ecosystem management. This analysis supports the CARB Scoping Plan with scientific literature from eight health co-benefit areas: heat impacts, children's health and development, economic security, food security, mobility and physical activity, urban greening, wildfires and smoke impacts, and housing affordability. It indicates the directional effects of each health outcome and gives details on the magnitude and extent of health effects when possible. The analysis includes discussion of benefits to community health and climate resilience, as well as potential inequities experienced at a community level. For example, a study by Masri et al. 102 reported that census tracts with predominantly Native American populations, older adults, and low-income populations are more likely to be highly impacted by wildfires. Overall, the qualitative analysis shows an overwhelming health benefit for the State in moving forward to carbon neutrality while continuing efforts to increase health equity and resilience in individual communities. California is not alone in experiencing climate impacts, and CARB would expect similar results nationwide. CARB therefore recommends that U.S. EPA add discussion on potential health co-benefits that are related to the reduction of GHG emissions resulting from the proposed rule. Organization: California Attorney General's Office, et al.

Strong emissions standards are necessary now to stave off the worst impacts of human-induced climate change and to confront inequitably distributed threats to public health and the environment from climate change as well as other forms of pollution. From extreme heat to wildfires to drought, our States and Cities are already experiencing the devastating impacts of climate change, which will continue to mount and compound with rising concentrations of GHGs in the atmosphere. Moreover, vehicle emissions of oxides of nitrogen (NOx), particulate matter (PM), and other criteria pollutants continue to endanger the health and welfare of our residents. [EPA-HQ-OAR-2022-0829-0746, p. 1]

BACKGROUND

A. Our States and Cities Confront a Growing Climate Crisis

Our States and Cities are currently experiencing the devastating effects of climate change. Increased temperatures, extreme heat events, wildfires, sea level rise, and coastal flooding—to highlight just a few of the effects—are currently causing and projected to continue to cause significant damage to our States and Cities. The Sixth Assessment Report of the Intergovernmental Panel on Climate Change ("IPCC") reconfirms these types of impacts are caused by anthropogenic climate change, and it projects that they will worsen.2 As average surface temperatures rise and the intensity and frequency of these types of extreme weather events increases, our States and Cities face direct and compounding challenges to protect the health and welfare of our residents, our economies, and our natural resources. [EPA-HQ-OAR-2022-0829-0746, pp. 2-3]

1. Increased Temperatures and Extreme Heat

Globally, "[t]he past nine years have been the warmest years since modern recordkeeping began in 1880;"3 and nine of the warmest eleven years on record in the United States have occurred since 2012.4 There is a "virtually certain" chance that 2023 will rank among the ten warmest years on record, with a 93% chance it will rank among the top five.5 The IPCC has determined that GHG emissions from human activities are already responsible for about 1.1 °C of warming since 1850-19006 and that "[h]uman influence has warmed the climate at a rate that is unprecedented in at least the last 2000 years."7 [EPA-HQ-OAR-2022-0829-0746, pp. 2-3]

7 Id. at 6.

As temperatures rise, threats to public health and the environment in our States and Cities continue to mount. For example, extreme heat events are happening more frequently, with more intensity,8 and for longer duration.9 In June 2021, a four-day heat wave across the Pacific Northwest set heat records all over the region, including heat so intense that roads buckled.10 The region experienced 600 excess deaths during the heat wave.11 In September 2022, a historic heat wave punished California, breaking high-temperature records in Northern California; it was considered "extraordinary" in part because of its "mind-blowing duration."12 Extreme heat events like these are "likely to become the new normal."13 By 2053, the number of counties experiencing at least one day with a heat index above 125 degrees Fahrenheit is projected to increase from 50 to over 1,000.14 [EPA-HQ-OAR-2022-0829-0746, pp. 2-3]

8 H.O. Pörtner et al., IPCC, Climate Change 2022: Impacts, Adaptation and Vulnerability, Working Group II Contribution to the Sixth Assessment Report of the Intergovernmental Panel on Climate Change (2022) ("IPCC Report 2022"), at 1963.

Extreme heat events threaten not only our quality of life, but our lives themselves.15 As temperatures rise, heat-related mortality is expected to increase, particularly in urban areas.16 One study found that by 2100, annual heat-related deaths in the United States are projected to increase from 12,000 to 36,000 in a moderate-warming scenario or 97,000 in a high-warming scenario.17 Another study predicted that by 2080 to 2099, hospital admissions for heat-related respiratory diseases in New York state will be 2 to 6 times higher than in 1991 to 2004.18 A third study concluded that extreme heat days were associated with higher all-cause mortality rates in the contiguous United States, and disproportionately affected some subgroups, including older adults and Black adults.19 On a global scale, new research indicates that for every 0.1 degree Celsius above present levels, about 140 million additional people will be exposed to dangerous levels of heat.20 [EPA-HQ-OAR-2022-0829-0746, p. 4]

2. Wildfires

Global warming is likely responsible for 66% to 88% of the atmospheric conditions fueling wildfires.21 It engenders warm and dry conditions,22 which have contributed to more extreme wildfires.23 Since the 1970s, the wildfire season in the western United States has extended from 5 months to over 7 months long.24,25 In the coming decades, climate change is projected to further increase fire activity across North America.26 [EPA-HQ-OAR-2022-0829-0746, pp. 4-6]

California is uniquely vulnerable to wildfires,31 and the projected impacts on California from an increase in wildfire risk are severe. In 2018, the Camp Fire burned 155,366 acres of land, destroying 18,804 structures—roughly 90% of the homes in the town of Paradise—and killing 85 people;32 it was then the deadliest and most destructive wildfire in California history. In 2021, a record number of acres burned in the Sierra Nevada, breaking the previous record set in 2020.33 The Dixie Fire, now the largest single wildfire in California history, also burned in 2021.34 As a result of climate change, the average annual area burned across California is projected to increase by around 77% by 2099, and the worst wildfire years could see burned area increases of more than 178% by the end of this century.35 [EPA-HQ-OAR-2022-0829-0746, pp. 4-6]

Moreover, wildfires pose significant public health risks due to air quality degradation.36 Exposure to wildfire smoke may cause respiratory morbidity, especially exacerbations of asthma and chronic obstructive pulmonary disease.37 “[W]ildfire-specific PM2.5 is up to 10 times more harmful on human health than PM2.5from other sources.”38,39 This public health concern grows as the frequency and intensity of wildfires increase and is not limited to States where the wildfires are burning. The rising heat from the wildfires takes particulate matter and toxic gases in the smoke into the jet stream, which can carry those hazardous substances thousands of miles and cause harmful air pollution across the country. During the 2020 wildfire season and again in July of 2021, smoke from wildfires burning on the West Coast caused New York City to experience some of the worst air quality in the world.40 And in June 2023, New York City was once again blanketed in smoke, resulting in the highest measurements of 2.5 micron particles since recording began in 1999.41 The combination of fierce wildfires in Canada and airflow patterns prompted the U.S. National Weather Service to issue air quality alerts for most of the Atlantic seaboard.42 [EPA-HQ-OAR-2022-0829-0746, pp. 4-6]

3. Sea Level Rise and Coastal Flooding

In the past three decades, rates of sea level rise have accelerated as a result of climate change,43 which causes ice sheets and glaciers to melt and seawater to warm and expand. By 2050, sea level along the contiguous United States’s coastline is conservatively estimated to rise by at least 1 foot,44 causing flooding, erosion, and infrastructure damage along the coastlines.45 By the middle of the century, flooding from rising sea levels and storms is likely to make billions of dollars of coastal property unusable,46 which is particularly problematic given that nearly 40% of Americans live in coastal counties.47 [EPA-HQ-OAR-2022-0829-0746, pp. 7-8]

"California is particularly vulnerable to sea level rise because approximately 80% of the population lives within 30 miles of the Pacific Ocean."48 Projections show that 31% to 67% of Southern California beaches may be completely lost by 2100, which will effectively eliminate their recreational and tourism value without large-scale intervention.49 Damages from the inundation of residential and commercial buildings under 20 inches of sea level rise could reach nearly $17.9 billion, and these costs would double if a 100-year coastal flood occurred on top of this sea level rise.50 In a worst case scenario, 6.6 feet of sea level rise combined with a 100-year storm would cause flooding in Southern California that could affect 250,000 people, $50 billion worth of property, and $39 billion worth of buildings.51 [EPA-HQ-OAR-2022-0829-0746, pp. 7-8]

51 Id.

Sea level rise also exacerbates coastal flooding. For example, by 2050, sea levels along the southern coastal region of Massachusetts are expected to rise over 2 feet, which will cause over 25 miles of road and more than 1,400 buildings in the region to flood every day at high tide.52 [EPA-HQ-OAR-2022-0829-0746, pp. 7-8]

52 Barbara Moran, Rising seas threaten Mass. South Coast and prosperous fishing port, report finds. Here are 5 takeaways, WBUR (Sep. 19, 2022), available at https://www.wbur.org/news/2022/09/19/massachusetts-south-coast-sea-level-rise-new-bedford.

The region also contains 4,900 acres of salt marsh, which filter water, offer wildlife habitat, and act as storm buffer; 23% of the salt marsh is expected to vanish by 2050.53 Coastal flooding may also contaminate groundwater.54 [EPA-HQ-OAR-2022-0829-0746, pp. 7-8]

1. Greenhouse Gas Emissions from Light-Duty and Medium-Duty Vehicles Require Urgent and Ambitious Action Now

It is critically important to reduce GHGs from light- and medium-duty vehicles and to do so as soon as is feasible. Transportation is the leading source of GHG emissions in the country, accounting for approximately 27.2% of total GHG emissions. 88 Fed. Reg. at 29,350 (citing U.S. GHG Emissions Inventory). Light-duty vehicles alone account for 57% of those transportation sector emissions, or approximately 15.5% of total U.S. GHG emissions. Id. Reductions of these emissions are thus crucial for the United States to achieve its climate targets and do its part to keep the rise in global mean temperatures below 1.5 °C to 2 °C.168 [EPA-HQ-OAR-2022-0829-0746, pp. 28-29]

168 United States, The United States of America Nationally Determined Contribution, Reducing Greenhouse Gases in the United States: A 2030 Emissions Target (2021), available at https://unfccc.int/sites/default/files/NDC/2022-06/United%20States%20NDC%20April%2021%202021%20Final.pdf.

Urgent emissions reductions are necessary, because GHGs can remain in the atmosphere for long time periods. For example, 40% of carbon dioxide emitted as a result of human activities will remain in the atmosphere after 100 years, and 20% will remain after 1000 years; only after about 10,000 years will all the carbon dioxide emitted now break down.169 As explained in the Fourth National Climate Assessment, "[w]aiting to begin reducing emissions is likely to increase the damages from climate-related extreme events (such as heat waves, droughts, wildfires, flash floods, and stronger storm surges due to higher sea levels and more powerful hurricanes)."170 [EPA-HQ-OAR-2022-0829-0746, pp. 28-29]

169 Ask the Experts: The IPCC Fifth Assessment Report, 5 CARBON MANAGEMENT 17, 24 (2014), available at https://www.tandfonline.com/doi/pdf/10.4155/cmt.13.80.

170 Fourth National Climate Assessment: Volume II, supra note 46, at 1488.

Moreover, there may be "tipping points" in the climate system such that even a small incremental change in temperature could push Earth's climate into catastrophic runaway global warming.171 Indeed, a 2022 study published in the journal Science warned that six out of nine major climate tipping points (including the accelerating ice loss from the West Antarctic ice sheet) move from "possible" to "likely" to be triggered at 1.5 °C of warming.172 Therefore, serious efforts to reduce GHG emissions are urgently needed to avoid scenarios where steeper (and vastly more expensive) emission reductions are needed later. Delaying efforts to mitigate carbon dioxide emissions will have negative—and potentially irreversible—consequences for global warming and its impacts, including more extreme wildfires, rising sea levels, greater ocean acidification, and increased risks to food security and public health. Moreover, the uneven distribution of these impacts demands urgent action to protect our most vulnerable populations from additional climate harms and to prevent the exacerbation of existing climate injustices.173 [EPA-HQ-OAR-2022-0829-0746, pp. 28-29]

172 David Armstrong McKay et al., Exceeding 1.5 °C global warming could trigger multiple climate tipping points, Science, Vol. 377, No. 6611 (Sep. 9, 2022), available at https://doi.org/10.1126/science.abn7950.

173 See USGCRP Study, supra n. 61, at 247-86; see e.g., EPA, Climate Change and Social Vulnerability in the United States: A Focus on Six Impacts, supra n. 65, at 35.

The science could not be clearer. We must act now to reduce pollution to stabilize the climate and avoid the most serious consequences of climate change. In California and many other states, the changing climate is already increasing the frequency and severity of drought, wildfires, and extreme weather events like heat waves, jeopardizing public health and economic stability. We likewise must continue to urgently pursue efforts to improve air quality and reduce toxic emissions and reduce the disparate impacts that have persisted for decades. In California and across the U.S., many low-income communities and communities of color are exposed to disproportionate levels of pollution from on-road vehicle emissions, which contributes to respiratory illness, cardiovascular disease, cancer, and premature death. These impacts are often compounded by the congregation of nearby industrial sources, including upstream, midstream, and downstream fuel production sources. Furthermore, many of these same communities are especially vulnerable to the effects of climate change, as the most severe harms from climate change fall disproportionately on these underserved communities who are least able to prepare for and recover from associated impacts. U.S. EPA's proposed standards are urgently needed to help address these issues. [EPA-HQ-OAR-2022-0829-0780, p. 7]

Despite significant progress reducing air pollution, California experiences some of the nation's poorest air quality, with more than 21 million Californians living in areas that exceed federal ozone standards. 3 Within these areas, there are many low-income and disadvantaged communities that are exposed to not only ozone, but also to particulate and toxic pollutant levels that are significantly higher than applicable federal standards and which have immediate and detrimental health effects. With new research demonstrating adverse health impacts even below NAAQS levels, it remains critically important to continue to reduce emissions wherever feasible. [EPA-HQ-OAR-2022-0829-0780, p. 8]

https://ww2.arb.ca.gov/sites/default/files/2022-08/2022_State_SIP_Strategy.pdf

In addition to ongoing air quality challenges, California is on the front lines of climate change. With the increasing severity and frequency of drought, wildfire, extreme heat, and other impacts, Californians need only look out their windows to know that climate change is real and rapidly getting worse. 4 The impacts we thought we would see in the decades to come are happening now and, as with air pollution, are disproportionately affecting low-income communities and communities of color. [EPA-HQ-OAR-2022-0829-0780, p. 8]

https://ww2.arb.ca.gov/sites/default/files/2023-04/2022-sp.pdf.

The Proposal Will Protect Public Health

Reducing motor vehicle pollution is imperative to protect public health. U.S. EPA's proposed emission standards, or a stronger version, would effectively reduce both GHGs and criteria pollutants like PM, leading to a wide array of vital public health benefits. While U.S. EPA has comprehensively summarized the potential public health benefits of its proposal, CARB finds that there are additional public health benefits that go beyond those described. CARB has summarized its findings and notes that were U.S. EPA to include this information it would better encompass the tremendous potential benefits resulting from the proposal. [EPA-HQ-OAR-2022-0829-0780, p. 52]

Cumulative impacts of climate change

U.S. EPA acknowledges that climate change can disproportionately affect people of color and low-income communities due to various factors, such as lower resilience to climate impacts. However, the analysis would benefit from an assessment of the cumulative impacts of multiple risk factors to thoroughly estimate climate vulnerability. The proposed rule would lower GHG emissions and mitigate the adverse effects of climate change on health outcomes and inequalities among these groups. [EPA-HQ-OAR-2022-0829-0780, pp. 54-55]

CARB's 2022 Scoping Plan for Achieving Carbon Neutrality 98 also recognizes that communities do not experience exposure to pollution sources and the resulting effects equally. Low-income communities and communities of color consistently experience significantly higher rates of pollution and adverse health conditions than others. Research has demonstrated that the "cumulative impacts" 99 of various social, economic, and environmental factors can worsen health conditions, and the combination of all these factors can compound the health effects of individual exposures. CARB has been working over the past decade to better understand and map cumulative impacts in California, in coordination with the California Office of Environmental Health Hazard Assessment (OEHHA), and to identify communities that are experiencing the highest levels of socioeconomic- and pollution-related vulnerability. CARB notes that U.S. EPA has also conducted research in this area, such as in its report, "Cumulative Impacts Research: Recommendations for EPA's Office of Research and Development." 100 CARB recommends U.S. EPA incorporate information from this report, which further illustrates the need to reduce climate stressors for vulnerable groups and the associated public health benefits of the proposed standards. [EPA-HQ-OAR-2022-0829-0780, pp. 54-55]

Co-benefits of climate action

Reducing GHG emissions can help mitigate climate impacts, as U.S. EPA has addressed. However, many actions to reduce GHG emissions also have health co-benefits that can improve the health and well-being of populations, as well as address climate change. CARB's 2022 Scoping Plan for Achieving Carbon Neutrality: Appendix G (Public Health) 101 included a qualitative analysis that evaluated the broad range of benefits of a dramatic reduction in fossil fuels by 2045 combined with healthier ecosystem management. This analysis supports the CARB Scoping Plan with scientific literature from eight health co-benefit areas: heat impacts, children's health and development, economic security, food security, mobility and physical activity, urban greening, wildfires and smoke impacts, and housing affordability. It indicates the directional effects of each health outcome and gives details on the magnitude and extent of health effects when possible. The analysis includes discussion of benefits to community health and climate resilience, as well as potential inequities experienced at a community level. For example, a study by Masri et al. 102 reported that census tracts with predominantly Native American populations, older adults, and low-income populations are more likely to be highly impacted by wildfires. Overall, the qualitative analysis shows an overwhelming health benefit for the State in moving forward to carbon neutrality while continuing efforts to increase health equity and resilience in individual communities. California is not alone in experiencing climate impacts, and CARB would expect similar results nationwide. CARB therefore recommends that U.S. EPA add discussion on potential health co-benefits that are related to the reduction of GHG emissions resulting from the proposed rule. [EPA-HQ-OAR-2022-0829-0780, pp. 55-56]

102 Masri S, Scaduto E, Jin Y, Wu J. Disproportionate Impacts of Wildfires among Elderly and Low-Income Communities in California from 2000-2020. Int J Environ Res Public Health. 2021 Apr 8;18(8):3921.

4. Environmental Justice Communities Disproportionately Bear the Burden of Climate Change Impacts

Climate change's impacts will continue to disproportionately fall on environmental justice communities.55 Environmental justice communities experience more severe climate impacts and are more vulnerable as the climate crisis worsens. [EPA-HQ-OAR-2022-0829-0746, pp. 8-10]

55 "Environmental justice" is defined by EPA as the "fair treatment and meaningful involvement of all people regardless of race, color, national origin or income with respect to development, implementation, and enforcement of environmental laws, regulations and policies." EPA, EJ 2020 Action Agenda: The U.S. EPA's Environmental Justice Strategic Plan for 2016-2020, EPA-300-B-1-6004, at 1 (Oct. 2016). For the purpose of this comment, the term "environmental justice community" refers to a community of color or community experiencing high rates of poverty that, due to past and/or current unfair and inequitable treatment, is overburdened by environmental pollution, and the accompanying harms and risks from exposure to that pollution because of past or current unfair treatment.

Severe climate harms are already a reality for many environmental justice communities. Globally, the last nine years have been the nine hottest on record, and that trend is expected to continue.56 Members of environmental justice communities tend to work in occupations with increased exposure to extreme heat, such as the agricultural, construction, and delivery industries.57 Farmworkers die of heat-related causes at 20 times the rate of the rest of the U.S. civilian workforce.58 Since 2005, the first year California began tracking the number of heat-related fatalities, 36% of California's heat-related worker deaths have been of farmworkers.59 Similarly, although construction workers comprise only 6% of the national workforce, they account for 36% of heat-related deaths.60 [EPA-HQ-OAR-2022-0829-0746, pp. 8-10]

60 Xiuwen Sue Dong et al., Heat-Related Deaths Among Construction Workers in the United States, 62 AM. J. INDUS. MED. (2019), at 1047-57.

At home, environmental justice communities suffer disproportionate impacts from extreme heat because they are more likely to lack air conditioning, tree canopy, and greenspace. Environmental justice communities have less access to air conditioning to cool down, and are less able to pay the utility bills required to run air conditioning units or fans.61 In urbanized environments, pavement, cement, and other non-vegetated areas contribute to the heat island effect, in which built environments retain heat, causing daytime temperatures to be from 1 °F to 6 °F hotter than suburban and rural areas and nighttime temperatures to be as much as 22 °F hotter.62 The heat island effect is inequitably distributed—it is most extreme in lower-income communities and communities of color.63 Contributing to this effect is the lack of tree canopy and greenspace in environmental justice communities, often due to lower historical and ongoing investment. Indeed, tree canopy and greenspace is highly correlated with historical redlining practices, in which federal housing policy directed investment away from lower-income communities, and especially communities of color, characterized as "risky" for loan servicing.64 Moreover, an EPA report found that individuals with lower incomes and individuals of color are respectively 11% to 16% and 8% to 14% more likely to live in areas with the highest projected increases in premature mortality from extreme heat.65 [EPA-HQ-OAR-2022-0829-0746, pp. 8-10]

In addition, flooding and drought from extreme weather events disproportionately affect environmental justice communities, and the inequity will grow as climate impacts worsen. Due to disinvestment, environmental justice communities often lack sufficient infrastructure to control flooding or ensure steady water supplies.66 They also suffer from more severe impacts, such as contaminated water from pollutant flows during floods and increased concentration of contaminants during droughts.67 EPA has also determined that individuals with lower incomes are more likely to live in areas with the highest projected land losses from sea level rise inundation and are more likely to face substantial traffic delays due to climate-driven changes in high-tide flooding.68 [EPA-HQ-OAR-2022-0829-0746, pp. 8-10]

The above impacts especially apply to tribal communities. Due to land dispossession and forced migration, tribal communities are more exposed to extreme heat and more likely to rely on local water sources that are less resilient to drought and more contaminated.69 Beyond those impacts, tribal communities also suffer cultural harms from the decimation or harm to local ecosystems and species of particular meaning to cultural practices.70 These cultural resources have intrinsic value, and they are also critical to tribal community identity and group cohesion, which translates into direct health benefits.71 Moreover, degradation of these cultural resources threatens traditional ecological knowledge, such as particularized understanding of local ecosystems, agriculture, and sustainable practices, that can help limit the impacts of climate change.72 Tribal communities with sovereign land holdings are also more vulnerable to climate impacts because they are unable to relocate.73 [EPA-HQ-OAR-2022-0829-0746, pp. 10-11]

Furthermore, environmental justice communities, including tribal communities, are environmentally overburdened due to greater existing pollution exposure.74 This disadvantage manifests in higher rates of chronic disease, premature death, and other adverse public health outcomes.75 Compounding these disparities, residents of environmental justice communities also have less access to health care—they are less likely to have health insurance and less likely to be able to afford necessary tests and procedures, and health care facilities are poorly staffed and equipped.76 Consequently, residents of environmental justice communities are less able to withstand climate impacts that further damage their health, such as increased local smog conditions.77 [EPA-HQ-OAR-2022-0829-0746, pp. 10-11]

In addition to being more vulnerable to the impacts of climate change, environmental justice communities endure structural disadvantages that blunt their ability to adapt to a changing climate. Environmental justice communities have less access to financial resources, such as income and wealth, that are critical to climate resilience.78 More financial resources equate to more mobility, more ability to spend (on utilities, health care, home adaptation, etc.) to reduce climate harms, and more safeguards (such as insurance) in the event of extreme climate events.79 Environmental justice communities have higher rates of limited English proficiency, which can reduce access to climate resilience programs and increase vulnerability in extreme climate events due to an inability to understand public health information.80 Social capital in the political process is critical to ensure environmental justice communities receive resources to increase climate resilience and to prevent further entrenching existing inequities. Organization: Ceres BICEP (Business for Innovative Climate and Energy Policy) Network

BICEP Network companies see climate change as a significant business risk, reducing GHG emissions as a major economic opportunity, and recognize the urgency of ensuring near-term reductions. In its most recent March 2023 report,1 the International Panel on Climate Change (IPCC) emphasized the necessity to "massively fast-track climate efforts by every country and every sector and on every timeframe,"2 underscoring the urgency of drastically reducing GHG emissions by 2030. Given that the transportation sector is the largest source of U.S. GHG emissions,3 strong vehicle emission standards are critical to meeting U.S. climate goals. Recent analysis from the International Council of Clean Transportation (ICCT) concludes that aligning the light-duty vehicle sector with climate goals would require a 77% zero- emission vehicle (ZEV) sales share in 2030.4 A key finding of BloombergNEF's 2023 Electric Vehicle Outlook was that "(d)irect electrification via batteries is the most efficient, cost-effective and commercially available route to fully decarbonizing road transport."5 Although ICCT predicts that IRA incentives could stimulate up to 56-67% electric vehicle sales by 2032,6 even Alternative 1 falls short of this level of electric vehicle sales share, let alone what is needed to meet climate goals. Further, given that ICE vehicles will make up the majority of the fleet for many years, it is also necessary to ensure greater GHG reductions from these vehicles. [EPA-HQ-OAR-2022-0829-0600, pp. 1-2]

BICEP members' abilities to meet their own climate commitments are contingent on strong standards that will ensure the availability of clean vehicles across the U.S. and drive the necessary shift to electrification. Unfortunately, the U.S. currently lags behind the European Union and China in EV sales,7and a recent study projects a shortage of EVs needed to meet American consumer demand.8 Strong U.S. vehicle emission standards are necessary to ensure the availability of clean vehicles for our members and the global competitiveness of the U.S. auto industry. Organization: Charles Forsberg

We conducted a series of workshops and wrote multiple papers on replacing all crude oil-domestically and internationally. By definition, this includes everything covered in the proposed EPA rule and all other uses of oil-based products. Based on those studies, the likely consequences of the proposed EPA rulemaking are much higher costs for light vehicles, failure to meet greenhouse gas reduction goals by decades, significant reductions in life expectancy and major reductions in incomes of the bottom 60% of the U.S. population. A summary of the basis for those conclusions and recommendations for EPA is provided herein. The recently published open-access paper (below) provides more detail and includes references to support these conclusions. [EPA-HQ-OAR-2022-0829-0738, p. 1]

Organization: Charles Gordon

CLIMATE MODELS are HIGHLY SPECULATIVE

The world has gotten warmer over the past 150 years. We have the measurements and we know the mechanism by which CO2 warms the world. These are facts. But we do not know what will happen in 10, 25 or 100 years. We have made guesses based on complex models. The predictions are not scientific facts as they purport to be. They are easily manipulated. They are created using lots of subjective judgement. Dr. Kooning, an expert, in his book "Unsettled" attached, shows. [EPA-HQ-OAR-2022-0829-0747, pp. 3-5]

That 10500 scientists swear by the model's predictions is not as meaningful as it appears. Ten thousand of those scientists are following the herd in areas outside their expertise. I have seen this in the l00's of scientists who I have dealt with in my OSHA career. Five hundred of those are experts in relevant areas with high standards for studies in their fields. But few scientists know or pay any attention to the historical record or pay much attention to conflicting data. [EPA-HQ-OAR-2022-0829-0747, pp. 3-5]

The models are created by having a computer expert create a speculative model. Then they see if it fits past data. It never does. So, changes are made to the model to see if it reflects past data better. This process is repeated many times until the model fits past data. That doesn't prove that it will fit the future, that is still a guess. Dr. Kooning explains this much more elegantly. Also because of the process of adjustment, the biases of the researchers will be incorporated, consciously or unconsciously. [EPA-HQ-OAR-2022-0829-0747, pp. 3-5]

Consequently, the models are easy to manipulate. When I was at OSHA, industry presented a complex pharmacokinetic model to show that a chemical was less dangerous than OSHA's simple, statistical model showed. So, an OSHA staffer asked an expert friend to see if he could create a pharmacokinetic model that showed more risk than OSHA's statistical model. He did! [EPA-HQ-OAR-2022-0829-0747, pp. 3-5]

I, myself, manipulated a model for fun. I had visited an old factory that used carbon disulfide. They had extensive exposure data and a study had been done showing excess cardiovascular risk of workers. I thought why might not the risk follow an S shaped curve, common for biologic functions rather than a linear or quadratic model. I made some fairly sensible adjustments to the exposure data. Sure enough, the risk followed an S shaped curve. The OSHA scientists laughed at me for being unscientific. But that is exactly what the scientists who make climate models do. [EPA-HQ-OAR-2022-0829-0747, pp. 3-5]

Also, at OSHA I worked with a scientist who was considered the country's foremost biostatistician. He worked for both industry and OSHA. With some exaggeration, he could make anything correlate or not correlate with anything else. [EPA-HQ-OAR-2022-0829-0747, pp. 3-5]

Yes, climate models provide some evidence about future climate change and the impacts of that change. But because of their speculative nature, they should not used to make massive changes in our technology and life style in a hurried way that will slow growth. They should be cautiously used to make adjustments at a slower pace to let the future tell us what the future is and what changes are needed or not needed. They should not be used to scare the population. [EPA-HQ-OAR-2022-0829-0747, pp. 3-5]

The EPA PRESENTS DATA in a MISLEADING WAY

The EPA presents reductions in CO_2 in terms of estimated millions of tons kept out of the atmosphere, an impressively large number. But the important number is the degree of warming prevented. That number was presented in the Wall Street Journal. As I recall, the proposed rule would reduce global warming by about 0.01 deg. C. The marginal benefits of reducing warming by the proposed 2027 rule must be balanced by the disruption, massive expensive changes required, and inconvenience to citizens caused. [EPA-HQ-OAR-2022-0829-0747, p. 5]

Although it is not within EPA's purview, the real problem is the coal being burned by India and China and that will increase. That is the own way that India can raise the standard of living of its extremely poor citizens. The same is true of much of Africa. There are more carbon friendly ways of providing energy to households, but not to industry except nuclear. We as a country and EPA forget that the burning of hydrocarbons over the past 150 years providing cheap and efficient energy is what made the West prosperous. That prosperity is what allows the West to afford to reduce the burning of hydrocarbons. [EPA-HQ-OAR-2022-0829-0747, p. 5]

Though this is not EPA's doing, presenting a temperature increase of 1.5 deg. C as causing terrible things and an increase of 2 deg. C as causing worse things is misleading as every EPA scientist knows. Various things happen over varying continuums and not at specific points. The use of the points 1.5 deg. C and 2 deg. Chas been very successfully used to generate regulatory and political action and to scare people. [EPA-HQ-OAR-2022-0829-0747, p. 5]

EPA presents the proposed reductions of particulates a health benefit. But EPA has been reducing particulate emissions from gas engines since 1968. I think it keeps claiming the same health benefits over and over. But the exhaust of gasoline engines is now so clean that further reductions are marginal. The major causes of particulates in the air are blown dirt, dust, tire scrubbing and clothes rubbing against clothes. If EPA reads auto magazines it will see that the particulate filters required on European cars reduce performance and economy. [EPA-HQ-OAR-2022-0829-0747, p. 5]

SCIENTISTS and their MODELS IGNORE the HISTORICAL RECORD

Fifteen thousand years ago the glaciers in the Northern Hemisphere retreated at a remarkably fast rate. That retreat led to human life as we know it. [EPA-HQ-OAR-2022-0829-0747, p. 6]

What if the cavemen had the power to prevent the glaciers from retreating which dramatically changed their life style. Where would we be today? That point is made by the cover drawing. [EPA-HQ-OAR-2022-0829-0747, p. 6]

There have been many changes in climate that had nothing to do with mankind. The warming and retreat of the glaciers 15,000 years ago - a short time in geological history. The warm Roman period which led to much wealth and prosperity. The cold of the middle-ages led to an increase in poverty and a loss of Roman technology on roads, water systems, sewage systems, medicine, etc. [EPA-HQ-OAR-2022-0829-0747, p. 6]

The Mayan civilization ended with drought not caused by man as did the Saharan Civilization. The England of Dickens was cold and snowy. The late 19th century was warm and England put its water and sewer pipes outside houses. When I lived in England in the 1960's we lived with frozen pipes from the cold of the 1950's and 60's. Time Magazine had a cover on the new cold era. [EPA-HQ-OAR-2022-0829-0747, p. 6]

The current climate change probably is partially affected by non-human caused factors. The climate modelers claim their models show that man is causing all the current climate change. But those models can't show that other factors in nature are not causing some of the change. Those models are designed to show man has caused it all - they don't explore alternate hypothesis. To make an estimate of how much climate change is caused by non-human factors a model has to be created to show that and then tested against the historical record. Like current models, it then has to be modified to fit the record, and then used to make a prediction of how much current climate change is caused by non-human factors. [EPA-HQ-OAR-2022-0829-0747, p. 6]

MAJOR CHANGES often have UNEXPECTED CONSEQUENCES

In the 1980's we worried about the ozone hole and its impact on humans and the environment. Scientists predicted that the escape of the coolant then used in air conditioners caused it. Countries then banned the use of that coolant and required the use of another coolant. The prediction was right and the change in coolant le to the shrinking of the ozone hole. But it turns out the escape of the new coolant adds to global warming. So now we will have to change our air conditioners to use another coolant which hopefully will not contribute to global warming. [EPA-HQ-OAR-2022-0829-0747, pp. 6-7]

In the 1970's we worried about the acidification of our lakes caused by sulfites and sulfates in the atmosphere. So, we phased-out the burning of high sulfur soft coal. That did reduce the acidification of lakes. But it turns out that the sulfites and sulfates in the atmosphere reflect sun light and kept the world cooler. So another change made by man had the unexpected consequence of warming the world. It takes hubris to think that ending the burning of hydrocarbons will not have unexpected consequences. One expected consequence is that overall, it will make the world's people poorer as switching will take the investment that otherwise would go to growth. [EPA-HQ-OAR-2022-0829-0747, pp. 6-7]

BENEFITS of GLOBAL WARMING

If EPA employees looked out their windows, they would see that global warming has some benefits - though not as great as its costs. Washington residents can move about much easier in the winter because of less snow. Heating bill are less. Washington has always had hot, hazy and humid summers. The½ degree F of summer warming is not noticeable. [EPA-HQ-OAR-2022-0829-0747, pp. 8-9]

The milder Chicago winters resulted in my mother and other older people not being housebound. Indeed, the entire Northeast has benefited from this warming. Warmer temperatures in Canada and Siberia will permit more wheat to be grown. Places like Anchorage will have a much more livable climate. Many, but not all species will adjust their habitat to the warmer climate. Crops will grow quicker more CO2 in the atmosphere. [EPA-HQ-OAR-2022-0829-0747, pp. 8-9]

Organization: Clean Fuels Alliance America

When considering options to help reduce greenhouse gas emissions from vehicles and equipment, there are two essential elements to consider: the amount of the reduction and when it happens. This is because carbon emissions are persistent and accumulate. The resulting increased levels of GHGs in the atmosphere contribute to global warming now and for decades to come. A reduction in GHG emissions now can avoid decades of associated heating, thus having significantly more value than carbon reductions made in the future. The time value of carbon is key, and the next decade is critical.3 The importance of reducing carbon today cannot be understated as the Intergovernmental Panel on Climate Change (IPCC) clearly reaffirmed in their

Sixth Assessment Report: Carbon reductions today are more important than carbon reductions in the future.4 [EPA-HQ-OAR-2022-0829-0626, p. 2]

Organization: Colorado Energy Office, Colorado Department of Transportation, and Colorado Department of Public Health and Environment

Our agencies strongly support EPA's development of national air pollution and GHG emission standards that are as robust as possible to ensure strong progress nationwide on air pollution and equity. A strong national light- and medium-duty vehicle standard is important to Colorado for at least three reasons. First, air pollution from nearby states crosses into Colorado and affects public health, and the longer duration and increased stringency of the proposed criteria air pollutant standards will reduce interstate air pollution transport into Colorado. Second, Colorado is already experiencing the impacts of climate change, including increased wildfires, floods, and drought. Climate change is a global issue that is impacted by all GHG emissions regardless of geographic source, and the reductions in GHG emissions from the proposed national rule will help reduce the long-term risks of climate change in Colorado. Finally, although the proposed national GHG emissions standards are not an explicit EV sales requirement like Advanced Clean Cars and Advanced Clean Cars II, complying with the standards will effectively require vehicle manufacturers to sell a significantly greater amount of EVs. The economies of scale encouraged by the proposed rules will support the production of more affordable EVs, easing the transition to zero emission vehicles and enabling greater access to their benefits for disproportionately impacted communities. [EPA-HQ-OAR-2022-0829-0694, p. 2]

Organization: Daniel Hellebuyck

Minimal Improvement on Global Warming: Reducing global warming requires a global effort. China and India- two countries with combined populations almost ten time the size of the Untied States- have not shown they are willing to do anything to reduce global warming. The US bearing the brunt of carbon emission reduction is an exercise in futility. In fact, global warming may actually be worse as companies shift jobs and factories from the United States to these low-wage countries to save money. [EPA-HQ-OAR-2022-0829-0526, p. 2]

Organization: David Hallberg

The Science is Incontrovertibly Clear

Contrary to OTAQ's false assurances, the rapid adoption of advanced engine technologies such as Gasoline Direct Injection (GDI) will dramatically increase emissions of the most harmful ultrafine particles (UFP) and secondary organic aerosols (SOAs) that bind with and insulate highly toxic polycyclic aromatic hydrocarbons (PAHs) and enable their long-range transport. The attached White Paper, authored by the UN Foundation's Special Advisor for Climate

Solutions and Chrysler's former Director for Regulatory Affairs, explains how the BTEX emissions threat is getting WORSE, not better. [EPA-HQ-OAR-2022-0829-0548, p. 2]

New White Paper Says The Real Cost of Gasoline …is to Our Health | Clean Fuels Development Coalition (cleanfuelsdc.org) [Link: https://cleanfuelsdc.org/2022/05/16/new-white-paper-says-the-real-cost-of-gasoline-is-to-our-health/] [EPA-HQ-OAR-2022-0829-0548, p. 2]

Many experts believe that the 20% BTEX fraction found in a typical gallon of U.S. gasoline poses the single greatest threat to public health and the environment. In their comments to the MY2023 LDV GHG Final Rule, the same two authors stated: "The effect of aromatics [BTEX] on pollution and human health is thus magnified twice over: Aromatics lead disproportionately to PAH formation, and PAHs lead disproportionately to SOA formation. Worse yet, PAHs hitch a ride on SOA for long distances and weaponize these particles as they travel through the human body…When SOA particles are formed in the presence of gas-phase PAHs, their formation and properties are significantly different from SOA particles formed without PAHs: They exhibit slower evaporation kinetics and have higher fractions of non-volatile components and higher viscosities, assuring their longer atmospheric lifetimes. This increased viscosity and decreased volatility act as a shield that protects PAHs from chemical degradation and evaporation, allowing for their long-range transport." [Detchon – Modlin MY2023 Final Rule comments, p. 17. RDRMCommentsEPA-HQ-OAR.pdf (cleanfuelsdc.org)] [Link: https://cleanfuelsdc.org/wp-content/uploads/2021/09/RDRMCommentsEPA-HQ-OAR.pdf] [EPA-HQ-OAR-2022-0829-0548, p. 2]

Organization: District of Columbia Department of Energy and Environment (DOEE)

As EPA mentions in Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles Section II, without substantial changes to the way people drive, how people travel, or what people use to travel, the District, and the United States as a whole, will not avoid the worst consequences of climate change. EPA recognizes that vehicles, including passenger vehicles, are major sources of air pollution and poor health, yet the proposed rulemaking from EPA fails to be analogous to the severity of the ensuing climate change impacts. In fact, EPA proposes to find that standards substantially more stringent than Alternative 1 would not be appropriate because of uncertainties concerning the cost and feasibility of such standards. EPA proposes to find that standards substantially less stringent than Alternative 2 or 3 would not be appropriate because they would forgo feasible emissions reductions that would improve the protection of public health and welfare. 88 FR 29201. [EPA-HQ-OAR-2022-0829-0550, p. 2]

DOEE recognizes that the costs involved in implementing and meeting stringent emissions requirements would be high. However, DOEE disagrees that standards substantially more stringent than Alternative 1 would be inappropriate due to cost and feasibility. The cost of inaction or insufficient action toward eliminating vehicle emissions in conjunction with climate change will be far greater to both public and environmental health and welfare. [EPA-HQ-OAR-2022-0829-0550, p. 2]

Organization: Donn Viviani

1) Why the proposed emission reductions are insufficient:

EPA has made significant progress in the past two years toward reducing GHG emissions. However, both EPA and OMB estimate that significant and extremely dangerous emissions will remain in the pipeline after implemen- tation of the Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles regulations (EV rule)2. This comment also takes into account other actions, i.e., the emission reduc- tions that will be achieved from the Infrastructure Investment and Jobs Act (IIJA)3 and the Inflation Reduction Act (IRA)4; implementation of the the new source performance standards for electrical generating units (EGU)5 and Greenhouse Gas Emissions Standards for Heavy-Duty Vehicles – Phase 36 . My comment shows that these actions will fall far short of keep- ing temperature rise to safe level and this threatens the initiation of nonlin- ear climate feedbacks. [EPA-HQ-OAR-2022-0829-0546, pp. 1-5]

5 https://www.federalregister.gov/documents/2023/05/23/2023-10141/new-source-perfor- mance-standards-for-greenhouse-gas-emissions-from-new-modified-and-reconstructed

6 https://nepis.epa.gov/Exe/ZyPDF.cgi?Dockey=P10178RN.pdf

The emissions remaining after implementation of these efforts will, accord- ing to EPA and OMB estimates, fail to restrict emissions sufficiently and in fact will consume the US share of the remaining carbon budget, which budget was conservatively calculated by the Intergovernmental Panel on Climate Change (IPCC)7. This budget must not be breached if we are to have a realistic chance to keep warming to 1.5 C, and avoid some of cli- mate change’s most catastrophic effects. [EPA-HQ-OAR-2022-0829-0546, pp. 1-5]

7 https://www.ipcc.ch/sr15/chapter/chapter-2/

Here’s why additional reductions are needed. According to the IPCC spe- cial report “Global Warming of 1.5 C “ 8 the remaining carbon budget is ~ 580 GtCO2 in order to have a 50% probability of limiting warming to 1.5°C, and ~420 GtCO2 for a 66% probability. The US has 4.25% of world population, so proportionally and at minimum (due to the oversize contribu- tion to the climate crisis attributable to our nation) the US has a remaining budget of ~ 26 GtCO2 for a 50% probability of limiting warming to 1.5°C, and a budget of ~19 GtCO2 for a 66% probability.9 [EPA-HQ-OAR-2022-0829-0546, pp. 1-5]

8 https://www.ipcc.ch/sr15/

9 The 95th percentile is the most common exposure limit used today by EPA.regulators (USEPA, 2016: Guidelines for Human Exposure Assessment), using the 50th or 66th percentile for a heat exposure limit is not conservative, allowing little room for modeling or other errors

While the EV RIA does not calculate the emissions remaining as a result of the rule, the emissions can be calculated from the reduction estimates. [EPA-HQ-OAR-2022-0829-0546, pp. 1-5]

The EV RIA predicts 7.3 Gt will be released from light and medium duty ve- hicles by 2055 if the EV penetration goals in the RIA10 are met. Transporta- tion is responsible for 28% of US

GHG emissions and the light and medium duty vehicles covered by the EV rule are responsible for ~57.5 % of that amount. [EPA-HQ-OAR-2022-0829-0546, pp. 1-5]

10 https://www.epa.gov/system/files/documents/2023-04/420d23003.pdf

The 7.3 Gt remaining after the rule is either ~ 28 % (for a 50% probability of avoiding 1.5C) or ~38% (for a 66% probability of avoiding 1.5C) of the entire remaining carbon budget But this regulated sector is responsible for only ~16% of total US emissions. Additionally after 2055 there will still be internal combustion vehicles on the road, and EGU will continue to emit GHGs to charge the BEV vehicles. So the EPA estimate is a bottom line for remaining emissions. Unless EPA has plans that will reduce emissions astonishingly fast in the other sectors, e.g., agriculture, construction, indus- try, etc., these reductions are insufficient. If EPA does have such plans, it is imperative they be made public. The public sector may have useful in- sights and suggestions. [EPA-HQ-OAR-2022-0829-0546, pp. 1-5]

OMB11 has calculated estimates of remaining emissions and time to zero emissions recently, these estimates were calculated prior to the EV pro- posal. However, these estimates don't properly meld or make sense with the emission reductions estimates found in three recent proposed rules: the light, medium and and heavy vehicle proposals; in the EGU proposal: or in the heavy duty vehicle proposal. For the OMB estimates to be correct, again, huge reductions would have to occur outside transportation and the power sector. I understand that these are all projections and estimates, but they are given weight in policy decisions, so they must fit together reason- ably well, or an explanation as to why they are so disparate is necessary. [EPA-HQ-OAR-2022-0829-0546, pp. 1-5]

11 https://www.whitehouse.gov/wp-content/uploads/2022/08/OMB-Analysis-Inflation-Reduction-Act.pdf

OMB12 characterized 2023 as a hinge point at which GHG emissions take a sharp downward trajectory. OMB had calculated that the US will reach zero emissions anywhere from 2044 to 2065 with a medium estimate of zero by 2055. This range depends on how aggressively various US incen- tives and rules are adopted. OMB posits possible annual emission de- clines of approximately 2.4%, 3.4% or 5.4% starting in 2023, with the rate depending on adoption of incentives and rules. OMB’s stated justification for the steady decline in the analysis is that "it's reasonable to assume" the emission reduction trajectory estimated by several models for 2023-2030 will continue forward at the same rate. [EPA-HQ-OAR-2022-0829-0546, pp. 1-5]

12 ibid

Based on OMB assumptions, the high, low and mid level adoptions give trajectories of emission reductions resulting in:
High adoption predicts a 5.4% decline and zero emissions in 2044 with ~58 Gt cumulative emissions left in the pipeline
Low adoption predicts a 2.4% decline and zero emissions in 2065 with ~115 Gt cumulative emissions left in the pipeline
Medium adoption predicts a 3.4% decline and zero emissions in 2055 with ~88 Gt cumulative emissions left in the pipeline [EPA-HQ-OAR-2022-0829-0546, pp. 1-5]

Emissions even at the most optimistic of these adoption rates would very quickly blow past the US share of the remaining carbon budget. [EPA-HQ-OAR-2022-0829-0546, pp. 1-5]

In any case, these “rosy” predictions are hard to credit. First, the IRA in- centives that drive the (modeled) 2023-2030 decline will all expire by 2033. Second, the two sectors, transportation and power generation, which have regulations proposed and that account for 53% of current emissions, don't decrease at those rapid rates. Both of these sectors will have Gt emissions still ongoing in 2055 and beyond, according to EPA's RIAs (regulatory im- pact analyses) of the power and transportation proposed rules. Third, the RIA for the phase 3 NSPS for heavy duty vehicles estimates ~12.8 Gt of emissions in the pipeline to 2055, with the methane emissions decreasing to about 2045 and then rising thereafter13. Fourth, there are no regulatory proposals for the sectors that comprise 47% of the remaining emissions, other than incentives in the IRA, which again, expire by the end of 2032 [EPA-HQ-OAR-2022-0829-0546, pp. 1-5]

13 https://nepis.epa.gov/Exe/ZyPDF.cgi?Dockey=P10178RN.pdf

To sum up, while the EPA and OMB estimates focussed on the GHG reduc- tions, this comment focusses on the GHG emissions that are still in the pipeline, i.e., will continue to be released after those reductions are real- ized. It laudatory that EPA is attempting to reduce emissions to the extent they have, but the important number is the emissions that EPA anticipates will still occur despite the incentives and regulations. These emissions un- dermine our decarbonization goals, in fact likely make them unreachable, and more importantly make much more probable catastrophic climate im- pacts and triggered irreversible feedbacks. EPA estimates that from the transportation sector (~20 Gt) and electric power sector (RIA estimates ~17 Gt through 2047)14 will release about 37 Gt through the mid 40s to mid 50s. None of these sectors will be at zero emissions, according to EPA by then, so these are minimum emission quantities. These are projections, and EPA must be congratulated for the complex modeling involved. They paint a dismal picture for achieving zero emissions by 2050. And a worse picture for avoiding the non-linear feedbacks that once they are triggered will act independent of additional emission. [EPA-HQ-OAR-2022-0829-0546, pp. 1-5]

14 https://www.epa.gov/system/files/documents/2023-05/utilities_ria_proposal_2023-05.pdf

Organization: Elders Climate Action

2. The Cost of Converting Auto and Truck Makers to ZEVs will be far less than the Cost to the National Economy of Climate Impacts

The Nation needs strong action from EPA now to achieve sharp reductions in CO2 emissions to slow the warming. Losses from climate related events cost the Nation an estimated $145 billion in 2021. Damage is expanding rapidly year over year. Delaying major reductions from the transport sector will have devastating consequences. [EPA-HQ-OAR-2022-0829-0737, p. 4]

The warmer climate has triggered a massive increase in damage from wildfire in the American West where an average of 1 million acres burned just 20 years ago, to over 15 million acres each in 2020 and 2021. Thousands of families have lost homes to fire, businesses were destroyed and communities lost schools, health care facilities, water and power supplies and other infrastructure. Smoke pollution smothered much of the West with dangerous levels of air pollution that added thousands of premature deaths across the region. The record setting heat wave in the Pacific NW in 2021 took hundreds of lives. Wildfire studies estimate deepening drought in the West will likely double the annual area destroyed by fire in this decade. We submit a review of the impacts of wildfire in the West and the expected impacts this decade because the social cost of carbon developed by the Interagency Working Group does not include wildfire impacts when estimating the damages associated with GHG emissions. [EPA-HQ-OAR-2022-0829-0737, p. 4]

In other regions of the U.S. more powerful hurricanes, extreme floods and massive tornadoes have caused devastation to hundreds of communities across the Gulf Coast, Mid- West and Northeast. These extreme weather events have become more powerful, more frequent and more destructive. [EPA-HQ-OAR-2022-0829-0737, p. 4]

The Nation needs your help now to slow the warming to protect our families and communities. Medium and heavy-duty vehicles are a major contributor to the warming. Medium- and heavy-duty trucks emit a quarter of climate pollution from transportation despite being only 10% of vehicles on the road. You must take action now that accelerates the transition to a zero emission transport sector. [EPA-HQ-OAR-2022-0829-0737, p. 4]

The latest climate modeling report (AR6) from the Intergovernmental Panel on Climate Change (IPCC) now makes clear that exceeding 1.5o C before 2050 is “more likely than not” even with implementation of the most aggressive GHG reduction scenario, but that the excursion above 1.5o C can be limited to a few decades if we reduce GHG emissions by half before 2030, and achieve net zero emissions by 2050. But if we fail to meet either of those targets, it is “more likely than not” that global temperatures will reach 2.0 o C with dire consequences for humanity. [EPA-HQ-OAR-2022-0829-0737, pp. 10-11]

To achieve net-zero emissions economy wide by 2050, zero emission technologies currently available must be deployed as soon as possible to put GHG emissions from our largest source of emissions – transportation – on the path toward zero. EPA’s proposed rule merely reduces carbon fuel combustion by less than 1%. A zero emission economy cannot be achieved if vehicles continue to burn carbon fuels. Internal combustion engines (ICEs) must be replaced as quickly as possible by zero emission vehicles (ZEVs). [EPA-HQ-OAR-2022-0829-0737, pp. 10-11]

EPA’s proposed L/MDV rule does not chart a course toward implementing either the national policy declared by President Biden or reflect the urgent need to cut GHG emissions in half by 2030 to avoid much worse future climate catastrophes. The rule preamble acknowledges that the proposed rule changes will reduce L/MDV CO_2 emissions by only .2 MMT during MY 2027 from 29 MMT to 28.8 MMT. Over the 20 year useful life of vehicles sold in MYs 2027-29 the rule will allow millions of diesel and gasoline vehicles to be added to the Nation’s highways which will emit an estimated 1.7 billion MT of CO_2. These emissions will wipe out more than half of the 3.1 billion MT of CO_2 reduction achieved by EPA’s SAFE 2 rule for light duty vehicles. These L/MDV emissions are the equivalent of operating 21 new coal-fired power plants. A large fraction of these emissions could be avoided if EPA adopted the CARB zero emission standard for L/MDVs in the ACT rule. The rule does not achieve, or describe how it will contribute to achieving, zero emissions by 2050. [EPA-HQ-OAR-2022-0829-0737, pp. 10-11]

We ask EPA to revise the rule to set a zero emission standard for all new L/MDVs by 2035, and establish a phase-in schedule for the standard that includes ZEV sales targets for MYs 2027-29 that are the same as the CARB ACT rule. [EPA-HQ-OAR-2022-0829-0737, pp. 10-11]

ZEV sales targets are needed now –

- to establish benchmarks for all engine manufacturers to create a level playing field that promotes competitive market conditions for zero emission vehicles based on performance, reliability and cost;

- to ensure a market for ZEVs that will justify early investment by third parties in the development of supply chains needed for production of batteries and fuel cells;

- to ensure the capacity of the industry to ramp up to 100% of sales to ensure that ZEVs will be available in time to replace on-road ICE vehicles by 2050;

- for MY 2027 to give the industry enough lead time to develop supply chains, plan the conversion of production facilities and develop marketing campaigns designed to assure public acceptance of their products. [EPA-HQ-OAR-2022-0829-0737, pp. 10-11]

B. Urgent Need for Zero GHG Emission Standard to Achieve GHG Reductions.

Harm to public health and the environmental, property and economic resources of our communities incorporated into the CAA definition of "public welfare" was anticipated and comprehensively described in the Administrator's Endangerment Finding that established the basis for regulating six GHGs under the CAA.4 All of the harms anticipated in 2009 have now been demonstrated to varying degrees, and are accelerating rapidly as the planet continues to heat up. [EPA-HQ-OAR-2022-0829-0737, pp. 11-13]

4 74 Fed. Reg. 66,496 (December 15, 2009).

1. The IPCC Findings.

Since the Endangerment Finding, EPA's catalogue of risks have been augmented by much more comprehensive modeling of warming trends, the warming expected from a range of global emission scenarios, and a description of the emission limitations that must be implemented to avoid more catastrophic climate outcomes. [EPA-HQ-OAR-2022-0829-0737, pp. 11-13]

The IPCC's 2018 report reviews and analyzes the then-available scientific literature to provide the best information available to answer two critical questions posed by world leaders at the Paris Climate conference: [EPA-HQ-OAR-2022-0829-0737, pp. 11-13]

1) What are the differences between the consequences of allowing the planetary climate system to rise 1.5o C compared to 2o C above the pre-industrial background?

2) What limitations on CO2 and other GHG emissions must be achieved to avoid overshooting a 1.5o C or a 2o C rise in global temperature?

(a) Consequences of 1.5o C and 2o C rise in global temperatures are both unacceptable, but 2o C is significantly worse. [EPA-HQ-OAR-2022-0829-0737, pp. 11-13]

The IPCC's 2018 report catalogues numerous expected adverse consequences of both a 1.5o C and a 2o C rise and in global mean temperature.5 Some of the effects of greatest concern are – [EPA-HQ-OAR-2022-0829-0737, pp. 11-13]

5 Global Warming of 1.5o C, Chapter 3: "Impacts of 1.5o C of global warming on natural and human systems."

1) increases in mean summer temperatures and the frequency of hot days above the 99th%ile of the baseline temperature range, and the increased duration of the summer dry season that, together, will more quickly desiccate the coastal and Cascade forests each year, increase the ignitability of forest fuels, increase the frequency and intensity of wildfires, increase the production of hazardous concentrations of fine particle pollution (smoke), and increase the adverse health consequences of public exposure to multi-day extreme hazard pollution episodes; [EPA-HQ-OAR-2022-0829-0737, pp. 11-13]

2) diminished summer stream flows that force curtailment of water for agricultural operations dependent on irrigation water, and contribute to warmer surface water temperatures that interfere with the survival of cold water fish species (e.g., salmonids) and contribute to algalblooms that produce toxic contamination of municipal and agricultural water supplies and fishery habitats; [EPA-HQ-OAR-2022-0829-0737, pp. 11-13]

3) increasing ocean acidification and ocean temperatures that together prevent reproduction and survival of some marine species, cause some native local species to abandon Oregon waters in search of cooler waters, and diminish productivity of species remaining in the local water column which in turn will reduce the catch, make commercial fishing unprofitable, and further reduce the food supply for human populations dependent on marine sources of protein and resident coastal orca populations that are now starving because of diminished food supply; [EPA-HQ-OAR-2022-0829-0737, pp. 11-13]

4) the frequency and duration of extreme precipitation events that cause flooding, erosion, displacement of human populations in flood-prone areas, the destruction of freshwater and anadromous fish spawning habitat and contamination of municipal water supplies; [EPA-HQ-OAR-2022-0829-0737, pp. 11-13]

5) warmer winter temperatures that convert winter snow precipitation events to rainfall thereby reducing the high altitude storage of water which diminishes water resources available for agriculture and municipal uses during the spring and summer, and increases the severity of drought by reducing stream flows, causing crop loss, loss of fishery habitat, and inadequate water supplies for residential and industrial users and fire fighting. [EPA-HQ-OAR-2022-0829-0737, pp. 11-13]

6) longer wildfire seasons and expanded burn zones that increase human exposure to hazardous levels of air pollution, including multi-week exposure to levels of fine particles (smoke) known to cause pre-mature death and other adverse health outcomes among vulnerable populations, and elevated concentrations of ground level ozone harmful to public health exacerbated by warmer summer temperature regimes that govern the chemistry of ozone formation in the atmosphere.6 [EPA-HQ-OAR-2022-0829-0737, pp. 11-13]

6 More Days With Haze: How Oregon is Adapting to the Public Health Risks of Increasing Wildfires," p. 5 (Oregon Health Authority, 2019) available at OHA 2688 More Days with Haze (oregon.gov).

All of these effects are occurring now, and are expected to increase in severity as climate warming accelerates. [EPA-HQ-OAR-2022-0829-0737, pp. 11-13]

(b) Expanding Wildfire Destruction and Smoke Mortality Correlates with Warming Climate.

The IPCC found that global mean temperature was about 1.0o C above the pre-industrial baseline in 2010. By 2010, the climate regime had not yet triggered large increases in wildfire conditions compared to historical fire patterns in the American West. But as the global mean advanced from 1.1 o C to 1.2 o C, new records were being set. The World Meteorological Organization (WMO) concluded that "[i]n 2020 – one of the three warmest years on record – the global average temperature was 1.2 °C above the pre-industrial baseline."7 [EPA-HQ-OAR-2022-0829-0737, pp. 13-15]

7 World Meteorological Organization, State of the Global Climate, 6 (April 2021); available at doc_num.php (wmo.int). WMO uses the "1850–1900 baseline as an approximation of pre-industrial levels." Id.

As the global temperature approached 1.2 °C, the frequency, intensity, areal extent and duration of wildfires have increased significantly in the last five years. In 2020 burns set records across the American West. California's burn area grew to nearly 5 million acres, and the total area burned in the 11 Western states exceeded 10 million acres: 2020 Western United States wildfire season - Wikipedia. The increasing area burned by wildfire in the American West tracks the Australian experience where annual fire zones expanded rapidly in response to drought leading to a massive wildfire season burning 46 million acres (an area equal to the State of Washington) during their 2019-20 austral summer.8 [EPA-HQ-OAR-2022-0829-0737, pp. 13-15]

8 List of major bushfires in Australia - Wikipedia, see Sept. 2019-March 2020.

During the 2017 fire season, wildfire in Oregon destroyed one-half million acres for the first time in the State's history. In 2018 wildfire consumed 660,000 acres of forest. In 2020 Oregon wildfires consumed 1.2 million acres,9 forced 500,000 Oregonians to evacuate their homes ahead of the flames, incinerated 4,000 homes displacing 10,000 Oregonians, leaving many families homeless, and killed 11. The 2020 burn area doubles the 2017 burn area, and is an order of magnitude greater than the statewide average of 120,000 acres burned during the 1990-2010 period. [EPA-HQ-OAR-2022-0829-0737, pp. 13-15]

9 https://en.wikipedia.org/wiki/2020_Oregon_wildfires (1,221,324 acres burned in 2020).

The 2018 IPCC report states that the global mean temperature is rising about 0.2o C per decade,10 twice the warming rate during the 20th Century. This accelerated warming rate suggested in 2018 that 1.5o C rise would be reached about 2035 unless large reductions in GHG emissions were achieved before 2030. New modeling performed for the 2021 IPCC report, AR6, indicates that 1.5o C above the pre-industrial baseline will be reached by 2030 if GHG emissions are held to current rates, and 2o C rise reached by 2050.11,12 WMO has since announced its estimate that the first annual 1.5o C rise in global temperature will likely occur by 2026.13 [EPA-HQ-OAR-2022-0829-0737, pp. 13-15]

10 Global Warming of 1.5o C, Chapter. 1 (Section 1.2.1.3).

11 "Analysis: When might the world exceed 1.5C and 2C of global warming? | Carbon Brief (Dec. 4, 2020).

12 Climate Change 2021: The Physical Basis (IPCC, 2021), Summary for Policy Makers, B.1.2. available at 2108-09 IPCC_AR6_WGI_SPM.pdf.

13 World Meteorological Organization, press release (May 27, 2021) available at https://public.wmo.int/en/media/press-release/new-climate-predictions-increase-likelihood-of-temporarily-reaching- 15-%C2%B0c-next-5.

Given that the frequency and ferocity of wildfire in the American West began to increase significantly after 2015 under the climate conditions associated with 1.1° C to 1.2° C rise above the 1850–1900 baseline, the march higher toward a 1.5o C rise between 2025 and 2030 can be expected to accelerate the frequency, severity and areal extent of damage caused by wildfire. [EPA-HQ-OAR-2022-0829-0737, pp. 13-15]

The Oregon Climate Assessment (OCAR5.pdf | Powered by Box, January 5, 2021) anticipates that the destruction of property, disruption of daily life, large costs to the economy, pollution of the atmosphere and water supplies, impairment of human health, and damage to wildlife, the environment and habitats will worsen in coming years as the climate continues to warm more rapidly. The Assessment cites studies predicting the effects of warming on seasonal heat causing a six-fold increase in hot days (>####90o F) in Oregon counties west of the Cascades during future Oregon summers (pp. 12-13), and reductions in summer precipitation (Table 2). Summers will be hotter and drier, and summer heat will start earlier and persist longer.14 The Assessment concludes that these conditions are conducive to "high-severity" wildfires: [EPA-HQ-OAR-2022-0829-0737, pp. 13-15]

14 Id., 3.

High-severity fires dominate wet, cool forests, including remnant old growth forests, in Oregon's Coast Range and western Cascade Range. High-severity wildfires in wet, cool forests typically are … facilitated by extremely dry and warm springs and summers or high winds. [EPA-HQ-OAR-2022-0829-0737, pp. 13-15]

As these conditions become more extreme, the area incinerated by wild fires is expected to increase (pp. 48-54). A 2017 forest modeling analysis "projected a 200% increase in median annual area burned in Oregon" during the 2010-2039 period compared to 1961-2004.15 Another 2017 study looking at fires across the American West estimates a 200-400% increase in the "annual probability of very large fires."16 Going forward, the Assessment makes clear that all "empirical models … consistently project that the area burned in Oregon will increase."17 [EPA-HQ-OAR-2022-0829-0737, pp. 13-15]

15 Climate Assessment, 53.

16 Id., 54.

17 Id., 53.

The fire zone doubled between 2017 and 2020. As predicted by forest science modeling, another doubling of the acres burned annually by 2025-30 is highly plausible as global temperature approaches 1.5° C above the pre-industrial baseline. [EPA-HQ-OAR-2022-0829-0737, pp. 13-15]

If fire zones expand to predicted levels in the Pacific NW, 25% to 40% of Oregon (15 to 25 million acres) and Washington (11 to 20 million acres) will be incinerated during this decade, economic activity will collapse and hazardous air quality will make the Northwest inhospitable to human habitation for most residents during the fire season. [EPA-HQ-OAR-2022-0829-0737, pp. 13-15]

The data and modeling estimates presented in the Oregon Climate Assessment and other sources predict a future in which the destruction of Oregon's forest resources by wildfire will continue until either 1) the cool and wet conditions that sustained Cascadia's forests during the 8,000 years before 1980 are restored, or 2) most of the standing forests are reduced to shrub or grasslands. [EPA-HQ-OAR-2022-0829-0737, pp. 13-15]

2. Impacts of Climate Warming on Public Health are Significant and Widespread.

Fire smoke and unprecedented hot temperatures are having a significant impact on human health as an example of the regional impact of heat waves, drought and wildfires. [EPA-HQ-OAR-2022-0829-0737, pp. 15-17]

The heat dome that raised temperatures above 110 F for three days in the Pacific NW in June 2021 caused over 200 heat-related deaths in Oregon and Washington. [EPA-HQ-OAR-2022-0829-0737, pp. 15-17]

Recent research demonstrates that emissions from wildfire are the largest source of fine particle pollution in large regions of the U.S., and contributed to thousands of pre-mature deaths. Wildfire in the western U.S. now accounts for half of all fine particle pollution in some areas of the West, doubling the exposure to PM2.5 [18] from non-fire sources including motor vehicles, power plants and industrial operations.19 [EPA-HQ-OAR-2022-0829-0737, pp. 15-17]

18 PM2.5 are particles smaller than 2.5 micrometers in diameter.

19 Burke, M. et al., The changing risk and burden of wildfire in the United States | PNAS (Jan 11, 2021).

A warming climate is responsible for roughly half of the increase in burned area in the United States (4), and future climate change could lead to up to an additional doubling of wildfire-related particulate emissions in fireprone areas (36) or a many-fold increase in burned area (37, 38). Costs from these increases include both the downstream economic and health costs of smoke exposure, as well as the cost of suppression activities, direct loss of life and property, and other adaptive measure (e.g., power shutoffs) that have widespread economic consequences.20 [EPA-HQ-OAR-2022-0829-0737, pp. 15-17]

20 Id.

Using satellite measurements of smoke plumes integrated with ground level monitored PM2.5 (fine particle) concentration data, Burke et al. estimate that between 7,000 and 14,500 deaths per year (depending on the dose/response curve used to estimate mortality from observed exposures) are attributable to fire smoke in the contiguous U.S. [EPA-HQ-OAR-2022-0829-0737, pp. 15-17]

Mortality and other health impacts such as asthma attacks and exacerbating COPD will be experienced most severely by communities already burdened by the adverse health effects of daily exposure to fine particle pollution emitted from tailpipes, power plants and industrial sources. Exposure to fire smoke in the American West during the 2020 fire season was universal. No communities were spared. But fire smoke at least doubled the annual exposure routinely suffered by BIPOC and low income communities living near major highways and industrial sources. [EPA-HQ-OAR-2022-0829-0737, pp. 15-17]

In Oregon, mortality attributed to fire includes many hundreds more deaths than the lives lost directly to fires. Statewide smoke pollution during the 2020 fires threatened lives and well- being with extreme hazard concentrations of particles known to cause pre-mature death and cancer, exacerbate asthma, COPD and other respiratory conditions, and cardio-vascular diseases. [EPA-HQ-OAR-2022-0829-0737, pp. 15-17]

The Oregon Health Authority (OHA) reports that “[t]he most severe recent air quality events in Oregon are due to wildfire smoke…”21 OHA cited a study finding that fire smoke in 2012 “caused hundreds of premature deaths, nearly 2,000 emergency room visits and more than $2 billion in health costs.”22 OHA points to the longer fire season as increasing the harm from exposure to smoke. “Fire seasons in Oregon are roughly 100 days longer than they were in the 1970s. Longer seasons mean more smoke in Oregon communities.”23 The greater density of smoke and longer duration of smoke exposure in 2020 likely at least doubled the mortality caused by smoke exposure compared to 2012. [EPA-HQ-OAR-2022-0829-0737, pp. 15-17]

21 Oregon Climate and Health Report, 40 (Oregon Health Authority, 2020).

22 Id., 33.

23 Id.,

In addition, low income families without air conditioning are much less able to escape smoke pollution by closing doors and windows during the summer heat to keep themselves safe. [EPA-HQ-OAR-2022-0829-0737, pp. 15-17]

Workers cannot avoid exposure to smoke pollution if required to work outdoors. [EPA-HQ-OAR-2022-0829-0737, pp. 15-17]

Beyond the economic and environmental damage, social disruption, and harm to health that will result from a longer fire season and expanded fire zones, more deadly air quality will likely make parts of the American West uninhabitable during the fire season for the most vulnerable populations such as the elderly, children and those with existing respiratory and cardiovascular conditions. [EPA-HQ-OAR-2022-0829-0737, pp. 15-17]

These recent data and other sources published since 2009, including the data discussed at length in the Administrator’s 2009 Endangerment Finding, 74 Fed. Reg. 66,496 (December 15, 2009), confirm the finding that EPA made 12 years ago: “The Administrator finds that the elevated atmospheric concentrations of the well-mixed greenhouse gases may reasonably be anticipated to endanger the public health and welfare of current and future generations.” Id., at 66,523. [EPA-HQ-OAR-2022-0829-0737, pp. 15-17]

3. Net-Zero Emissions Must be Achieved as Soon as Possible to Protect Public Health and the Public Welfare.

The climate will need to be stabilized as soon as possible to – [EPA-HQ-OAR-2022-0829-0737, pp. 17-19]

- protect public health from the deadly effects of heat waves and wildfire smoke particles;

- preserve the health, safety and quality of life in the American West from the devastation caused by massive uncontrollable wildfires;

- preserve the health, safety and quality of life for millions of Americans living along the Gulf Coast from the devastation caused by super hurricanes,

- preserve the health, safety and quality of life for hundreds of millions of Americans living in the Mid-West and Northeast from the deaths and devastation caused by massive flooding,

- to protect the health, safety and quality of life for millions living in Tornado Alley from the Great Plains to the upper South;

- to protect forests so that they may serve as a sink for CO2 rather than as an emission source;

- preserve habitat for wildlife and a resource for forest products and other industries dependent on them, and

- protect the vitality of the marine web of life from collapse as a result of acidification.

[EPA-HQ-OAR-2022-0829-0737, pp. 17-19]

The IPCC provided clear guidance in its 2018 report that to stop the warming and stabilize the climate, the economy must transition to a zero carbon (CO2 and methane) emission energy system, and forests must be expanded to extract CO2 from the atmosphere. Climate stability can be achieved only by reducing GHG emissions to net-zero. [EPA-HQ-OAR-2022-0829-0737, pp. 17-19]

To stabilize global temperature at any level, 'net' CO2 emissions would need to be reduced to zero. This means the amount of CO2 entering the atmosphere must equal the amount that is removed. Achieving a balance between CO2 'sources' and 'sinks' is often referred to as 'net zero' emissions or 'carbon neutrality'.24 [EPA-HQ-OAR-2022-0829-0737, pp. 17-19]

24 Global Warming of 1.5o C, Chapter 2, FAQs.

Limiting warming to 1.5°C implies reaching net zero CO2 emissions globally around 2050 and concurrent deep reductions in emissions of non-CO2 forcers, particularly methane25 (high confidence). Such mitigation pathways are characterized by energy-demand reductions, decarbonization of electricity and other fuels, electrification of energy end use, deep reductions in agricultural emissions, and some form of CDR [carbon dioxide reduction] with carbon storage on land or sequestration in geological reservoirs.26 [EPA-HQ-OAR-2022-0829-0737, pp. 17-19]

25 Methane (CH4, i.e, unburned natural gas) is 20 times more powerful than CO2 as a climate forcer.

26 Id., Exec, Summary.

Zero GHG emissions to stabilize the climate must be achieved sooner than later to minimize the losses and deaths associated with devastating warmer climate effects. Zero emissions cannot be achieved without transforming transportation which is the largest source of GHG emissions. For most transportation sources such as on-road vehicles, zero emissions can be cost-effectively achieved by electrification with batteries or fuel cells. [EPA-HQ-OAR-2022-0829-0737, pp. 17-19]

The latest IPCC modeling report (AR6, 2021) concludes based on the latest climate data and updated modeling that – [EPA-HQ-OAR-2022-0829-0737, pp. 17-19]

Under the five illustrative [GHG emissions] scenarios, in the near term (2021-2040), the 1.5°C global warming level is very likely to be exceeded under the very high GHG emissions scenario (SSP5-8.5), likely to be exceeded under the intermediate and high GHG emissions scenarios (SSP2-4.5 and SSP3-7.0), more likely than not to be exceeded under the low GHG emissions scenario (SSP1-2.6) and more likely than not to be reached under the very low GHG emissions scenario (SSP1-1.9).27 [EPA-HQ-OAR-2022-0829-0737, pp. 17-19]

27 Climate Change 2021, Summary for Policymakers, B.1.3. (available at IPCC_AR6_WGI_SPM.pdf.)

The opportunity to stay below 1.5°C and to prevent the additional devastation that such level of warming will cause, has been frittered away by inaction and delay. At the current global mean temperature, the climate has warmed enough to endanger public health, cause devastating destruction of homes and businesses, loss of life and the disruption of natural systems by extreme floods, drought, wildfires, hurricanes and tornadoes. The harm we will experience above 1.5°C will be orders of magnitude greater. [EPA-HQ-OAR-2022-0829-0737, pp. 17-19]

But the IPCC offers the hope that "for the very low GHG emissions scenario (SSP1-1.9), it is more likely than not that global surface temperature would decline back to below 1.5°C toward the end of the 21st century, with a temporary overshoot of no more than 0.1°C above 1.5°C global warming."28 [EPA-HQ-OAR-2022-0829-0737, pp. 17-19]

28 Id.

That hope turns on cutting global CO2 emissions in half by 2030, and to net-zero by 2050 along with large reductions in non-CO2 climate forcers such as methane. EPA has not set out a regulatory path for achieving those reductions. EPA's current proposed rule will not achieve anywhere near those reductions, and fails to identify any future strategy for achieving those reductions. To fulfill the Agency's statutory mission to protect public health and welfare it must issue regulations that achieve these targets. [EPA-HQ-OAR-2022-0829-0737, pp. 17-19]

C. Petition for Finding --

Based on these data and other available evidence, we petition the Administrator to find that – climate warming already caused by GHG emissions harms the public health and is causing unacceptable adverse impacts on public welfare and the human environment, and the expected increase in the severity and frequency of harms to health and the public welfare that will be caused by more extreme events that will occur as the global mean temperature advances toward and above the 1.5°C level resulting from growing GHG concentrations in the atmosphere, establish the need for a zero GHG emissions standard for L/MDVs pursuant to section 202(a)(1) and (3)(A) of the Clean Air Act. [EPA-HQ-OAR-2022-0829-0737, p. 20]

We petition the Administrator to make this finding as the predicate for re-opening this rulemaking for the purpose of promulgating a zero emission standard for L/MDVs, and a phase-in schedule that prescribes for each automaker a share of total L/MDV sales that must be ZEVs beginning with the 2027 MY. [EPA-HQ-OAR-2022-0829-0737, p. 20]

Organization: Electrification Coalition (EC)

In addition to our national security challenges, the U.S. also faces the rapidly growing threat of climate change. The latest National Climate Assessment4, which Congress mandated in 1990 under the Global Change Research Act, shows that the U.S. has been observing the impacts of climate change for decades and that more frequent and extreme weather and climate-related events are creating new and increasing risks across U.S. communities – which we have recently seen with wildfires that have ravaged the country, more powerful hurricanes causing loss of lives and immense destruction, more intense tornadoes destroying communities, and extreme weather events in areas that we should not expect to see these weather events in. [EPA-HQ-OAR-2022-0829-0588, p. 2]

To overcome these national security concerns from climate change, the U.S. must reduce carbon emissions. The EPA notes that the transportation sector is the largest source of greenhouse gas emissions, representing 27% of total greenhouse gas emissions.5 [EPA-HQ-OAR-2022-0829-0588, p. 2]

Organization: Energy Innovation

I. The U.S. must transition LDVs and MDVs to zero-emission technologies [i] quickly to reduce their emissions, which contribute to climate change and air pollution—both of which endanger public health and welfare. Adoption of the most stringent tailpipe standards for new vehicles is the most effective tool to achieve this goal. [EPA-HQ-OAR-2022-0829-0561, pp. 1-2]

i This includes technologies that eliminate tailpipe GHG emissions and other pollutants, namely battery electric vehicles for LDVs and MDVs.

. THE U.S. MUST TRANSITION LIGHT-DUTY AND MEDIUM-DUTY VEHICLES TO ZERO-EMISSION TECHNOLOGIES QUICKLY TO REDUCE THEIR EMISSIONS, WHICH CONTRIBUTE TO CLIMATE CHANGE AND AIR POLLUTION—BOTH OF WHICH ENDANGER PUBLIC HEALTH AND WELFARE. ADOPTION OF THE MOST STRINGENT TAILPIPE STANDARDS FOR NEW VEHICLES IS THE MOST EFFECTIVE WAY TO ACHIEVE THESE GOALS. [EPA-HQ-OAR-2022-0829-0561, p. 3]

We appreciate and agree with the EPA's thorough articulation of the sizable impact LDVs and MDVs have on climate and public health. The transportation sector is the largest U.S. source of GHG emissions as of 2021,2 and LDVs and MDVs combined are the largest contributor within the sector (with LDVs alone accounting for more than 57 percent).3 These vehicles also emit pollutants such as ozone, particulate matter (PM), nitrogen dioxide (NO_2), sulfur dioxide (SO_2), carbon monoxide (CO), and air toxics—all of which contribute to poor air quality and are linked to adverse health outcomes, with disproportionate impacts on children,4 people of color, and people with low socioeconomic status living near or attending school near major roads.5 [EPA-HQ-OAR-2022-0829-0561, p. 3]

2 "Fast Facts on Transportation Greenhouse Gas Emissions," United States Environmental Protection Agency (U.S. EPA), Green Vehicle

Guide, 2021, https://www.epa.gov/greenvehicles/fast-facts-transportation-greenhouse-gas-emissions. [EPA-HQ-OAR-2022-0829-0561, p. 3]

3 U.S. EPA, "Proposed Rules," May 5, 2023, 29186.

4 U.S. EPA, 29211.

5 U.S. EPA, 29186 and 29395-7.

The inherently slow stock turnover challenge in the ground transportation sector means that new vehicles—and the standards they are built to in the coming years—will have long-lasting effects on the vehicle fleet 10 and even 20 years from now. This, in turn, will have long-lasting impacts on climate, public health, and welfare. [EPA-HQ-OAR-2022-0829-0561, pp. 3-4]

The EPA clearly articulates the primary takeaways from the well-established body of scientific research regarding the public health impacts of climate change throughput the proposed rule, and we concur with their summary: “elevated concentrations of GHGs have been warming the planet, leading to changes in the Earth’s climate including changes in the frequency and intensity of heat waves, precipitation, and extreme weather events, rising seas, and retreating snow and ice. The changes taking place in the atmosphere as a result of the well- documented buildup of GHGs due to human activities are changing the climate at a pace and in a way that threatens human health, society, and the natural environment.”6 [EPA-HQ-OAR-2022-0829-0561, pp. 3-4]

6 U.S. EPA, 29207-8.

The latest Intergovernmental Panel on Climate Change report corroborates these findings and makes clear that this is the decade for action if we are to reverse course on untenable and dangerous climate change: “In this decade, accelerated action to adapt to climate change is essential to close the gap between existing adaptation and what is needed. Meanwhile, keeping warming to 1.5°C above pre-industrial levels requires deep, rapid and sustained [GHG] emissions reductions in all sectors. Emissions should be decreasing by now and will need to be cut by almost half by 2030, if warming is to be limited to 1.5°C.” [EPA-HQ-OAR-2022-0829-0561, pp. 3-4]

7 Intergovernmental Panel on Climate Change, “Press Release: Urgent Climate Action Can Secure a Liveable Future for All,” March 20, 2023,

https://www.ipcc.ch/report/ar6/syr/downloads/press/IPCC_AR6_SYR_PressRelease_en.pdf. [EPA-HQ-OAR-2022-0829-0561, pp. 3-4]

Organization: Environmental. and Public Health Organizations

EPA has both an opportunity and an obligation to dramatically reduce emissions of greenhouse gases (GHGs) and other pollutants from light-duty vehicles (LDVs) and medium-duty vehicles (MDVs). The Agency’s mandate to protect public health and welfare is made urgent by the ever more dire impacts of climate change, as well as the continuing harms to public health from vehicle criteria pollution. And the opportunity to significantly reduce these impacts is clear. Zero-emission vehicles (ZEVs) are not only feasible and cost-reasonable—they are rapidly penetrating the fleet, with more than 250,000 fully battery electric vehicles sold in the first quarter of 2023 alone, a 44.9% increase over the same period last year.1 In addition, numerous emission control technologies for combustion vehicles are also feasible, cost-reasonable, and already extensively deployed on the fleet, yet still have potential for greater application within the fleet of new combustion vehicles that will continue to be produced. [EPA-HQ-OAR-2022-0829-0759, p. 8]

1 Cox Automotive, Another Record Broken: Q1 Electric Vehicle Sales Surpass 250,000, as EV Market Share in the U.S. Jumps to 7.2% of Total Sales (Apr. 12, 2023), https://www.coxautoinc.com/market-insights/q1-2023-ev-sales/.

While the market is clearly heading in the right direction, EPA's standards should facilitate even greater deployment of zero-emission and combustion vehicle technologies to help protect the public from the destructive effects of climate change and air pollution generally. To this end, we urge EPA to finalize the strongest possible emission standards. While we do not believe it is necessary for EPA to set standards beyond 2032 at this point, it is critical that the final standards are sufficiently stringent through model year 2032 to ensure that the U.S. is on track to reach 100% new ZEV sales in 2035. The standards in Alternative 1, but with greater stringency after 2030, are feasible and would better serve EPA's statutory mandate to address the environmental and health impacts of air pollution from light- and medium-duty vehicles. Finalizing such standards will provide feasible, critical air pollution emission reductions, as directed by Congress in the Clean Air Act. [EPA-HQ-OAR-2022-0829-0759, pp. 8-9]

Once EPA makes an endangerment finding, it must set standards that are commensurate to the magnitude of the danger to public health and welfare posed by the covered emissions.12 The Clean Air Act defines "effects on welfare" broadly, including "effects on . . . weather . . . and climate."13 The dangers to public health and welfare posed by GHGs that EPA originally cited in the 2009 Endangerment Finding—"risks associated with changes in air quality, increases in temperatures, changes in extreme weather events, increases in food- and water-borne pathogens, and changes in aeroallergens,"14 to name a few—have only increased. EPA recognized that this was likely to happen in the Endangerment Finding itself, finding that these "risk[s] and the severity of adverse impacts on public welfare are expected to increase over time."15 As for criteria pollutants and air toxics—PM, ozone, VOCs, NOx, SOx, CO, diesel exhaust, formaldehyde, acetaldehyde, acrolein, benzene, butadiene, ethylbenzene, naphthalene, and POM/PAHs—their harmful health and environmental effects have long been known, and EPA has recognized the need for continued reductions in their emissions.16 [EPA-HQ-OAR-2022-0829-0759, p. 10]

12 See Massachusetts, 549 U.S. at 532 (noting that Section 202(a) "charge[s] [EPA] with protecting the public's 'health' and 'welfare'"); Coal. for Responsible Regulation v. EPA, 684 F.3d 102, 117, 122 (D.C. Cir. 2012) (stating that EPA must carry out "the job Congress gave it in § 202(a)—utilizing emission standards to prevent reasonably anticipated endangerment from maturing into concrete harm"). See also S. Rep. No. 91-1196, at 24 (1970), reprinted in A Legislative History of the Clean Air Amendments of 1970, at 424 (1974) (Section 202(a) requires EPA to "make a judgment on the contribution of moving sources to deterioration of air quality and establish emission standards which would provide the required degree of control."). Cf. 74 Fed. Reg. at 66505 ("the Administrator is required to protect public health and welfare, but she is not asked to wait until harm has occurred. EPA must be ready to take regulatory action to prevent harm before it occurs.").

III. Further Reductions in Emissions of GHGs and Criteria Pollutants from Motor Vehicles Are Necessary to Protect Public Health and the Environment.

A. Vehicular emissions of greenhouse gases gravely endanger public health and welfare by intensifying the climate crisis.

Emissions of GHGs from the transportation sector pose mortal dangers to public health and the environment; EPA's exercise of its responsibilities under the Clean Air Act must take account of and mitigate these dangers. Over thirteen years ago, based upon a massive scientific record, the EPA found that new motor vehicles and engines contribute to emissions of GHGs that drive climate change and endanger the health and welfare of current and future generations.46 Specifically, EPA found that the intensifying climate crisis increased the frequency of warmer temperatures, heat waves, and other extreme weather, worsened air quality by increasing regional ozone pollution, increased the spread of food and water-borne illnesses, increased the frequency and severity of seasonal allergies, and increased the severity of coastal storm events due to rising sea levels.47 [EPA-HQ-OAR-2022-0829-0759, p. 14]

46 74 Fed. Reg. at 66496.

47 74 Fed. Reg. at 66525–26.

Since EPA issued the Endangerment Finding in 2009, dire evidence of the current and future impacts of climate change has continued to accumulate. Recent studies demonstrate that climate change continues to cause heat waves and extreme weather events across the United States.48 Between May and mid-September, 2022, "nearly 10,000 daily maximum temperature records were broken."49 Additionally, 2022 was "one of the top 10 hottest years on record for daily maximum temperatures" in 13 states, as well as one of the top 10 hottest for daily minimum (nighttime low) temperatures for 31 states.50 Warmer temperatures endanger public health by increasing the risk of heart disease, worsening asthma and chronic obstructive pulmonary disease from increases of ground-level ozone, and causing dehydration and many other ailments.51 Studies have also found that heat waves and extreme weather events cause severe psychiatric and mental health impacts.52 Climate change continues to lead to higher than normal pollen concentrations and earlier and longer pollen seasons, causing worse allergies and asthma.53 The intensifying climate crisis also increases the risk of drought across the U.S, which impacts water supply, agriculture, transportation, and energy, and increases the risk and magnitude of wildfires.54 And recent projections show that sea level rise is anticipated to be on the high end of model projections.55 Studies have found that many of the dangers wrought by climate change exact a higher toll on people with low incomes and people of color.56 [EPA-HQ-OAR-2022-0829-0759, pp. 14-15]

The transportation sector has been responsible for an increasing percentage of GHG emissions in the U.S. since 2009, thereby playing an outsized role in intensifying the climate crisis. When EPA made its Endangerment Finding for GHGs, the transportation sector was responsible for 23% of total annual U.S. GHG emissions.57 Since then, transportation sector GHG emissions have only increased as a share of U.S. emissions, surpassing the electric power sector as the largest U.S. source of GHG emissions and contributing 27.2% of total GHG emissions in 202058 and 28.5% in 2021.59 After dipping in 2020 due to the COVID-19 pandemic, carbon dioxide (CO2) emissions from the transportation sector increased by 11.5% between 2020 and 2021.60 Transportation as an end use sector "account[ed] for 1,757.4 [million metric tons] CO2 in 2021 or 37.9% of total CO2 emissions from fossil fuel combustion."61 Adopting stringent GHG emission standards for light- and medium-duty vehicles will lead to massive public health benefits by limiting these pollutants.62 [EPA-HQ-OAR-2022-0829-0759, p. 16]

The IPCC's most recent synthesis of its Sixth Assessment Report confirms the danger to public health and welfare posed by GHG emissions from the transportation sector. The report found that global surface temperature was around 1.1°C higher in 2011-2020 than it was in 1850-1900.63 While average annual GHG emissions growth has slowed in certain sectors such as energy supply and industry, growth in GHG emissions from the transportation sector has remained relatively constant at about 2% per year.64 The latest IPCC report warned that "[d]eep, rapid and sustained GHG emissions reductions, reaching net zero CO2 emissions and including strong emissions reductions of other GHGs . . . are necessary to limit warming to 1.5°C . . . or less than 2°C . . . by the end of the century."65 To have a chance at limiting global temperature increase to 1.5? and avoid the worst impacts of climate change, current GHG emissions from the transportation sector must drop by 59% by 2050 compared to 2020 emissions.66 [EPA-HQ-OAR-2022-0829-0759, p. 16]

Air pollution has become so significant that the public health burdens attributable to air pollution are "now estimated to be on a par with other major global health risks such as unhealthy diet and tobacco smoking, and air pollution is now recognized as the single biggest environmental threat to human health."70 Researchers at the University of Chicago studied the impact of air pollution on life expectancy and found that "the impact of particulate pollution on life expectancy is comparable to that of smoking, more than three times that of alcohol and unsafe water and sanitation, six times that of HIV/AIDS, and 89 times that of conflict and terrorism."71 [EPA-HQ-OAR-2022-0829-0759, p. 17]

These reductions are significant on a national and global scale because greenhouse gas emissions from light- and medium-duty vehicles are a consequential portion of both national and international GHG emissions. Emissions from the transportation sector are the largest source

(29%) of GHGs in the country, and light- and medium-duty vehicles are the largest portion of that.77 The United States is responsible for a large portion of global CO2 emissions—approximately 14% as of 2019—and is the second largest emitter in the world.78 Reducing GHG emissions from light- and medium- duty vehicles is therefore one of the most consequential steps EPA—or the United States—can take to mitigate climate change harm. And, as the Supreme Court found in Massachusetts v. EPA, "[a] reduction in domestic emissions would slow the pace of global emissions increases, no matter what happens elsewhere." 549 U.S. 497, 500 (2007). [EPA-HQ-OAR-2022-0829-0759, p. 19]

A. Protective standards are urgently needed to safeguard public health.

The transportation sector is now the single largest source of greenhouse gas emissions in the United States, and passenger cars and trucks are the largest contributor, at 58 percent of all transportation sources and 17 percent of total U.S. greenhouse gas emissions. [EPA-HQ-OAR-2022-0829-0786, p. 6]

Organization: Governing for Impact and Evergreen Action (GFI)

In addition to contributing to the climate crisis, light and medium duty passenger vehicles are responsible for emitting harmful pollutants including carbon monoxide, particulate matter, and nitrogen oxides, which can cause or contribute to significant negative public health outcomes such as lung and heart diseases.15 These harmful health outcomes disproportionately affect low income populations and communities of color, who are exposed to greater amounts of vehicle pollution.16 Unfortunately, these same communities are at the greatest risk of harm from the impacts of climate change, and often lack sufficient resources or support to protect themselves from these harmful impacts.17 Strong transportation emissions standards — for both GHGs and criteria pollutants — will limit the present and imminent public health threats that vulnerable populations face due to vehicle pollution. [EPA-HQ-OAR-2022-0829-0621, pp. 2-3]

Organization: GreenLatinos et al.

The strongest possible HDV and L/MDV standards will help reach the urgent goal to cut greenhouse gas emissions by 60% by 2030 and will put American cars and trucks on a clear path towards achieving 100% zero emission electric vehicle (EV) sales by 2035 or earlier. [EPA-HQ-OAR-2022-0829-0789, p. 2]

The Biden administration's leadership in setting strong HDV and L/MDV standards is instrumental to mitigate the inequitable tailpipe pollution experienced by Latino/e and other frontline communities, which triggers asthma and other sometimes fatal respiratory illnesses. [EPA-HQ-OAR-2022-0829-0789, p. 2]

We need the cleanest possible vehicles now. Our lives literally depend on it. [EPA-HQ-OAR-2022-0829-0789, p. 2]

Organization: Institute for Policy Integrity at NYU School of Law et al.

Other key legal commitments compel this same conclusion. For instance, the United Nations Framework Convention on Climate Change—to which the United States is a party26— declares that national "policies and measures to deal with climate change should be cost- effective so as to ensure global benefits at the lowest possible cost."27 The Convention further commits parties to evaluate global climate effects in their policy decisions, by "employ[ing] appropriate methods, for example impact assessments . . . with a view to minimizing adverse effects on the economy, on public health and on the quality of the environment, of projects or measures undertaken by them to mitigate or adapt to climate change."28 The unmistakable implication of the Convention is that parties—including the United States—must account for global economic, public health, and environmental effects in their impact assessments. In 2008, a group of U.S. senators—including then-Senator John Kerry, who helped ratify the framework convention on climate change—agreed with this interpretation of the treaty language, saying that "[u]pon signing this treaty, the United States committed itself to considering the global impacts of its greenhouse gas emissions."29 [EPA-HQ-OAR-2022-0829-0743, p. 5]

Framework Convention on Climate Change art. 3(3), May 9, 1992, 1771 U.N.T.S. 107 (emphasis added); see also id. art. 3(1) ("The Parties should protect the climate system for the benefit of present and future generations of humankind, on the basis of equity and in accordance with their common but differentiated responsibilities and respective capabilities.") (emphasis added); id. art. 4(2)(a) (committing developed countries to adopt policies that account for "the need for equitable and appropriate contributions by each of these Parties to the global effort").

28 Id. art. 4(1)(f) (emphasis added); see also id. art. 3(2) (requiring parties to give "full consideration" to those developing countries "particularly vulnerable to the adverse effects of climate change"); see also North American Agreement on Environmental Cooperation art. 10(7), Jan. 1, 1994, 32 I.L.M. 1480 (committing the United States to the development of principles for transboundary environmental impact assessments).

29 Comment Letter from U.S. Sens. Feinstein, Snowe, Nelson, Cantwell, Sanders, Kerry, Durbin, Reed, Boxer, & Cardin to Mary Peters, Sec'y, U.S. Dep't of Transp. on Proposed Rule for Average Fuel Economy Standards, Passenger Cars and Light Trucks; Model Years 2011–2015 (July 1, 2008).

This flurry of activity is just the latest evidence of reciprocity in international climate actions. Some past reciprocity has been explicit. The Kigali Amendment, for example, is the latest internationally negotiated climate treaty, with more than 120 parties so far committing to common but differentiated responsibilities to phase down hydrofluorocarbons.46 Previously, under the Copenhagen Accord and the Paris Agreement, some parties, including the European Union and Mexico, have at times explicitly made conditional pledges, promising to ratchet up their efforts if other countries make comparable reductions.47 By contrast, when the United States "failed to take action to reduce greenhouse gas emissions during the George W. Bush Administration and during . . . the Trump Administration," as economist Michael Greenstone has testified before the U.S. House of Representatives, "both periods were characterized by little [international] progress, and indeed many instances of backsliding, in reducing emissions globally."48 By failing to take international climate damages into account, in other words, EPA and other U.S. agencies would incentivize other countries to do the same, which in turn would cause greater greenhouse gas pollution originating in other countries that causes climate damage within the United States. 2. Use of the Global Values Recognizes Spillover Impacts from Climate Change

As EPA further recognizes, spillover impacts into the United States also support the use of global damage valuations.53 Significant costs to trade, human health, and security will inevitably "spill over" to the United States as other regions of the planet experience climate change damages.54 Due to its unique place among countries—both as the largest economy with trade- and investment-dependent links throughout the world, and as a military superpower—the United States is particularly vulnerable to effects that will spill over from other regions of the world. The use of global damage values recognizes these spillover effects, which were ignored under the Trump administration's domestic-only valuation. [EPA-HQ-OAR-2022-0829-0743, p. 9]

53 RIA at 10-11; see also Draft SC-GHG Update, supra note 9, at 11–13.

54 Though some positive spillover effects are also possible, such as technology spillovers that reduce the cost of mitigation or adaptation, see S. Rao et al., Importance of Technological Change and Spillovers in Long-Term Climate Policy, 27 ENERGY J. 123–39 (2006), overall climate spillovers are likely strongly negative, see Jody Freeman & Andrew Guzman, Climate Change and U.S. Interests, 109 COLUM. L. REV. 1531 (2009).

These spillover effects take many forms. In terms of trade-related impacts, for one, as climate change disrupts the economies of other countries, decreased availability of imported inputs, intermediary goods, and consumer goods will cause supply shocks to the U.S. economy, causing particularly damaging disruptions in sectors such as agriculture and technology. [EPA-HQ-OAR-2022-0829-0743, p. 9]

Similarly, the U.S. economy will experience demand shocks as climate-affected countries decrease their demand for U.S. goods. U.S. trade and businesses that rely on foreign-owned infrastructure, services, and resources will suffer.55 Financial markets will also suffer as foreign countries become less able to loan money to the United States and as the value of U.S. firms declines with shrinking foreign profits. As seen historically, economic disruptions in one country can cause financial crises that reverberate globally at a breakneck pace.56 [EPA-HQ-OAR-2022-0829-0743, p. 9]

55 U.S. Global Change Res. Prog., Fourth National Climate Assessment, Volume II: Impacts, Risks, and Adaptation in the United States, Chapter 16: Climate Effects on U.S. International Interests 608 (2018) [hereinafter "NCA4"].

56 See Steven L. Schwarcz, Systemic Risk, 97 GEO. L.J. 193, 249 (2008) (observing that financial collapse in one country is inevitably felt beyond that country's borders).

Climate change is also predicted to exacerbate existing security threats—and possibly catalyze new security threats—to the United States.57 Besides threats to U.S. military installations and operations at home and abroad from flooding, storms, extreme heat, and wildfires,58 climate change is also a "source[] of conflict around the world"59 and a "threat multiplier" that, as recognized by the Department of Defense, will "aggravate stressors abroad such as poverty, environmental degradation, political instability, and social tensions—conditions that can enable terrorist activity and other forms of violence."60 Climate change will create and exacerbate new conflicts and humanitarian crises that will require a U.S. response, even as climate change also complicates the logistics of deploying forces and achieving missions. [EPA-HQ-OAR-2022-0829-0743, pp. 9-10]

57 See CNA Military Advisory Board, National Security and the Accelerating Risks of Climate Change (2014).

60 U.S. Dep't of Def., Quadrennial Defense Review 2014 at vi, 8 (2014).

Climate change will also very directly cause spillover damages across transboundary resources. As illustrated by recent high-pollution events, the United States has already begun to experience increased smoke from Canadian wildfires and drought conditions that spread along the U.S.-Mexico border.61 The United States shares a maritime border with 21 other countries, shares water resources like the Columbia River with our neighbors, and shares ecosystems—including the oceans through which migratory species with high economic and ecosystem-service values, like the Pacific hake, travel and live.62 [EPA-HQ-OAR-2022-0829-0743, p. 10]

61 NCA4, supra note 55, at 607.

62 Id. at 615.

All of these individual spillover effects can also interact and trigger feedback loops that will propagate additional spillover damages.63 Economic shocks around the world can make it more difficult for other countries to continue investing in mitigation and abatement, thus hastening the pace of climate change.64 Conflict and political instability caused by climate change can further reduce the willingness or ability of countries to engage in domestic climate policy or international cooperation.65 Spillover effects can chain together: if climate change accelerates migration, the attendant economic ripple effects and spread of health risks may cause political instability, which in turn can cause more migration and further economic ripple effects, thus starting the feedback loop again.66 [EPA-HQ-OAR-2022-0829-0743, p. 10]

Howard & Livermore, supra note 63.

A. EPA Reasonably Relies on Climate-Damage Estimates from an Interagency Working Group, But Should Conduct Further Analysis With Its Own Estimates

To monetize the Proposed Rule's climate benefits, EPA appropriately relies on four valuations produced by the Interagency Working Group on the Social Cost of Greenhouse Gases ("Working Group"). Those values—though widely agreed to underestimate the full social costs of greenhouse gas emissions75—are appropriate to use for now as conservative estimates. They have been applied in dozens of previous rulemakings76 and upheld in federal court.77 Policy Integrity, along with five other non-profit organizations, has submitted separate comments to this docket in support of the Proposed Rule's use of the Working Group's climate-damage estimates. [EPA-HQ-OAR-2022-0829-0601, pp. 12-14]

75 Interagency Working Group on the Social Cost of Greenhouse Gases, Technical Support Document: Social Cost of Carbon, Methane, and Nitrous Oxide – Interim Estimates Under Executive Order 13,990 at 4 (2021) [hereinafter 2021 TSD] (acknowledging that current social cost valuations "likely underestimate societal damages from [greenhouse gas] emissions"). Richard L. Revesz et al., Global Warming: Improve Economic Models of Climate Change, 508 NATURE 173 (2014) (co-authored with Nobel Prize-winning economist Kenneth Arrow).

76 Peter Howard & Jason A. Schwartz, Think Global: International Reciprocity as Justification for a Global Social Cost of Carbon, 42 COLUM. J. ENV'T L. 203, 270–84 (2017) (listing all uses through mid-2016).

77 Zero Zone v. Dept. of Energy, 832 F.3d 654, 679 (7th Cir. 2016).

As those joint comments further explain, however, EPA should conduct additional analysis using draft climate-damage valuations that EPA recently published.78 Though the Working Group's valuations relied on the best science available at the time of their initial development in 2010, they are now widely recognized to understate the true costs of climate change. In

November 2022, EPA released updated draft climate-damage estimates.79 EPA's draft valuations faithfully apply recent advances in science and economics on the costs of climate change and implement the roadmap laid out in 2017 by the National Academies of Sciences for updating the social cost of greenhouse gases.80 And while EPA's draft valuations remain underestimates,81 they more fully account for the costs of climate change by incorporating the latest available research on climate science, damages, and discount rates. [EPA-HQ-OAR-2022-0829-0601, pp. 12-14]

78 EPA External Review Draft of Report on the Social Cost of Greenhouse Gases (2022) [Draft SC-GHG Update].

79 Id.

80 Nat'l Acads. Sci., Engineering & Med., Valuing Climate Damages: Updating Estimation of the Social Cost of Carbon Dioxide (2017).

81 Draft SC-GHG Update, supra note 78, at 4 ("[B]ecause of data and modeling limitations . . . estimates of the SC- GHG are a partial accounting of climate change impacts and, as such, lead to underestimates[.]"); id. at 72.

Unsurprisingly, given the developing state of the science and economics around climate change, EPA's draft valuations find that the incremental cost of greenhouse gas emissions is substantially higher than the Working Group projected. Using these valuations will provide a more complete picture of the climate damages from the Proposed Rule and its alternatives. While EPA should apply the Draft SC-GHG Update in sensitivity analysis if it finalizes this regulation before it finalizes that update, it should consider applying those valuations in its primary analysis (with the Working Group's estimates in sensitivity analysis) should it finalize the SC-GHG Update before this rule. [EPA-HQ-OAR-2022-0829-0601, pp. 12-14]

Table 2 shows the climate benefits of the Proposed Rule and Alternative 1 using EPA's "central" certainty-equivalent near-term discount rate of 2%,82 which Policy Integrity generated using OMEGA and inputting the climate-damage valuations from the Draft Update. For comparison, Table 2 presents these estimates alongside the four climate-damage estimates from the Working Group that EPA provides in the Proposed Rule. [EPA-HQ-OAR-2022-0829-0601, pp. 12-14]

82 Id. at 9 (describing 2% as the "central" rate).

Table 2: Climate Benefits Using Draft SC-GHG Update (2020$ Billion)

	Proposed Program	Alternative 1
Working Group 5% Average	82	91
Working Group 3% Average	330	360
Working Group 2.5% Average	500	560
Working Group 3% 95th percentile	1000	1100
Draft Update (2% discount)83	1200	1300

[EPA-HQ-OAR-2022-0829-0601, pp. 12-14]

83 Emissions in future years are discounted back to present value using a 3% discount rate. This is consistent with EPA's approach to the climate-damage valuations using non-standard discount rates of 2.5% and 5%.

As Table 2 illustrates, the climate benefits of the Proposed Rule and its alternatives are higher under EPA's draft climate-damage valuations than using the four Working Group valuations that EPA now applies. [EPA-HQ-OAR-2022-0829-0601, pp. 12-14]

Organization: International Council on Clean Transportation (ICCT)

ALIGNMENT WITH GREENHOUSE GAS EMISSION REDUCTION TARGETS AND CLIMATE GOALS

ICCT strongly supports the proposed Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles and recommends its finalization. This rulemaking is critical to achieving the pace and scale of needed transportation emission reductions in the United States. There is a clear and urgent need to rapidly transition the transportation sector to zero-emission vehicles. Continued and strengthened standards are important to protect public health and deliver on national air quality and climate change goals. [EPA-HQ-OAR-2022-0829-0569, pp. 12-15]

On his first day in office, President Biden issued an executive order for the United States to rejoin the Paris Climate Agreement.33 With this executive order, the U.S. joined nearly every country on earth with the shared goal of limiting global warming to well below 2 degrees Celsius.34 Delivering on the goals of this Agreement will require a significant reduction in greenhouse gas emissions. The transportation sector is the largest contributor to climate pollution in the United States, with light-duty vehicles—passenger cars, SUVs, and pickup trucks—accounting for more than half of these emissions. Therefore, a shift to zero-emission vehicles like battery electric vehicles, along with increased efficiency of new gasoline vehicles, is needed. [EPA-HQ-OAR-2022-0829-0569, pp. 12-15]

33 U.S. Department of State. (2021, February 19). The United States officially rejoins the Paris Agreement. https://www.state.gov/the-united-states-officially-rejoins-the-paris-agreement/

34 Denchak, M. (2021, February 19). Paris Climate Agreement: Everything you need to know. Natural Resources Defense Council. https://www.state.gov/the-united-states-officially-rejoins-the-paris-agreement/

The ICCT's global modeling assessment for the Zero Emission Vehicle Transition Council shows that for the U.S. to be on a path to limiting global warming to well below 2° C, at least 67% of new passenger vehicle sales will need to be plug-in electric by 2030, with the vast majority (65%) being battery electric vehicles (BEVs).35 In parallel, new gasoline vehicles would need to improve at about 3.5% per year for the U.S. to be on a path to be Paris-compatible. Previous ICCT research estimated that the 2030 U.S. EPA standard would need to be about 57 grams CO_2/mile by 2030 to achieve this combination of new gasoline vehicle improvement with greatly increased BEV penetration that aligns with the Paris Agreement.36 [EPA-HQ-OAR-2022-0829-0569, pp. 12-15]

35 Sen, A., and Miller, J. (2022). Emissions reduction benefits of a faster, global transition to zero-emission vehicles. International Council on Clean Transportation. https://theicct.org/publication/zevs-global-transition-benefits-mar22/; ZEV Transition Council. https://zevtc.org/

36 Slowik, P., and Miller, J. (2022, December 19). Aligning the U.S. greenhouse gas standard for cars and light trucks with the Paris climate agreement. International Council on Clean Transportation. https://theicct.org/us-ghg- standard-paris-agreement-dec22/

The figure below summarizes the path from the current standard of 161 gCO2 per mile in 2026 to 57 gCO2e per mile in 2030 for the whole light duty fleet (top panel). This represents a combination of continued gasoline vehicle efficiency improvements (middle panel) and accelerated EV uptake to reach 67% sales in 2030 (bottom panel), including 65% BEVs and about 2% PHEVs. This assumed composition of battery electric vs. plug-in hybrid electric vehicles is based on BEVs' substantial economic and environmental benefits relative to PHEVs. Of course, if plug-in hybrids make up a greater share of EV sales than assessed here, then the fleetwide standards would have to be more stringent than 57 gCO2e per mile to be Paris-compatible.37 [EPA-HQ-OAR-2022-0829-0569, pp. 12-15]

37 Slowik. P., Isenstadt, A., Pierce, L, Searle, S. (2022). Assessment of light-duty electric vehicle costs and consumer benefits in the United States in the 2022-2035 time frame. International Council on Clean Transportation. https://theicct.org/publication/ev-cost-benefits-2035-oct22/; Bieker, G. (2021). A global comparison of the life-cycle greenhouse gas emissions of combustion engine and electric passenger cars. International Council on Clean Transportation. https://theicct.org/publication/a-global-comparison-of-the-life-cycle-greenhouse-gas-emissions-of- combustion-engine-and-electric-passenger-cars/

SEE ORIGINAL COMMENT FOR Figure 3. Stringency of model year 2030 GHG targets to be Paris-compatible [EPA-HQ-OAR-2022-0829-0569, pp. 12-15]

Graph 1: Fleetwide GHG Target including EVs (gCO2/mi)

Graph 2: Fleet average gasoline vehicle performance (gCO2/mi)

Graph 3: Electric vehicle share [EPA-HQ-OAR-2022-0829-0569, pp. 12-15]

This Paris-compatible path is ambitious yet achievable. As the middle panel shows, the 3.5% annual improvement for gasoline vehicles beyond 2026 is less than the rate of improvement needed to meet the current standards through 2026. As discussed above, EV uptake consistent with this scenario is possible through a combination of the new federal electric vehicle incentives and investments from the Inflation Reduction Act and state policies. [EPA-HQ-OAR-2022-0829-0569, pp. 12-15]

Although reaching 57 gCO2e per mile by 2030 requires a steeper decline in GHG emissions compared to the current EPA standards through 2026, ICCT's analysis finds this rate of improvement to be cost-effective for combustion and battery electric vehicles alike.38 In addition, the associated consumer benefits grow well into the tens of billions of dollars annually by 2027 due to greatly reduced upfront electric vehicle prices and lower fuel and maintenance costs compared to fossil fuel vehicles.39 [EPA-HQ-OAR-2022-0829-0569, pp. 12-15]

38 Lutsey, N., Meszler, D., Isenstadt, A., German, J., and Miller, J. (2017). Efficiency technology and cost assessment for U.S. 2025-2030 light-duty vehicles. INTERNATIONAL POLICY COMPARISON

The United States is not alone in its commitment to transition to cleaner cars. The number of national and subnational governments around the world that are committed to cleaner vehicles continues to rise. The sections below summarize and compare the U.S. EPA proposal with the standards in other leading markets around the world in terms of greenhouse gas emissions requirements, projections for electric vehicle uptake, and criteria pollutant emissions standards. [EPA-HQ-OAR-2022-0829-0569, pp. 16-18]

Greenhouse gas emissions standards

Figure 5 illustrates the U.S. trajectories of average CO2 emissions performance and CO2 emissions targets for new passenger cars and light trucks over the years, in comparison with other global vehicle markets that have CO2 emissions targets at least as of 2022. For a consistent basis of comparison, CO2 emissions values for all markets have been converted to the same U.S. test cycles (referred to as the CAFE cycle), where needed, using the ICCT cycle conversion factors44. The CO2 emissions targets are shown for both enacted and proposed targets for each country, where applicable including for the U.S. [EPA-HQ-OAR-2022-0829-0569, pp. 16-18]

44 Kühlwein, J. et al. (2014). Development of test cycle conversion factors among worldwide light-duty vehicle CO2 emission standards. International Council on Clean Transportation. https://theicct.org/publication/development-of- test-cycle-conversion-factors-among-worldwide-light-duty-vehicle-co2-emission-standards/; Yang, Z. (2014).

Improving the conversions between the various passenger vehicle fuel economy/CO2 emission standards around the world. International Council on Clean Transportation. https://theicct.org/improving-the-conversions-between- the-various-passenger-vehicle-fuel-economy-co2-emission-standards-around-the-world/ [EPA-HQ-OAR-2022-0829-0569, pp. 16-18]

SEE ORIGINAL COMMENT FOR Figure 5. Global comparison of historical data and standards for passenger car CO2 emissions and fuel consumption, normalized to CAFE cycle. [EPA-HQ-OAR-2022-0829-0569, pp. 16-18]

SEE ORIGINAL COMMENT FOR Figure 6. Global comparison of historical data and standards for light truck CO2 emissions and fuel consumption, normalized to CAFE cycle. [EPA-HQ-OAR-2022-0829-0569, pp. 16-18]

The historical trend shows that the U.S. CO2 emissions were historically one of the highest across the global markets, which began to reduce substantially through stringent GHG emissions standards starting from 2012. While the GHG emissions standards have significantly contributed to controlling emissions of the fleet over the years, the recent U.S. CO2 emissions and enacted targets are still higher than the average trajectories for a few markets such as the EU, Japan, South Korea, and UK for passenger cars and Chile, Japan, and UK for light trucks. [EPA-HQ-OAR-2022-0829-0569, pp. 16-18]

The proposed standards for 2027 and later model year vehicles make the U.S. one of the most ambitious, forward-looking markets for CO2 standards. The proposed standard levels are more stringent compared to most of the global markets, except for the EU and UK. The EU has already adopted 0 g CO2 per km standard by 2035. The UK targets are still in the proposal phase; however, the UK has set strong ZEV mandates for 100% ZEV sales of light-duty vehicles by 2035. [EPA-HQ-OAR-2022-0829-0569, pp. 16-18]

Thus, the proposed U.S. targets are more ambitious compared to the current trajectories for most of the global markets, yet not stringent enough to align with the most ambitious international targets. [EPA-HQ-OAR-2022-0829-0569, pp. 16-18]

Organization: MCS Referral & Resources (MCSRR)

The EPA does not mention CO in any of the sections of the proposed rule that discuss greenhouse gas (GHG) emissions. Some discussion of CO emissions should be added to these sections because, according to the IPCC, the indirect Global Warming Potential of CO over 20 years is 2.8 to 10, which is in addition to CO's direct GWG potential of approximately 1.3. While the GWP of CO is modest, the total annual CO emissions from vehicles in the US exceed those of all other criteria and toxic air pollutants combined, so EPA should not exclude CO. See: https://archive.ipcc.ch/ipccreports/tar/wg1/249.htm#tab69 [EPA-HQ-OAR-2022-0829-0615, pp. 3-4]

Organization: Metropolitan Washington Air Quality Committee (MWAQC) et al.

Strengthening the greenhouse gas emissions standards will also provide considerable support for metropolitan Washington and communities across the United States to meet their greenhouse gas emissions reduction goals. Unfortunately, our region is already experiencing the impacts of climate change. Observations in metropolitan Washington show that temperatures and the water surface level in the Potomac River are rising and will likely continue to rise. Extreme weather events and increases in the number of days with extreme heat or extreme cold will increase risks to health, energy usage patterns, plant and animal habitats, and infrastructure. These changes in our weather patterns are also affecting stormwater, drinking water, and wastewater. Broad-based climate change mitigation and adaptation strategies, such as national rules, are necessary to reduce the impacts of climate change and fight the adverse effects of climate change on our region and planet. [EPA-HQ-OAR-2022-0829-0503, p. 2]

The National Capital Region has goals to reduce greenhouse gas emissions 50% by 2030 and 80% by 2050, compared to 2005 levels. In 2022, the TPB adopted the same goals, but specifically for on-road transportation. As such, MWAQC, CEEPC, and the TPB believe that the newly proposed greenhouse gas emissions standards for model years 2027 and later light-duty and medium-duty vehicles, which are estimated by EPA to reduce carbon dioxide emissions by 47% in 2055 (Table 2 of the Federal Register Notice), are necessary for the region to achieve its greenhouse gas reduction goals. [EPA-HQ-OAR-2022-0829-0503, p. 2]

The metropolitan Washington region has implemented emissions reduction measures across all sectors, including on-road transportation, which contributes approximately 31% and 39% of the region's greenhouse gas and NOx emissions, respectively. The region relies heavily on federal control programs for a significant amount of additional greenhouse gas and NOx emissions reductions since these programs provide benefits across the economy. The federal government's leadership in delivering effective regulatory limits on greenhouse gas emissions from motor vehicles could also help reduce ozone and fine particle precursors and is a critical component of our ability to meet adopted environmental objectives and standards. [EPA-HQ-OAR-2022-0829-0503, p. 2]

Organization: Minnesota Pollution Control Agency (MPCA)

The MPCA has supported EPA's previous efforts to strengthen vehicle emissions standards and appreciates the opportunity to comment on the proposed rule. We see the proposed rulemaking as an opportunity to advance climate action, reduce harm to Minnesotans from criteria pollutants and air toxics, and accelerate the transition to electric vehicles in our state. [EPA-HQ-OAR-2022-0829-0557, pp. 1-2]

Importance of new federal greenhouse gas standards for climate action

The transportation sector represents the largest source of greenhouse gas emissions in Minnesota. The top three sources in the transportation sector are light-duty trucks, heavy-duty trucks, and passenger cars.1 These categories are inclusive of light and medium-duty vehicles discussed in this proposal. [EPA-HQ-OAR-2022-0829-0557, pp. 1-2]

Stronger vehicle emissions standards at the federal level have lowered greenhouse gas emissions from vehicles generally. However, the long-term consumer trend of choosing larger vehicles and the general trend of more miles driven (except during the pandemic) are counteracting more significant emissions reductions in this sector. Increased emissions stringency at the federal level is critical to continuing the trend of emission reductions in this sector. Accelerating light- and medium-duty vehicle electrification is vital for Minnesota to meet its climate and air pollution goals. Specifically, adopting new light- and medium-duty vehicle emissions standards would: [EPA-HQ-OAR-2022-0829-0557, pp. 1-2]

1 Greenhouse gas emissions in Minnesota 2005-2020, https://www.pca.state.mn.us/sites/default/files/lraq-2sy23.pdf.

- Help the state meet economy-wide greenhouse gas emissions reduction goals. [EPA-HQ-OAR-2022-0829-0557, pp. 1-2]

In 2022, as part of the publication of the state's Climate Action Framework,2 Governor Walz and Lieutenant Governor Flanagan endorsed the economy-wide greenhouse gas emissions reduction goal for the state to reduce emissions by 50% by 2030 and to become carbon-neutral by 2050. In May 2023, Minnesota codified these targets in statute. Achieving these goals will require action at all levels of government, across businesses, and by individuals. The proposed multipollutant standards will be critical for reducing emissions from the transportation sector. [EPA-HQ-OAR-2022-0829-0557, pp. 1-2]

2 Minnesota's Climate Action Framework, https://climate.state.mn.us/minnesotas-climate-action-framework.

- Advance transportation actions and targets in the state's Climate Action Framework. [EPA-HQ-OAR-2022-0829-0557, pp. 1-2]

Minnesota's Climate Action Framework is a plan that sets a vision for how the state will address and prepare for climate change. The framework broadly guides the direction of climate action toward a carbon-neutral, resilient, and equitable future for Minnesota and contains immediate, near-term actions, as well as key progress indicators with measurable targets. The framework was developed based on significant input from stakeholders, the public, and the Tribal Nations located within Minnesota's modern borders. [EPA-HQ-OAR-2022-0829-0557, pp. 1-2]

The proposed light- and medium-duty vehicle standards would advance the following actions in the Clean Transportation goal: [EPA-HQ-OAR-2022-0829-0557, pp. 1-2]

-- Increase the use of clean fuels, including lower-carbon biofuels (Sub-initiative 1.2.1)

-- Expand electric vehicle (EV) charging infrastructure (Sub-initiative 1.2.2)

-- Increase EV availability and access (Sub-initiative 1.2.3)

-- Accelerate the transition to EVs and clean transportation (Sub-initiative 1.2.4)

-- Improve vehicle efficiency and emissions standards (Sub-initiative 1.2.5)

[EPA-HQ-OAR-2022-0829-0557, pp. 1-2]

Additionally, the proposed standards would advance the following targets for the Clean Transportation goal: [EPA-HQ-OAR-2022-0829-0557, pp. 1-2]

-- Reduce greenhouse gas emissions from the transportation sector 80% by 2040

-- Reach 20% electric vehicles on Minnesota roads by 2030 [EPA-HQ-OAR-2022-0829-0557, pp. 1-2]

Organization: National Farmers Union (NFU)

The results of climate change, brought on by GHG emissions to the earth's atmosphere resulting from human activity, will be detrimental to both human health and the economy. As a family farm organization, NFU is particularly concerned with the challenges that climate change poses to family farmers' ability to pursue improvements in global food security. Anticipated disruptions to agricultural production caused by climate include: rising temperatures; changes in precipitation; increasing frequency of extreme weather events; new pest, disease and weed pressures; and increases in heat stress on livestock. As formidable as these challenges may be, farmers, ranchers and rural communities can contribute to climate resilience and help circumvent serious harm to the economy and human health. Efforts by farmers, ranchers and rural communities along this front are supported by the biofuels industry that eases the burdens on farmers and provides additional markets to facilitate a move toward sustainable practices and climate mitigation actions. [EPA-HQ-OAR-2022-0829-0581, pp. 3-4]

Organization: National Parks Conservation Association (NPCA)

II. Pollution from Light and Medium-Duty Vehicles Furthers Climate Change and Harms our Parks and Communities.

The irrefutable consensus among leading scientists has demonstrated time and again that climate change poses an increasingly existential threat to America's national parks and the world around them. According to the Intergovernmental Panel on Climate Change (IPCC) in their recently released Synthesis for the 6th Assessment Report (AR6): [EPA-HQ-OAR-2022-0829-0607, p. 2]

[h]uman activities, principally through emissions of greenhouse gases, have unequivocally caused global warming, with global surface temperature reaching 1.1°C above 1850–1900 in 2011–2020. Global greenhouse gas emissions have continued to increase, with unequal historical

and ongoing contributions arising from unsustainable energy use, land use and land-use change, lifestyles and patterns of consumption and production across regions, between and within countries, and among individuals.8 [EPA-HQ-OAR-2022-0829-0607, p. 2]

8 IPCC, Synthesis Report of the IPCC Sixth Assessment Report (AR6): Summary for Policymakers, Doc. 4, p.4. Available at https://www.ipcc.ch/report/ar6/syr/.

The IPCC further states that current policies and laws "fall short of the levels needed to meet climate goals across all sectors and regions," and will likely result in warming that "will exceed 1.5°C during the 21st century and make it harder to limit warming below 2°C."9 [EPA-HQ-OAR-2022-0829-0607, p. 2]

9 Id. at 10.

Our national park system hosts some of America's most beloved natural and cultural resources, yet our parks are especially vulnerable to the changing climate because of their sensitive and fragile ecosystems and unique geographic locations.10 The burning of fossil fuels driving global warming has resulted in national park mean annual temperatures increasing "at double the rate of the U.S. as a whole" between 1895 and 2010.11 The ecological turmoil caused by this warming and the resulting extreme weather conditions is disastrous for the vast majority of national park units and is expected to only get worse. As temperatures increase, climate effects are felt across all park geographic regions and locations, from coastal areas to mountain ranges.12 These climate effects include: (1) rising sea levels; (2) increasingly intense wildfires; (3) threat and harm to wildlife habitats and lifestyles, particularly those at high altitudes with low adaptation buffers; (4) the rapid growth of disruptive, invasive species; (5) extreme weather damage; (6) drier conditions leading to difficult droughts; (7) loss of glaciers, snowpack and ice; (8) changing landscapes and disrupted ecosystems; (9) destruction of irreplaceable park structures and artifacts; and (10) altered visitation patterns and significant losses to valuable tourism revenue.13 [EPA-HQ-OAR-2022-0829-0607, pp. 2-3]

RES. LETTERS 1 (2018), https://perma.cc/99FL-CA3S.

Due to the propensity of extreme events to damaging national parks, our findings indicate that climate change is a very real and significant concern for 80 percent of the nation's parks.14 If climate change continues at this rate, park wildlife and plant species' populations will plummet, and extinctions are likely to occur. In the decades to come, destruction from climate change could very well cause the near total loss of numerous namesake natural features across the park system, including, but not limited to, glaciers in Glacier National Park, everglade forests in Everglades National Park, saguaro cacti in Saguaro National Park, Joshua trees in Joshua Tree National Park, and giant sequoias in Sequoia National Park. Moreover, threats such as sea-level rise and storm related flooding and erosion put a long list of cultural park resources at risk, including historic structures from the National Mall in Washington, DC to the Golden Gate National Recreation Area in San Francisco. [EPA-HQ-OAR-2022-0829-0607, pp. 2-3]

14 NPCA, Air and Climate Report: Polluted Parks, NPCA.org (2019), https://www.npca.org/reports/air-climate-report.

The transportation sector is now the largest source of GHG emissions in the United States, and LDVs and MDVs are the single largest contributor of domestic GHGs within the sector.15 EPA's proposed light and medium-duty GHG standards will help address this top source of climate altering pollution, and, in so doing, help protect our parks from the worst of this devastation. Taking strong action to reduce greenhouse gas emissions from LDVs and MDVs will be an important step to limit warming below 2°C and protect our treasured national parks. [EPA-HQ-OAR-2022-0829-0607, pp. 2-3]

15 EPA, Inventory of U.S. Greenhouse Gas Emissions and Sinks 1990-2018 at ES-25 (2020), https://perma.cc/98ZR- XNTR.

National parks are suffering some of the most dire effects of our warming world. We urgently need to cut significant levels of greenhouse gas emissions from light and medium-duty vehicles, which are among the single largest contributors to the global climate crisis. EPA's proposed MY 2027 and later LDV and MDV GHG rule represents a necessary step to reduce greenhouse gas emissions, but the alternatives fall short of both CAA requirements and what is needed to ensure the health and welfare of our parks, communities and climate. [EPA-HQ-OAR-2022-0829-0607, p. 5]

Organization: National Tribal Air Association (NTAA)

Climate Change and Greenhouse Gas Mitigation

The acute and continuous impacts of climate change on Native Americans and Alaska Native Villagers are well documented. Unfortunately, new consequences of this global crisis continue to be revealed. For multiple reasons including vulnerability and geographic constraints, Tribal communities are disproportionately suffering from these changes. The U.S. Fourth National Climate Assessment (NCA4)1 noted, in part, that "Climate change increasingly threatens indigenous communities' livelihoods, economies, health, and cultural identities by disrupting interconnected social, physical, and ecological systems." A more focused examination of Tribal needs to address the impacts of climate change is presented in 2021 publication The Status of Tribes and Climate Change (STACC)2. [EPA-HQ-OAR-2022-0829-0504, pp. 1-2]

1 USGCRP, 2018: Impacts, Risks, and Adaptation in the United States

2 The Status of Tribes and Climate Change (STACC), Institute for Tribal Environmental Professionals, 2021

The NTAA has a long history of information sharing with EPA and advocacy for reducing emissions of greenhouse gases. Multiple reports, policy statements, and comment letters are compiled and accessible on our organization's website3. NTAA's Status of Tribal Air Reports (STAR) including STAR 20224 document climate change impacts on Tribal lands and people. [EPA-HQ-OAR-2022-0829-0504, pp. 1-2]

I. The Strongest Feasible Emissions Standards Are Needed.

Earth's climate is changing faster than it has at any point in the history of civilization, driven unequivocally by GHG emissions from human activities. The impacts—including more frequent and intense precipitation and wind events, flooding, heat waves, drought, wildfires, retreating snow and ice pack, ocean warming and acidification, accelerating sea level rise, and large-scale biodiversity loss—are being felt by communities across the globe and will worsen in coming years. Because GHGs can persist in the atmosphere for decades to centuries, how much worse these impacts will become depends on how deeply and rapidly humanity can decarbonize all economic sectors. Each additional ton of carbon dioxide (CO2) and other GHGs emitted into the atmosphere contributes to future climate warming and associated impacts.4 [EPA-HQ-OAR-2022-0829-0584, p. 2]

4 See Intergovernmental Panel on Climate Change (IPCC), Sixth Assessment Report of the IPCC (AR6), AR6 Synthesis Report: Climate Change 2023 (2023), https://www.ipcc.ch/report/ar6/syr/; see also IPCC, Climate Change 2022: Mitigation of Climate Change, Contribution of Working Group III to the AR6 (2022), https://www.ipcc.ch/report/ar6/wg3/; IPCC, Climate Change 2022: Impacts, Adaptation and Vulnerability, Contribution of Working Group II to the AR6 (2022), https://www.ipcc.ch/report/ar6/wg2/; IPCC, Climate Change 2021: The Physical Science Basis, Contribution of Working Group I to the AR6 (2021), https://www.ipcc.ch/report/ar6/wg1/.

Global CO2 emissions reached their highest ever annual level in 2022, surpassing the previous record high set in 2021.5 The United States has released more CO2 into the atmosphere than any nation in history and remains the second largest emitter today.6 At 28 percent, transportation is the largest source of U.S. GHG emissions and is expected to remain so through 2050, as population growth, expansion of urban centers, a growing economy, and increasing international trade will generate increased passenger and freight movement in coming years. Collectively, LDVs, MDVs, and Class 4-8 heavy-duty vehicles account for 82 percent of GHG emissions from the U.S. transportation sector, or 23 percent of total U.S. GHG emissions. LDVs alone are responsible for more than 15 percent of total U.S. GHG emissions.7 [EPA-HQ-OAR-2022-0829-0584, p. 2]

7 EPA, Inventory of U.S. Greenhouse Gas Emissions and Sinks: 1990-2021, https://www.epa.gov/ghgemissions/inventory-us-greenhouse-gas-emissions-and-sinks-1990-2021 (2023).

Organization: Our Children's Trust (OCT)

2. The federal government has long known that burning fossil fuels causes dangerous climate change that imperils the health and wellbeing of American children. The environmental consequences of vehicle emissions are well documented and are contributing to the catastrophic

heat, drought, and wildfires terrorizing the West coast and hurricanes, flooding and tornadoes horrifying the East coast. The costs of these climate change-induced disasters are staggering and many of the victims will be unable to recover. A study shows that children will experience many more of these extreme, life-threatening adults than their elders living today, including the ones making these policy decisions. [EPA-HQ-OAR-2022-0829-0542, p. 2]

There is simply no legal, scientific, or economic basis to continue burning fossil fuels, as was proven in the recent children's constitutional climate trial, Held v. Montana in Helena Montana, June 12-20, where leading scientists testified that fossil fuels endanger children's health and that powering every state in the nation with 100% clean renewable energy is not only technically feasible right now, but is economically beneficial and will save states and consumers billions of dollars in energy bills. [EPA-HQ-OAR-2022-0829-0542, p. 2]

Excess accumulation of greenhouse gases in our atmosphere results in an Earth energy imbalance and thus an accumulation of heat in our climate system. 6 The best available science informs that Earth's energy balance can only be restored by returning the atmospheric CO_2 concentration to below 350 ppm by 2100. [EPA-HQ-OAR-2022-0829-0542, p. 3]

Experts have opined that it is economically and technically feasible to achieve the science-based greenhouse gas emission reduction target of close to 100% by 2050, while simultaneously enhancing sequestration capacity of sinks to draw down historical cumulative CO_2 emissions, placing the U.S. on an emissions trajectory consistent with returning atmospheric CO_2 to below 350 ppm by 2100, which would bring long-term heating of the Earth back down to approximately 1.0°C above preindustrial temperatures, stabilizing the climate. 8 Please explain how the proposed rule aligns with restoring Earth's Energy Imbalance. [EPA-HQ-OAR-2022-0829-0542, p. 3]

for a Scientifically Based Standard of Fundamental Rights Protection in Constitutional Climate Change Cases, 40 Va. Env't L.J. 102 (2022).

Current increased average temperatures of 1°C and greater (now at ~1.2°C) are already dangerous according to the IPCC. 9 Basing policies and decisions that align with temperature targets of 1.5°C is catastrophic for our children and posterity. 10 The IPCC special report on Global Warming of 1.5°C (2018) stated that allowing a temperature rise of 1.5°C "is not considered 'safe' for most nations, communities, ecosystems and sectors and poses significant risks to natural and human systems as compared to the current warming of 1°C (high confidence)." 11 The 2023 IPCC Summary for Policymakers for the Synthesis Report (AR6) stated: "Risks and projected adverse impacts and related losses and damages from climate change will escalate with every increment of global warming (very high confidence). They are higher for global warming of 1.5°C than at present, and even higher at 2°C (high confidence)." 12 Medical experts have recently recognized that "[t]he science is unequivocal; a global increase of 1.5°C above the pre-industrial average and the continued loss of biodiversity risk catastrophic harm to health that will be impossible to reverse." 13 As such, 1.5°C should not be used to guide U.S. policy that is required to be based on best available science. The EPA should not be advancing policies that knowingly make the climate crisis worse, and potentially unsolvable. [EPA-HQ-OAR-2022-0829-0542, pp. 3-4]

9 IPCC, Summary for Policymakers, in Synthesis Report of the IPCC Sixth Assessment Report (AR6) (2023), https://report.ipcc.ch/ar6syr/pdf/IPCC_AR6_SYR_SPM.pdf.

10 See IPCC, Overarching Frequently Asked Questions: FAQ 3: How will climate change affect the lives of today's children tomorrow, if no immediate action is taken? in Climate Change 2022: Impacts, Adaptation and Vulnerability (2022) ("[T]oday's children and future generations are more likely to be exposed and vulnerable to climate change and related risks such as flooding, heat stress, water scarcity, poverty, and hunger. Children are amongst those suffering the most . . . [C]hildren aged ten or younger in the year 2020 are projected to experience a nearly four-fold increase in extreme events under 1.5°C of global warming by 2100[.]")

11 M.R. Allen et al., Technical Summary, in Global Warming of 1.5°C, at 44 (2018); see also Assessing "Dangerous Climate Change". This was similarly noted in the IPCC, Summary for Policymakers, in Climate Change 2022: Impacts, Adaptation and Vulnerability, at 13 (2022): "Global warming, reaching 1.5°C in the near-term, would cause unavoidable increases in multiple climate hazards and present multiple risks to ecosystems and humans (very high confidence)." Note that global warming was at ~1.0°C when this report was finalized; it has now risen to 1.2°C.

12 IPCC, Summary for Policymakers, in Synthesis Report of the IPCC Sixth Assessment Report (AR6) (2023), https://report.ipcc.ch/ar6syr/pdf/IPCC_AR6_SYR_SPM.pdf.

13 Lukoye Atwoli et al., Call for Emergency Action to Limit Global Temperature Increases, Restore Biodiversity, and Protect Health, 398 The Lancet 939 (2021) (emphasis added), https://doi.org/10.1016/S0140-6736(21)01915-2.

Climate change is causing a public health emergency that is already adversely impacting the physical and mental health of American children through, among other impacts, extreme weather events, rising temperatures and increased heat exposure, decreased air quality, altered infectious disease patterns, and food and water insecurity. 14 Children are uniquely vulnerable to climate change impacts because of their developing bodies, higher exposure to air, food, and water per unit body weight, unique behavior patterns, dependence on caregivers, political powerlessness, and longevity on the planet. 15 The protection of constitutional rights of children, by following the science, is of the utmost importance and must be incorporated in all relevant EPA rulemaking and policies. The Held v. Montana trial also put forward unrefuted expert testimony of the harms children face from the ongoing allowance of fossil fuel energy. EPA must listen to the pediatricians, psychiatrists, and public health experts on the damage every ton of emissions continues to have on our nation's children. See Expert Reports. [EPA-HQ-OAR-2022-0829-0542, pp. 4-5]

14 IPCC, Summary for Policymakers, in Climate Change 2022: Impacts, Adaptation and Vulnerability, at 11, 17 (2022). This summary found that the current level of global warming is already driving heat waves that cause human morbidity, heavy rains, flooding, extreme fires and drought, coral bleaching and demise, massive shifts in species habitats, loss of glaciers, snow and permafrost, as well as more destructive hurricanes. Id. at 11.

Organization: Pearson Fuels

As highlighted by the Sixth Assessment Report of the Intergovernmental Panel on Climate Change ("IPCC"), emissions from fossil fuels are the dominant contributor to climate change and continue to increase in scope:

Growth in anthropogenic emissions has persisted across all major groups of GHGs since 1990, albeit at different rates. By 2019, the largest growth in absolute emissions occurred in CO2 from fossil fuels and industry followed by CH4, whereas the highest relative growth occurred in fluorinated gases, starting from low levels in 1990 (high confidence).4 [EPA-HQ-OAR-2022-0829-0577, p. 3]

SEE ORIGINAL COMMENT FOR CHART of Global net anthropogenic emissions have continued to rise across all major groups of greenhouse gases. [EPA-HQ-OAR-2022-0829-0577, p. 3]

Organization: Sierra Club et al.

Under the U.S. Nationally Determined Contribution to the Paris Agreement, we committed to cut economy-wide greenhouse gas (GHG) emissions by 50 to 52 percent in 2030, compared to 2005 levels. Meeting that commitment is more important than ever. According to the Intergovernmental Panel on Climate Change's recently released Sixth Assessment Report, we are on course to exceed a 1.5° Celsius increase in global average temperature above pre-industrial levels within the coming decades. This level of warming would be catastrophic for our health, our welfare, and our planet. [EPA-HQ-OAR-2022-0829-0668, p. 1]

Organization: Southern Environmental Law Center (SELC)

Tailpipe emissions from light- and medium-duty vehicles cause significant environmental, public health, and economic impacts. [EPA-HQ-OAR-2022-0829-0591, pp. 1-2]

a. Light- and medium-duty vehicles are one of the largest sources of climate change- causing GHG emissions in the United States, resulting in tremendous harm. [EPA-HQ-OAR-2022-0829-0591, pp. 1-2]

The transportation sector is the largest source of GHG emissions in the United States,2 and this is also true in the South. In fact, transportation is the primary source of carbon dioxide (CO2)—the most prevalent GHG in our atmosphere—in every state in SELC's region except for Alabama, where it is the second largest source.3 In Georgia, North Carolina, South Carolina, Tennessee, and Virginia, emissions from transportation sources account for nearly half of all CO2 emissions.4 [EPA-HQ-OAR-2022-0829-0591, pp. 1-2]

2 The transportation sector generates 27.2 percent of all GHG annual emissions in the United States. See id. at 29186 (May 5, 2023).

3 Based on 2020 CO2 emissions. U.S. ENERGY INFO ADMIN., State Carbon Dioxide Emission Data Tables, tbl. 3 (Oct. 11, 2022), https://www.eia.gov/environment/emissions/state/.

4 Id.

Nationwide, light-duty vehicles are responsible for the majority of GHG pollution from the transportation sector, contributing 57.1 percent of all transportation sector GHG emissions—which amounts to 15.5 percent of total GHG emissions in the United States.5 Light-duty vehicles are also responsible for a disproportionate share of GHG pollution in the South. In Virginia, for example, emissions from light-duty vehicles generate 53 percent of all transportation-related GHG emissions in the state;6 in North Carolina, these vehicles produce 74 percent of all transportation-related GHG emissions.7 [EPA-HQ-OAR-2022-0829-0591, pp. 1-2]

GHG emissions are the primary driver of climate change,8 and the United States is already experiencing the environmental, public health, and economic impacts of a changing climate.9 While the effects of climate change are well-documented nationwide, the geography and demographics of the South make the region particularly vulnerable to climate change. A 2023 analysis of climate vulnerabilities across the United States found that the 100 census tracts with the highest overall climate vulnerability are located in 28 counties in nine southern states, including Alabama, Georgia, Tennessee, North Carolina, and South Carolina.10 Climate vulnerability, or the likely damage from climate change-related hazards due to "greater exposure to climate risks and lower ability to prepare, adapt, and recover from their effects," often correlates with race, income, and other socioeconomic factors.11 The two counties with the most census tracts among the 100 most vulnerable are located within SELC's region: Shelby County, Tennessee has 21 of the top 100 most vulnerable tracts, and Mobile County, Alabama has 14.12 [EPA-HQ-OAR-2022-0829-0591, pp. 2-4]

Rising temperatures are one of the many effects of climate change. The decade from 2010 to 2020 was the warmest on record in the South, and the region is already experiencing a higher percentage of heat waves than other parts of the country.13 Longer and more intense heat waves reduce air quality and cause heat-related illnesses like heat cramps, heatstroke, heat exhaustion, kidney-associated diseases, and asthma.14 These health effects are especially likely in vulnerable populations such as children, outdoor workers, and the elderly.15 In addition, the South is home to some of the fastest-growing metropolitan areas in the country.16 Sprawling, auto-oriented development like that typical in the South often increases impervious surfaces and reduces tree canopy cover, which combined with climate change can create and exacerbate heat island effects and result in greater emergency-room visits, reduced life expectancy, and worsened mental health outcomes in impacted communities.17 These impacts are often most acute in communities of color that have experienced a longstanding history of environmental injustice.18 [EPA-HQ-OAR-2022-0829-0591, pp. 2-4]

With over 12,000 miles of coastline,19 the South is also experiencing frequent flooding due to increased extreme storm events and sea level rise. Sea level has been rising at a rate about three times the global pace along the mid-Atlantic coast.20 In the Hampton Roads region of Virginia—which has the highest rate of sea level rise on the East Coast21—the sea level has risen by more than a foot over the last 80 years,22 and scientists predict an additional rise of 1.5 to 2 feet by 2050.23 As warmer ocean temperatures result in heavier, more frequent rainfalls and slower-moving hurricanes, inland flooding is also increasing.24 The number of Category 4 and 5 hurricanes in the mid-Atlantic basin—such as Hurricanes Ian, Irma, Michael, Matthew, and Florence—has grown substantially since the 1980s.25 These weather events cause serious injuries and fatalities,26 property damage, respiratory effects from mold exposure, and may lead to public emergencies and infrastructure disruptions, stressing health services and communities.27 [EPA-HQ-OAR-2022-0829-0591, pp. 2-4]

There are also major economic costs to climate change, and studies have found that the future costs will be unequally distributed across the United States.28 Relative to the rest of the nation, the South will face the largest economic losses from climate change, with low-income and minority communities particularly affected.29 Lower income counties in the South may lose between 5 and 20 percent of gross domestic product per year—compared to an average yearly loss of 1.2 percent nationally—for every additional degree of warming by the 2080s.30 [EPA-HQ-OAR-2022-0829-0591, p. 4]

Organization: Steven G. Bradbury

Furthermore, EPA has deliberately left out of its cost-benefit equation entirely the upstream carbon dioxide emissions associated with EV production.49 The minerals and components used in EV batteries are mostly processed or manufactured in China using power generated from coal. While the U.S. has achieved huge reduc- tions in carbon dioxide emissions by converting coal-fired power plants to natural gas, China's and other Asian nations' carbon emissions are growing rapidly because of their heavy reliance on coal, and EPA's rules will only accelerate that dynamic.50 An automotive engineering analysis published in 2022 estimated that the carbon dioxide emissions from producing the battery used in one small EV (the Nissan Leaf) were equivalent to driving an ICE vehicle 24,000 miles (two years of driving), and those from producing the battery used in a large EV (the Tesla Model S) were equivalent to driving an ICE vehicle 60,000 miles (five years of driving).51 In these rulemaking proposals, EPA has completely ignored the fact that EVs start out their lives on the road with such a huge head start (two to five years worth) in carbon dioxide emissions over their ICE counterparts. Organization: Strong Plug-in Hybrid Electric Vehicle (PHEV)

Because of the urgency of the climate and air pollution crises worldwide and the challenges of predicting consumer acceptance, it is important to take an all-hands-on-deck approach and have multiple types of zero-emission car and truck technologies in the final regulation including Strong PHEVs. [EPA-HQ-OAR-2022-0829-0646, p. 25]

- Strong PHEVs offer more options for consumers which means a faster path to zero CO_2 worldwide when combined with BEV and FCEV options especially given supply chain, utility grid and charging infrastructure challenges we face today.

- Many areas of the world are relying on EPA's leadership to commercialize new zero carbon solutions to transportation such as Strong PHEVs.

- The longer-term goal should be PHEVs with 100% zero carbon electricity generation for almost all of their electric miles, and advanced biofuels or other ultra-low carbon fuel for the remaining miles. [EPA-HQ-OAR-2022-0829-0646, p. 25]

Organization: Tesla, Inc.

Tesla supports EPA's efforts to accelerate light-duty vehicle electrification as it is essential for reducing greenhouse gas (GHG) and criteria pollutants and addressing the rapidly escalating climate crisis. [EPA-HQ-OAR-2022-0829-0792, p. 6]

As the agency highlights, light-duty vehicles are major emitters of climate-warming GHGs, stating: [EPA-HQ-OAR-2022-0829-0792, p. 7]

The transportation sector is the largest U. S. source of GHG emissions, representing 27.2 percent of total GHG emissions. Within the transportation sector, light-duty vehicles are the largest contributor, at 57.1 percent, and thus comprise 15.5 percent of total U.S. GHG emissions, even before considering the contribution of medium-duty Class 2b and 3 vehicles which are also included under this rule.45 [EPA-HQ-OAR-2022-0829-0792, p. 7]

45 88 Fed. Reg. at 29816-17.

As EPA has already determined, vehicle GHG emissions endanger public health and welfare.46 Since the issuance of the Endangerment Finding continued peer-reviewed scientific analysis has further elucidated the level of GHG emission reduction needed to adequately protect the public welfare.47 In finalizing the requisite level of emissions reduction in the new light-duty standards, the agency should look first toward the consensus UNFCCC and IPCC goal of limiting global warming to below 1.5 degrees Celsius compared to pre-industrial levels as its baseline.48 The U.S. has adopted an international commitment to put policies in place consistent with this protective aim.49 To meet this new target the U.S. has committed to achieve a 50-52 percent reduction from 2005 levels in economy wide GHG pollution in 2030.50 This commitment is part of the national effort to prevent significant domestic impacts from climate change51 and embodies near term action commensurate with meeting this benchmark.52 Further, EPA recognizes the need to promulgate regulations that "would contribute toward the goal of holding the increase in the global average temperature to well below 2 °C above pre-industrial levels, and subsequently reduce the probability of severe climate change related impacts including heat waves, drought, sea level rise, extreme climate and weather events, coastal flooding, and wildfires."53 [EPA-HQ-OAR-2022-0829-0792, pp. 7-9]

53 88 Fed. Reg. at 29199.

As part of this effort, numerous studies have highlighted that electrifying the light-duty fleet as rapidly possible will enable the U.S. to meet its commitment and equitably contribute to emissions reductions that adequately protect the country's health and welfare.54 For example, a central component of the U.S. long-term climate strategy in transportation is the "rapid expansion of zero-emission vehicles—in as many applications as possible across light-, medium-, and heavy-duty applications."55 Moreover, the American Lung Association (ALA) found that the environmental benefits from electrifying the transportation sector in the form of avoided climate change impacts, as expressed as the social cost of carbon,56 could surpass $113 billion in 2050 as transportation systems combust far less fuel and our power system comes to rely on cleaner, non-combustion renewable energy.57 [EPA-HQ-OAR-2022-0829-0792, pp. 7-9]

In order to produce supplies of renewables, China is increasing its construction of coal- fired power plants. This increases carbon emissions and reduces EPA's benefits from U.S. emissions reduction. America has 225 coal-fired power plants, and China has 1,118 (half of all the coal-fired plants in the world).31 That is one reason why China has increased carbon emissions by over 5,000 million metric tons over the past 16 years.32 In contrast, America's carbon emissions have declined by over 1,000 million metric tons over the same period due to the use of clean natural gas.33 (See Figure 1.) China has not committed to reducing emissions until 2027. Research has shown that even completely eliminating all fossil fuels from the United States would result in less than 0.2 degrees Celsius in temperature mitigation by 2100.34 Americans, particularly poor and middle class, would be bearing major costs in higher electricity prices, higher food prices, and a forced switch to costly electric vehicles without benefits for the environment. They would pay the price for President Biden's energy agenda. [EPA-HQ-OAR-2022-0829-0674, pp. 7-8]

SEE ORIGINAL COMMENT FOR GRAPH CO2 Emissions Trends in Key Countries, 2005-2021 Figure 1 [EPA-HQ-OAR-2022-0829-0674, pp. 7-8]

Environmental benefits overstated

The study substantially overstates the environmental benefits of the rule. See Tables 172-187. All of the environmental benefits, even if accurately measured, are limited to benefits in local areas of the United States. There may well be reductions in CO2 and other emissions where a vehicle is driven. But the environmental harms elsewhere are substantial: [EPA-HQ-OAR-2022-0829-0674, p. 14]

- Environmental harms from the poorly supervised extraction of rare-earth minerals in developing countries;

- Environmental harms transporting the rare earth minerals to battery factories in other countries, but principally in China;

- Environmental harms from the manufacture of batteries in other countries, but principally in China; and

- In addition, environmental harms from the generation and transmission of electricity, even with renewable generation, in the United States.

For these and other reasons, the environmental benefits are substantially overstated and may well be negative. [EPA-HQ-OAR-2022-0829-0674, p. 14]

Best scientific practice uses models that work and does not seriously consider those that do not. This is standard when formulating the daily weather forecast, and should be the standard with regard to climate forecasts. [EPA-HQ-OAR-2022-0829-0674, p. 24]

The IPCC's recently released Sixth Assessment Report (AR6) uses a new suite of models, designated CMIP6. As shown by McKitrick and Christy (2020) however, the CMIP6 models are even worse.62 Of the two models that work, the Russian INM-CM4.8, has even less warming than its predecessor, with an ECS of 1.8°C, compared to the CMIP6 community value of around four degrees.63 The other one is also a very low ECS model from the same, group, INM-CM5. The model mean warming rate exceeds observation by more than two times at altitude in the tropics. [EPA-HQ-OAR-2022-0829-0674, p. 24]

62 R. McKitrick and J. Christy. 2020. Pervasive Warming Bias in CMIP6 Tropospheric Layers. Earth and Space Science Volume 7, Issue 9, https://agupubs.onlinelibrary.wiley.com/doi/10.1029/2020EA001281.

63 Most (not all) of the CMIP-6 models were available for McKitrick and Christy (2020); this figure is the mean ECS of what was released through late 2020.

SEE ORIGINAL COMMENT FOR GRAPH OF 5-yr Running mean 300-200hPa Tropical Temperature Anomalies CMIP-6 (Historical + ssp245 after 2014) [EPA-HQ-OAR-2022-0829-0674, p. 24]

Quoting from McKitrick and Christy's conclusion: [EPA-HQ-OAR-2022-0829-0674, p. 24]

The literature drawing attention to an upward bias in climate model warming responses in the tropical troposphere extends back at least 15 years now … Rather than being resolved, the problem has become worse, since now every member of the CMIP6 generation of climate models exhibits an upward bias in the entire global troposphere as well as in the tropics. [EPA-HQ-OAR-2022-0829-0674, p. 24]

Zeke Hausfather, hardly a climate skeptic, has noted that while the CMIP6 models are warmer than the previous generation, the warmer they are, the more they over-forecast warming in recent decades, confirming what McKitrick and Christy found.64 [EPA-HQ-OAR-2022-0829-0674, p. 24]

64 Zeke Hausfather, “Cold Water on Hot Models,” The Breakthrough Institute, February 11, 2020, https://thebreakthrough.org/issues/energy/cold-water-hot-models.

Zhu, Poulsen, and Otto-Bliesner (2020) used a CMIP6 model called CESM2 to project warming from an emission scenario that reaches 855 parts per million by 2100—roughly three times the pre-industrial concentration. Despite being tuned to match the behavior of 20th century climate, CESM2 produced a global mean temperature “5.5°C greater than the upper end of proxy temperature estimates for the Early Eocene Climate Optimum.” That was a period when CO2 concentrations of about 1,000 ppm persisted for millions of years.65 Moreover, the modeled tropical land temperature exceeded 55°C, “which is much higher than the temperature tolerance of plant photosynthesis and is inconsistent with fossil evidence of an Eocene Neotropical rainforest.”66 [EPA-HQ-OAR-2022-0829-0674, p. 24]

65 NOAA National Centers for Environmental Information, Early Eocene Period, 54 to 48 Million Years Ago, https://www.ncdc.noaa.gov/global-warming/early-eocene-period.

66 Jiang Zhu, Christopher J. Poulsen & Bette L. Otto-Bliesner. 2020. High climate sensitivity in CMIP6 model not supported by paleoclimate. Nature Climate Change volume 10, pages 378–379, https://www.nature.com/articles/s41558-020-0764-6.

under more realistic assumptions regarding agricultural productivity and climate sensitivity, the mean SCC essentially drops to zero and in many cases has a substantial probability of being negative. At a minimum, Dayaratna et al. (2020) further demonstrates that the SCC is highly sensitive to very reasonable changes in assumptions. The models can therefore suggest a variety of outcomes of climate change - ranging from catastrophic disaster or continued prosperity to climate change – all under very reasonable assumptions. As a result of the uncertainty summarized in the above published analysis, the proposed rule is arbitrary and capricious and therefore should not be implemented. Miniscule Temperature Impact Not Discussed In the Proposed Rule The proposed rule begins by saying: [EPA-HQ-OAR-2022-0829-0674, p. 30]

Motor vehicle emissions contribute to ozone, particulate matter (PM), and air toxics, which are linked with premature death and other serious health impacts, including respiratory illness, cardiovascular problems, and cancer. This air pollution affects people nationwide, as well as those who live or work near transportation corridors. In addition, there is consensus that the effects of climate change represent a rapidly growing threat to human health and the environment, and are caused by GHG emissions from human activity, including motor vehicle transportation. Recent trends and developments in emissions control technology, including vehicle electrification and other advanced vehicle technologies, indicate that more stringent emissions standards are feasible at reasonable cost and would achieve significant improvements in public health and welfare. Addressing these public health and welfare needs will require substantial additional reductions in criteria pollutants and GHG emissions from the transportation sector. (p.29186) [EPA-HQ-OAR-2022-0829-0674, p. 30]

Subsequently, the rule states: “The transportation sector is the largest U.S. source of GHG emissions, representing 27.2% of total GHG emissions." (p. 29186). Since the policy is intended to avert climate change it is necessary to quantify the climate impact of the proposed rule. At The Heritage Foundation, we used the Model for the Assessment of Greenhouse Gas Induced Climate Change version 6, developed by researchers at the EPA to quantify the climate impact. We found that assuming a climate sensitivity of 5.0 degrees C (the upper bound of estimated climate sensitivities indicated by the Intergovernmental Panel on Climate Change), there would be less than 0.0305 degrees C temperature mitigation by 2050 and less than 0.0644 by 2100. [EPA-HQ-OAR-2022-0829-0674, p. 30]

If the objective of the proposed rule is to avert climate change, then it is insufficient for the rule to be based solely on GHG emission reductions; the EPA should go a step further to take these missions and calculate temperature impacts as done above. As a result, the proposed rule is arbitrary and capricious and should not be implemented. [EPA-HQ-OAR-2022-0829-0674, p. 30]

Organization: U.S. Conference of Catholic Bishops (USCCB)

4. Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles]. Docket ID No EPA–HQ–OAR–2022–0829

Personal vehicles—cars, light-duty trucks (including sport utility vehicles, crossover utility vehicles, minivans, and pickup trucks), and motorcycles—are responsible for 58 percent of U.S. transportation sector GHG emissions, in addition to being a major source of other pollutants with adverse effects to human health.16 The EPA's proposed rule for more stringent emissions standards for light and medium-duty vehicles addresses pollution from personal vehicles taking into account industry trends and investments in electric vehicles (EVs) outlined in the Inflation Reduction Act (IRA) and other policies. 88 Fed. Reg. 29184 (May 5, 2023). The EPA offers that these "more stringent emissions standards are feasible at reasonable cost and would achieve significant improvements in public health and welfare." 88 Fed. Reg. at 29186. The goals of improved public health, welfare and reduced GHG emissions are consistent with Catholic Social Teaching. As a general matter, it is good to consider strengthening vehicle emissions standards, as the USCCB stated in 2018: "If any modifications are made to existing fuel efficiency and greenhouse gas emission standards, we would urge these standards be strengthened, not weakened, to further protect human and environmental health."17 [EPA-HQ-OAR-2022-0829-0540, pp. 3-4]

Organization: Wisconsin Department of Natural Resources

In addition to the criteria pollutant benefits, the rule's revised GHG standards are critical to achieving long-term climate goals in Wisconsin. Federally regulated mobile sources are a significant contributor to Wisconsin's greenhouse gas levels. On-road light- and medium-duty gasoline vehicles were responsible for about 23.2 million metric tons of carbon dioxide (CO2) equivalent (MMCO2E), or 16% of the state's total greenhouse gas emissions inventory in 2018.1 Given that Wisconsin lacks the authority to address GHG emissions from on-road vehicles, EPA's action to update these standards is needed to help Wisconsin meet its climate objectives. [EPA-HQ-OAR-2022-0829-0507, p. 2]

3. Emissions Standards are Necessary to Protect Public Health and the Environment

This rule will accelerate investment in electric technologies that will lead to significant emissions reductions and improved health outcomes. Americans are keeping their cars longer, meaning the need for EPA action to reduce emissions from these types of personal vehicles is even more urgent.55 Failing to rapidly electrify these classes of vehicles means that fossil fuel-powered vehicles rolling off assembly lines today will remain on the road for many years to come, adding millions of collective vehicle miles and associated deadly emissions over the coming decades. [EPA-HQ-OAR-2022-0829-0638, pp. 13-14]

55 "Americans are keeping their cars longer amid sky-high prices, rising interest rates," CNBC, (May 15, 2023) https://www.cnbc.com/2023/05/15/americans-are-keeping-their-cars-longer-amid-rising-interest-rates.html

As discussed in more detail below, ICEVs are a constant and ongoing hazard to public health and the environment. They are also major contributors to anthropogenic climate change. [EPA-HQ-OAR-2022-0829-0638, pp. 13-14]

Electrification presents the most commercially viable pathway to reducing pollution from the transportation sector and unlocking tangible environmental and public health benefits. [EPA-HQ-OAR-2022-0829-0638, pp. 13-14]

Accordingly, EPA should finalize emissions standards for LMDVs that result in deep cuts to GHG and criteria pollutant emissions through continued growth in the EV sector. Implementing and upholding robust emissions standards that decarbonize the transportation sector through electrification is a national public health, climate, and equity imperative. [EPA-HQ-OAR-2022-0829-0638, pp. 13-14]

b. Reducing Transportation Emissions Protects the Environment and the Climate

Never has the evidence been more clear that climate change is anthropogenic, and recent atmospheric research provides new indications of human-caused climate change associated with increases in CO2 emissions. Differences between tropospheric and lower stratospheric temperature trends have long been recognized as a fingerprint of human effects on the climate.68 A new study published in the Proceedings of the National Academy of Sciences has factored in temperature from the mid to upper stratosphere–25 to 50 kilometers above the Earth's surface–into these comparisons.69 The results further underscore the impact humans are having on our atmosphere and the potentially catastrophic effects that are increasingly likely to result such as more frequent wildfires, longer periods of drought in some regions, and an increase in the wind intensity and rainfall from tropical cyclones.70,71 [EPA-HQ-OAR-2022-0829-0638, p. 16]

As the nature of anthropogenic climate change is becoming increasingly evident, the urgency needed in addressing its causes is becoming greater.72 Between 1971 and 2020, around 380,000,000,000,000,000,000,000 joules of energy—equivalent to 25 atomic bombs—have been trapped in the atmosphere as a result of warming, according to a 2023 study published in Earth System Science Data.73 In 2021, the U.S. emitted 6,340 million metric tons of CO2—of which, fossil fuel combustion was responsible for nearly 75%.74 A significant portion of that fossil fuel combustion occurs within the transportation sector, which accounts for 28% of total emissions and is the largest emitting sector.75 Light-duty vehicles account for 57% of transportation GHG emissions and light-duty ICEVs emit around 19 pounds of carbon dioxide and other global-warming gasses for every gallon of gasoline consumed.76 [EPA-HQ-OAR-2022-0829-0638, p. 16]

As EPA explains in the proposed rule, automaker investments in electric technologies implicitly acknowledge that the sector believes electric vehicles are the cleaner alternative. EVs produce zero tailpipe emissions and studies have shown that in every state in the U.S.—even states with fossil fuel intensive electricity grids—driving an electric vehicle leads to significantly fewer GHG emissions.77 In Kentucky, for example, where the electricity mix is 71.8% coal and 20.6% natural gas, driving an EV results in 6,903 fewer pounds of CO2 annually than driving an ICEV.78 [EPA-HQ-OAR-2022-0829-0638, p. 17]

78 "Emissions from Electric Vehicles," Department of Energy's Alternative Fuels Data Center, accessed June 26, 2023 https://afdc.energy.gov/vehicles/electric_emissions.html

Diesel emissions are of particular concern for environmental outcomes. Many class 2b and 3 vehicles continue to be powered by diesel engines.79 Emissions from diesel engines have detrimental impacts not only on human health, but on natural ecosystems as well. A study from the University of Southampton demonstrated that exposure to diesel exhaust has negative impacts on pollinators and that NOx emissions altered the smell of five out of the eleven most common single compound floral odors.80 In areas where diesel exhaust is present, a 2022 study found that there were 70% fewer pollinators and 90% fewer flower visits.81 A separate study from the Journal of Environmental Health Science and Engineering suggests that prolonged exposure to internal combustion engine exhaust has potentially significant impacts on agro-ecosystems and plant germination.82 [EPA-HQ-OAR-2022-0829-0638, p. 17]

EPA Summary and Response

Summary:

Many commenters (e.g., American Council for an Energy-Efficient Economy, American Lung Association (ALA), National Parks Conservation Association (NPCA), Southern Environmental Law Center (SELC), Zero Emission Transportation Association (ZETA)) stressed that climate change is a top public health priority and a public health emergency. These commenters stated that climate change is endangering the public health and welfare of all populations, including children, by increasing risks of heart disease, mental health, pollen seasons, allergies, drought, frequent flooding, and other listed impacts. One of these commenters stated that climate change also poses an increasing threat to America’s national parks (National Parks Conservation Association). These commenters stated that massive economic costs to climate change and studies have found that the future costs will be unequally distributed across the US. where, the geography and demographics of the South make the region particularly vulnerable to climate change.

Many of the commenters identified a litany of harms associated with the on-going climate crisis, and the light-duty sector’s contribution to the GHG emissions which are driving that crisis. Harms identified in the comments included:

- Worsening air quality (e.g., ACEEE, ALA, California Attorney General's Office, Metropolitan Washington Air Quality Committee (MWAQC))
- -- rise in vector borne disease (American Lung Association)
- -- flooding, drought, excessive heat, wildfires (e.g., California Attorney General's Office, Elders Climate Action, Institute for Policy Integrity at NYU School of Law, National Parks Conservation Association (NPCA), Northeast States for Coordinated Air Use Management (NESCAUM) and the Ozone Transport Commission (OTC), Southern Environmental Law Center (SELC), Tesla, Inc.
- Adverse mental health implications (e.g., American Lung Association (ALA), Environmental and Public Health Organizations Our Children’s Trust)
- -- impacts from sea level rise (e.g., National Parks Conservation Association (NPCA), Southern Environmental Law Center (SELC))

- -- disproportionate impact on disadvantaged communities and children, both domestic and worldwide (BlueGreen Alliance (BGA), Southern Environmental Law Center (SELC), Our Children's Trust)
- --national security implications (Institute for Policy Integrity)
- Disastrous impacts on parks from invasive species and loss of glaciers, snowpack and ice (National Parks Conservation Association)

Our Children's Trust also asserts that failure to manage, protect, and prevent substantial impairment to the earth, air, and climate would violate the federal government's fiduciary obligations under the Fifth Amendment of the Constitution and the Public Trust Doctrine. The commenter also asserted that in this rule the Ninth Circuit's findings in *Juliana v. United States*, 947 F.3d 1159, 1164 (9th Cir. 2020), on the federal government's role should guide EPA's policies and practices so that EPA can identify, and alter, those policies that exacerbate American youth's existing climate change injuries. Finally, the commenter argued that 1.5°C presents significant risks to the planet when compared to 1°C, and that therefore the EPA should not use a 1.5°C target to guide policy.

A few commentors assert that serious anthropogenic climate threats are inconsistent with evidence (American Enterprise Institute). Arizona State Legislature stated that the proposed rule is arbitrary and capricious because it fails to model and calculate the climate change impacts in order to weigh the benefits against the costs and what they claim is the transformative nature of the proposed rule. Without a showing that the rule will result in some type of quantifiable effect to prevent climate harms, this commenter questions its legality, and asserted that EPA's summary conclusion that the standards would contribute towards the goal is not good enough.

<u>Response:</u>

The EPA appreciates that many commenters are concerned about past, present, and future climate change and the many impacts on human health and welfare that result from climate change. The GHG reductions resulting from this rule will be a meaningful contribution to slowing the rate of future climate change. Importantly, EPA has found in the record for this rulemaking that the standards will reduce GHG emissions – almost 8 billion metric tons in net CO_2 equivalent cumulative emission reductions between 2027 and 2055. See preamble Section VI and RIA Chapter 8, which provide more detail on these emissions estimates and how they were calculated. This is a meaningful contribution, especially because it is due to one action, for one sector, for one nation. *See Coalition for Responsible Regulation*, 684 F. 3d at 332 ("EPA found that the emission standard would result in meaningful mitigation of greenhouse gas emissions. For example, EPA estimated that the Rule would result in a reduction of about 960 million metric tons of CO2e emission over the lifetime of the model year 2012-2016 vehicles affected by the new standards.") Climate change is not expected to be solved by any single action, but rather a large number of them. Moreover, as the Supreme Court recognized, "Agencies, like legislatures, do not generally resolve massive problems in one fell regulatory swoop. And reducing domestic automobile emissions is hardly a tentative step." Massachusetts v. E.P.A., 549 U.S. 497, 524 (2007) . Thus, EPA disagrees with the commenters that EPA has not provided a basis consistent with the requirements of CAA section 202(a)(1)-(2). See Section 3.3.1 of this RTC for response to comments regarding the stringency of the final rule relative to the proposal.

While EPA did not conduct additional climate modeling in support of this rulemaking, EPA is not required to do so in setting the standards under CAA section 202(a)(1)-(2). See *Coal. For Resp. Regulation*, 684 F. 3d at 128 (noting that EPA section 202(a)(1) authority is not "conditioned on evidence of a particular level of mitigation" but rather that authority is triggered by a showing of significant contribution, which was made in EPA's Endangerment Finding, and that, as just quoted above, furthermore the record for the vehicle standards rule at issue included an EPA estimate of the millions of tons that would be reduced by the rule). Indeed, CAA section 202(a)(1)-(2) does not require the agency to calculate the benefits of its rulemaking at all, and the commenter failed to adduce any statutory authority or other legal basis for the proposition that EPA must calculate benefits generally or specifically must model avoided temperature change or sea level rise.

We also note that, for purposes of E.O. 12866, EPA has estimated the value of the benefits of these reductions by applying the SC-GHG, which is a sufficient means of calculating benefits and so makes it unnecessary to conduct any further climate modelling for that purpose. The development of the SC-GHG involves the use of climate models in order to estimate the damages of an additional ton of emissions and is therefore a reasonable approach that uses the appropriate tool in benefit-cost analysis. When considering those monetized climate benefits, the monetized benefits of the rule far exceed its costs. EPA's reliance on SC-GHG to assess the climate benefits of this rulemaking is clearly reasonable. As we explain in preamble Section VIII.E and RIA Chapter 6.2, the SC-GHG is based on a voluminous record, significant public process, and the well-considered judgment of experts.

In response to Our Children's Trust, EPA follows applicable guidance and best practices when conducting its benefit-cost analyses, including OMB Circular A-4 and EPA's Guidelines for Preparing Economic Analyses. With respect to the application of discount rates, EPA notes that we "use constant discount rates (1.5-percent, 2-percent, and 2.5-percent) similar to the near-term Ramsey discount rates to calculate the present and annualized value of SC-GHGs for internal consistency" (from the notes on Table VII-2 in the preamble for the final rule). That approach to discounting follows the same approach that the February 2021 TSD recommends "to ensure internal consistency—i.e., future damages from climate change using the SC-GHG at 2.5 percent should be discounted to the base year of the analysis using the same 2.5 percent rate." EPA has also consulted the National Academies' 2017 recommendations on how SC-GHG estimates can "be combined in RIAs with other cost and benefits estimates that may use different discount rates." The National Academies reviewed "several options," including "presenting all discount rate combinations of other costs and benefits with [SC-GHG] estimates." With regards to Our Children's Trust criticism and assertions regarding a 1.5°C target, the EPA is setting standards under Clean Air Act section 202(a)(1)-(2) as described in preamble sections I and II. With regards to Our Children's Trust discussion of the unique vulnerability of children to climate change, the EPA does recognize these vulnerabilities (see, e.g., the EPA report *Climate Change Impacts on Children's Health and Well-Being in the U.S.*), and the emissions reductions resulting from this rule will make an important contribution to efforts to limit climate change and its anticipated impacts to children relative to a future without this rule. The Agency does not dispute that climate change poses a serious threat, nor that addressing climate change requires the active involvement of the federal government. With regard to commenters' novel Constitutional and Public Trust legal theories, see Section 2.3 of the RTC for our response.

EPA follows applicable guidance and best practices when conducting its benefit-cost analyses, including OMB Circular A-4 and EPA's Guidelines for Preparing Economic Analyses. With respect to the application of discount rates, EPA notes that it used the same discount rate as the rate used to discount the value of damages from future GHG emissions, for internal consistency. That approach to discounting follows the same approach that the February 2021 TSD recommends "to ensure internal consistency—i.e., future damages from climate change using the SC-GHG at 2.5 percent should be discounted to the base year of the analysis using the same 2.5 percent rate." EPA has also consulted the National Academies' 2017 recommendations on how SC-GHG estimates can "be combined in RIAs with other cost and benefits estimates that may use different discount rates." The National Academies reviewed "several options," including "presenting all discount rate combinations of other costs and benefits with [SC-GHG] estimates."

Comments by Organizations

Organization: A. Longo

Moreover, it is important to critically evaluate the direct correlation between these proposed regulations and substantial improvements in health conditions. While reducing emissions can have positive effects on respiratory health, it is essential to acknowledge that multiple factors influence overall health outcomes. A systematic review published in The Lancet Planetary Health journal analyzed various studies on air pollution and health outcomes. The review found that while reductions in air pollution are associated with improvements in health, the relationship between specific regulatory measures and health outcomes is complex and context-dependent [3]. [EPA-HQ-OAR-2022-0829-0517, pp. 1-2]

Organization: Alliance for Automotive Innovation

7. Environmental Justice Considerations

We agree with EPA that a reduction in heavy aromatics in gasoline will produce beneficial reductions in PM emissions that will further national environmental justice goals. EPA notes in the NPRM that people living and working near roadways will benefit from fuel improvements that reduce PM formation, that those individuals are more likely to be people of color and/or have a low socioeconomic status (SES), and that lower-SES neighborhoods are likely to have more vehicles with higher emissions than higher-SES neighborhoods.442 A fuel-based regulation to reduce PM emissions would do so for all vehicles in the on-road fleet. Importantly, the greatest absolute emissions reductions will occur in and benefit lower-SES communities, as those communities are more likely to have the highest-emitting vehicles, i.e., a higher proportion of older vehicles with the highest emissions levels (due to their vehicle's age). [EPA-HQ-OAR-2022-0829-0701, pp. 270-271]

Organization: American Fuel & Petrochemical Manufacturers

As previously mentioned, EPA did not fully consider the impact of the rule on fleet turnover. The Agency is aware that the higher purchase price of new ZEVs will keep older cars and trucks on the road longer and that new ZEVs will increase particulate matter ("PM") emissions through increased tire and road wear. In another example of EPA's biased analysis, EPA estimated the value of health benefits from reductions in PM2.5 emissions by multiplying PM2.5-related benefit-per-ton ("BPT") values by the annual reduction in tons of directly emitted PM2.5 and PM2.5 precursor emissions (NOx and SO2) from displaced ICEVs.206 However, EPA ignored the fleet turnover benefit that would result from replacing older ICEVs with new, more efficient, ICEVs.

EPA also ignored its own National Emissions Inventory, which shows that roadway dust contributes more PM2.5 emissions than the tailpipe. Roadway dust emissions, including particles from tire wear, are correlated with vehicle weight, so increases in fleet average vehicle weight would be expected to increase roadway dust PM2.5 emissions.207 Converting ICEs to ZEVs under the Proposal would significantly increase the average vehicle weight on U.S. roadways, which in turn would increase the entrained road dust emissions. Yet EPA did not include these PM sources or increases in the analysis. There also exist overall medium-duty truck weight restrictions, which could require a greater number of ZEVs to move the same tonnage of cargo, thus increasing the number of vehicles needed to haul the same amount of freight, vehicle miles traveled, and resulting PM emissions. [EPA-HQ-OAR-2022-0829-0733, p. 45]

207 EPA, "2020 National Emissions Inventory (NEI) Data," available at https://www.epa.gov/air-emissions- inventories/2020-national-emissions-inventory-nei-data.

Those emissions are significant and may offset or eliminate the benefits that EPA calculates. [EPA-HQ-OAR-2022-0829-0733, p. 45]

Organization: American Lung Association (ALA) et al.

The American Lung Association's most recent "State of the Air" report noted that approximately 120 million Americans live in communities impacted by unhealthy levels of ozone and/or particle pollution.1 Exposure to air pollution can contribute to asthma attacks, heart attacks and stroke, lung cancer, low birthweight and premature birth, premature death and other health risks. Traffic pollution specifically is associated with premature death due to cardiovascular disease, lung cancer death, asthma onset in children and adults and other negative outcomes.2 The burdens of air pollution are not equally shared: people of color make up the majority of those living in the communities with unhealthy air and a person of color in the United States is 3.7 times more likely to live in a community with the worst air pollution in the nation than a white person. . [EPA-HQ-OAR-2022-0829-0745, p. 1]

Organization: California Air Resources Board (CARB) (Part 1 of 5)

Despite significant progress reducing air pollution, California experiences some of the nation's poorest air quality, with more than 21 million Californians living in areas that exceed federal ozone standards. 3 Within these areas, there are many low-income and disadvantaged communities that are exposed to not only ozone, but also to particulate and toxic pollutant levels that are significantly higher than applicable federal standards and which have immediate and detrimental health effects. With new research demonstrating adverse health impacts even below NAAQS levels, it remains critically important to continue to reduce emissions wherever feasible. [EPA-HQ-OAR-2022-0829-0780, p. 8]

3 California Air Resources Board (CARB). 2022 State Strategy for the State Implementation Plan. October 2021.
https://ww2.arb.ca.gov/sites/default/files/2022-08/2022_State_SIP_Strategy.pdf

In addition to ongoing air quality challenges, California is on the front lines of climate change. With the increasing severity and frequency of drought, wildfire, extreme heat, and other impacts, Californians need only look out their windows to know that climate change is real and rapidly getting worse. 4 The impacts we thought we would see in the decades to come are happening now and, as with air pollution, are disproportionately affecting low-income communities and communities of color. [EPA-HQ-OAR-2022-0829-0780, p. 8]

4 CARB. 2022 Scoping Plan for Achieving Carbon Neutrality. December 2022.
https://ww2.arb.ca.gov/sites/default/files/2023-04/2022-sp.pdf.

The Proposal Will Protect Public Health

Reducing motor vehicle pollution is imperative to protect public health. U.S. EPA's proposed emission standards, or a stronger version, would effectively reduce both GHGs and criteria pollutants like PM, leading to a wide array of vital public health benefits. While U.S. EPA has comprehensively summarized the potential public health benefits of its proposal, CARB finds that there are additional public health benefits that go beyond those described. CARB has summarized its findings and notes that were U.S. EPA to include this information it would better encompass the tremendous potential benefits resulting from the proposal. [EPA-HQ-OAR-2022-0829-0780, p. 52]

Health Risk from Respiratory Infections like COVID

Exposure to elevated pollution levels is not only linked to worsening respiratory and cardiovascular diseases but also to increased vulnerability to illnesses. The recent COVID-19 pandemic raised new concerns about air pollution increasing the disproportionate burden of infectious illnesses, particularly among vulnerable communities of color because of higher PM exposures in their neighborhoods. U.S. EPA's 2022 Supplement to the 2019 PM ISA briefly described multiple recent studies in this area. CARB's recently funded research has also demonstrated the link between chronic exposure to elevated PM2.5 levels and increased cases of premature death and illness from COVID-19 in the State. 95, 96 For instance, English et al. (2022) determined that if all areas of California had PM2.5 levels below the 2022 PM2.5 NAAQS of 12.0 μg/m³, a total of 4,250 COVID-19 deaths could have been prevented during the period of this study. 97 CARB recommends that U.S. EPA add a discussion specifically about the benefits of improving air quality to reducing risks for infectious respiratory diseases, especially in the wake of the COVID pandemic [EPA-HQ-OAR-2022-0829-0780, pp. 53-54].

Disproportionate impact of exposure to Traffic-Related Air Pollution (TRAP)

While U.S. EPA conducted an extensive literature review on disparities in exposure to TRAP across U.S. populations, CARB has identified several national studies and a series of California studies that enrich the existing literature already documented by U.S. EPA for the proposed standards. [EPA-HQ-OAR-2022-0829-0780, pp. 56-57]

A recent nationwide study reported that people of color experience disproportionate exposures to PM2.5. 103 The study found that the systemic PM2.5 exposure disparity experienced by people of color is related to emission sources from almost all major emission categories. The largest sources of the disparities are industry, light-duty gasoline vehicles, construction, and heavy-duty diesel vehicles. Moreover, the disproportionate exposures have been seen in individual U.S. states, in individual urban and rural areas, across incomes, and across exposure levels. Another national study showed that zip codes with more White and Native American populations have lower average PM2.5 levels than ZIP codes with more Black, Asian, and Hispanic or Latino populations. 104 The disparities in PM2.5 exposure is also shown in zip codes with low-income populations compared to zip codes with high-income populations. Moreover, people of color in the U.S. not only face longer-term PM2.5 exposure but also short-term PM2.5 exposure (e.g., more days with PM2.5 concentrations above the thresholds) than non-Hispanic Whites. 105 [EPA-HQ-OAR-2022-0829-0780, pp. 56-57]

105 Collins TW, Grineski SE. Racial/Ethnic Disparities in Short-Term PM2.5 Air Pollution Exposures in the United States. Environ Health Perspect. 2022 Aug;130(8):87701.

Environmental pollutants affect children more than adults, and children in low-income and urban areas near industrial, rail, and traffic sources face particularly high health risks. Results from CARB’s groundbreaking, long-term children’s health study in Southern California demonstrated that particle pollution may significantly reduce lung function growth in children 106, 107, 108 and indicates these effects are likely permanent. 109 Additionally, increased exposure to vehicular traffic pollution was associated with adverse childhood health impacts, including slower lung development, 110 increased symptoms and medication use in asthmatic children, 111, 112 and increases in the development of asthma in children. 113 Compared with non-Hispanic White children, the cohort's Hispanic White children, especially those with more Native American ancestry, tended to live closer to a freeway or a major nonfreeway road. Furthermore, a higher percentage of asthma was observed among the Hispanic White children with more than 50 percent Native American ancestry who lived near a major nonfreeway road compared to those who lived farther away. 114 CARB is submitting these studies to U.S. EPA to further demonstrate the increased impacts on vulnerable populations from TRAP, pointing to the urgent need to adopt more stringent emission standards to protect these groups. CalEnviroScreen 4.0 is a screening tool developed by the California Office of Environmental Health Hazard Assessment to help identify California communities that are disproportionately burdened by multiple sources of pollution and socioeconomic indicators. Approximately 95 percent of the census tracts in this community are in the top 25 percent (75-100th percentile) of the CalEnviroScreen 4.0 120 (CES) scores within the State. The maximum overall CES score for any census tract in the community is the 99th percentile, which means that people living in that census tract are in the top 1 percent of the most impacted census tracts in the State. Most of the census tracts in this community are considered disadvantaged under California law. 121 [EPA-HQ-OAR-2022-0829-0780, pp. 60-64]

120 The Office of Environmental Health Hazard Assessment (OEHHA) released the California Communities Environmental Health Screening Tool: CalEnviroScreen 4.0 in October 2021. https://oehha.ca.gov/media/downloads/calenviroscreen/report/calenviroscreen40reportf2021.pdf

121 Disadvantaged community designations per Senate Bill (SB) 535 (De León, Chapter 830, Statutes of 2012).

Table 4 and Table 5 present the number of census tracts in the community that are in the top 25 percent (75-100th percentile) of impacted tracts in the State, as well as the maximum percentile for exposure (e.g., ozone, PM2.5, diesel PM, traffic impacts), health status (asthma, cardiovascular disease, low birth weight), and socio-economic (education, linguistic isolation, poverty, unemployment, and housing burden) indicators for the census tracts in this community. [EPA-HQ-OAR-2022-0829-0780, pp. 60-64]

Table 4. CalEnviroScreen (CES) 4.0 Overall Score in the East LA/Boyle Heights/West Commerce Community

CES 4.0 Overall Score: CES Score

Number of Census Tracts with Highest CES Scores (Top 25%, 75-100th Percentile): 51
Percent of Census Tracts with Highest CES Scores (Top 25%, 75-100th Percentile): 91%
Maximum Percentile in Community: 99.9 – (122)

[EPA-HQ-OAR-2022-0829-0780, pp. 60-64]

122 The percentages for the overall CES 4.0 score represent the number of census tracts in this community that are considered “disadvantaged” per SB 535 (75th percentile or top 25% of all census tracts in the State)

[See original for table titled “Table 5. CalEnviroScreen (CES) 4.0 Scores for Key Exposure, Health, and Socio-Economic Indicators in the East LA/Boyle Heights/West Commerce Community”]123 [EPA-HQ-OAR-2022-0829-0780, pp. 60-64]

123 The percentages for the individual CES 4.0 metrics present the number of census tracts in the community that are in the top 25 percent of census tracts for a given indicator.

Figure 6 compares the average scores for exposure (e.g., ozone, PM2.5 concentrations, diesel PM emissions, traffic impacts), health status (asthma, cardiovascular disease, low birth weight), and socio-economic (education, linguistic isolation, poverty, unemployment, and housing burden) indicators in the community against statewide averages—the community scores for these key indicators are generally higher compared to the statewide averages. [EPA-HQ-OAR-2022-0829-0780, pp. 60-64]

[See original for graph titled “Figure 6. CalEnviroScreen 4.0 Scores for Key Indicators in the East LA/Boyle Heights/West Commerce Community Relative to Statewide Averages”] [EPA-HQ-OAR-2022-0829-0780, pp. 60-64]

The indicators discussed above also explain the disparate effects of air pollution faced by other communities in California, which extends to numerous other communities across the nation. Figure 7 presents the average scores for PM2.5 concentrations and diesel PM emissions relative to statewide averages for a few communities across the State; vehicle emissions contribute predominantly to the particulate matter and diesel PM impacts in these communities. The chart includes asthma-related emergency room visits and linguistic isolation (i.e., limited English speaking) as proxies for demographic and socio-economic disadvantages faced by these communities. [EPA-HQ-OAR-2022-0829-0780, pp. 60-64]

[See original for graph titled "Figure 7. CalEnviroScreen 4.0 Scores for PM2.5 Concentration, Diesel PM Emissions, and Socio-economic Indicators in California Communities"] [EPA-HQ-OAR-2022-0829-0780, pp. 60-64]

Many California communities experience significantly higher levels of both regional and near-source air pollution, and the demographic and socio-economic characteristics of these communities exacerbate their susceptibility and vulnerability to the adverse effects of air pollution. A 2019 CARB research study revealed on-road vehicles and industrial activity to be the top two sources of exposure in California, each contributing to 24 percent of the total PM2.5 exposure, and disproportionately impacting non-white and low-income populations. 124 Existing scientific literature conclusively links air pollution to adverse health outcomes, including pre-mature mortality, and the disproportionate pollution and health burden on poor and socially disadvantaged communities. OEHHA's CES 4.0 report provides an exhaustive review of existing literature connecting each of the indicators used in the CES method to pollution burden and population sensitivities. 125 [EPA-HQ-OAR-2022-0829-0780, pp. 60-64]

124 Apte J. et al (2019). A Method to Prioritize Sources for Reducing High PM2.5 Exposures in Environmental Justice Communities in California. CARB Research Contract Number 17RD006. https://ww2.arb.ca.gov/sites/default/files/classic//research/apr/past/17rd006.pdf

125 OEHHA CES 4.0 Report. October 2021. pp. 29-197. https://oehha.ca.gov/media/downloads/calenviroscreen/report/calenviroscreen40reportf2021.pdf

The East LA, Boyle Heights, West Commerce community is just one example of many such communities across the nation that bear the consequences of near-roadway emissions, in addition to impacts from other sources of air pollution in their neighborhoods. For these communities, reducing emissions from on-road vehicles is a priority. [EPA-HQ-OAR-2022-0829-0780, pp. 60-64]

Organization: California Attorney General's Office, et al.

Strong emissions standards are necessary now to stave off the worst impacts of human-induced climate change and to confront inequitably distributed threats to public health and the environment from climate change as well as other forms of pollution. From extreme heat to wildfires to drought, our States and Cities are already experiencing the devastating impacts of climate change, which will continue to mount and compound with rising concentrations of GHGs in the atmosphere. Moreover, vehicle emissions of oxides of nitrogen (NOx), particulate matter (PM), and other criteria pollutants continue to endanger the health and welfare of our residents. [EPA-HQ-OAR-2022-0829-0746, p. 1]

B. Public Health Challenges and Poor Air Quality

Our States and Cities also face public health challenges caused by emissions of criteria pollutants and air toxics, such as fine particulate matter ("PM2.5"), nitrogen oxides ("NOx"), and non- methane organic gases ("NMOG").81 While our States and Cities are committed to reducing emissions of these harmful air pollutants,82 among other actions, federal involvement is necessary to help States attain the National Ambient Air Quality Standards ("NAAQS")83 and to reduce emissions that are outside of our control. EPA's proposed PM and NMOG+NOx emissions standards will significantly reduce emissions of harmful air pollutants from new motor vehicles sold nationwide, 88 Fed. Reg. at 29,257-58, and these reductions are critical to our

States and Cities' ability to meet our public health and environmental justice goals as well as to protect our residents. [EPA-HQ-OAR-2022-0829-0746, pp. 10-12]

1. Particulate Matter, Nitrogen Oxides, and Ozone Pollution Negatively Impact Human Health

The transportation sector is one of the largest sources of emissions of PM2.5, NOx, and other harmful air pollutants in the United States.84 88 Fed. Reg. at 29,186 ("Light- and medium-duty vehicles will account for approximately 20 percent, 19 percent, and 41 percent of 2023 mobile source NOx, PM2.5, and VOC emissions, respectively.").85 In some states and urban areas, mobile sources are the primary contributors of emissions of these harmful air pollutants.86 EPA projects that its standards will significantly reduce emissions of PM in addition to NOx and NMOGs, both of which contribute to ozone formation. Id. at 29,198, 29,344, 29,351. These reductions are crucial to avoid the serious adverse health consequences associated with these pollutants. [EPA-HQ-OAR-2022-0829-0746, pp. 12-13]

84 Calvin A. Arter, et al., Mortality-based damages per ton due to the on-road mobile sector in the Northeastern and Mid-Atlantic U.S. by region, vehicle class and precursor, 16 ENVIRONMENTAL RESEARCH LETTERS 1-2, 5 (June 2021), available at https://doi.org/10.1088/1748-9326/abf60b ("The mobile source sector remains one of the largest contributors to PM2.5 and O3 [ozone] globally and in the U.S."); 88 Fed. Reg. at 29,214 ("The primary source of NO2 is motor vehicle emissions ").

85 Volatile organic compounds (VOCs) are certain carbon compounds "which participate[] in atmospheric photochemical reactions," 40 CFR § 51.100(s), and include several NMOGs.

86 See, e.g., Vermont Department of Environmental Conservation, Agency of Natural Resources, Mobile Sources, available at https://dec.vermont.gov/air-quality/mobile-sources (onroad mobile sources contribute 49% of the NOx emissions in Vermont); California Air Resources Board, 2020 Mobile Source Strategy (Oct. 28, 2021), at 19-20, available at https://ww2.arb.ca.gov/sites/default/files/2021-12/2020_Mobile_Source_Strategy.pdf ("Every year, over 5,000 premature deaths and hundreds of illnesses and emergency room visits for respiratory and cardiovascular disease in California are linked to PM2.5 pollution, of which more than half is produced by mobile sources.").

Specifically, exposure to PM2.5 is causally related to premature mortality87 and cardiovascular impacts; consistently associated with asthma and chronic obstructive pulmonary disease exacerbation; and associated with birth outcomes, such as low birth weight and fetal growth outcomes.88 Exposure to NOx is causally related to asthma exacerbation; likely causally related to respiratory effects; and possibly causally related to cardiovascular effects, mortality, diabetes, cancer, and birth defects. 88 Fed. Reg. at 29,214. Exposure to ozone is causally related to respiratory effects, including lung function decrements, pulmonary inflammation, exacerbation of asthma, respiratory-related hospital admissions, and mortality; likely causally related to metabolic effects and complications due to diabetes; and possibly causally related to cardiovascular effects and central nervous system effects. Id. at 29,213-14. [EPA-HQ-OAR-2022-0829-0746, pp. 12-13]

> 87 Harvard T.H. Chan School of Public Health, Fossil fuel air pollution responsible for 1 in 5 deaths worldwide (Feb. 9, 2021), available at https://www.hsph.harvard.edu/c-change/news/fossil-fuel-air- pollution-responsible-for-1-in-5-deaths-worldwide/ ("[R]esearchers [were able] to directly attribute premature deaths from fine particulate pollution (PM2.5) to fossil fuel combustion") (citing Karn Vohra, et al., Global mortality from outdoor fine particle pollution generated by fossil fuel combustion: Results from GEOS-Chem, 195 ENVIRONMENTAL RESEARCH (Apr. 2021)); Arter, supra n. 84, at 5 ("The largest source of both PM2.5 and O3[ozone]-attributable premature mortalities are LDT [light-duty trucks] at 1234 and 1229 mortalities, respectively. LDT PPM emissions are responsible for 46% of PM2.5 mortalities, and LDT NOx emissions are responsible for 80% of O3 [ozone] mortalities.")

> 88 See Comment of California Air Resources Board on "Proposed Rule for National Ambient Air Quality Standards (NAAQS) for Particulate Matter" (Jun. 29, 2020), EPA-HQ-OAR-2015-0072-0975.

2. Air Toxics Threaten Public Health

EPA projects that its standards would result in the reduction of emissions of air toxics. 88 Fed. Reg. at 29,199, 29,359. These reductions will also benefit public health and welfare, given the link between toxic air pollutants and cancer and other serious health effects. Id. at 29,216 ("Light- and medium-duty engine emissions contribute to ambient levels of air toxics that are known or suspected human or animal carcinogens, or that have noncancer health effects."); 72 Fed. Reg. 8,428, 8,430 (Feb. 26, 2007). Of all the outdoor air toxics, benzene contributes the most to nationwide cancer risk, and most of the nation's benzene emissions come from mobile sources. Id. at 8,432. In New Jersey, for example, mobile sources are the largest contributors of air toxics emissions and responsible for over 50% of the state's ambient benzene.89 In Allegheny County in Pennsylvania, mobile sources account for over 9% of the estimated cancer risk from hazardous air pollutants, largely due to gasoline-powered vehicles.90 [EPA-HQ-OAR-2022-0829-0746, p. 13]

> 89 New Jersey Department of Environmental Protection, 2021 New Jersey Air Quality Report (Sep. 2022), at 10-1, 10-10, available at https://www.nj.gov/dep/airmon/pdf/2021-nj-aq-report.pdf.

3. Criteria Pollutant and Air Toxics Emissions from Light- and Medium-Duty Vehicles Disproportionately Impact Environmental Justice Communities

Criteria pollutant emissions from light- and medium-duty vehicles disproportionately endanger residents of environmental justice communities by exposing them to harmful air pollution that causes significant health impacts. Light- and medium-duty vehicles' emissions are concentrated along transportation corridors. 88 Fed. Reg. at 29,396. Aggravating historical injustices, decision-makers disproportionately site highways and other transportation infrastructure in lower-income communities and communities of color. The burden of vehicle emissions therefore falls inequitably on environmental justice communities, which also face industrial pollution cumulatively with vehicle emissions.91 [EPA-HQ-OAR-2022-0829-0746, pp. 13-15]

91 See, e.g., EPA, Estimation of Population Size and Demographic Characteristics among People Living Near Truck Routes in the Coterminous United States (Feb. 16, 2022), EPA-HQ-OAR-2019-0055-0982, at 11-12, Fig. 3, 17-19, Fig. 9 (finding that individuals living near major truck routes are more likely to be people of color and lower-income); see also Michelle Meyer and Tim Dallmann, The Real Urban Emissions Initiative, Air quality and health impacts of diesel truck emissions in New York City and policy implications (2022), at 7 Fig. 5 (concluding that Black and Latino individuals in New York City are disproportionately exposed to PM2.5 along freight corridors); Gaige Hunter Kerr, et al., COVID-19 Pandemic Reveals Persistent Disparities in Nitrogen Dioxide Pollution, 118 PROC. NAT'L ACAD. SCIENCES 30 (2021); Mary Angelique G. Demetillo, et al. Space-Based Observational Constraints on NO2 Air Pollution Inequality from Diesel Traffic in Major US Cities, GEOPHYSICAL RESEARCH LETTERS 48 (2021); Paul Allen, et al., Newark Community Impacts of Mobile Source Emissions: A Community- Based Participatory Research Analysis (2020); Maria Cecilia Pinto de Moura, et al., Union of Concerned Scientists, Inequitable Exposure to Air Pollution from Vehicles in Massachusetts (2019); Iyad Kheirbek, et al., The Contribution of Motor Vehicle Emissions to Ambient Fine Particulate Matter Public Health Impacts in New York City: a Health Burden Assessment, 15 ENV'T HEALTH 89 (2016).

For example, EPA modeling has shown that race and income are significantly associated with living near major roadways nationally, even when controlling for other factors.92 EPA research has also indicated that people of color are more likely to live within 300 feet of major transportation facilities and go to school within 200 meters of the largest roadways.93 Environmental justice communities bear the effects of these land use patterns. In the Northeast and Mid-Atlantic Region, average concentrations of exposures to PM2.5 are 75%, 73%, and 61% higher for Latinx residents, Asian-American residents, and African American residents, respectively, than they are for white residents.94 PM2.5 and NO2 concentrations are also highest for Black and Latinx communities in Massachusetts, in part because of their proximity to industrial facilities and highways, and these concentrations have increased over time even though overall exposure to those pollutants has decreased in the Commonwealth.95 [EPA-HQ-OAR-2022-0829-0746, pp. 13-15]

6029002812	Bakersfield	72.5%	94th	100th	96th
6029002813	Bakersfield	76.6%	94th	100th	95th

[EPA-HQ-OAR-2022-0829-0746, pp. 13-15]

96 Data from CalEnviroScreen 4.0, California Office of Environmental Health Hazard Assessment, available at https://oehha.ca.gov/calenviroscreen/report/calenviroscreen-40. Metrics for ozone, PM2.5, and diesel particulate matter exposure are the census tract's percentile ranking as compared to all census tracts in California, demonstrating that these census tracts are among those with the greatest pollution exposure statewide. The raw data for these percentile rankings are available on the CalEnviroScreen 4.0 website. The eight census tracts shown here are examples of the 29 census tracts in California that rank above the 90th percentile statewide for exposure to ozone, fine particulate matter, and diesel particulate matter, all of which are communities in Bakersfield or the Inland Empire near major transportation thoroughfares.

Refineries, drilling sites, and other upstream sources of emissions are also disproportionately located in or near environmental justice communities.97 These facilities routinely emit dozens of toxic air contaminants, such as formaldehyde and benzene, and can cause accidental releases of air toxics that require emergency response. 98 Many of these upstream emissions sources also release other pollution, such as water contaminants.99 Residents of communities near these sites tend to have higher rates of health problems, such as cancers, chronic disease, and adverse birth outcomes, even after accounting for other demographic factors.100 As with transportation corridors, census tract-level data from California demonstrate these concerns. For example, the census tracts near the California refinery with the largest output (the Marathon Refinery in Carson)101 are overwhelmingly communities of color with high cumulative pollution burdens and adverse health outcomes: [EPA-HQ-OAR-2022-0829-0746, pp. 15-16]

[EPA-HQ-OAR-2022-0829-0746, pp. 15-16]

102 Data from CalEnviroScreen 4.0, supra n.96. Metrics for overall pollution burden, toxic releases, asthma, and heart disease are the census tract's percentile ranking as compared to all census tracts in California, demonstrating that these census tracts are among those with the greatest pollution exposure and detrimental health impacts statewide.

Accordingly, achieving emissions reductions from light- and medium-duty vehicles is a critical step to begin dismantling historical patterns of environmental injustice burdening communities near transportation infrastructure and upstream emissions sources. See CARB's Comment at 84- 96. [EPA-HQ-OAR-2022-0829-0746, pp. 15-16]

2. Reductions in Criteria and Air Toxic Pollution Are Urgently Needed to Protect Public Health and Welfare

EPA's Proposal will advance another important, urgent objective of our States and Cities and of Congress: reductions in criteria and toxic air pollution. GHG reductions mitigate the public health harms from other pollutants, because "[i]n a warmer future world, stagnant air, coupled with higher temperatures and absolute humidity, will lead to worse air quality even if air pollution emissions remain the same."174 Additionally, the Proposal's tightened standards for criteria and toxics pollution will directly aid our States and Cities in attaining and maintaining NAAQS for criteria pollutants, securing better health and welfare outcomes for their residents, and promoting environmental justice in their communities. [EPA-HQ-OAR-2022-0829-0746, pp. 29-31]

174 Nat'l Research Council, Advancing the Science of Climate Change (2010) at 326, available at http://nap.edu/12782.

a. More stringent standards will help protect public health and support NAAQS attainment

Various locations throughout our States and Cities have been unable to attain, or face difficulty maintaining, the NAAQS—designed to protect public health—for ozone and

PM2.5.175 42 U.S.C.§ 7409(b). For example, multiple counties in California are registering serious, severe, or extreme nonattainment with the 8-Hour Ozone NAAQS. As EPA notes, the two major precursors of ozone are NOx and volatile organic compounds ("VOCs"). 88 Fed. Reg. at 29,210. The proposed standards would cut NOx emissions from light- and medium-duty vehicles by 41% and VOC emissions by 50% by 2055, while the Alternative 1 standards would cut these emissions by 44% and 55%, respectively. Id. at 29,198, 29,204. These major reductions are crucial to helping States attain and maintain the ozone NAAQS. [EPA-HQ-OAR-2022-0829-0746, pp. 29-31]

175 EPA, Current Nonattainment Counties for All Criteria Pollutants, supra n. 81 (providing NAAQS compliance status of all counties); CARB, Criteria Pollutant Emission Reductions from California's Zero-Emission Vehicle Standards for Model Years 2017-2025 (Jul. 6, 2021), at 5, App. A to Comments of States and Cities in Support of EPA Reversing Its SAFE 1 Actions.

While California has adopted stringent emission standards for ozone precursors for vehicles sold in-state, federal standards will further reduce ozone impacts from vehicles sold out of state that travel into California. Reductions in ozone due to the proposed standards would thus provide critical clean air benefits to these locations. Nonattainment areas outside of California will experience similar benefits. For example, more stringent standards may result in a reduction of ozone precursors in Colorado's Denver Metro/North Front Range, which includes a major transportation corridor and a refinery. In 2022, EPA reclassified this area from serious to severe nonattainment for the 2008 8-Hour Ozone NAAQS, and, thus, any and all reductions in ozone precursors are needed. Likewise, counties in Connecticut, New Jersey's and New York are in serious to severe nonattainment with the 2008 8-Hour Ozone NAAQS and are in moderate nonattainment with the 2015 8-Hour Ozone NAAQS. These challenges in attaining the NAAQS are due in part to ozone-forming pollution from out-of-state upwind sources, which EPA's standards will help reduce.176 84 Fed. Reg. 44,223, 44,245, 44,248, 44,251–44,252 (Aug. 23, 2019) ("EPA acknowledges the role interstate transport of precursors to ozone pollution plays in the efforts of downwind areas to attain and maintain the NAAQS."). New Jersey has taken action to reduce NOx and VOC emissions from mobile sources and from stationary sources, including power plants and refineries, in an attempt to attain the NAAQS.177 But New Jersey and other States cannot attain or maintain the NAAQS alone,178 and EPA's standards will provide important emissions reductions in upwind states and across the country.179 [EPA-HQ-OAR-2022-0829-0746, pp. 29-31]

178 Id. at xii.

179 EPA, Current Nonattainment Counties for All Criteria Pollutants, supra note 81.

Several counties in our States are in moderate to serious nonattainment for the 1997, 2006, and 2012 PM2.5 NAAQS,180 and the projected 35% reductions in PM2.5 that the proposed standards will yield by 2055 will help States attain and maintain NAAQS for PM2.5. See 88 Fed. Reg. at 29,198, 29,204 (describing expected emissions reductions). Moreover, PM2.5 exposure at any level is associated with adverse health impacts, so reductions in PM2.5 emissions will bring public health benefits to our States and Cities regardless of whether our regions have attained the NAAQS.181 Indeed, because PM2.5 exposure below the current NAAQS is clearly harmful, a multi-state coalition, which includes many of the signatories to this comment, petitioned EPA to reconsider its 2020 decision not to strengthen the current NAAQS for Particulate Matter. See CARB Comment at 76-77. On January 27, 2023, EPA proposed to find the current NAAQS are inadequate to protect public health with an adequate margin of safety and to tighten the primary NAAQS for PM2.5. 88 Fed. Reg. 5,558, 5,561 (Jan. 27, 2023). [EPA-HQ-OAR-2022-0829-0746, pp. 29-31]

Organization: Center for American Progress (CAP)

It is critically important that EPA finalize the strongest possible standard by the end of 2023. Americans' health and the climate crisis cannot afford to wait for reductions in vehicle emissions. The American Lung Association's (ALA) 2023 State of the Air Report finds that 36 percent of Americans live in areas with failing grades for ozone or particulate pollution.1 Research from Harvard University finds 17,000 to 20,000 deaths per year in the U.S. can be attributed to particulate matter (PM) pollution from transportation alone.2 Achieving the Biden Administration's goal of zero transportation emissions by 2050, as called for in the National Blueprint for Transportation Decarbonization, would have immense health benefits.3 The ALA estimates that achieving zero transportation emissions as well as zero power sector emissions would avoid 110,000 premature deaths between 2020 and 2050 in addition to 2.78 million avoided asthma attacks and 13.4 million lost workdays. This translates to $1.2 trillion in health benefits and $1.7 trillion in climate benefits by 2050.4 [EPA-HQ-OAR-2022-0829-0658, p. 1]

Organization: Ceres BICEP (Business for Innovative Climate and Energy Policy) Network

Finally, on-road vehicles are largely responsible for the harmful pollutant emissions that disproportionally impact historically low-income and BIPOC16 communities located near fleet depots, major transportation corridors, distribution centers, and ports. 36% of Americans live in communities with unhealthy air pollution, and a person of color is 64% more likely than a white person to live in such a community.17 Further, the American Lung Association predicts that the

U.S. could see $978 billion in public health benefits from cleaner air by 2050 as the nation shifts to 100% zero-emission new passenger vehicle sales and clean electricity generation.18 EPA's decision to reduce multipollutant vehicle emissions is positive, and we urge EPA to finalize LMDV emission standards at least as strong as those proposed as soon as possible to protect the health of those in these vulnerable communities and realize these significant economic benefits. Organization: Clean Fuels Development Coalition et al.

The MY2027 and Later Multipollutant Emissions is an ambitious undertaking and Administrator Regan is to be commended as it appears to contain many worthwhile initiatives. However, unless significant changes are made to the NPRM before it is finalized—including those offered here—it will leave huge opportunities to improve climate and health unfulfilled. [EPA-HQ-OAR-2022-0829-0630, pp. 1-2]

In December 2021, EPA finalized the landmark MY2023 and Later LDV GHG Rule to which we registered strong opposition. Unfortunately, like this NPRM, EPA did not address the dramatic increases in SOA + PAH emissions that are already being caused by the rapid adoption of GDI engines in the absence of gasoline BTEX controls. Of even greater concern—as the U.S. LDV fleet rapidly adopts GDI engines, the most harmful UFP + PAH emissions will dramatically INCREASE. [EPA-HQ-OAR-2022-0829-0630, pp. 1-2]

We understand that the primary thrust of this rulemaking is to drive commercialization of electric vehicles. However, it is also widely understood that this process will take many years/decades, perhaps even generations. For many years, ICE-powered vehicles will require gasoline and other liquid fuels, and trillions of miles will be driven on them before EVs dominate the U.S. fleet. EPA staff recently pledged [Link: https://insideepa.com/node/238985] that the rule would reflect a "balanced approach" taking into account both electrification trends and a projection that 100 million conventional light- and medium-duty vehicles could be sold before any full transition to electric vehicles (EVs). [EPA-HQ-OAR-2022-0829-0630, pp. 1-2]

When Congress was banning leaded gasoline for its horrific health effects in the 1990 Clean Air Act Amendments, it went to extraordinary lengths to ensure that EPA avoided making the same mistake with BTEX compounds which are in many respects worse than lead. Congress knew that fuel quality and vehicle emissions control systems were part of an integrated system and that three-way catalysts were unable to capture BTEX combustion by-products. Consequently, Congress gave EPA the nondiscretionary duty to reduce BTEX emissions by the "greatest degree achievable", (Sec 202(l)(2)) as explained in more detail below. [EPA-HQ-OAR-2022-0829-0630, pp. 1-2]

Many experts believe that the 20% BTEX fraction found in a typical gallon of U.S. gasoline poses the single greatest threat to public health and the environment. "The effect of aromatics [BTEX] on pollution and human health is thus magnified twice over: Aromatics lead disproportionately to PAH formation, and PAHs lead disproportionately to SOA formation. Worse yet, PAHs hitch a ride on SOA for long distances and weaponize these particles as they travel through the human body…When SOA particles are formed in the presence of gas-phase PAHs, their formation and properties are significantly different from SOA particles formed without PAHs: They exhibit slower evaporation kinetics and have higher fractions of non-volatile components and higher viscosities, assuring their longer atmospheric lifetimes. This increased viscosity and decreased volatility act as a shield that protects PAHs from chemical degradation and evaporation, allowing for their long-range transport.” [Detchon – Modlin MY2023 Final Rule comments, p. 17. RDRMCommentsEPA-HQ-OAR.pdf (cleanfuelsdc.org)] [Link: https://cleanfuelsdc.org/wp-content/uploads/2021/09/RDRMCommentsEPA-HQ-OAR.pdf] [EPA-HQ-OAR-2022-0829-0630, pp. 1-2]

Americans cannot escape the harmful emissions produced by tens of billions of gallons of BTEX contained in U.S. gasoline. That is why last fall we wrote Administrator Regan to commend him on his aggressive actions to control emissions of highly persistent, pervasive, and toxic PFAS. ReganDuranteFinePMPFAs8-30-22 (cleanfuelsdc.org) [Link: https://cleanfuelsdc.org/wp-content/uploads/2022/09/ReganDuranteFinePMPFAs8-30-22.pdf] We urged the Administrator to apply those same exacting standards to regulating BTEX-produced MSATs under the Fine PM and MY2027 Multipollutant NPRMs, because “By any metric, gasoline PAH emissions are as bad or worse than PFAS for public health and the environment.” [p. 4] In fact, many experts believe that SOA-bound PAH are more pervasive, have a higher “deposition efficiency”, and are less susceptible to remediation than PFAS once they are emitted from the tailpipe and undergo atmospheric transformation. [EPA-HQ-OAR-2022-0829-0630, pp. 1-2]

PAHs are not only carcinogenic and highly carbon-intensive, they are also mutagenic and reprotoxic (CMR) and widely recognized by health experts as ubiquitous endocrine disruptor compounds (EDCs). [See discussion of 2018 EPA Riedel study on p. 9, ResearchGate https://www.researchgate.net/publication/315864231_Mutagenicity_an d_Carcinogenicity] [EPA-HQ-OAR-2022-0829-0630, pp. 1-2]

The science is indisputable: unless EPA recognizes and honors its legal obligation to substantially reduce gasoline BTEX levels in the final MY2027 rule, it will among other undesirable consequences violate President Biden’s Executive Order 13045, “Protection of Children from Environmental Health Risks and Safety Risks”. Beginning at p. 598 of the NPRM, EPA states “that the environmental health risks or safety risks of the pollutants addressed by this action may have a disproportionate effect on children”. It goes on to describe how children are more susceptible than adults to air pollutants. In fact, the SOA-bound PAHs that are either deliberately or inadvertently omitted from the NPRM have been widely acknowledged by health experts as a predominant cause of some of the most adverse health end points for children, including pre-term births, IQ loss, asthma, cardiopulmonary conditions, and a wide range of cancers. [EPA-HQ-OAR-2022-0829-0630, pp. 1-2]

Criteria Pollutant Standards for ICE Vehicles. At p. 42, EPA proposes a particulate matter (PM) standard of 0.5 mg/mi and makes the remarkable (and untrue) assertion that “the standards will reduce tailpipe PM emissions from ICE vehicles by more than 95 percent”! It goes on to say that the proposal will also “reduce emissions of mobile source air toxics.” According to the Health Effects Institute: “It is estimated that about 50% of the benzene produced in the exhaust is the result of decomposition of aromatic hydrocarbons in the fuel…two studies showed that lowering aromatics levels in gasoline significantly reduces toxic benzene emissions from vehicles exhausts.” [Detchon – Modlin, p. 6, FH #23. RDRMCommentsEPA-HQ-OAR.pdf (cleanfuelsdc.org)] [Link: https://cleanfuelsdc.org/wp-content/uploads/2021/09/RDRMCommentsEPA-HQ-OAR.pdf]

Despite OTAQ assurances, continuation of “business as usual” will ensure dramatic increases in the most harmful ultrafine particulates and their associated PAH and other toxics. False assurances like these threaten public health and the environment by lulling the public, health experts, and policymakers into a false sense of complacency that all is well, when the reality is that things are bad and rapidly getting worse. [EPA-HQ-OAR-2022-0829-0712, pp. 2-3]

Despite the magnitude and immediacy of the health threat, EPA attempts to address its gasoline quality “Achilles’ heel” beginning at p. 572, “Consideration of Potential Fuels Controls for a Future Rulemaking”. EPA states “there is an opportunity to further address PM emissions from the existing vehicle fleet, the millions of vehicles produced during the phase-in period…through changes in market fuel composition…we expect that tens of millions of gasoline-powered sources will remain in use well into the 2030s.” [EPA-HQ-OAR-2022-0829-0712, pp. 2-3]

However, despite the nondiscretionary duty Congress imposed on it in the 1990 CAAA, EPA does what it has done for more than 30 years—defers “potential” action to a “future rulemaking” by requesting comment on possible changes to “gasoline fuel property standards”. EPA falsely states that it must act under CAA section 211c and that “such changes are beyond the scope of this rulemaking”. In fact, the NPRM rests its authority upon CAA section 202, and section 202(l) imposes a clear nondiscretionary requirement that EPA must ensure that fuel quality improvement— specifically BTEX reduction—is employed as a co-equal regulatory tool to reinforce vehicle technology advances. [EPA-HQ-OAR-2022-0829-0712, pp. 2-3]

No action could be more germane to this rule than reducing gasoline BTEX content to achieve substantial, and immediate, reductions in the most toxic and carbon intensive ICE tailpipe emissions. In fact, after more than 30 years of inaction, EPA’s failure to comply with CAA section 202(l) unquestionably qualifies as “action unreasonably withheld”. Accepting more years of inaction will unnecessarily harm yet another generation of American children. [EPA-HQ-OAR-2022-0829-0712, pp. 2-3]

In a letter to Doug Sombke, South Dakota Farmers Union president, Christopher Grundler, then-director of OTAQ, described his view of CAA section 202(l): “With respect to CAA section 202(l), the EPA has acted twice under this specific authority, including the February 2007 rule that addresses the aromatics content of gasoline through required limits on benzene…Since Congress established section 202(l) in the CAAA of 1990, the net result of the EPA regulations and market shifts has been a reduction in gasoline benzene levels by roughly two thirds and aromatics levels by roughly one third…In combination, these fuel and vehicle standards have already dramatically reduced air toxics emissions. While the EPA continues to look for opportunities to further reduce air toxics, as required by CAA section 202(l), we must also consider technological feasibility and costs, among other factors. We take our regulatory authority very seriously and must ensure the appropriateness of taking further regulatory action before doing so.”1 [EPA-HQ-OAR-2022-0829-0712, pp. 2-3]

1 Christopher Grundler, EPA Office of Transportation and Air Quality, letter to Doug Sombke, SDFU president, March 15, 2018.

It should be noted that Mr. Grundler cites the non-benzene aromatics reductions which occurred not due to EPA's actions, but thanks to Congressional ethanol requirements under Renewable Fuel Standards 1 and 2. Experts have estimated that the RFS program—which made E10 the nation's in-use fuel—displaced nearly 10 billion gallons per year of aromatics as refiners adjusted their blendstocks to accommodate ethanol's higher octane. [EPA-HQ-OAR-2022-0829-0712, pp. 2-3]

The NPRM indirectly acknowledged the importance of ethanol's rise in the nation's gasoline pool at p. 579: "A common thread across the market shifts in T90 has been a decreasing gasoline-to-distillate ratio (GDR) in the product slates produced by refiners…Perhaps the most important factor affecting GDR was the influx of ethanol into gasoline. The increasing ethanol volume displaced a portion of petroleum, which caused refiners to move more of the midrange gasoline cut into the distillate pool. Ethanol's octane also allowed refiners to back out aromatic content." [Emphasis supplied.] [EPA-HQ-OAR-2022-0829-0712, pp. 2-3]

For many years, automakers have implored EPA to ensure the availability of higher- octane fuels (HOFs) because "octane is the single most important fuel property in designing an internal combustion engine", according to Mercedes Benz. In the U.S., only two commercially available octane boosting compounds are legally permitted for use in gasoline—benzene-based aromatic compounds commonly known as BTEX (benzene, toluene, ethyl-benzene, xylene) and ethanol. A typical gallon of U.S. gasoline contains approximately 20% BTEX and 10% ethanol. Congress has directed EPA to reduce the carcinogenic mobile source air toxics (MSATs) produced by the incomplete combustion of BTEX "the greatest degree of emission reduction achievable through the application of technology which will be available". RDRMCommentsEPA-HQ-OAR.pdf (cleanfuelsdc.org) [Link: https://cleanfuelsdc.org/wp-content/uploads/2021/09/RDRMCommentsEPA-HQ-OAR.pdf] [p. 2] [EPA-HQ-OAR-2022-0829-0712, pp. 2-3]

This comment will explain some of the many obstacles that stand in the way of EPA finalizing this proposed rule: an absence of statutory authorization, the commands of the APA, the infeasibility of electrification scheme, and the tremendous and overlooked costs associated with the plan. All these failures result from the Biden's Administration's myopic conclusion that electric vehicles are the best and only way to reduce greenhouse-gas emissions from the transportation sector. This is foolish. [EPA-HQ-OAR-2022-0829-0712, pp. 2-3]

Renewable fuels are a far more feasible, cost effective, and lawful way to reduce emissions from light-duty vehicles. The blending of 10 percent renewable ethanol in the nation's fuel supply already reduces greenhouse gas emissions from the light-duty fleet by tens of millions of tons a year. And we could do better. EPA has determined that E15 is suitable for use in all model year 2001 and later vehicles. Many newer vehicles on the road could run on mid-level blends like E25. Every automaker could readily make vehicles designed to run on mid-level blends with only minimal design changes. These mid-level blends reduce the carbon intensity of liquid fuels, enable more fuel-efficient engines, and reduce aromatics and particulate matter. EPA has the statutory authority to account for these savings in its standard setting, and it has done so in the past. Reinstituting such a system would incentivize the use of more renewable fuels, and allow automakers to achieve greater emissions reductions, in a shorter time frame, and at a net savings to consumers. At the very least, EPA can reform the way engines are tested to better align with reality. [EPA-HQ-OAR-2022-0829-0712, pp. 2-3]

Section 202(l)'s mandatory directive is unique for its "legislative endangerment" language, as well as the legislative history's clear Congressional expectation that EPA would employ "technology-forcing" regulatory strategies to improve gasoline quality by substantially reducing BTEX content. While it was banning the use of poisonous tetraethyl lead in leaded gasoline in the 1990 Clean Air Act Amendments, Congress took extraordinary steps to ensure that EPA used its authority to require petroleum refiners to improve fuel quality and thus complement automakers' efforts to improve vehicle technologies. In the ensuing years, OTAQ has ignored the "technology-forcing" requirements imposed by Congress by refusing to improve gasoline quality by requiring an orderly reduction in BTEX and replacement with ethanol's superior, low-carbon, low-toxics octane. [See Detchon – Modlin MY2023 Final Rule comments discussion on "EPA's response to a legislative mandate" pp. 21 – 31] [EPA-HQ-OAR-2022-0829-0630, pp. 3-5]

The Clean Air Act makes it perfectly clear that EPA requires only one "metric" for guidance on how best to reduce BTEX content—and it is not some permutation of the GDR. It is the mandatory language in CAA section 202(l). [EPA-HQ-OAR-2022-0829-0630, pp. 3-5]

> Technology-Forcing Legal Precedents Put the Burden on EPA to Encourage E30 HOLC Fuels. "Technology-forcing" language has been used by Congress throughout the Clean Air Act, not only in section 202(l) [see NRDC v. EPA, 655 F.2d 318, 328 (DC Circuit 1981): "Congress intended the agency to project future advances in pollution control technology. It was expected to press for development and application of improved technology rather than be limited by that which exists today." Ecology Law Quarterly, FN#126]. However, as the record makes clear, OTAQ has done the exact opposite. It has gone to extraordinary, even unlawful, lengths to OBSTRUCT the development of higher quality fuels which are required to complement advanced engine technologies.

EPA's sub-sim interpretation that prohibits the use of HOLC fuels like E30 in existing vehicles is unlawful and contrary to Congressional intent. Since EPA established E10 as the nation's certification fuel in January 2017, it cannot prohibit increased concentrations of ethanol for use in existing vehicles unless it complies with all of the steps that Congress set forth in CAA section 211c. The burden of proof is on EPA, including the legal precedents set by 42 U.S.C. 7545, which require EPA to prove that prohibiting increased ethanol use will NOT result in the use of another octane substitute—BTEX—that makes tailpipe emissions even worse. Especially now with the rapid adoption of GDI engines, EPA cannot make such a finding. Finally, section 202(l) and the 1990 CAAA also require EPA to apply Maximum Achievable Control Technology (MACT) standards to fuel quality improvements. The U.S. light-duty vehicle (LDV) fleet's ICE vehicles require gasoline of sufficient—ideally much higher than today's—octane or they will not operate properly. Fuel efficiency improvements and carbon reductions require the use of HOLC Fuels. EPA cannot comply with the statute's "greatest emissions reduction achievable" requirement unless it encourages an orderly transition to nationwide use of E30 "clean octane" fuels. By blocking such use, EPA is imposing a "de facto" BTEX mandate on U.S. consumers because there are only two commercially available, cost effective, and (at least thus far) legally permissible octane enhancing compounds: BTEX and ethanol. Subsequent Congressional decisions in both RFS1 and RFS2 (2005 EPACT and 2007 EISA) make it clear that Congress intended for ethanol to replace BTEX—and that EPA's duty is to promulgate the necessary regulations to optimize those results. [EPA-HQ-OAR-2022-0829-0630, p. 5]

Unfortunately, EPA has spent the past thirty years doing the exact opposite. In fact, EPA's fuel efficiency demands have driven automakers to accelerate the introduction of gasoline direct injection (GDI) engines which in the absence of BTEX controls dramatically increase emissions of the most harmful ultrafine particulates and their associated toxics, especially polycyclic aromatic hydrocarbons (PAHs). [EPA-HQ-OAR-2022-0829-0630, p. 5]

Restricting BTEX Controls to "High-Boiling" Aromatics Will Not Solve the Problem. [EPA-HQ-OAR-2022-0829-0630, p. 7]

At p. 572 of the NPRM, EPA introduced the concept of limiting "high-boiling compounds in gasoline" that have been linked to increased tailpipe PM emissions. The Agency noted that "the high-boiling tail of gasoline contains a high proportion of aromatics and that the heaviest few percent of this material has very high leverage on PM emissions". [EPA-HQ-OAR-2022-0829-0630, p. 7]

As interesting as this discussion is—and while it is a worthy goal to limit high-boiling compounds—we are concerned by EPA's apparent interest in limiting BTEX control to a "few percent" of the average twenty percent fraction contained in a typical gallon of U.S. gasoline. Limiting BTEX control to the small high-boiling fraction would most certainly not be consistent with the spirit and letter of the Congressional mandate in CAA section 202(l) that requires EPA to reduce BTEX by the "greatest degree of emission reduction achievable through the application of technology which will be available." In fact, OTAQ experts implicitly admitted that more is needed when they issued their 2016 report on the 2015 UFP Workshop when they said this: [EPA-HQ-OAR-2022-0829-0630, p. 7]

> OTAQ experts admitted that its MOVES Model was defective and in need of replacement more than seven years ago: "a new SOA paradigm has been developed". [see Detchon/Modlin comments, p. 19, FN#109].

"[SOA] particles play an important role in air quality but for many years available atmospheric models were not able to predict SOA formation. The main issue was the fact that all models relied on the assumptions that SOA particles were well-mixed low viscosity solutions and maintained equilibrium with the gas-phase by rapid mixing in the condensed phase with evaporation and condensation. Recent studies using the multidimensional characterization approach demonstrated that these assumptions were wrong and that SOA particles must be viscous semi-solid. These studies showed also that there is a synergetic effect between PAHs and SOA since PAHs trapped inside the SOA particles slow down SOA evaporation and increase SOA yield and lifetime. This can explain the long-range transport of toxic compounds like PAHs and other persistent pollutants. In conclusion, a new SOA paradigm has been developed."3 (Emphasis supplied] [EPA-HQ-OAR-2022-0829-0630, p. 7]

> 3 Richard W. Baldauf et al., "Ultrafine Particle Metric and Research Considerations: Review of the 2015 UFP Workshop," International Journal of Environmental Research and Public Health (2016):13(11): p.13: https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5129264/pdf/jerph-13-01054.pdf (accessed Feb. 24, 2021).

For all these reasons, EPA cannot focus only on the few percent of the "high boiler" BTEX fraction of gasoline—it must reduce BTEX to the greatest degree achievable as required by Congress. [EPA-HQ-OAR-2022-0829-0630, p. 7]

Despite its enormous deterrent effect on EPA's regulation of mobile source air toxics, however, EPA has yet to correct MOVES. In fact, EPA continues to use the MOVES Model to support its most consequential rulemakings, including the MY2023 and Later LDV GHG Rule, see end notes, p. 20-22. [EPA-HQ-OAR-2022-0829-0630, p. 7]

SOA from Gasoline Aromatics. On p. 591, EPA noted that “Mobile sources are an important contributor to secondary aerosols formed from nitrate, sulfate and organic precursors. Studies have shown that secondary organic aerosol (SOA) formation from gasoline vehicle exhaust can exceed directly emitted (tailpipe) PM emissions, and that changes to gasoline formulation can have impacts on SOA that are larger than the associated shifts in direct PM emissions.” [EPA-HQ-OAR-2022-0829-0630, p. 8]

This statement seems at odds with the Agency’s claim that the proposed rule would reduce PM emissions by “more than 95 percent”. In fact, EPA historically has vastly understated the substantial contributions mobile sources—especially gasoline BTEX— make to SOA + PAH formation. [EPA-HQ-OAR-2022-0829-0630, p. 8]

Former OTAQ Director Grundler offered this explanation to SDFU President Sombke: “With respect to your concern that the EPA’s models incorrectly predict the contribution of light-duty gasoline vehicles to PM (e.g., as compared to leaf blowers) it is important to note that the EPA estimates cited in the Wall Street Journal refer only to directly emitted PM. We agree that ambient levels of PM are a result of secondarily formed particles in addition to direct PM emissions, and that light-duty gasoline vehicles are important sources of precursors to PM formation.”4 [Emphasis supplied] [EPA-HQ-OAR-2022-0829-0630, p. 8]

4 Supra, Grundler letter to Sombke, March 15, 2018.

It took several exchanges to elicit this admission five years ago. It is clear from EPA’s claim that the proposed rule would reduce PM emissions by “more than 95 percent” that the Agency continues to downplay the disproportionate role SOA plays in fine and ultrafine particulate emissions. [EPA-HQ-OAR-2022-0829-0630, p. 8]

Leading experts are convinced that aromatics (“organics”) are the primary culprit. “An important recent study, co-authored by the Nobel Prize winner Mario Molina, concluded that reducing the smallest (ultrafine) particles “without simultaneously limiting organics from automobile emissions is ineffective and can even exacerbate this problem”. [Detchon/Modlin 2021 comments, p. 2.] This has implications not only for GDI engine emissions effects, but also for the NPRM’s gasoline particulate filter (GPF) strategies. [EPA-HQ-OAR-2022-0829-0630, p. 8]

Detchon and Modlin went on to note that “Emissions from aromatic compounds in gasoline were thought to be short-lived, thus posing little threat to human health. But that was wrong. A recent General Motors study found that nearly 96% of the fine particle emissions from gasoline are caused by the aromatics in the fuel”. [Ibid., p. 1] [EPA-HQ-OAR-2022-0829-0630, p. 8]

In a letter to Acting OAR Administrator Joseph Goffman, former Senate Majority Leader Tom Daschle cited these experts and then cautioned EPA that failure to control BTEX would severely compromise, perhaps doom, EPA’s PM control strategies DaschleGoffmanHOLCAexecutedjune2021.pdf: [Link: file:///C:/Users/dehbi/AppData/Local/Microsoft/Windows/INetCache/Content.Outlook/OFSN24IW/DaschleGoffmanHOLCAexecutedjune2021.pdf] [EPA-HQ-OAR-2022-0829-0630, p. 8]

"Given the role of aromatic hydrocarbons in PM formation and given the propensity of GDI engines to increase emissions of UFPs, EPA's strategies for regulating fine particle pollution in urban areas are doomed to failure unless they significantly reduce gasoline aromatics." A prescient statement that is proving itself to be even more true as GDI engines dominate the U.S. fleet. [EPA-HQ-OAR-2022-0829-0630, p. 8]

D. Higher ethanol blends enable reduced particulate matter and other criteria pollutant emissions.

Ethanol also improves gasoline fuel properties to reduce particulate matter emissions. EPA's proposed rule sets aggressive standards for particulate matter and justifies its electrification plan in part by the impact it will have on these criteria pollutants. But as explained above, millions of liquid fueled vehicles will remain on the road for decades, even under the most aggressive electrification standards. [EPA-HQ-OAR-2022-0829-0712, p. 42]

Increasing the blending of ethanol in liquid fuels can reduce the particulate emissions from all these vehicles. In EPA's most recent study of particulate matter emissions, it found that reducing the heavy aromatic content of liquid fuels reduced exhaust particulate matter. See Exhaust Emission Impacts of Replacing Heavy Aromatic Hydrocarbons in Gasoline with Alternate Octane Sources, EPA-420-R-23-008, Environmental Protection Agency (Apr. 2023). Of each of the four fuels examined in that study, the most promising results came from E15, which showed reductions of particular matter of nearly 40 percent. [EPA-HQ-OAR-2022-0829-0712, p. 42]

These results are corroborated by other studies. For example, a 2023 study published in Fuel examined the exhaust emissions from a fleet of 20 light-duty vehicles running on both E10 and E15. Tianbo Tang, et al., Expanding the ethanol blend wall in California: Emissions comparison between E10 and E15, 350 Fuel 128836 (Oct. 15, 2023), https://www.sciencedirect.com/science/article/pii/ S0016236123014497#ab010. While the study showed that total hydrocarbons, non- methane hydrocarbons, and carbon monoxide all had either marginally or statistically significant reductions when the fuel was switched to E15, reductions of PM emissions were even greater. Id. "The weighted PM emissions showed strong fuel effects, with E15 being 18% lower than E10 across the fleet of 20 vehicles at a statistically significant level. For the cold-start and hot-running phases, PM emissions demonstrated statistically significant reductions of 16% and 54%, respectively, for E15 compared to E10. The hot-start phase showed a 43% marginally statistically significant reduction in PM emissions for E15 compared to E10." Id. [EPA-HQ-OAR-2022-0829-0712, pp. 42-43]

There are about twenty times as many vehicles on the road in the United States as will be sold in each model year that EPA projects, all of which emit far more on average than new internal combustion engine vehicles. Switching those existing vehicles from E10 to E15 would result in greater particulate matter emissions reductions than converting all new vehicles to electric vehicles for several model years.23 [EPA-HQ-OAR-2022-0829-0712, pp. 42-43]

23 And this only accounts for tailpipe emissions. As has been well documented, the higher weight of electric vehicles leads to increased road and tire wear, and thus higher particulate emissions from non-tailpipe sources.

Additional benefits include avoiding the air quality and health impacts from significant increases in tire wear from electric vehicles, as well as the increases in CO2 emissions that will result from manufacturing more electric generation infrastructure, transmission, distribution, and charging equipment, and the manufacturing of electric vehicles themselves, which produce far more upstream emissions than their internal combustion engine counterparts. [EPA-HQ-OAR-2022-0829-0712, pp. 6-7]

Organization: Colorado Energy Office, Colorado Department of Transportation, and Colorado Department of Public Health and Environment

Environmental impacts from the transportation sector—and the resulting health and economic consequences—are a major concern. Vehicles are the top source of greenhouse gas (GHG) emissions in Colorado, and are also a top source of particulate matter, NOx, and other criteria air pollutants that have disproportionate impacts on communities living near highways and freight routes. Transportation is one of the two largest sources of ozone precursors in Colorado along with oil and gas production, largely due to NOx emissions from vehicles, and reducing transportation emissions is a critical strategy to meet federal health-based air quality standards. [EPA-HQ-OAR-2022-0829-0694, p. 1]

Our agencies strongly support EPA's development of national air pollution and GHG emission standards that are as robust as possible to ensure strong progress nationwide on air pollution and equity. A strong national light- and medium-duty vehicle standard is important to Colorado for at least three reasons. First, air pollution from nearby states crosses into Colorado and affects public health, and the longer duration and increased stringency of the proposed criteria air pollutant standards will reduce interstate air pollution transport into Colorado. Second, Colorado is already experiencing the impacts of climate change, including increased wildfires, floods, and drought. Climate change is a global issue that is impacted by all GHG emissions regardless of geographic source, and the reductions in GHG emissions from the proposed national rule will help reduce the long-term risks of climate change in Colorado. Finally, although the proposed national GHG emissions standards are not an explicit EV sales requirement like Advanced Clean Cars and Advanced Clean Cars II, complying with the standards will effectively require vehicle manufacturers to sell a significantly greater amount of EVs. The economies of scale encouraged by the proposed rules will support the production of more affordable EVs, easing the transition to zero emission vehicles and enabling greater access to their benefits for disproportionately impacted communities. [EPA-HQ-OAR-2022-0829-0694, p. 2]

Organization: David Hallberg

Toxicologists commenting on the health threat from Canadian wildfires—which are being widely covered by media as more than one hundred million Americans are being affected every day—confirm that the smaller fine PM/PAH/SOA emissions pose the greatest health threat. https://theconversation.com/wildfire-smoke-can-harm-human-a206057 However, due to EPA's false assurances that vehicle emissions control systems are capturing the SOA-bound PAHs and other toxics, the media and public don't know that they are being exposed to far worse on a 24/7 basis because OTAQ refuses to improve gasoline quality as required by Congress. [EPA-HQ-OAR-2022-0829-0548, p. 2]

The Reuters article linked below should more accurately read "Lacking Cleaner Gasoline, U.S. Cars Set to Emit a Septillion More Particles". It most certainly makes no sense to wait another fifteen or more years for the LDV fleet to transition to gasoline particulate filters (as the

EPA seems to propose in this rule) when these enormous quantities of highly potent UFP + PAH emissions can be substantially reduced immediately by replacing BTEX with ethanol. [EPA-HQ-OAR-2022-0829-0548, p. 2]

1,000,000,000,000,000,000,000,000 is a SEPTILLION, otherwise known as a googol. Experts say PAHs pose substantial threat to human health in the parts per trillion. [Detchon-Modlin comments, supra, p. 20-21] [EPA-HQ-OAR-2022-0829-0548, p. 2]

This means that a breathtaking number of highly lethal UFPs will be forced into Americans lungs over the next 20 years—septillions of the most HARMFUL PARTICLES THAT EPA REFUSES TO TELL THE AMERICAN PUBLIC WILL GET WORSE RATHER THAN BETTER. Millions of avoidable morbidities and premature mortalities will occur due to EPA's unlawful refusal to enforce section 202(l). It will cost U.S. taxpayers hundreds of billions of dollars in avoidable health expenditures and lost productivity. [EPA-HQ-OAR-2022-0829-0548, pp. 2-3]

Lacking filters, U.S. cars set to emit a septillion more particles - research | Reuters [Link: https://www.reuters.com/business/autos-transportation/lacking-filters-us-cars-set-emit-septillion-more-particles-research-2022-04-27/] [EPA-HQ-OAR-2022-0829-0548, pp. 2-3]

The Science is Incontrovertibly Clear

Contrary to OTAQ's false assurances, the rapid adoption of advanced engine technologies such as Gasoline Direct Injection (GDI) will dramatically increase emissions of the most harmful ultrafine particles (UFP) and secondary organic aerosols (SOAs) that bind with and insulate highly toxic polycyclic aromatic hydrocarbons (PAHs) and enable their long-range transport. The attached White Paper, authored by the UN Foundation's Special Advisor for Climate Solutions and Chrysler's former Director for Regulatory Affairs, explains how the BTEX emissions threat is getting WORSE, not better. [EPA-HQ-OAR-2022-0829-0548, p. 2]

New White Paper Says The Real Cost of Gasoline …is to Our Health | Clean Fuels Development Coalition (cleanfuelsdc.org) [Link: https://cleanfuelsdc.org/2022/05/16/new-white-paper-says-the-real-cost-of-gasoline-is-to-our-health/] [EPA-HQ-OAR-2022-0829-0548, p. 2]

Many experts believe that the 20% BTEX fraction found in a typical gallon of U.S. gasoline poses the single greatest threat to public health and the environment. In their comments to the MY2023 LDV GHG Final Rule, the same two authors stated: "The effect of aromatics [BTEX] on pollution and human health is thus magnified twice over: Aromatics lead disproportionately to PAH formation, and PAHs lead disproportionately to SOA formation. Worse yet, PAHs hitch a ride on SOA for long distances and weaponize these particles as they travel through the human body…When SOA particles are formed in the presence of gas-phase PAHs, their formation and properties are significantly different from SOA particles formed without PAHs: They exhibit slower evaporation kinetics and have higher fractions of non-volatile components and higher viscosities, assuring their longer atmospheric lifetimes. This increased viscosity and decreased volatility act as a shield that protects PAHs from chemical degradation and evaporation, allowing for their long-range transport." [Detchon – Modlin MY2023 Final Rule comments, p. 17. RDRMCommentsEPA-HQ-OAR.pdf (cleanfuelsdc.org)] [Link: https://cleanfuelsdc.org/wp-content/uploads/2021/09/RDRMCommentsEPA-HQ-OAR.pdf] [EPA-HQ-OAR-2022-0829-0548, p. 2]

The Law is Also Incontrovertibly Clear

OTAQ's experts are highly intelligent people, but they apparently missed the memo about the mandatory Clean Air Act provisions that require EPA to reduce gasoline BTEX content as much as technology (including technology improvements that EPA is expected by Congress to actively encourage) permits. In the 1990 Clean Air Act Amendments (1990 CAAA), Congress went to extraordinary lengths to avoid a repeat of the horrific societal and economic costs of leaded gasoline because it knew that BTEX health effects would be even worse. Section 202(l) of the CAA imposes a nondiscretionary duty upon EPA to reduce the mobile source air toxics (MSATs) produced by the incomplete combustion of BTEX by "the greatest degree of emission reduction achievable through the application of technology which will be available". RDRMCommentsEPA- HQ-OAR.pdf (cleanfuelsdc.org) [Link: https://cleanfuelsdc.org/wp-content/uploads/2021/09/RDRMCommentsEPA-HQ-OAR.pdf], p. 2. [EPA-HQ-OAR-2022-0829-0548, p. 3]

Since 1990, Congress has spoken many times about the critical need for EPA to encourage the substitution of ethanol's superior "clean octane" for BTEX "dirty octane". Three primary inflection points stand out: [EPA-HQ-OAR-2022-0829-0548, pp. 3-4]

1990 Clean Air Act Amendments

In the same law that finally banned the use of leaded gasoline, Congress overcame fierce opposition from oil interests in a bid to avoid a repeat of the leaded gasoline disaster. The most important provision was section 202(l), the express language of which constitutes a "legislative endangerment" finding (EPA has no discretion in the matter under 211c as it claims). [EPA-HQ-OAR-2022-0829-0548, pp. 3-4]

Technology-Forcing Legal Precedents Put the Burden on EPA to Encourage E30 HOLC Fuels. Importantly, Congress also used "technology-forcing" language and imposed for the first time Maximum Achievable Control Technology (MACT) standards on fuels. [EPA-HQ-OAR-2022-0829-0548, pp. 3-4]

> "Technology-forcing" language has been used by Congress throughout the Clean Air Act, not only in section 202(l) [see NRDC v. EPA, 655 F.2d 318, 328 (DC Circuit 1981): "Congress intended the agency to project future advances in pollution control technology. It was expected to press for development and application of improved technology rather than be limited by that which exists today." Ecology Law Quarterly, FN#126]

Unfortunately, OTAQ has done the exact opposite and made a mockery of the provision by imposing technology "advances" that increase harmful emissions while blocking the fuel quality improvements that automakers require to complement their GDI engines. It has gone to extraordinary, even unlawful, lengths to OBSTRUCT the development of higher quality fuels which are required to complement advanced engine technologies. EPA's sub-sim interpretation is unlawful—it cannot prohibit increased concentrations of ethanol for use in existing vehicles unless it follows the steps set forth in section 211c. The burden of proof is on EPA, including the legal precedents set by 42 U.S.C. 7545, which require EPA to conclusively prove that prohibiting increased ethanol use will NOT result in the use of another additive that will result in more harmful emissions (see below). [EPA-HQ-OAR-2022-0829-0548, pp. 3-4]

Finally, the MSAT provision sponsors—both Senate and House—made it clear that EPA should prioritize fuel quality controls as much, if not more, than vehicle technology improvements. Section 202(l) and the 1990 CAAA require EPA to apply Maximum Achievable Control Technology (MACT) standards to fuel quality improvements. The U.S. light-duty vehicle (LDV) fleet of 270+ million vehicles requires gasoline to have sufficient octane number or they will not operate properly. EPA cannot comply with the statute's "greatest emissions reduction achievable" requirement unless it encourages an orderly transition to nationwide use of E30 "clean octane" fuels. By blocking such use, EPA is imposing a "de facto" BTEX mandate on U.S. consumers because there are only two commercially available, cost effective, and (at least thus far) legally permissible octane enhancing compounds: BTEX and ethanol. [EPA-HQ-OAR-2022-0829-0548, p. 4]

1995 Renewable Oxygenate Requirement (ROR)

The Senate vote upholding EPA's ROR is often overlooked, but it sparked an extremely important DC Circuit Court of Appeals decision AMERICAN PETROLEUM INSTITUTE v. Renewable Fuels Association, Intervenor. (1995) | FindLaw [Link: https://caselaw.findlaw.com/court/us-dc-circuit/1104431.html] (decided in favor of oil interests) but that inadvertently set the stage for ultimate enactment of the Renewable Fuel Standards (RFS 1 and 2). [EPA-HQ-OAR-2022-0829-0548, pp. 4-5]

The ROR would have required an increasing scale of "renewable" oxygenate use under Section 211(k), the 1990 CAAA oxyfuel provision (up to a 30% market share). Inexplicably, EPA avoided any reference to the MSAT 202l provision in its rulemaking. Instead, EPA's exclusive emphasis was on ozone control, which handicapped ethanol (E10, not E30) use in the summertime, and forced the conversation to ethers. Had EPA informed the court about E30's lower volatility, the importance of higher octane, and ethanol's improved cost structure, the outcome would have been far different. [EPA-HQ-OAR-2022-0829-0548, pp. 4-5]

The Court struck down EPA's rule under Section 7545(k)(1) (the oxy fuel provision, not 202l) on the grounds "that the plain meaning of the statute…precludes the adoption of RFG rules that are not directed toward the reduction of VOCs and toxics emissions, and since the statute is unambiguous, EPA improperly interpreted the section as giving it the broader power to adopt the ROR…The whole purpose of the RFG program is to reduce air pollution…". [EPA-HQ-OAR-2022-0829-0548, pp. 4-5]

While API's attention was focused on the RFG section 211(k) provision, the court was cognizant of section 202(l). It emphasized the importance of EPA achieving maximum reductions in "year- round toxics" (which to the provision's sponsors was even more important than ozone controls over which OTAQ has prioritized for 30 years). While the oil industry got the outcome it wanted, it won the battle but lost the war: when MTBE contaminated water supplies in many cities several years later, and states banned MTBE use, it set the stage for Congressional enactment of the nationwide RFS standards. [EPA-HQ-OAR-2022-0829-0548, pp. 4-5]

One noteworthy piece of the court's ruling was its mention of 42U.S.C.7545, which prohibits EPA from blocking increased concentrations of any fuel additive already in commerce if that prohibition would result in an increase in harmful mobile source emissions "Our conclusion is supported by 42 U.S.C. § 7545(c), which authorizes EPA to control or prohibit the manufacture or sale of fuels or fuel additives if the agency finds that such fuels or fuel additives cause or contribute to air pollution or impair the performance of emission control devices.1 Before it can prohibit a fuel or fuel additive, EPA must do several things, including publish a finding that such prohibition will not cause the use of any other fuel or fuel additive which will produce emissions that will endanger the public health to the same or greater degree than use of the fuel or additive to be prohibited. 42 U.S.C. § 7545(c)(2)(C). [EPA-HQ-OAR-2022-0829-0548, pp. 4-5]

The MY2027 NPRM acknowledged the importance of ethanol's increased role in the nation's gasoline pool at p. 579: "A common thread across the market shifts in T90 has been a decreasing gasoline-to-distillate ratio (GDR) in the product slates produced by refiners…Perhaps the most important factor affecting GDR was the influx of ethanol into gasoline. The increasing ethanol volume displaced a portion of petroleum, which caused refiners to move more of the midrange gasoline cut into the distillate pool. Ethanol's octane also allowed refiners to back out aromatic content." [Emphasis supplied.] [EPA-HQ-OAR-2022-0829-0548, p. 6]

Key Takeaways If EPA Truly Wants to "Be Driven by Science and the Rule of Law"

I. Ethanol is the only technically effective, commercially viable and legally permissible alternative to BTEX as a gasoline octane enhancer. Despite EPA barriers, ethanol has already helped to significantly reduce BTEX levels while maintaining market gasoline octane levels. A gradual transition to nationwide E30 Clean Octane—patterned after EPA's successful and much more challenging transition from leaded to unleaded gasoline—would add hundreds of billions of dollars annually to the nation's balance sheet in the form of reduced health and oil import costs. It would also benefit petroleum refiners: they could use their existing crude oil slates and produce the same 84 sub-octane BOBs as they do now. Terminals and dispensers are ready to splash-blend the additional 20% ethanol on top of today's E10 to produce 100+ RON E30 finished gasoline at a much lower cost to consumers with enhanced performance and greatly reduced emissions. This is precisely what Congress envisioned when it enacted the 1990 CAAA. [EPA-HQ-OAR-2022-0829-0548, pp. 6-7]

BTEX poses the predominant—and dramatically expanding—threat to public health and the environment, in large part driven by the rapid adoption of GDI engine technology. [EPA-HQ-OAR-2022-0829-0548, p. 7]

III. EPA RFS "Set" Rule encourages RD cannibalization of ethanol D6 RINs, thus blocking ethanol from displacing BTEX with E30 HOLC Fuels.

"As in recent years, we believe that excess volumes of BBD beyond the BBD volume requirements will be used to satisfy the advanced biofuel volume requirement within which the BBD volume requirement is nested," the agency said in the final rule. "Historically, the BBD standard has not independently driven the use of BBD in the market. This is due to the nested nature of the standards and the competitiveness of BBD relative to other advanced biofuels. Instead, the advanced biofuel standard has driven the use of BBD in the market. Moreover, BBD can also be driven by the implied conventional renewable fuel volume requirement as an alternative to using increasing volumes of corn ethanol in higher level ethanol blends such as E15 and E85. We believe these trends will continue through 2025.
[read more [Link: https://www.governorsbiofuelscoalition.org/epa-explains-thinking-behind-biomass-based-diesel-volumes-other-reaction-to-rfs-volumes/] …] [EPA-HQ-OAR-2022-0829-0548, p. 7]

EPA's Actions constitute an unlawful violation of CAA section 202(l)'s nondiscretionary language to replace BTEX with ethanol.

"In the U.S., only two commercially available octane boosting compounds are legally permitted for use in gasoline—benzene-based aromatic compounds commonly known as BTEX (benzene, toluene, ethyl-benzene, xylene) and ethanol. A typical gallon of U.S. gasoline contains approximately 20% BTEX and 10% ethanol. Congress has directed EPA to reduce the carcinogenic mobile source air toxics (MSATs) produced by the incomplete combustion of BTEX "the greatest degree of emission reduction achievable through the application of technology which will be available". RDRMCommentsEPA-HQ-OAR.pdf (cleanfuelsdc.org) [Link: https://cleanfuelsdc.org/wp-content/uploads/2021/09/RDRMCommentsEPA-HQ-OAR.pdf] [EPA-HQ-OAR-2022-0829-0548, pp. 7-8]

Conclusion. Indirectly, by finally admitting to the undeniable linkage between BTEX and SOA bound PAH emissions, EPA's MY2027 Multipollutant NPRM requires it to encourage substantial reductions in BTEX content in the final rulemaking. Last year, in West Virginia vs. EPA, SCOTUS elevated the Major Questions Doctrine and relegated the Chevron Deference Doctrine. Most experts expect SCOTUS to take Chevron off life support next year. The bottom line: the test for endurable EPA regulations will be whether they are consistent with the statute's "plain meaning" and with Congressional intent. The courts will also look closely to ascertain how EPA regulations impact the nation's economy, energy security, and environment. [EPA-HQ-OAR-2022-0829-0548, pp. 7-8]

Substituting ethanol for toxic, expensive, and carbon intensive BTEX synthesized from crude oil meets the Supreme Court's criteria for sustainable EPA regulations. [EPA-HQ-OAR-2022-0829-0548, pp. 7-8]

EPA does not have the discretionary authority to embark on another 30 year "snipe hunt" to study whether BTEX "high boiling aromatics" are bad for public health and the environment. Congress has already made that determination and best available science confirms that Congress got it right thirty years ago. 30 years is long enough for the nation's public health and environment to wait: EPA must finally do its job and enforce the law. [EPA-HQ-OAR-2022-0829-0548, pp. 7-8]

2005 EPACT & 2007 EISA (RFS1 and 2)

In order to defuse the MTBE contamination crisis, maintain gasoline octane levels by substituting ethanol to compensate for MTBE's lost octane, and improve the nation's energy security, Congress enacted the landmark 2005 Energy Policy Act (EPACT) and the 2007 Energy Independence and Security Act (EISA). These two pieces of legislation were primarily driven by the nation's reaction to the 9/11 attacks and the Iraq War. [Another reminder of ethanol's many benefits: in addition to the enormous health and carbon reduction benefits, a nationwide E30 Clean Octane standard would reduce U.S. oil imports by approximately one billion barrels annually, or $100 billion/year assuming average oil costs of $100/barrel.] [EPA-HQ-OAR-2022-0829-0548, pp. 5-6]

Congress dropped the 1990 CAAA "fuel neutral" principle as oil companies raced to get out of the MTBE business and rescinded the section 211(k) RFG oxygenated fuel standard provision. However, when oil interests also pushed for elimination of section 202(l), Congressman Henry

Waxman, powerful chairman of the House Energy and Commerce Committee, insisted on retaining the provision he had championed in the 1990 act. Instead, Congress doubled down and in section 1504 of the 2005 EPACT law, required EPA to at long last promulgate the 2007 MSAT Final Rule within eighteen months. [EPA-HQ-OAR-2022-0829-0548, pp. 5-6]

EPA was only 12 years late in issuing the MSAT Rule. Predictably, its assumptions were laughable even then. The factual predicates upon which EPA relied in the 2007 MSAT Final Rule have changed so radically that legal precedents compel it to go back to the drawing board with a fresh set of facts and best available science. [EPA-HQ-OAR-2022-0829-0548, pp. 5-6]

EPA itself opened the door to revisiting the 2007 MSAT Final Rule when it said that it would be compelled to do so if “evidence supports a role for aromatics in secondary PM formation”. [Detchon-Modlin comments, supra, p. 23-24] In the MY2027 NPRM, EPA finally concedes that there is a direct linkage between aromatics/BTEX and SOA PM. At p. 572 of the NPRM, EPA introduced the concept of limiting “high-boiling compounds in gasoline” that have been linked to increased tailpipe PM emissions. The Agency noted that “the high-boiling tail of gasoline contains a high proportion of aromatics and that the heaviest few percent of this material has very high leverage on PM emissions”. As the CFDC et al. comments point out, the statute does not permit EPA to limit its BTEX control efforts to only the high boiling aromatics—reducing SOA-bound PAH by the greatest degree achievable requires substantial BTEX reductions. [EPA-HQ-OAR-2022-0829-0548, pp. 5-6]

EPA’s MSAT Rule did get one thing right in 2007—the U.S. ethanol industry did not have sufficient capacity to replace significant amounts of BTEX. So Congress called OTAQ’s bluff and enacted RFS1 and 2. Thanks to Congressional action, experts estimate that the RFS program—which made E10 the nation’s in-use fuel—displaced nearly 10 billion gallons per year of aromatics as refiners adjusted their blend stocks to accommodate ethanol’s higher octane. [EPA-HQ-OAR-2022-0829-0548, pp. 5-6]

Organization: District of Columbia Department of Energy and Environment (DOEE)

Particulate Matter Health Impacts

In addition, EPA’s proposed standards impede the District’s ability to achieve the World Health Organization’s (WHO) Air Quality Guidelines, which the District of Columbia has committed to achieving through the C40 Clean Air Accelerator.2 The WHO guidelines set the annual 24-hour PM2.5 guidelines at 5 μg/m3 and the 24-hour PM2.5 guidelines at 15 μg/m3. Meanwhile, the WHO annual PM10 guidelines are set at 15 μg/m3 and 45 μg/m3 for the 24-hour PM10 guidelines.3 The WHO used leading scientific evidence from an abundance of research and evaluation by air quality experts to determine that an annual PM concentration higher than 5 μg/m3 is detrimental to public health.4 In fact, according to the Lancet Planetary Health study released March 6, 2023, 99 percent of the world’s population is exposed to unhealthy levels of PM2.5–levels over 5 micrograms per cubic meter.5 [EPA-HQ-OAR-2022-0829-0550, pp. 2-3]

The Lancet Planetary Health. https://www.thelancet.com/journals/lanplh/article/PIIS2542-5196(23)00008-6/fulltext

Annually, 100,000-200,000 people in the United States, and 7,000,000 worldwide, die from exposure to air pollution, figures that require an expeditious and substantial response.6 In the District alone, around 120 people die from diseases attributable to PM2.5 pollution annually, while approximately 30 people visit the Emergency Department annually.7 Particulate matter is singlehandedly responsible for up to 30,000 premature deaths each year in the United States and over 4,000,000 worldwide.8 EPA must put the health of people and the environment at the forefront of their decision-making and develop more stringent and protective vehicle emission standards. Ozone Health Impacts

Based on the current preliminary data, the District of Columbia's current design value of 70 ppb means the District currently meets the federal ozone standards. This is determined by a 3-year average of the fourth-highest daily maximum ozone concentrations. Meeting this standard is a major priority for the District. However, air pollution from sources like vehicles results in challenges for the District to maintain clean data. The WHO also sets the annual 8-hour ozone at 100 µg/m3, which is approximately 51 ppb, far stricter than the current NAAQS. [EPA-HQ-OAR-2022-0829-0550, p. 3]

The District of Columbia requires more reductions to ensure that we can maintain clean data and progress toward meeting the WHO goals. This is especially important given how precarious our clean ozone data is and how much ozone results from emissions produced by light-duty and medium-duty vehicles operating in and around the District, but not registered in the District. According to source apportionment modeling conducted by the Ozone Transport Commission 17% of ozone caused by controllable sources on exceedance days is due to gasoline-powered vehicles, making it the highest source of controllable ozone precursors affecting the District's ozone levels on exceedance days.9 The reductions in ozone precursors that will result from Alternative 1 will be necessary to both maintain the ozone NAAQS and progress toward WHO goals. [EPA-HQ-OAR-2022-0829-0550, p. 3]

9 Ozone Transport Commission. Ozone Transport Commission/ Mid-Atlantic Northeastern Visibility Union 2016 Based Modeling Platform Support Document. January 2023. https://otcair.org/upload/Documents/Reports/2016TSD_January2023_withAppendices.pdf

In addition, data from the Centers for Disease Control and Prevention shows that, nationally, Black and Indigenous people statistically have significantly higher asthma rates than their counterparts in other races.11 In the District, children who live in predominately Black communities have 20 to 25 times more asthma-related emergency room visits than their counterparts in majority White communities.12 [EPA-HQ-OAR-2022-0829-0550, pp. 4-5]

11 Center for Disease Control. Most Recent National Asthma Data. https://www.cdc.gov/asthma/most_recent_national_asthma_data.htm.

Studies also illustrate links between increased school absenteeism and ozone exposure.13 This is a District-wide concern as disparities already exist in the education system between students of color and White students. In particular, the literacy disparities have grown since the Covid-19 pandemic: 28% of Black and 30% of Hispanic students were proficient on a fall 2021 test, while 70% of White students were proficient. In the fall of 2019, 44% of Black students and 42% of Hispanic students hit these benchmarks, compared with 73% of White students.14 [EPA-HQ-OAR-2022-0829-0550, pp. 4-5]

13 Daniel L Mendoza et al 2020 Environ. Res. Lett. in press https://doi.org/10.1088/1748-9326/abbf7a

14 Perry Stein. 2022 The Washington Post. "Literacy scores show widening achievement gap in D.C. during pandemic." https://www.washingtonpost.com/education/2022/03/17/dc-schools-achievement-gap-pandemic-reading/

On-road vehicle emissions constitute one of the most significant individual contributors to local air pollution-related health burdens, making up 23% of all pollution-related premature deaths in the District. On-road vehicle emissions are estimated to contribute to 51% of NO2-attributable new asthma cases and 13% of pollution-attributable premature deaths in the District. Regional emissions from all sectors, which originate outside of the District's jurisdiction, contribute disproportionately to the District's air pollution- related new asthma cases and premature deaths (89% and 57%, respectively). [EPA-HQ-OAR-2022-0829-0550, p. 5]

These studies illustrate that air quality is an issue connected to all aspects of people's lives. The pollution from vehicle emissions affects District residents, creating poor air quality and living conditions and with it, a myriad of health, wellness, and educational discrepancies. The District strives to reduce pollution as much as possible; however, pollution from light-duty and medium-duty vehicles must be solved at a larger scale as light-duty and medium-duty vehicles from states across the United States travel into the District. Therefore, the District cannot solve all its pollution problems without action from EPA. EPA needs to set stronger light-duty and medium-duty vehicle emission standards to relieve overburdened and bystander communities experiencing the adverse impacts of vehicle emissions. [EPA-HQ-OAR-2022-0829-0550, p. 5]

Organization: Donn Viviani

Also not addressed is evidence that the increased weight of BEVs compared to comparable ICE vehicles, because of battery weight, will result in nonexhaust emissions (NEE) of particulate matter (PM) that will significantly lessen or even may exceed the proposal's anticipated reductions. While there is controversy as to whether NEE PM is as large as exhaust PM, with evidence on both sides. What is known for certain however, is that heavier vehicles produce more NEE PM and BEVs are significantly heavier than in-ternal combustion vehicles.17 While it is true BEVs regenerative braking removes most brake-NEE, the greater torque of BEVs will cause some aggressive drivers to produce increased NEE PM.18 This needs to be acknowledged and to the extent practicable included in the benefit assessment. In my view, the potential climate benefits of the necessary transition to EVs is too important to risk with an inadequate analysis as to other effects. [EPA-HQ-OAR-2022-0829-0697, pp. 5-6]

3. Public Health Urgency.

Diesel trucks and buses are also major sources of other deadly air pollutants. Medium and heavy-duty diesel engines emit more than 60% percent of the deadly particle pollution from vehicles. Particle pollution cuts short tens of thousands of US lives per year and contributes to the heavy burden of asthma on our nation's children. Diesels are the primary source of particles in communities near heavily-trafficked highways where 65 million Americans are exposed to harmful concentrations. [EPA-HQ-OAR-2022-0829-0737, pp. 4-5]

Vehicle pollution inequitably harms Black and Latinex communities that are much more likely compared to whites to reside near heavy truck traffic on highways, and at truck terminals, ports and distribution centers. [EPA-HQ-OAR-2022-0829-0737, pp. 4-5]

NOx from diesels combines with heat and sunlight in the atmosphere to form ground level ozone, or smog, a lung irritant and asthma trigger. Heavy duty vehicle emissions are a major contributor to urban smog in the 230 urban counties where pollution concentrations violate national air quality standards. [EPA-HQ-OAR-2022-0829-0737, pp. 4-5]

The need for national zero emission standards is greatest in the urban areas that EPA has designated "extreme" (South Coast AQMD) and "severe" (San Joaquin Valley AQMD), or recently bumped-up to "serious" for ozone. NOx emissions from L/MDVs are a primary contributor to their numerous elevated violations of the ozone NAAQS. These areas are not able to achieve sufficient emissions reductions to attain the NAAQS without significant NOx reductions from L/MDVs. [EPA-HQ-OAR-2022-0829-0737, pp. 4-5]

Organization: Energy Innovation

I. The U.S. must transition LDVs and MDVs to zero-emission technologies [i] quickly to reduce their emissions, which contribute to climate change and air pollution—both of which endanger public health and welfare. Adoption of the most stringent tailpipe standards for new vehicles is the most effective tool to achieve this goal. [EPA-HQ-OAR-2022-0829-0561, pp. 1-2]

i This includes technologies that eliminate tailpipe GHG emissions and other pollutants, namely battery electric vehicles for LDVs and MDVs.

In addition to improvements to public health and welfare that the EPA's proposed tailpipe GHG standards would achieve, the proposed multi-pollutant standards will help reduce criteria pollutants and air toxics from remaining internal combustion engine (ICE) vehicles. As LDVs and MDVs transition away from combustion and tailpipes that cause harmful air pollution, these multi-pollutant standards are critical to saving the lives and improving the health of the people and children harmed by transportation pollution.15 Although we do not provide detailed comments on this aspect of the proposed rule, we encourage the EPA to adopt the most stringent standards feasible to mitigate the harmful effects of these pollutants. The EPA aptly points out that "reducing human exposure to these pollutants results in significant and measurable health benefits,"16 especially to frontline communities, communities of color, and low-income communities and individuals that bear the burden of bad air quality from tailpipe emissions.17 Adopting more stringent multi-pollutant standards will also help states meet National Ambient Air Quality Standards18 and improve air quality in all communities. III. Further Reductions in Emissions of GHGs and Criteria Pollutants from Motor Vehicles Are Necessary to Protect Public Health and the Environment.

A. Vehicular emissions of greenhouse gases gravely endanger public health and welfare by intensifying the climate crisis.

Emissions of GHGs from the transportation sector pose mortal dangers to public health and the environment; EPA's exercise of its responsibilities under the Clean Air Act must take account of and mitigate these dangers. Over thirteen years ago, based upon a massive scientific record, the EPA found that new motor vehicles and engines contribute to emissions of GHGs that drive climate change and endanger the health and welfare of current and future generations.46 Specifically, EPA found that the intensifying climate crisis increased the frequency of warmer temperatures, heat waves, and other extreme weather, worsened air quality by increasing regional ozone pollution, increased the spread of food and water-borne illnesses, increased the frequency and severity of seasonal allergies, and increased the severity of coastal storm events due to rising sea levels.47 [EPA-HQ-OAR-2022-0829-0759, p. 14]

46 74 Fed. Reg. at 66496.

47 74 Fed. Reg. at 66525–26.

Since EPA issued the Endangerment Finding in 2009, dire evidence of the current and future impacts of climate change has continued to accumulate. Recent studies demonstrate that climate change continues to cause heat waves and extreme weather events across the United States.48 Between May and mid-September, 2022, “nearly 10,000 daily maximum temperature records were broken.”49 Additionally, 2022 was “one of the top 10 hottest years on record for daily maximum temperatures” in 13 states, as well as one of the top 10 hottest for daily minimum (nighttime low) temperatures for 31 states.50 Warmer temperatures endanger public health by increasing the risk of heart disease, worsening asthma and chronic obstructive pulmonary disease from increases of ground-level ozone, and causing dehydration and many other ailments.51 Studies have also found that heat waves and extreme weather events cause severe psychiatric and mental health impacts.52 Climate change continues to lead to higher than normal pollen concentrations and earlier and longer pollen seasons, causing worse allergies and asthma.53 The intensifying climate crisis also increases the risk of drought across the U.S, which impacts water supply, agriculture, transportation, and energy, and increases the risk and magnitude of wildfires.54 And recent projections show that sea level rise is anticipated to be on the high end of model projections.55 Studies have found that many of the dangers wrought by climate change exact a higher toll on people with low incomes and people of color.56 [EPA-HQ-OAR-2022-0829-0759, pp. 14-15]

The transportation sector has been responsible for an increasing percentage of GHG emissions in the U.S. since 2009, thereby playing an outsized role in intensifying the climate crisis. When EPA made its Endangerment Finding for GHGs, the transportation sector was responsible for 23% of total annual U.S. GHG emissions.57 Since then, transportation sector GHG emissions have only increased as a share of U.S. emissions, surpassing the electric power sector as the largest U.S. source of GHG emissions and contributing 27.2% of total GHG emissions in 202058 and 28.5% in 2021.59 After dipping in 2020 due to the COVID-19 pandemic, carbon dioxide (CO2) emissions from the transportation sector increased by 11.5% between 2020 and 2021.60 Transportation as an end use sector "account[ed] for 1,757.4 [million metric tons] CO2 in 2021 or 37.9% of total CO2 emissions from fossil fuel combustion."61 Adopting stringent GHG emission standards for light- and medium-duty vehicles will lead to massive public health benefits by limiting these pollutants.62 [EPA-HQ-OAR-2022-0829-0759, p. 16]

The IPCC's most recent synthesis of its Sixth Assessment Report confirms the danger to public health and welfare posed by GHG emissions from the transportation sector. The report found that global surface temperature was around 1.1°C higher in 2011-2020 than it was in 1850-1900.63 While average annual GHG emissions growth has slowed in certain sectors such as energy supply and industry, growth in GHG emissions from the transportation sector has remained relatively constant at about 2% per year.64 The latest IPCC report warned that "[d]eep, rapid and sustained GHG emissions reductions, reaching net zero CO2 emissions and including strong emissions reductions of other GHGs . . . are necessary to limit warming to 1.5°C . . . or less than 2°C . . . by the end of the century."65 To have a chance at limiting global temperature increase to 1.5? and avoid the worst impacts of climate change, current GHG emissions from the transportation sector must drop by 59% by 2050 compared to 2020 emissions.66 [EPA-HQ-OAR-2022-0829-0759, p. 16]

There is consistent evidence showing the relationship between short-term exposure to PM and mortality, particularly cardiovascular and respiratory mortality. Short- and long-term exposure to PM2.5 can cause harmful health impacts such as heart attacks, strokes, worsened asthma, and early death.72 In addition, short-term PM exposure has been linked to increases in infant mortality, hospital admissions for cardiovascular disease, hospital admissions and emergency visits for chronic obstructive pulmonary disease, and severity of asthma attacks and hospitalization for asthma in children. Year-round exposure to PM is associated with elevated risks of early death, primarily from cardiovascular and respiratory problems such as heart disease, stroke, influenza, and pneumonia.73 These findings show the critical need for EPA to minimize the harmful emissions from the transportation sector. Doing so will only improve public health and the environment. [EPA-HQ-OAR-2022-0829-0759, pp. 17-18]

72 See EPA, Supplement to the 2019 Integrated Science Assessment for Particulate Matter (Final Report, 2022), at ES-ii, 2-3, 2-4, https://cfpub.epa.gov/ncea/isa/recordisplay.cfm?deid=354490; EPA, Integrated Science Assessment (ISA) for Particulate Matter (Dec. 2019),https://cfpub.epa.gov/ncea/isa/recordisplay.cfm?deid=347534.

73 Am. Lung Ass'n, State of the Air 2023 Report (2023) at 25, https://www.lung.org/getmedia/338b0c3c-6bf8-480f-9e6e-b93868c6c476/SOTA-2023.pdf?ext=.pdf.

2. Reductions in criteria pollution emissions will bring health benefits to environmental justice communities.

This rulemaking presents a critical opportunity to mitigate the adverse health impacts plaguing communities that are overburdened by air pollution from motor vehicles and other sources. According to the American Lung Association's (ALA) 2023 State of the Air report, which grades counties on daily and long-term measures of particle pollution and daily measures of ozone, more than 119 million Americans live in places that received failing grades for unhealthy levels of ozone or PM in their air.88 The report notes:

88 Am. Lung Ass'n, State of the Air 2023 Report (2023) at 12, https://www.lung.org/getmedia/338b0c3c-6bf8-480f-9e6e-b93868c6c476/SOTA-2023.pdf?ext=.pdf.

Although people of color are 41% of the overall population of the U.S., they are 54% of the nearly 120 million people living in counties with at least one failing grade. And in the counties with the worst air quality that get failing grades for all three pollution measures, 72% of the 18 million residents affected are people of color, compared to the 28% who are white.89 [EPA-HQ-OAR-2022-0829-0759, pp. 21-22]

89 Id.

In addition to the disproportionate impact on people of color noted above, ALA outlines other "high-risk" groups that are impacted by the pollution in these regions. For example, low-income communities are particularly vulnerable and at risk of health impacts from pollution. More than 14.6 million people whose incomes meet the federal definition for living in poverty reside in counties that received a failing grade on at least one of the ALA's pollutant indicators, while nearly 2.6 million people living in poverty reside in counties that received failing grades on all three pollutant measures.90 In addition, around 27 million children (under age 18) and 18 million older adults (age 65 or older) live in counties that received a failing grade on at least one pollutant.91 [EPA-HQ-OAR-2022-0829-0759, p. 22]

90 Id. at 20.

91 Id.

In fact, it is well established that communities of color and economically disadvantaged communities are disproportionately exposed to environmental burdens from a variety of sources. The White House Council on Environmental Quality (CEQ) released (and recently updated) a Climate and Economic Justice Screening Tool, which identifies communities around the country that are "marginalized, underserved, and overburdened by pollution"92 and would therefore qualify for Justice4093 investments (President Biden's key environmental justice initiative). The Screening Tool identifies census tracts as "disadvantaged" if they are above the threshold for one or more environmental or climate indicators (e.g., exposure to diesel PM or PM2.5, traffic proximity and volume, or proximity to hazardous waste sites) and above the threshold for socioeconomic indicators related to income and education.94 A recent analysis found that 64% of the population in census tracts the Screening Tool identifies as disadvantaged are Hispanic/Latino, Black or African American, or American Indian or Alaskan Native.95 Overall, 50% of Hispanic/Latino, Black or African American, and American Indian or Alaskan Native individuals in the country reside in disadvantaged communities, compared to just 17% of White, Non-Hispanic/Latino individuals.96 [EPA-HQ-OAR-2022-0829-0759, pp. 22-23]

Once EPA makes an endangerment finding, it must set standards that are commensurate to the magnitude of the danger to public health and welfare posed by the covered emissions.12 The Clean Air Act defines "effects on welfare" broadly, including "effects on . . . weather . . . and climate."13 The dangers to public health and welfare posed by GHGs that EPA originally cited in the 2009 Endangerment Finding—"risks associated with changes in air quality, increases in temperatures, changes in extreme weather events, increases in food- and water-borne pathogens, and changes in aeroallergens,"14 to name a few—have only increased. EPA recognized that this was likely to happen in the Endangerment Finding itself, finding that these "risk[s] and the severity of adverse impacts on public welfare are expected to increase over time."15 As for criteria pollutants and air toxics—PM, ozone, VOCs, NOx, SOx, CO, diesel exhaust, formaldehyde, acetaldehyde, acrolein, benzene, butadiene, ethylbenzene, naphthalene, and POM/PAHs—their harmful health and environmental effects have long been known, and EPA has recognized the need for continued reductions in their emissions.16 . The American Lung Association (ALA) released its updated State of the Air report and finds that nearly 36% of Americans—119.6 million people—still live in places with failing grades for unhealthy levels of ozone or particle pollution.3 The number of people living in counties with failing grades for daily spikes in deadly particle pollution was 63.7 million, the most ever reported under the current national standard. The report also finds again that the burden of living with unhealthy air is not shared equally. Although people of color are 41% of the overall population of the U.S., they are 54% of the nearly 120 million people living in counties with at least one failing grade. And in the counties with the worst air quality that get failing grades for all three pollution measures, 72% of the 18 million residents affected are people of color, compared to the 28% who are white. [EPA-HQ-OAR-2022-0829-0786, pp. 6-7]

3 American Lung Association, State of the Air, Key Findings, 2023. https://www.lung.org/research/sota/key-findings (Attachment C)

ALA also recently released a new report that estimates the health and economic benefits of a transition to 100 percent zero-emission new passenger vehicle sales by 2035, coupled with non-combustion electricity generation.4 ALA find that, by 2050, the national public health benefits in the U.S. due to cleaner air could reach $978 billion in public health benefits, 89,300 fewer premature deaths, 2.2 fewer asthma attacks and 10.7 million fewer lost work days. [EPA-HQ-OAR-2022-0829-0786, pp. 6-7]

4 American Lung Association, “Driving to Clean Air: Health Benefits of Zero-Emission Cars and Electricity,” June 2023. https://www.lung.org/clean-air/electric-vehicle-report/driving-to-clean-air. (Attachment D)

These recent studies align with and reinforce the need for and the feasibility of protective emissions standards for passenger vehicles in the timeframe proposed by EPA. [EPA-HQ-OAR-2022-0829-0786, pp. 6-7]

Organization: Gabrielle Lawrence

I am a child psychologist and am speaking today as a climate activist who worries and loses sleep thinking of the damage that the pollution we have in our air is causing. Damage to both adults and most importantly to children. With poorer children being the most severely damaged. Daily, clouds of mercury, arsenic and dozens of other heavy metals from power plants and tail pipe fill our air and water, including one of the worst pollutant, the small particle, PM2.5, soot coming from our cars, trucks and buses. With all of those, we are poisoning ourselves and our children. [EPA-HQ-OAR-2022-0829-0455, pp. 1-2]

Daily in my office, I see children who struggle to sit still for even a moment, who struggle in school because of learning disorders impacting reading and math, with ADHD preventing them from focusing and Autism Spectrum Disorder that impacts them socially and in many other ways, All of these impairments have increased dramatically in the last decade. Concerning Autism Spectrum Disorder, we know that it is directly related to brain impairment and that impairment may be related to air-pollution. Today, the CDC indicated that 1 in 44 children, or 2.3 % of children in our country have been diagnosed with Autism Spectrum disorder.
That number is now 241 % higher than in 2020. For these children, multiple peer reviewed, scientific studies have been done using brain-imaging methods to investigate genetic variations in brain development. The studies investigating air-pollution exposure have found a deficit in white matter, brain connectivity, and vascularization (Chen et al. 2015). A relationship has also been found with air pollutants such as; nitrogen oxide (Kalkbrenner et al. 2015), the particulate matter, PM2.5, (Jung et al. 2013), polyaromatic hydrocarbons, diesel exhaust, and carbon monoxide. These are only three studies among dozens of studies that suggest a strong connection between Autism Spectrum Disorder and air-pollution. Numerous other studies with adults have investigated the relationship between air-pollution and cognitive impairment such as Alzheimer’s and other dementias. Those studies also give evidence that the same air-pollutants listed above, also create cognitive impairment in adults. [EPA-HQ-OAR-2022-0829-0455, pp. 1-2]

Organization: Governing for Impact and Evergreen Action (GFI)

In addition to contributing to the climate crisis, light and medium duty passenger vehicles are responsible for emitting harmful pollutants including carbon monoxide, particulate matter, and nitrogen oxides, which can cause or contribute to significant negative public health outcomes such as lung and heart diseases.15 These harmful health outcomes disproportionately affect low income populations and communities of color, who are exposed to greater amounts of vehicle pollution.16 Unfortunately, these same communities are at the greatest risk of harm from the impacts of climate change, and often lack sufficient resources or support to protect themselves from these harmful impacts.17 Strong transportation emissions standards — for both GHGs and criteria pollutants — will limit the present and imminent public health threats that vulnerable populations face due to vehicle pollution. [EPA-HQ-OAR-2022-0829-0621, pp. 2-3]

17 See generally, EPA "Climate Change and Social Vulnerability in the United States: A Focus on Six Impacts," 430-R-21- 003 (2021), available at: https://www.epa.gov/cira/social-vulnerability-report.

Organization: GreenLatinos et al.

Pollution from vehicles makes us sick and kills us. The data shows this over and over again. We need long-term protective regulation now. [EPA-HQ-OAR-2022-0829-0789, p. 2]

For example, Latino/e children are three times more likely (https://www.jpedhc.org/article/S0891-5245(06)00737-1/fulltext) than white children to live in counties with low air quality. About 10% of Latino/e children (https://www.edf.org/blog/2014/04/22/why-latinos-are-disproportionately-affected-asthma-and-what-we-can-do#:~:text=Today%20in%20the%20United%20States,from%20this%20chronic%20respiratory%20illness.) suffer from asthma, and Latino/e children are 40% more likely to die from asthma than non-Latino white children. These disparities have only increased over time relative to the air quality standards set by the U.S. EPA. [EPA-HQ-OAR-2022-0829-0789, p. 2]

Organization: Growth Energy

A. Other Pollutants

In discussing the impacts of the rule on emissions of other pollutants, EPA entirely leaves out consideration of biofuels. As discussed above, ethanol has lower emissions of many pollutants than petroleum gasoline. Indeed, recent studies by the University of California Riverside and the University of Illinois at Chicago found that use of more ethanol and ethanol- blended fuel significantly reduces harmful pollutants such as particulate matter (PM), carbon monoxide, and benzene.19 Just as with GHGs, that failure renders EPA's assessment of emissions of other pollutants inaccurate. And just as with GHGs, EPA misses an opportunity to reduce emissions through incentivizing biofuel use. [EPA-HQ-OAR-2022-0829-0580, p. 12]

19 Patrick Roth et al., Investigating the Effect of Varying Ethanol and Aromatic Fuel Blends on Secondary Organic Aerosol (SOA) Forming Potential for a FFV-GDI Vehicle: Comparison of Exhaust Emissions Between E10 CaRFG and Splash Blended E15, University of California Riverside (2018); Steffen Mueller, The Impact of Higher Ethanol Blend Levels on Vehicle Emissions in Five Global Cities, University of Illinois at Chicago Energy Resources Center (November 2018).

That failure is particularly egregious in the context of EPA's efforts reduce aromatics in petroleum fuels that contribute to PM emissions. 88 Fed. Reg. at 29,401. As discussed above, ethanol has an excellent octane rating, and blending it into gasoline in greater quantities can therefore allow reductions in aromatics and associated PM emissions. EPA explicitly sought comment on ways to reduce aromatic content, but it completely ignored that increasing the ethanol content of gasoline is a simple way to do so that has significant benefits. Multiple studies continue to show that increasing ethanol content in gasoline reduces PM emissions.20 Indeed, the benefits of ethanol in reducing PM were recently confirmed in EPA's own work with Environment and Climate Change Canada.21 In that study, fuel with increased ethanol content showed the deepest reduction in PM compared to the baseline fuel with heavy aromatics. Growth Energy therefore urges EPA to explore the widespread use of higher ethanol blends to replace heavy aromatics to significantly reduce PM emissions. [EPA-HQ-OAR-2022-0829-0580, p. 12]

20 Growth Energy has provided such studies in previous submissions to EPA, including our comment in support of EPA's proposal to implement the "Request from States for Removal of Gasoline Volatility Waiver."

Organization: HF Sinclair Corporation

Second, PEVs are heavier, and will increase particulate matter emissions through increased brake, tire, and road wear.

Organization: Interfaith Power & Light

In addition, electrifying cars and light trucks will be key to improving air quality and saving lives across the nation. More than 119 million American residents currently live in areas with unhealthy levels of air pollution. According to research from Harvard University, more than 8 million people died from the effects of fossil fuel combustion in 2018, meaning that fossil fuels like oil and coal are linked to 1 in 5 deaths worldwide. Pollutants caused by burning fossil fuels have been linked to early death, heart attacks, respiratory disorders, stroke, and asthma. [EPA-HQ-OAR-2022-0829-0530, p. 1]

Organization: International Council on Clean Transportation (ICCT)

Additionally, a full assessment of relative air quality and health benefits across demographics, as done for the heavy-duty multi-pollutant rule, is recommended for this light-duty and medium-duty multi-pollutant rule. It is widely understood that heavy-duty vehicles contribute to racial disparities in exposure to air pollution, and EPA reported the projected air quality impacts across demographics in their finalized heavy-duty multi-pollutant rule. Inequities in air pollution exposure exist for light-duty vehicle emissions as well. One study finds that on a national level, people of color are exposed to 46% more ambient PM2.5 from light-duty gasoline vehicles than

White people.142 This is a greater disparity than that of HDVs; the same study finds that people of color exposed to 35% higher ambient PM2.5 levels from heavy-duty diesel vehicles compared to White people. Additionally, the health benefits from the heavy-duty multipollutant rule, as projected by the EPA, are on similar scales to that of the proposed light-duty and medium-duty vehicle rule.143 Thus, as the environmental justice and health implications of the light-duty and medium-duty vehicle rule are significant, a full assessment of the projected distribution of changes in PM2.5 and ozone concentrations by geography, race/ethnicity, and income is recommended for the finalized rule. [EPA-HQ-OAR-2022-0829-0569, pp. 53-54]

142 Tessum, C et al. (2021). PM2.5 Polluters Disproportionately and Systemically Affect People of Color in the United States," Science Advances 7, no. 18: eabf4491, https://doi.org/10.1126/sciadv.abf4491.

143 EPA's proposed light-duty and medium-duty rule is estimated to result in $63 billion and $280 billion (for 7% and 3% discount rates, respectively) in total monetized health benefits from 2027 to 2055. EPA's finalized heavy-duty multipollutant rule is projected to result in $53–150 billion and $91–260 billion (for 7% and 3% discount rates, respectively) in total monetized health benefits from 2027 to 2045.

Benefits and cost-effectiveness of the proposal

The LDV and MDV proposal is projected to reduce 15,000 tons of PM2.5, 66,000 tons of NOx, and 220,000 tons of hydrocarbons from 2027 to 2055.144 These benefits are compared to 2055 levels without the proposal. Based on the previous section on Particulate Matter emission standards, health benefits associated with PM reductions could be greater than EPA's projections. The proposed standards would reduce air pollution near-road where affected populations are often low-income or communities of color. Reducing these emissions will provide cleaner air and are critical to improving public health. [EPA-HQ-OAR-2022-0829-0569, p. 55]

144 US EPA. (2023). Multi-Pollutant emission standards for Model years 2027 and later Light-duty and Medium-duty vehicles Program Announcement. https://www.epa.gov/system/files/documents/2023-04/420f23009.pdf

In addition to the feasible cost, the continuing technology improvement will bring greater climate and health benefits. As discussed in the DRIA Chapter 3.2.4, the introduction of more electric vehicles will help make the declining FTP NMOG + NOX fleet average fully feasible. The MY2021 test data shows 19 vehicles with emissions performance currently below 15 mg/mile, and two below 10 mg/mile from a range of automakers. Similarly, MDV 2022 and 2023 also show similar low emission performance compared to the proposal limit. [EPA-HQ-OAR-2022-0829-0569, p. 55]

Organization: John Graham

The heavier weight of BEVs not only increases cost, but also generates higher tire wear and brake wear particulate emissions. These impacts were not considered in the proposed rule.32 [EPA-HQ-OAR-2022-0829-0585, p. 21]

32 DRIA Section 9.6 page 9-26 states only, "Using the miles traveled (for tailpipe, tire wear and brake wear emissions) and liquid fuel consumed (for evaporative and fuel spillage emissions), we can then generate sets of emission rates for use in OMEGA." This suggests that weight was not a factor in evaluating tire wear and brake wear emissions.

Organization: Jonathan Walker

[*From Hearing Testimony, May 10, 2023*] I hope to offer a unique viewpoint as part of the supporting the strongest emission standards possible. You have heard about the health consequences of these kind of emissions and how the public health issues fall disproportionately on people of color and poverty and also support the greenhouse gas emission control, but I am here because I am an ophthalmologist and in particular, I am a retina specialist, which means I treat diseases that cause blindness which means macular degeneration and diabetic retinopathy, things you cannot fix with glasses or Lasik or cataract surgery. When the retina is damaged, it's gone forever and so is the vision. The tiny blood vessel in the retina are an early marker for that damage before that damage shows up elsewhere in the body. Basically the retina is like a canary in the coal mine when it comes to the effect of pollution on the human body and the research clearly shows that the emissions produced by the vehicles can worsen retina health in a way that risks permanent vision loss. There are measurable effects on the retina with even relatively low levels of exposure and I am going to drop some references in the chat and you can also just Google air pollution and retina damage and I'll also be submitting written comments on the docket. To thank you, you are all doing important work to protect us from the threats to the planet and our overall health but I want you to know that you are helping to avoid blindness too. And we know that industry representatives as have been pointed out have a duty to provide reasons to weaken the law and you guys need to balance all the viewpoints and what I am about to say sounds harsh but I think it applies, the tobacco industry in the 1950s when it was clear that smoking caused cancer yet their lobby sowed doubt and uncertainty when there was none causing untold harm as people kept smoking. So please continue to keep our air clean by continue to working to keep the law strong. [From Hearing Testimony, EPA-HQ-OAR-2022-0829-5115, Day 2]

Organization: Metropolitan Washington Air Quality Committee (MWAQC) et al.

Poor air quality affects the residents living and working in metropolitan Washington. The region is currently designated as being in nonattainment of federal National Ambient Air Quality Standards (NAAQS) for ozone. Nitrogen Oxides (NOx) are a precursor pollutant of ground-level ozone. In addition, NOx is a precursor to secondary particulate matter, such as particulate matter 2.5 micrometers in diameter and smaller (PM2.5). Exposure to PM2.5, along with ground-level ozone, is associated with premature death, increased hospitalizations, and emergency room visits due to exacerbation of chronic heart and lung diseases and other serious health impacts.
Some communities in metropolitan Washington face higher rates of illnesses such as asthma than the national average, and these illnesses are aggravated by these pollutants. As such, reductions in NOx emissions will provide health benefits from both reduced ozone and PM2.5 pollution. [EPA-HQ-OAR-2022-0829-0503, pp. 1-2]

While significant progress has been made in metropolitan Washington to reduce NOx emissions, addressing sources of NOx, including those from on-road vehicles, is critical to continuing to deliver cleaner air for the residents of the region. Over the last five ozone seasons, the region recorded an annual average of eight unhealthy air days, which are in part caused by emissions transported into the region, making this not only a regional issue but a national one. EPA estimates that strengthening these standards will reduce NOx and PM2.5 emissions by 41%

and 35% in 2055, respectively, as shown in Table 4 of the Federal Register notice. [EPA-HQ-OAR-2022-0829-0503, pp. 1-2]

Organization: MCS Referral & Resources (MCSRR)

At II.B.5, EPA describes Carbon Monoxide as “a colorless, odorless gas emitted from combustion processes.” This is a true statement as far as it goes but incomplete and misleading. EPA should acknowledge that CO is concentrated in rainwater, freshwater, saltwater, and some soils to higher levels than found in air. CO also is released by some vegetation and higher in mammals, who excrete some of the CO they produce endogenously via their lungs, skin, and eyes whenever the level of CO in ambient air is lower. Lastly, CO also is produced in the atmosphere from the oxidation of methane, isoprene, terpene, and acetone.
See: https://www.ipcc.ch/site/assets/uploads/2018/03/TAR-04.pdf [EPA-HQ-OAR-2022-0829-0615, p. 4]

At II.B.6, EPA says “The lifetimes of the components present in diesel exhaust range from seconds to days.” This is not true of CO. According to a 2012 review by Louis Jaffe, “the exact duration of CO in the lower atmosphere is not known with certainty; however, the mean residence time has been variously estimated to be between 0.3 and 5.0 years.”
See: https://www.tandfonline.com/doi/abs/10.1080/00022470.1968.10469168 [EPA-HQ-OAR-2022-0829-0615, p. 4]

At II.C.5, EPA claims:

“Controlled human exposure studies of subjects with coronary artery disease show a decrease in the time to onset of exercise-induced angina (chest pain) and electrocardiogram changes following CO exposure. “[EPA-HQ-OAR-2022-0829-0615, p. 4]

EPA gives no reference for this claim, which is not true. While a few studies commissioned by EPA from Aronow et al in the 1970s and Allred et al in the 1980s claimed to find this result, both were undermined by falsifying their methods and results. See:
https://www.dropbox.com/s/fmwp8bmke2e8zfo/Donnay%202015%20SOT%20poster%20on%20EPA%20CO%20 NAAQS%20Fraud.pdf?dl=0 [EPA-HQ-OAR-2022-0829-0615, p. 4]

Not surprisingly, subsequent efforts to reproduce these findings have been unsuccessful. At least 14 studies have reported insignificant results: [EPA-HQ-OAR-2022-0829-0615, p. 4]

https://pubmed.ncbi.nlm.nih.gov/?term=29343136,24923364,21933352,17321552,16937915,11696871,104926
50,8210613,8441830,6695663,6750056,7304396,7389699,4640286&format=abstract [EPA-HQ-OAR-2022-0829-0615, p. 4]

Given this evidence, EPA should stop claiming that people with coronary artery disease show a decrease in time to exercise-induced angina or ECG changes after CO exposure. They do not. [EPA-HQ-OAR-2022-0829-0615, p. 4]

Organization: Minnesota Corn Growers Association (MCGA)

CRITERIA POLLUTANTS AND PARTICULATE MATTER

Bringing high octane fuel to market in the form of midlevel ethanol blends will be significantly less capital-intensive than attempting to increase blend stock octane with hydrocarbon components at refineries. It will also be incredibly cleaner. The avoided production cost and offset emissions lower end-costs to consumers, reducing both economic costs and social costs related to health and environment, key considerations in advancing environmental justice and avoiding adverse impacts from oil refineries on communities that have historically borne them. [EPA-HQ-OAR-2022-0829-0612, pp. 9-10]

Increased volumes of ethanol in fuel displace the most harmful compounds from gasoline.25 These aromatic hydrocarbon additives (i.e. benzene, toluene, ethylbenzene, xylene – or BTEX) have high cancer-causing potential. Increasing the ethanol volume in fuel to a midlevel blend has a positive impact on tailpipe emissions of toxins, including significant reductions in particulates and carbon monoxide. These same aromatic hydrocarbons are also precursors to the formation of secondary organic aerosols (SOA), which in turn are a major contributor to particulate matter emissions (PM 2.5). [EPA-HQ-OAR-2022-0829-0612, pp. 9-10]

25 Environmental and Energy Study Institute. Ethanol and Air Quality – Separating Fact from Fiction. October 12, 2018. https://www.eesi.org/articles/view/ethanol-and-air-quality-separating-fact-from-fiction.

According to EPA's review for the 2020 Anti-backsliding Study, ethanol does not form SOA directly or affect SOA formation. However, as EPA states, toluene is a large contributor to SOA. Ethanol's high-octane value "greatly reduces the need for other high-octane components including aromatics such as toluene."26 [EPA-HQ-OAR-2022-0829-0612, pp. 9-10]

26 U.S. Environmental Protection Agency, Clean Air Act Section 211 (v)(1) Anti-backsliding Study, (2020) Appendix A, Page 61.

As explained in EPA's Fuel Trends Report: Gasoline 2006-2016, "Ethanol's high-octane value has also allowed refiners to significantly reduce the aromatic content of the gasoline, a trend borne out in the data." EPA's data shows that aromatics' share of gasoline volume dropped from nearly 25 percent to 19.3 percent, and benzene volume dropped from 0.99 percent to 0.58 percent between 2000 and 2016, the same time as ethanol blending increased from 1 percent to at least 10 percent. [EPA-HQ-OAR-2022-0829-0612, pp. 9-10]

EPA's data demonstrates the air quality and human health benefits of increased ethanol blending in gasoline by replacing harmful aromatics with clean octane from ethanol. Limiting the aromatics content of gasoline and using higher ethanol blends in high octane fuel would further reduce risks from SOA formation and exposure to PM 2.5, which causes serious respiratory, cardiovascular, and other health harm, including premature death, according to the American Lung Association. The same GDI engine advancements that help lower GHG emissions have the unfortunate side effect of increasing particulate emissions, which could be reduced by use of midlevel ethanol blends. [EPA-HQ-OAR-2022-0829-0612, pp. 9-10]

Petroleum-based aerosol particles represent a significant source of pollution, especially in population-dense urban areas. Health issues related to PM and other emission-based pollutants can be reduced by lowering the volume of petroleum in the domestic gasoline pool, which can be accomplished by increasing octane with higher ethanol blends and replacing more hydrocarbon aromatics with ethanol. [EPA-HQ-OAR-2022-0829-0612, pp. 9-10]

It is well known that particulate emissions are a strong function of aromatic fuel components with a high double bond equivalent and low vapor pressure, and the particulate forming potential is well represented by the "PMI" metric developed by Honda.27 The value of the PMI metric has been validated in many other studies including the joint auto-oil Coordinating Research Council28 and the EPA.29 PMI and particulate emissions can be reduced by altering refinery processes to reduce heavy aromatic content of the fuel, and, as noted, ethanol can replace those aromatics. [EPA-HQ-OAR-2022-0829-0612, pp. 9-10]

27 Aikawa, Sakurai, and Jetter, "Development of a Predictive Model for Gasoline Vehicle Particulate Matter Emissions", SAE paper 2010-01-2115, 2010; https://doi.org/10.4271/2010-01-2115.

28 Coordinating Research Council, "Evaluation and Investigation of Fuel Effects on Gaseous and Particulate Emissions on SIDI In-Use Vehicles," Report No. E- 94-2, March 2016; http://crcsite.wpengine.com/wp-content/uploads/2019/05/CRC_2017-3-21_03-20955_E94-2FinalReport-Rev1b.pdf.

29 Environmental Protection Agency, "Exhaust Emission Impacts of Replacing Heavy Aromatic Hydrocarbons in Gasoline with Alternate Octane Sources", report EPA-420-R-23-008, April 2023.

Perhaps the most credible and comprehensive study on the effects of ethanol on particulate emissions topic was published by the University of California Center for Environmental Research and Technology.30 The study showed statistically significant improvements in particulate emissions for E15 compared to E10. [EPA-HQ-OAR-2022-0829-0612, pp. 9-10]

30 Tang et al., "Expanding the ethanol blend wall in California: Emissions comparison between E10 and E15", Fuel, June 2023; https://doi.org/10.1016/j.fuel.2023.128836.

EPA should adopt rules to limit PMI of both finished fuels and the hydrocarbon blend stocks used for E10, E15, and E85. Limiting PMI of hydrocarbon blend stocks will ensure that the particulate emissions benefits of ethanol are not offset by negative changes at refineries. [EPA-HQ-OAR-2022-0829-0612, pp. 10-11]

Improved fuel property standards should be a high priority because they can achieve significantly lower particulate emissions and dramatically lower GHG emissions. California's Low Carbon Fuel Standard already recognizes the importance of fuel standards, and it has led to dramatic increases in sales of E85 and other low- carbon biofuels. High-octane low-carbon fuels are a key enabler for continued GHG emissions improvements in the millions of liquid-fueled vehicles which will be produced over the next 10+ years, as documented by the U.S. Department of Energy Co-Optimization of Fuels & Engines initiative and in numerous other studies, such as those by MIT and by automakers. A detailed proposed blueprint for future high-octane low-carbon fuels exists in the Next Generation Fuels Act, and EPA has the statutory authority to make these changes without waiting for Congress to act. [EPA-HQ-OAR-2022-0829-0612, pp. 10-11]

Organization: Minnesota Pollution Control Agency (MPCA)

The MPCA has supported EPA's previous efforts to strengthen vehicle emissions standards and appreciates the opportunity to comment on the proposed rule. We see the proposed rulemaking as an opportunity to advance climate action, reduce harm to Minnesotans from criteria pollutants and air toxics, and accelerate the transition to electric vehicles in our state. [EPA-HQ-OAR-2022-0829-0557, pp. 1-2]

Importance of new federal greenhouse gas standards for climate action

The transportation sector represents the largest source of greenhouse gas emissions in Minnesota. The top three sources in the transportation sector are light-duty trucks, heavy-duty trucks, and passenger cars.1 These categories are inclusive of light and medium-duty vehicles discussed in this proposal. [EPA-HQ-OAR-2022-0829-0557, pp. 1-2]

Stronger vehicle emissions standards at the federal level have lowered greenhouse gas emissions from vehicles generally. However, the long-term consumer trend of choosing larger vehicles and the general trend of more miles driven (except during the pandemic) are counteracting more significant emissions reductions in this sector. Increased emissions stringency at the federal level is critical to continuing the trend of emission reductions in this sector. Accelerating light- and medium-duty vehicle electrification is vital for Minnesota to meet its climate and air pollution goals. Specifically, adopting new light- and medium-duty vehicle emissions standards would: [EPA-HQ-OAR-2022-0829-0557, pp. 1-2]

1 Greenhouse gas emissions in Minnesota 2005-2020, https://www.pca.state.mn.us/sites/default/files/lraq-2sy23.pdf.

- Help the state meet economy-wide greenhouse gas emissions reduction goals. [EPA-HQ-OAR-2022-0829-0557, pp. 1-2]

In 2022, as part of the publication of the state's Climate Action Framework,2 Governor Walz and Lieutenant Governor Flanagan endorsed the economy-wide greenhouse gas emissions reduction goal for the state to reduce emissions by 50% by 2030 and to become carbon-neutral by 2050. In May 2023, Minnesota codified these targets in statute. Achieving these goals will require action at all levels of government, across businesses, and by individuals. The proposed multipollutant standards will be critical for reducing emissions from the transportation sector. [EPA-HQ-OAR-2022-0829-0557, pp. 1-2]

2 Minnesota's Climate Action Framework, https://climate.state.mn.us/minnesotas-climate-action-framework.

- Advance transportation actions and targets in the state's Climate Action Framework. [EPA-HQ-OAR-2022-0829-0557, pp. 1-2]

Minnesota's Climate Action Framework is a plan that sets a vision for how the state will address and prepare for climate change. The framework broadly guides the direction of climate action toward a carbon-neutral, resilient, and equitable future for Minnesota and contains immediate, near-term actions, as well as key progress indicators with measurable targets. The framework was developed based on significant input from stakeholders, the public, and the Tribal Nations located within Minnesota's modern borders [EPA-HQ-OAR-2022-0829-0557, pp. 1-2].

The proposed light- and medium-duty vehicle standards would advance the following actions in the Clean Transportation goal: [EPA-HQ-OAR-2022-0829-0557, pp. 1-2]

-- Increase the use of clean fuels, including lower-carbon biofuels (Sub-initiative 1.2.1)

-- Expand electric vehicle (EV) charging infrastructure (Sub-initiative 1.2.2)

-- Increase EV availability and access (Sub-initiative 1.2.3)

-- Accelerate the transition to EVs and clean transportation (Sub-initiative 1.2.4)

-- Improve vehicle efficiency and emissions standards (Sub-initiative 1.2.5)

[EPA-HQ-OAR-2022-0829-0557, pp. 1-2]

Additionally, the proposed standards would advance the following targets for the Clean Transportation goal: [EPA-HQ-OAR-2022-0829-0557, pp. 1-2]

-- Reduce greenhouse gas emissions from the transportation sector 80% by 2040

-- Reach 20% electric vehicles on Minnesota roads by 2030 [EPA-HQ-OAR-2022-0829-0557, pp. 1-2]

Importance of new federal standards for reducing harm from non-greenhouse gas pollution

It is the MPCA's responsibility to protect Minnesotans' health and environment in collaboration with the federal government through cooperative federalism. Minnesota is attaining all National Ambient Air Quality Standards; however, as we better understand the health impacts of air pollution, EPA continues to make these standards more stringent. As emissions from stationary sources continue to decline, it is increasingly important to drive down emissions from vehicles. [EPA-HQ-OAR-2022-0829-0557, p. 2]

Organization: National Corn Growers Association (NCGA)

As explained in EPA's Fuel Trends Report: Gasoline 2006-2016, "Ethanol's high-octane value has also allowed refiners to significantly reduce the aromatic content of the gasoline, a trend borne out in the data." EPA's data shows that aromatics' share of gasoline volume dropped from nearly 25 percent to 19.3 percent, and benzene volume dropped from 0.99 percent to 0.58 percent between 2000 and 2016, the same time as ethanol blending increased from 1 percent to at least 10 percent. [EPA-HQ-OAR-2022-0829-0643, p. 8]

EPA's data demonstrates the air quality and human health benefits of increased ethanol blending in gasoline by replacing harmful aromatics with clean octane from ethanol. Limiting the aromatics content of gasoline and using higher ethanol blends in high octane fuel would further reduce risks from SOA formation and exposure to PM 2.5, which causes serious respiratory, cardiovascular, and other health harm, including premature death, according to the American Lung Association. The same GDI engine advancements that help lower GHG emissions have the unfortunate side effect of increasing particulate emissions, which could be reduced by use of midlevel ethanol blends. [EPA-HQ-OAR-2022-0829-0643, p. 8]

Petroleum-based aerosol particles represent a significant source of pollution, especially in population-dense urban areas. Health issues related to PM and other emission-based pollutants can be reduced by lowering the volume of petroleum in the domestic gasoline pool, which can be accomplished by increasing octane with higher ethanol blends and replacing more hydrocarbon aromatics with ethanol. [EPA-HQ-OAR-2022-0829-0643, p. 8]

It is well known that particulate emissions are a strong function of aromatic fuel components with a high double bond equivalent and low vapor pressure, and the particulate forming potential is well represented by the "PMI" metric developed by Honda. 27 The value of the PMI metric has been validated in many other studies including the joint auto-oil Coordinating Research

Council 28 and the EPA. 29 PMI and particulate emissions can be reduced by altering refinery processes to reduce heavy aromatic content of the fuel, and, as noted, ethanol can replace those aromatics. [EPA-HQ-OAR-2022-0829-0643, p. 8]

27 Aikawa, Sakurai, and Jetter, "Development of a Predictive Model for Gasoline Vehicle Particulate Matter Emissions", SAE paper 2010-01-2115, 2010; https://doi.org/10.4271/2010-01-2115

Organization: National Farmers Union (NFU)

Higher vehicle weight also increases wear and tear on vehicle tires, which causes higher particulate emissions, as illustrated in Figure 56 reproduced below.22 [EPA-HQ-OAR-2022-0829-0581, pp. 10-11]

22 Alan Stanard et al., Brake and Tire Wear Emissions-Project 17RD016: Final Report, Revision 2, Eastern Research Group, Inc. report prepared for California Air Resources Board, at 87, Feb. 11, 2021, available at https://ww2.arb.ca.gov/sites/default/files/2021-04/17RD016.pdf.

[See original comment for Figure 56. Total vehicle test cycle PM mass emissions vs simulated vehicle test weight, categorized by pad material] [EPA-HQ-OAR-2022-0829-0581, pp. 10-11]

EPA has regulated tailpipe particulate emissions for many years, but there is abundant evidence that wear particles from tires and brakes are at least as important as tailpipe emissions.23 According to one study, "[h]alf a tonne of battery weight can result in tire emissions that are almost 400 more times greater than real-world tailpipe emissions, everything else being equal."24 Moreover, minority and low-income communities are more likely to be exposed to higher traffic-related air pollution, causing environmental justice concerns.25 [EPA-HQ-OAR-2022-0829-0581, p. 12]

23 See, e.g., Xiaoliang Wang, et al., Evidence of non-tailpipe emission contributions to PM2.5 and PM10 near southern California highways, Environmental Pollution, Vol. 317, Jan. 15, 2023, https://doi.org/10.1016/j.envpol.2022.120691.

24 Emissions Analytics, Gaining Traction, Losing Tread – Pollution from tire wear now 1,850 times worse than exhaust emissions, May 10, 2022 Newsletter - Tyre Emissions, https://www.emissionsanalytics.com/news/gaining- traction-losing-tread.

25 Xiaoliang Wang, et al., supra n.23.

But the proposed emissions standards fail to address the large and growing problem of particulate emissions from tires, and instead focus on more stringent tailpipe particulate standards which will add cost without necessarily improving air quality. EPA should not artificially incentivize heavy BEVs by counting them as "zero emissions," when lighter weight solutions can provide similar GHG emissions benefits and better safety. EPA needs to look beyond the tailpipe and create holistic standards which incentivize real improvements. [EPA-HQ-OAR-2022-0829-0581, p. 12]

Organization: National Tribal Air Association (NTAA)

Air Toxics

As reflected in the title of the proposed rule, the benefits of reduced emissions from light-duty and medium-duty vehicles will include reduced exposures to multiple tailpipe emissions. In addition to greenhouse gases and smog-forming compounds, an array of pollutants will be addressed that are harmful to human health. These include benzene, a known human carcinogen6. Tribes in or near urban environments and those with residents near roadways will benefit from decreased exposure to these multiple toxic air pollutants. [EPA-HQ-OAR-2022-0829-0504, p. 2]

6 Benzene; CASRN 71-43-2, U.S.EPA, National Center for Environmental Assessment, Integrated Risk Information System (IRIS)

Organization: Reginald Modlin and B. Reid Detchon

We note the comment in the Proposed Rule that "in addition to substantially reducing GHG emissions, a longer-term rulemaking could also address criteria pollutant and air toxics emissions from the new light-duty vehicle fleet – especially important considerations during the transition to zero-emission vehicles." Most vehicles entering the market today use gasoline direct injection (GDI) to enhance performance. DOE studies have identified a notable increase in ultrafine particle emissions from GDI engines. The increased number of particles and their size include emissions of toxic polycyclic aromatic hydrocarbons (PAHs). [EPA-HQ-OAR-2022-0829-0570, pp. 2-3]

For mobile source air toxics, such as PAHs derived from gasoline emissions, the Clean Air Act requires "the greatest degree of emission reduction achievable through the application of technology which will be available." In that context, just as with greenhouse gas emissions, vehicles and fuels must be seen as parts of an integrated system. The Department of Energy clearly understands the need for such an approach. Since 2016, the Co-Optimization of Fuels & Engines initiative (known as Co-Optima) has explored how simultaneous innovations in fuels and engines can boost fuel economy and vehicle performance, while reducing emissions. The Co-Optima team views fuels "not as standalone elements in the transportation system, but as dynamic design variables that can work with modern engines to optimize and revolutionize the entire on-road fleet." Their work will be useful as EPA considers the adoption of improved fuels in current and future rulemakings. [EPA-HQ-OAR-2022-0829-0570, pp. 2-3]

Emissions from aromatic compounds in gasoline were commonly thought to be short-lived, thus posing little threat to human health. But that was wrong. A recent General Motors study found that nearly 96% of the fine-particle emissions from gasoline are caused by the aromatics in the fuel. Fine particle pollution from fossil fuel combustion is the leading cause of premature death in the world, responsible for cardiovascular, respiratory, and other health effects that kill more than 8 million people annually. [EPA-HQ-OAR-2022-0829-0570, pp. 4-5]

Not all particles are alike. Among the worst are polycyclic aromatic hydrocarbons (PAHs). Once inhaled, these ultrafine particles reach the deepest part of the lungs and enter the bloodstream, where they can cross biological membranes, even the placental barrier, and reach the brain. Fetal exposure to extremely low levels of PAHs has been associated with developmental delay at age 3 and reduced IQ at age 5. [EPA-HQ-OAR-2022-0829-0570, pp. 4-5]

Research has shown that PAHs attach themselves to ultrafine particles in the exhaust stream, extending their lives over long distances and durations. This new understanding is one reason why EPA's atmospheric models, by the agency's own admission, have been unable to predict the formation of secondary organic aerosols as a class – a major component of fine particle pollution in urban areas. [EPA-HQ-OAR-2022-0829-0570, pp. 4-5]

The Clean Air Act Amendments of 1990 required control of toxic emissions from motor vehicles. EPA responded in 2001 with standards based on the technologies and understanding of health effects at that time. However, time and science have moved on. Vehicle engine technologies have advanced, the composition of gasoline has changed, and the public health effects of aromatics have become better understood: Carburetors and port fuel injection have largely been replaced by gasoline direct injection (GDI) technology. More than half of the vehicles entering the market use this technology to enhance fuel economy performance. Unfortunately, GDI technology greatly increases emissions of ultrafine particles when using today's gasoline. [EPA-HQ-OAR-2022-0829-0570, p. 5]

It doesn't have to be this way. Technologies and products have come together to define a new solution for what the Clean Air Act requires: "the greatest degree of emission reduction achievable through the application of technology which will be available." Along with a rapid transition to electric vehicles, a complementary program should include adoption of higher ethanol blends, which have been shown by U.S. National Laboratories to enable higher fuel economy and vehicle performance. Such blends would enable a 40% reduction in the use of toxic aromatics in gasoline. An important recent study, co-authored by the Nobel Prize winner Mario Molina, concluded that reducing the smallest (ultrafine) particles "without simultaneously limiting organics from automobile emissions is ineffective and can even exacerbate this problem." [EPA-HQ-OAR-2022-0829-0570, p. 5]

I. Emissions from the use of toxic chemicals in gasoline – aromatic hydrocarbons – are causing thousands of premature deaths annually in the United States and harming the cognitive development of children. [EPA-HQ-OAR-2022-0829-0570, pp. 6-7]

1. The effect on public health in brief [EPA-HQ-OAR-2022-0829-0570, pp. 6-7]

a. Incomplete combustion of the aromatics in gasoline (comprising 20% of every gallon) results in tailpipe emissions of fine particles. Inhalation of fine particles from fossil fuel combustion is the leading cause of premature death in the world, killing more than 8 million people annually. [EPA-HQ-OAR-2022-0829-0570, pp. 6-7]

d. Not all particles are alike – some may be benign, while others are clearly toxic. Among the worst are polycyclic aromatic hydrocarbons (PAHs), which mix and combine with other gasoline emissions to persist over longer times and distances than previously thought possible. [EPA-HQ-OAR-2022-0829-0570, pp. 6-7]

6 Alla Zelenyuk et al., “The Effect of Gas-Phase Polycyclic Aromatic Hydrocarbons on the Formation and Properties of Biogenic Secondary Organic Aerosol Particles,” Faraday Discussions (2017): 200: pp. 143-164: https://pubs.rsc.org/en/content/articlelanding/2017/FD/C7FD00032D#!divAbstract (accessed Feb. 24, 2021).

e. Fetal exposure to extremely low levels of PAHs – levels that are common in dense urban areas – has been associated with developmental delay at age 3 years and reduced IQ at age 5 years, similar to the effects reported for children with elevated concentrations of lead in their blood. [EPA-HQ-OAR-2022-0829-0570, pp. 6-7]

7 Frederica P. Perera et al., “Prenatal Airborne Polycyclic Aromatic Hydrocarbon Exposure and Child IQ at Age 5 Years,” Pediatrics (2009): 124(2): pp. e195-e202: https://www.ncbi.nlm.nih.gov/pmc/articles/PMC2864932/ (accessed Feb. 24, 2021).

1. A recent General Motors study found that nearly 96% of the PM emissions from gasoline are caused by the aromatics in the fuel. Due to an increase in heavy aromatics in the U.S. gasoline pool in the last three years, the gasoline particulate index has increased by more than 30% since 2016 and now is worse than in the EU and China. The authors observed: “Fuel quality improvements are not only important for new vehicles, which are designed for it, but also will benefit the whole fleet of legacy vehicles in the market and off-highway engines.” [EPA-HQ-OAR-2022-0829-0570, pp. 10-12]

33 Elana Chapman et al., “Global Market Gasoline Quality Review: Five Year Trends in Particulate Emission Indices,” SAE International (2021): SAE Technical Paper 2021-01-0623: https://saemobilus.sae.org/content/2021-01-0623/ (accessed June 17, 2021).

v. Ultrafine particles (UFPs) are so small that they can only be detected with an electron microscope, and they are more usefully measured by particle number, not mass. They comprise more than 80% of the particles in urban air but are a negligible fraction of PM2.5 mass. [EPA-HQ-OAR-2022-0829-0570, pp. 10-12]

34 Christina H. Fuller et al., “Indoor and outdoor measurements of particle number concentration in near-highway homes,” Journal of Exposure Science and Environmental Epidemiology (2013): 23: p. 506: https://www.nature.com/articles/jes2012116.pdf (accessed Feb. 24, 2021).

1. Studies have shown associations between UFPs and increased asthma symptoms, cardiovascular disease markers, and decreased cognitive function. [EPA-HQ-OAR-2022-0829-0570, pp. 10-12]

35 Ibid.

a. In a recent U.S. study, prenatal UFP exposure was linked to asthma development in children: Children whose mothers were exposed to high levels of UFPs during pregnancy were four times more likely to develop asthma than those whose mothers were exposed to lower levels – roughly the difference between a quiet street and a busy road. Most of the diagnoses occurred just after three years of age, and overall 18% of the infants developed asthma. The researchers took account of other factors, including the age of the mothers and obesity, as well as other air pollutants. [EPA-HQ-OAR-2022-0829-0570, pp. 10-12]

36 Rosalind J. Wright et al., “Prenatal Ambient Ultrafine Particle Exposure and Childhood Asthma in the Northeastern United States,” American Journal of Respiratory and Critical Care Medicine (2021): https://www.atsjournals.org/doi/abs/10.1164/rccm.202010-3743OC (accessed June 11, 2021).

37 Damian Carrington, “Asthma in toddlers linked to in-utero exposure to air pollution, study finds,” The Guardian (May 21, 2021): https://www.theguardian.com/environment/2021/may/21/asthma-in-toddlers-linked-to-in-utero-exposure-to-air-pollution-ufps-study-finds (accessed June 11, 2021).

2. UFPs contain large amounts of toxic components, and their adverse health effects potential would not be predicted from their mass alone. Particle number, surface area, and chemical composition are more important than mass as a health-relevant metric. [EPA-HQ-OAR-2022-0829-0570, pp. 10-12]

38 Paul A. Solomon, U.S. Environmental Protection Agency, “An Overview of Ultrafine Particles in Ambient Air,” EM: The Magazine for Environmental Managers (2012): 5: pp. 20-21: https://cfpub.epa.gov/si/si_public_record_report.cfm?Lab=NERL&dirEntryId=241266 (accessed Feb. 24, 2021).

3. There is a growing concern in the public health community about the contribution of UFPs to human health. Despite their modest mass and size, they dominate in terms of the number of particles in the ambient air. A particular concern about UFPs is their ability to reach the most distal lung regions (alveoli) and circumvent primary airway defenses. Moreover, UFPs have a high surface area and a capacity to adsorb a substantial amount of toxic organic compounds. Harmful systemic health effects of PM10 or PM2.5 are often due to the UFP fraction. [EPA-HQ-OAR-2022-0829-0570, pp. 10-12]

39 Hyouk-Soo Kwon et al., “Ultrafine particles: unique physicochemical properties relevant to health and disease,” Experimental & Molecular Medicine (2020): 52: pp. 318-28: https://www.nature.com/articles/s12276-020-0405-1.pdf (accessed June 11, 2021).

5. The ability of inhaled particles to be captured within the human body, called the deposition efficiency, is a function of particle size, with the particle deposition efficiency rapidly

increasing as the particles become smaller and smaller. [EPA-HQ-OAR-2022-0829-0570, pp. 10-12]

40 Felipe Rodriguez et al., "Recommendations for Post-Euro 6 Standards for Light-Duty Vehicles in the EU" (2019), International Council on Clean Transportation, p. 8: https://theicct.org/sites/default/files/publications/Post_Euro6_standards_report_20191003.pdf (accessed June 11, 2021).

6. UFPs can cross biological membranes, and their mobility within the body is thought to be high. There is considerable evidence to show that inhaled UFPs can gain access to the bloodstream and are then distributed to other organs in the body. They can even cross the placental barrier. [EPA-HQ-OAR-2022-0829-0570, pp. 10-12]

41 Howard, op. cit., supra note 3, pp. 12-15.

7. UFPs have been shown to directly translocate to the brain along the olfactory nerves. In addition, they can pass intact into cells, where they can have direct access to cytoplasmic proteins and organelles – for example, the mitochondria impacting the respiratory chain and DNA in the nucleus – enhancing the toxic potential of these particles. [EPA-HQ-OAR-2022-0829-0570, pp. 12-13]

42 Solomon, op. cit., supra note 38, p. 21.

8. Results indicating that particles may contribute to the overall oxidative stress burden of the brain are particularly troublesome, as these long-term health effects may accumulate over decades. [EPA-HQ-OAR-2022-0829-0570, pp. 12-13]

43 Annette Peters et al., "Translocation and potential neurological effects of fine and ultrafine particles a critical update," Particle and Fibre Toxicology (2006): 3(13): https://pubmed.ncbi.nlm.nih.gov/16961926/ (accessed Feb. 24, 2021).

vi. Research also suggests that the introduction of excessive UFPs into the atmosphere results in surprising side effects, such as changes in the distribution and intensity of rainfall, causing either drought or flooding in extreme cases. Such drastic climate change affects the global hydrological cycle and thereby affects global public health both directly and indirectly. [EPA-HQ-OAR-2022-0829-0570, pp. 12-13]

44 Kwon et al., op. cit., supra note 39.

vii. In most urban areas, on-road vehicles are the primary source of UFP emissions. These areas observe a peak in UFPs in the morning during rush hour associated with motor vehicle emissions and a second peak during the afternoon, enhanced during the summer, associated with photochemistry, or one slightly later in the afternoon due to rush hour traffic that is enhanced during cooler conditions. [EPA-HQ-OAR-2022-0829-0570, pp. 12-13]

45 Ibid.

46 Solomon, op. cit., supra note 38, p.19.

viii.. An important recent study co-authored by Nobel Prize winner Mario Molina found "remarkable formation of UFPs from urban traffic emissions": [EPA-HQ-OAR-2022-0829-0570, pp. 12-13]

47 Guo et al., op. cit., supra note 2.

1. Photooxidation of vehicular exhaust yields abundant UFP precursors, and organics dominate formation of UFPs under urban conditions. Measurements of gaseous species inside the chamber showed high levels of aromatics, including toluene and C8 and C9 aromatics. [EPA-HQ-OAR-2022-0829-0570, pp. 12-13]

48 Ibid.

2. The authors concluded: “Recognition of this source of UFPs is essential to assessing their impacts and developing mitigation policies. Our results imply that reduction of primary particles or removal of existing particles without simultaneously limiting organics from automobile emissions is ineffective and can even exacerbate this problem.” (emphasis added) [EPA-HQ-OAR-2022-0829-0570, pp. 12-13]

49 Ibid.

b. According to EPA’s 2011 National Air Toxics Assessment,: secondary formation is the largest contributor to cancer risks nationwide, accounting for 47% of the risk. On-road mobile sources contribute the most cancer risk from directly emitted pollutants (about 18%) and the most to non-cancer risks (34%).[EPA-HQ-OAR-2022-0829-0570, pp. 15-16]

66 U.S. Environmental Protection Agency, “Overview of EPA’s 2011 National Air Toxics Assessment,” online fact sheet (2015): https://www.epa.gov/sites/production/files/2015-12/documents/2011-nata-fact-sheet.pdf (accessed Feb. 24, 2021).

i. A recent study found higher toxicity in combustion aerosols than non-combustion aerosols, with emissions from vehicle engine exhaust scoring higher on overall toxicity than even those from coal combustion. [EPA-HQ-OAR-2022-0829-0570, pp. 15-16]

67 Minhan Park et al., “Differential toxicities of fine particulate matters from various sources,” Nature, Scientific Reports (2018): 8(17007): https://www.nature.com/articles/s41598-018-35398-0 (accessed Feb. 24, 2021).

c. EPA said in 2005: “Aromatic compounds … are considered to be the most significant anthropogenic SOA precursors and have been estimated to be responsible for 50 to 70% of total SOA in some airsheds. … The experimental work of Odum and others showed that the secondary organic aerosol formation potential of gasoline could be accounted for solely in terms of its aromatic fraction” (emphasis added) [EPA-HQ-OAR-2022-0829-0570, pp. 16-17]

68 Daniel Grosjean and John H. Seinfeld, “Parameterization of the formation potential of secondary organic aerosols,” Atmospheric Environment (1967): 23(8): pp. 1733-47: https://www.sciencedirect.com/science/article/abs/pii/0004698189900589 (accessed Feb. 24, 2021) and J.R. Odum et al., “The atmospheric aerosol-forming potential of whole gasoline vapor,” Science (1997): 276(5309): pp. 96-9: https://pubmed.ncbi.nlm.nih.gov/9082994/ (accessed Feb. 24, 2021), cited in U.S. Environmental Protection Agency, “Proposed Rule To Implement the Fine Particle National Ambient Air Quality Standards,” Federal Register (2005): 70(210): p. 65996: https://www.govinfo.gov/content/pkg/FR-2005-11-01/pdf/05-20455.pdf (accessed Feb. 24, 2021).

i. The effect of aromatics on SOA does not seem to be linear: Increasing the level of aromatics in test fuels by less than 30% (from 28.5% to 36.7%) was shown to cause a 3- to 6-fold increase in SOA formation. [EPA-HQ-OAR-2022-0829-0570, pp. 16-17]

69 Jianfei Peng et al., “Gasoline aromatics: a critical determinant of urban secondary organic aerosol formation,” Atmospheric Chemistry and Physics (2017): 17: pp. 10743-52: https://www.atmos-chem-phys.net/17/10743/2017/acp-17-10743-2017.pdf (accessed Feb. 24, 2021).

d. One study estimated that SOA from aromatics in gasoline is responsible for 3,800 annual premature deaths and annual social costs of $28.2 billion in 2006 dollars. [EPA-HQ-OAR-2022-0829-0570, pp. 16-17]

70 von Stackelberg et al., op. cit., supra note 24: https://ehjournal.biomedcentral.com/articles/10.1186/1476-069X-12-19 (accessed Feb. 24, 2021).

i. Those mortality numbers can be compared to the impact of EPA ozone regulation, a major focus of the Clean Air Act – predicted to reduce premature mortalities by 4,300-7,100 deaths per year. [EPA-HQ-OAR-2022-0829-0570, pp. 16-17]

71 U.S. Environmental Protection Agency, "Clean Air Act Overview: Progress Cleaning the Air and Improving People's Health," online fact sheet: https://www.epa.gov/clean-air-act-overview/progress-cleaning-air-and-improving-peoples-health (accessed Feb. 24, 2021).

e. Ozone "forms in the atmosphere through a series of complex, non-linear chemical interactions of precursor pollutants." The cost of ozone regulation has been estimated to be more than $14 billion annually, with benefits of more than $55 billion per year. [EPA-HQ-OAR-2022-0829-0570, pp. 16-17]

72 U.S. Environmental Protection Agency, "The Benefits and Costs of the Clean Air Act from 1990 to 2020" (2011): p. 4-2: https://www.epa.gov/sites/production/files/2015-07/documents/fullreport_rev_a.pdf (accessed Feb. 24, 2021).

73 Ibid., p. 3-8.

74 Ibid., p. 7-5.

i. Many air toxics contribute to ozone formation, especially aromatics, so there is a double benefit to reducing them. However, an EPA assessment of the Clean Air Act found approximately 98% of avoided premature mortalities were due to reductions in PM concentrations, not ozone." [EPA-HQ-OAR-2022-0829-0570, pp. 16-17]

75 Ibid., p. 1-11

76 Barnes and Becker, op. cit., supra note 19.

77 U.S. EPA, "The Benefits and Costs of the Clean Air Act," op. cit., supra note 72, p. 8-12.

5. Emissions from aromatics: Polycyclic aromatic hydrocarbons (PAHs)

a. Not all particles are alike – some may be benign, while others are clearly toxic. Polycyclic aromatic hydrocarbons (PAHs) are among the worst. EPA has classified seven PAHs as probable human carcinogens. [EPA-HQ-OAR-2022-0829-0570, pp. 17-18]

78 U.S. Environmental Protection Agency, "Polycyclic Organic Matter," online fact sheet: https://www.epa.gov/sites/production/files/2016-09/documents/polycyclic-organic-matter.pdf (accessed June 17, 2021).

i. The Occupational Safety and Health Administration has set a limit of 0.2 milligrams of PAHs per cubic meter of air (0.2 mg/m3). [EPA-HQ-OAR-2022-0829-0570, pp. 17-18]

79 Agency for Toxic Substances and Disease Registry, U.S. Department of Health and Human Services, "ToxFAQs for Polycyclic Aromatic Hydrocarbons (PAH)" (1996): https://www.atsdr.cdc.gov/toxfaqs/tfacts69.pdf (accessed Feb. 24, 2021).

b. A subset of polycyclic organic matter (POM), PAHs consist of three to seven benzene rings. The PAH family includes more than 100 different compounds of a similar chemical nature, all products of incomplete combustion of organic materials. Among all sources, vehicular exhaust is the major source for PAH air pollution in most urban areas. [EPA-HQ-OAR-2022-0829-0570, pp. 17-18]

80 U.S. EPA, "Polycyclic Organic Matter," op. cit., supra note 78.

81 Z. Fan and L. Lin, "PAHs" in "Exposure Science: Contaminant Mixtures," Encyclopedia of Environmental Health (Second Edition) (2011), Elsevier Reference Collection in Earth Systems and Environmental Sciences: pp. 805-15: https://www.sciencedirect.com/topics/earth-and-planetary-sciences/polycyclic-aromatic-hydrocarbon (accessed June 21, 2021).

c. Complex mixtures of various PAH compounds are spread with the wind in the environment, where their presence poses a risk to human health through ingestion and inhalation. PAHs do not easily degrade in the environment – they undergo long-distance transport and accumulate in aquatic sediment, where some of them pose a threat to aquatic life. [EPA-HQ-OAR-2022-0829-0570, pp. 17-18]

82 Popek, op. cit., supra note 8: pp. 58-59.

d. PAHs are commonly divided into two categories based on their size. PAHs with two to three fused aromatic rings are considered low molecular weight PAHs, while those with four and more fused rings are high molecular weight PAHs, including the most carcinogenic PAH, benzo[a]pyrene (BaP). [EPA-HQ-OAR-2022-0829-0570, pp. 17-18]

83 Stephen Richardson, "Polycyclic Aromatic Hydrocarbons (PAH)": https://www.enviro.wiki/index.php?title=Polycyclic_Aromatic_Hydrocarbons_(PAHs) (accessed Feb. 24, 2021).

i. The larger PAHs are of greatest concern for human health due to their recalcitrance to degradation, persistence, bioaccumulation, carcinogenicity, genotoxicity and mutagenicity. Since these high molecular weight PAHs exist almost exclusively on fine particles, they travel deep into the human respiratory system and pose a serious health risk. [EPA-HQ-OAR-2022-0829-0570, pp. 17-18]

84 M.N. Igwo-Ezikpe et al., "High Molecular Weight Polycyclic Aromatic Hydrocarbons Biodegradation by Bacteria Isolated from Contaminated Soils in Nigeria," Research Journal of Environmental Sciences (2010): 4: pp. 127-37: https://scialert.net/fulltext/?doi=rjes.2010.127.137 (accessed Feb. 24, 2021).

85 Yan Lv et al., "Size distributions of polycyclic aromatic hydrocarbons in urban atmosphere: sorption mechanism and source contributions to respiratory deposition," Atmospheric Chemistry and Physics (2016): 16: p. 2976: https://acp.copernicus.org/articles/16/2971/2016/acp-16-2971-2016.pdf (accessed Feb. 24, 2021).

ii. More than 95% of the lung deposition of PAHs is due to fine particles, and ultrafine particles are responsible for 10 times more PAH deposition in the alveolar region than their share of PM mass. [EPA-HQ-OAR-2022-0829-0570, pp. 17-18]

86 Youhei Kanawaka et al., "Size Distributions of Polycyclic Aromatic Hydrocarbons in the Atmosphere and Estimation of the Contribution of Ultrafine Particles to Their Lung Deposition," Environmental Science & Technology (2009): 43(17): p. 6855: https://pubmed.ncbi.nlm.nih.gov/19764259 (accessed Feb. 24, 2021).

e. Combustion of vehicle fuels appears to be the principal source of inhalation exposure for the larger PAHs, such as BaP, that are associated with particulate matter. [EPA-HQ-OAR-2022-0829-0570, pp. 18-20]

87 Health Effects Institute Air Toxics Review Panel, "Polycyclic Organic Matter" in Mobile-Source Air Toxics: A Critical Review of the Literature on Exposure and Health Effects, HEI Special Report 16 (2007): pp. 117-33: https://www.healtheffects.org/system/files/SR16-Polycyclic_Organic_Matter.pdf (accessed Feb. 24, 2021).

i. BaP is one of 12 Level 1 priority compounds among the "toxic, persistent and bioaccumulative" chemicals targeted for "virtual elimination" by the Great Lakes Binational Toxics Strategy signed by the U.S and Canada in 1997. It is almost entirely produced by vehicular emissions. [EPA-HQ-OAR-2022-0829-0570, pp. 18-20]

88 The Great Lakes Binational Toxics Strategy: Canada - United States Strategy for the Virtual Elimination of Persistent Toxic Substances in the Great Lakes: U.S. Environmental Protection Agency archive document (1997): https://archive.epa.gov/greatlakes/p2/web/pdf/bnssign.pdf (accessed Feb. 24, 2021).

89 Lv et al., op. cit., supra note 85, pp. 2978-79.

f. Motor vehicles account for as much as 90% of the particle-bound PAH mass in the urban air of major metropolitan areas. Roadway tunnel and dynamometer studies have shown that diesel vehicle emissions are rich in the lower molecular weight PAHs, whereas the higher molecular weight PAHs (of greatest concern for human health) are associated with gasoline vehicle emissions. [EPA-HQ-OAR-2022-0829-0570, pp. 18-20]

90 A. Polidori et al., "Real-time characterization of particle-bound polycyclic aromatic hydrocarbons in ambient aerosols and from motor-vehicle exhaust," Atmospheric Chemistry and Physics (2008): 8: pp. 1277-91: https://www.atmos-chem-phys.net/8/1277/2008/acp-8-1277-2008.pdf (accessed Feb. 24, 2021).

91 Douglas R. Lawson et al., "DOE's Gasoline/Diesel PM Split Study" (2004), PowerPoint presentation: https://www.energy.gov/sites/prod/files/2014/03/f9/2004_deer_lawson.pdf (accessed Feb. 24, 2021).

i. In a tunnel study, for example, diesel trucks were the major source of lighter PAHs, whereas light-duty gasoline vehicles were the dominant source of higher molecular weight PAHs, such as BaP. PAH emissions from gasoline were almost entirely ultrafine particles (UFPs). [EPA-HQ-OAR-2022-0829-0570, pp. 18-20]

92 Antonio H. Miguel et al., "On-Road Emissions of Particulate Polycyclic Aromatic Hydrocarbons and Black Carbon from Gasoline and Diesel Vehicles," Environmental Science & Technology (1998): 32(4): pp. 450-55: https://pubs.acs.org/doi/10.1021/es970566w (accessed Feb. 24, 2021).

1. Only the high molecular weight aromatics markedly affect particle number. [EPA-HQ-OAR-2022-0829-0570, pp. 18-20]

93 Fatouraie et al., op. cit., supra note 61.

2. As the molecular weight of a specific PAH increases, the carcinogenicity of PAHs also increases. [EPA-HQ-OAR-2022-0829-0570, pp. 18-20]

94 Khaiwal Ravindra et al., "Atmospheric polycyclic aromatic hydrocarbons: Source attribution, emission factors and regulation," Atmospheric Environment (2008): 42(13): pp. 2895-2921: https://www.sciencedirect.com/science/article/abs/pii/S1352231007011351 (accessed Feb. 24, 2021).

3. A comparison of PM2.5 with smaller particles attributed about 86% of the total carcinogenic potency to the PM1 fraction (particles smaller than 1 micrometer in diameter). [EPA-HQ-OAR-2022-0829-0570, pp. 18-20]

95 Gordana Pehnec and Ivana Jakovljevi?, “Carcinogenic Potency of Airborne Polycyclic Aromatic Hydrocarbons in Relation to the Particle Fraction Size,” International Journal of Environmental Research and Public Health (2018): 15(11), p. 2485: https://www.mdpi.com/1660-4601/15/11/2485/htm (accessed Feb. 24, 2021).

4. UFPs contain a higher percentage of organic carbon than fine and coarse particles, which is relevant to their biologic potency, and the enhanced biologic potency of UFPs is correlated with the PAH content. [EPA-HQ-OAR-2022-0829-0570, pp. 18-20]

96 Ning Li et al., “Ultrafine Particulate Pollutants Induce Oxidative Stress and Mitochondrial Damage,” Environmental Health Perspectives (2003): 111(4): p. 459: https://ehp.niehs.nih.gov/doi/pdf/10.1289/ehp.6000 (accessed Feb. 24, 2021).

ii. Just as with SOA, the effect of aromatics on PAH formation does not seem to be linear: Increasing the aromaticity of the fuel by 12% to 46% was found to increase PAH emissions by 8 to 74%. [EPA-HQ-OAR-2022-0829-0570, pp. 18-20]

97 M.R. Guerin, Oak Ridge National Laboratory, “Energy Sources of Polycyclic Aromatic Hydrocarbons” (1977): p. 16: https://www.osti.gov/servlets/purl/7303055 (accessed Feb. 24, 2021), referencing: National Research Council, “Particulate Polycyclic Organic Matter” (1972): https://www.nap.edu/catalog/20453/particulate-polycyclic-organic-matter (accessed Feb. 24, 2021), citing G.P. Gross, “First Annual Report on Gasoline Composition and Vehicle Exhaust Gas Polynuclear Aromatic Content,” U.S. Department of Health, Education, and Welfare (1970), and Charles R. Begeman and Joseph M. Colucci, “Polynuclear Aromatic Hydrocarbon Emissions from Automotive Engines,” SAE Transactions 79 (1970), p. 1685: www.jstor.org/stable/44716200 (accessed Feb. 24, 2021).

iii. The presence of PAHs has a large effect on SOA formation – increasing mass loadings by factors of two to five, and particle number concentrations, in some cases, by more than a factor of 100. [EPA-HQ-OAR-2022-0829-0570, pp. 18-20]

99 Zelenyuk et al., op. cit., supra note 6.

- Note: The effect of aromatics on pollution and human health is thus magnified twice over: Aromatics lead disproportionately to PAH formation, and PAHs lead disproportionately to SOA formation. Worse yet, PAHs hitch a ride on SOA for long distances and weaponize these particles as they travel through the human body. [EPA-HQ-OAR-2022-0829-0570, pp. 18-20]

g. Groundbreaking research at Pacific Northwest National Laboratory (PNNL) has led to new understanding of the process by which PAHs persist and are transported long distances. It was shown that the most carcinogenic PAH, benzo[a]pyrene (BaP) – often used as a marker for PAH content generally – is efficiently bound to and transported with atmospheric particles: [EPA-HQ-OAR-2022-0829-0570, pp. 20-21]

i. In the laboratory, particle-bound BaP degrades in a few hours, but field observations indicate it persists much longer in the atmosphere and is transported far from its sources – increasing its global lung cancer risk as much as fourfold. BaP from East Asia, for example, has been shown to travel thousands of miles over the Pacific Ocean, reaching the west coast of the United States. [EPA-HQ-OAR-2022-0829-0570, pp. 20-21]

99 Manish Shrivastava et al., “Global long-range transport and lung cancer risk from polycyclic aromatic hydrocarbons shielded by coatings of organic aerosol,” Proceedings of the National Academy of Sciences (2017): 114(6): pp. 1246-51: https://www.pnas.org/content/114/6/1246 (accessed Feb. 24, 2021).

ii. When SOA particles are formed in the presence of gas-phase PAHs, their formation and properties are significantly different from SOA particles formed without PAHs: They exhibit slower evaporation kinetics and have higher fractions of non-volatile components and higher viscosities, assuring their longer atmospheric lifetimes. This increased viscosity and decreased volatility act as a shield that protects PAHs from chemical degradation and evaporation, allowing for their long-range transport. [EPA-HQ-OAR-2022-0829-0570, pp. 20-21]

100 Zelenyuk et al., op. cit., supra note 6.

h. Based on numerous experimental studies, PAHs are also widely accepted to be precursors for soot, or black carbon – a major contributor to climate change. Products of toluene combustion (one of the BTEX aromatics) are known precursors of PAHs that are involved in soot formation. [EPA-HQ-OAR-2022-0829-0570, pp. 20-21]

101 H. Richter and J.B. Howard, “Formation of polycyclic aromatic hydrocarbons and their growth to soot – a review of chemical reaction pathways,” Progress in Energy and Combustion Science (2000): 26(4-6), pp. 565-608: http://citeseerx.ist.psu.edu/viewdoc/download?doi=10.1.1.467.9757&rep=rep1&type=pdf (accessed Feb. 24, 2021).

102 Qian Mao et al., “Formation of incipient soot particles from polycyclic aromatic hydrocarbons,” Carbon (2017): 121: pp. 380-88: https://www.sciencedirect.com/science/article/pii/S0008622317305766 (accessed Feb. 24, 2021).

103 Gabriel da Silva et al., “Toluene Combustion: Reaction Paths, Thermochemical Properties, and Kinetic Analysis for the Methylphenyl Radical + O2 Reaction,” The Journal of Physical Chemistry A (2007): 111(35): pp. 8663-76: https://pubmed.ncbi.nlm.nih.gov/17696501/ (accessed Feb. 24, 2021).

i. Black carbon is considered the second most important human emission in terms of climate forcing; only carbon dioxide (CO2) has a greater overall effect. The short-term (20-year) global warming potential per ton of black carbon is 3200 times that of CO2. [EPA-HQ-OAR-2022-0829-0570, pp. 20-21]

Black carbon emissions associated with the shift to GDI engines will lead to increased warming over the U.S., especially in urban regions. [EPA-HQ-OAR-2022-0829-0570, pp. 20-21]

104 Raza et al., op. cit., supra note 25: p. 5.

ii. However, black carbon is rapidly removed from the atmosphere by deposition, and its atmospheric concentrations respond quickly to reductions in emissions. Reductions in black carbon are thus an attractive near-term mitigation strategy to slow the rate of climate change. [EPA-HQ-OAR-2022-0829-0570, pp. 20-21]

105 T.C. Bond et al., “Bounding the role of black carbon in the climate system: A scientific assessment,” Journal of Geophysical Research Atmospheres (2013): 118(11): pp. 5380-5552: https://agupubs.onlinelibrary.wiley.com/doi/full/10.1002/jgrd.50171 (accessed Feb. 24, 2021).

c. EPA sets air standards for PM2.5 based on mass, when the more important measure of health risk may be the number of extremely lightweight ultrafine particles. [EPA-HQ-OAR-2022-0829-0570, p. 22]

111 U.S. Environmental Protection Agency, "National Ambient Air Quality Standards (NAAQS) for PM," online fact sheet: https://www.epa.gov/pm-pollution/national-ambient-air-quality-standards-naaqs-pm (accessed Feb. 24, 2021).

i. This is particularly important because gasoline direct-injection (GDI) engines (the new automotive norm) emit a higher level of PM emissions measured by particle number than the prior technology, port fuel injection engines. [EPA-HQ-OAR-2022-0829-0570, p. 22]

112 Raza et al., op. cit., supra note 25: p. 1.

d. EPA's assessment of the health risks of PAHs, as reflected in its modeling protocols, is also based on a limited sample of the PAH universe. This approach understates the total carcinogenic potency of PAHs by an estimated 85.6%. [EPA-HQ-OAR-2022-0829-0570, p. 22]

113 Vera Samburova et al., "Do 16 Polycyclic Aromatic Hydrocarbons Represent PAH Air Toxicity?", Toxics (2017): 5(3): 17: https://www.mdpi.com/2305-6304/5/3/17/htm (accessed Feb. 24, 2021).

7. Health effects of PAH exposure

a. Toxic air pollutants can affect health and functioning over the course of life by launching a trajectory of adverse effects related to the initial physical or developmental impairment, and/or by "seeding" latent disease that becomes evident only in later life. [EPA-HQ-OAR-2022-0829-0570, pp. 23-24]

114 Frederica P. Perera, "Multiple Threats to Child Health from Fossil Fuel Combustion: Impacts of Air Pollution and Climate Change," Environmental Health Perspectives (2017): 125(2): p. 145: https://ehp.niehs.nih.gov/doi/full/10.1289/EHP299 (accessed Feb. 24, 2021).

b. In cells UFPs have been found to induce heme oxygenase-1 (HO-1) expression, a sensitive marker for oxidative stress, directly correlated with the high organic carbon and PAH content of UFPs. Oxidative stress is associated with numerous diseases, including cardiovascular disease, hypertension, and diabetes. [EPA-HQ-OAR-2022-0829-0570, pp. 23-24]

115 Li et al., op. cit., supra note 96: p. 455.

c. Fetal exposure to PAHs, as measured by prenatal air monitoring for the marker PAH benzo[a]pyrene during the third trimester of pregnancy, was assessed in a long-term observational epidemiological study in New York. Exposure levels were characterized relative to a median of 2.66 nanograms per cubic meter (ng/m3) – that is, 100,000 times less than the OSHA air standard of 0.2 mg/m3. (A nanogram is one-millionth of a milligram.) [EPA-HQ-OAR-2022-0829-0570, pp. 23-24]

116 Frederica P. Perera et al., "Effects of Transplacental Exposure to Environmental Pollutants on Birth Outcomes in a Multiethnic Population," Environmental Health Perspectives (2003): 111(2): p. 203: https://www.ncbi.nlm.nih.gov/pmc/articles/PMC1241351/pdf/ehp0111-000201.pdf (accessed Feb. 24, 2021).

i. Fetal exposure above the median was associated with developmental delay at age 3 years and reduced IQ at age 5 years, as well as increased anxiety and depression, possibly by interfering with knowledge acquisition or slowing cognitive processing. The observed decrease in full-scale IQ is similar to that reported for children with elevated concentrations of lead in their blood. [EPA-HQ-OAR-2022-0829-0570, pp. 23-24]

117 Frederica P. Perera et al., “Prenatal Polycyclic Aromatic Hydrocarbon (PAH) Exposure and Child Behavior at Age 6–7 Years,” Environmental Health Perspectives (2012): 120(6): pp. 921-26: https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3385432/ (accessed Feb. 24, 2021).

118 Perera et al., “Prenatal Airborne Polycyclic Aromatic Hydrocarbon Exposure and Child IQ at Age 5 Years,” op. cit., supra note 7.

1. The effects of lead exposure include neurological effects in children and cardiovascular effects (e.g., high blood pressure and heart disease) in adults. Infants and young children are especially sensitive to even low levels of lead, which may contribute to behavioral problems, learning deficits, and lowered IQ. [EPA-HQ-OAR-2022-0829-0570, pp. 23-24]

119 Texas Commission on Environmental Quality, “Air Pollution from Lead,” online fact sheet: https://www.tceq.texas.gov/airquality/sip/criteria-pollutants/sip-lead (accessed Feb. 24, 2021).

ii. DNA adducts are a form of DNA damage caused by attachment of a chemical entity to DNA. Adducts that are not removed by the cell can cause mutations that may give rise to cancer. The formation of PAH-DNA adducts has been widely studied in experimental models and has been documented in human tissues. Higher levels of PAH-DNA adducts found in umbilical cord blood were associated with reduced scores on neurocognitive tests. [EPA-HQ-OAR-2022-0829-0570, pp. 23-24]

120 “DNA adducts,” Nature.com: https://www.nature.com/subjects/dna-adducts (accessed Feb. 24, 2021).

121 M. Margaret Pratt et al., “Polycyclic Aromatic Hydrocarbon (PAH) Exposure and DNA Adduct Semi-Quantitation in Archived Human Tissues,” International Journal of Environmental Research and Public Health (2011): 8(7): pp. 2675-91: https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3155323/ (accessed Feb. 24, 2021).

d. A long-term study in California also found an association between exposure to airborne PAHs during the last 6 weeks of pregnancy and early preterm birth – with median exposure at the extremely low level of 3.6 ng/m3. [EPA-HQ-OAR-2022-0829-0570, pp. 24-25]

123 Amy M. Padula et al., "Exposure to Airborne Polycyclic Aromatic Hydrocarbons During Pregnancy and Risk of Preterm Birth,” Environmental Research (2014): 135: pp. 221-226: https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4262545/ (accessed Feb. 24, 2021).

i. Preterm birth is a predictor of infant mortality and later-life morbidity. Despite recent declines, the rate of preterm birth remains high in the U.S. Research increasingly suggests a possible relationship between a mother's exposure to common air pollutants, including PM2.5 and preterm birth of her baby. [EPA-HQ-OAR-2022-0829-0570, pp. 24-25]

124 Jina J. Kim et al., "Preterm birth and economic benefits of reduced maternal exposure to fine particulate matter," Environmental Research (2019): 170: pp. 178-86: https://www.sciencedirect.com/science/article/abs/pii/S001393511830642X (accessed Feb. 24, 2021).

Groundbreaking research at Pacific Northwest National Laboratory (PNNL) has led to new understanding of the process by which PAHs persist and are transported long distances. It was shown that the most carcinogenic PAH, benzo[a]pyrene (BaP) – often used as a marker for PAH content generally – is efficiently bound to and transported with atmospheric particles: [EPA-HQ-OAR-2022-0829-0570, pp. 20-21]

i. In the laboratory, particle-bound BaP degrades in a few hours, but field observations indicate it persists much longer in the atmosphere and is transported far from its sources – increasing its global lung cancer risk as much as fourfold. BaP from East Asia, for example, has been shown to travel thousands of miles over the Pacific Ocean, reaching the west coast of the United States. [EPA-HQ-OAR-2022-0829-0570, pp. 20-21]

ii. When SOA particles are formed in the presence of gas-phase PAHs, their formation and properties are significantly different from SOA particles formed without PAHs: They exhibit slower evaporation kinetics and have higher fractions of non-volatile components and higher viscosities, assuring their longer atmospheric lifetimes. This increased viscosity and decreased volatility act as a shield that protects PAHs from chemical degradation and evaporation, allowing for their long-range transport. [EPA-HQ-OAR-2022-0829-0570, pp. 20-21]

100 Zelenyuk et al., op. cit., supra note 6.

h. Based on numerous experimental studies, PAHs are also widely accepted to be precursors for soot, or black carbon – a major contributor to climate change. Products of toluene combustion (one of the BTEX aromatics) are known precursors of PAHs that are involved in soot formation. [EPA-HQ-OAR-2022-0829-0570, pp. 20-21]

i. Black carbon is considered the second most important human emission in terms of climate forcing; only carbon dioxide (CO2) has a greater overall effect. The short-term (20-year) global warming potential per ton of black carbon is 3200 times that of CO2. [EPA-HQ-OAR-2022-0829-0570, pp. 20-21]

Black carbon emissions associated with the shift to GDI engines will lead to increased warming over the U.S., especially in urban regions. [EPA-HQ-OAR-2022-0829-0570, pp. 20-21]

104 Raza et al., op. cit., supra note 25: p. 5.

ii. However, black carbon is rapidly removed from the atmosphere by deposition, and its atmospheric concentrations respond quickly to reductions in emissions. Reductions in black carbon are thus an attractive near-term mitigation strategy to slow the rate of climate change. [EPA-HQ-OAR-2022-0829-0570, pp. 20-21]

105 T.C. Bond et al., "Bounding the role of black carbon in the climate system: A scientific assessment," Journal of Geophysical Research Atmospheres (2013): 118(11): pp. 5380-5552: https://agupubs.onlinelibrary.wiley.com/doi/full/10.1002/jgrd.50171 (accessed Feb. 24, 2021).

II. Thirty years ago Congress required EPA to control these hazardous air pollutants to the greatest degree achievable, yet aromatics still comprise a fifth of the nation's gasoline supply, amounting to more than 25 billion gallons a year. [EPA-HQ-OAR-2022-0829-0570, pp. 24-25]

1. EPA's response to a legislative mandate

a. The Clean Air Act Amendments of 1990 contained the following requirement, codified as Section 202(l)(2) of the Clean Air Act, Mobile source-related air toxics – Standards: [EPA-HQ-OAR-2022-0829-0570, pp. 24-25]

"Within 54 months after November 15, 1990, the [EPA] Administrator shall … promulgate (and from time to time revise) regulations … containing reasonable requirements to control hazardous air pollutants from motor vehicles and motor vehicle fuels. The regulations shall contain standards for such fuels or vehicles, or both, which the Administrator determines reflect the greatest degree of emission reduction achievable through the application of technology which will be available, taking into consideration the standards established under subsection (a), the availability and costs of the technology, and noise, energy, and safety factors, and lead time." (emphasis added) [EPA-HQ-OAR-2022-0829-0570, pp. 24-25]

125 42 U.S. Code, sec.?7521, "Emission standards for new motor vehicles or new motor vehicle engines," P.L. 101-549, sec. 206, enacted Nov. 15, 1990: https://www.law.cornell.edu/uscode/text/42/7521 (accessed Feb. 24, 2021).

i. Congress made its intent clear by specifically naming the BTEX aromatics (benzene, toluene, ethylbenzene, and xylenes), along with polycyclic organic matter, as hazardous air pollutants. [EPA-HQ-OAR-2022-0829-0570, pp. 24-25]

126 42 U.S. Code, sec.?7412, "Hazardous air pollutants," P.L. 101-549, sec. 301, enacted Nov. 15, 1990: https://www.law.cornell.edu/uscode/text/42/7412 (accessed Feb. 24, 2021).

ii. Additionally, in the section requiring reformulated gasoline in areas with high summertime ozone levels, the statute requires "the greatest reduction in … emissions of toxic air pollutants (during the entire year) achievable through the reformulation of conventional gasoline" – with the term "toxic air pollutants" specifically defined as including polycyclic organic matter (POM). [EPA-HQ-OAR-2022-0829-0570, pp. 24-25]

127 42 U.S. Code, sec.?7545, "Regulation of fuels," at (k)(1)(A) and (k)(10)(c): P.L. 101-549, sec. 219, enacted Nov. 15, 1990: https://www.law.cornell.edu/uscode/text/42/7545 (accessed June 17, 2021).

iii. As EPA recently noted in its proposed rule setting new GHG standards for light-duty vehicles, the agency's obligation to act under this section is mandatory. [EPA-HQ-OAR-2022-0829-0570, pp. 24-25]

128 U.S. Environmental Protection Agency, "Revised 2023 and Later Model Year Light-Duty Vehicle Greenhouse Gas Emissions Standards," Federal Register (2021): 86(151): p. 43751: https://www.govinfo.gov/content/pkg/FR-2021-08-10/pdf/2021-16582.pdf (accessed Aug. 18, 2021). e. In December 2020 EPA issued a "Fuels Regulatory Streamlining" rule that relieved refineries of their responsibility to report regularly on the aromatics levels in reformulated gasoline (approximately 30% of the national gasoline pool). An industry-led annual sampling program will be used instead. Refineries also are no longer required to estimate emissions of air toxics, including polycyclic organic matter. [EPA-HQ-OAR-2022-0829-0570, pp. 28-29]

143 U.S. Environmental Protection Agency, "Fuels Regulatory Streamlining," Federal Register (2020): 85(234), "Program Design," p. 78414, and "Key Differences Between Part 1090 and Part 80," p. 78436: https://www.govinfo.gov/content/pkg/FR-2020-12-04/pdf/2020-23164.pdf (accessed June 17, 2021).

f. In August 2021, EPA proposed revised greenhouse gas emissions standards for new cars that again failed to address the importance of vehicle fuels. EPA noted only that "in addition to substantially reducing GHG emissions, a longer-term rulemaking could also address criteria pollutant and air toxics emissions from the new light-duty vehicle fleet – especially important considerations during the transition to zero-emission vehicles." [EPA-HQ-OAR-2022-0829-0570, pp. 28-29]

144 U.S. EPA, "Revised 2023 and Later Model Year Light-Duty Vehicle Greenhouse Gas Emissions Standards," op. cit., supra note 128: p. 43730.

i. Indeed, the very basis on which EPA proceeded, according to the Proposed Rule, was the requirement in Section 202(a) "to establish standards for emissions of air pollutants from new motor vehicles which, in the Administrator's judgment, cause or contribute to air pollution which may reasonably be anticipated to endanger public health or welfare." The requirements of Section 202(l)(2), cited above, were enacted concurrently and explicitly based on that same provision of Section 202(a). [EPA-HQ-OAR-2022-0829-0570, pp. 28-29]

145 Ibid., p. 43728.

146 42 U.S. Code, sec.?7521, op.cit.,supra note 125.

IV. The urgency of action

Dr. Frederica P. Perera is Professor of Environmental Health Sciences and Founding Director of the Columbia Center for Children's Environmental Health, currently serving as Director of Translational Research. She is internationally recognized for pioneering the field of molecular epidemiology, utilizing biomarkers to understand links between environmental exposures and disease. Her research, cited above, addresses the multiple impacts of fossil fuel combustion on children's health and development – both from the toxic pollutants emitted, such as PAHs, and from climate change related to CO2 emissions. The following commentary, while not addressing aromatics specifically, is nonetheless eloquently on point. It is drawn from her paper "Multiple Threats to Child Health from Fossil Fuel Combustion: Impacts of Air Pollution and Climate Change": [EPA-HQ-OAR-2022-0829-0570, pp. 46-47]

255 Perera is the lead author of five works cited here. See supra notes 7, 114, 116, 117, and 122.

Fossil-fuel combustion by-products are the world's most significant threat to children's health and future and are major contributors to global inequality and environmental injustice. The emissions include a myriad of toxic air pollutants and carbon dioxide (CO2), which is the most important human-produced climate-altering greenhouse gas. Synergies between air pollution and climate change can magnify the harm to children. Impacts include impairment of cognitive and behavioral development, respiratory illness, and other chronic diseases – all of which may be "seeded" in utero and affect health and functioning immediately and over the life course. [EPA-HQ-OAR-2022-0829-0570, pp. 46-47]

By impairing children's health, ability to learn, and potential to contribute to society, pollution and climate change cause children to become less resilient and the communities they live in to become less equitable. The developing fetus and young child are disproportionately affected by these exposures because of their immature defense mechanisms and rapid development, especially those in low- and middle-income countries where poverty and lack of resources compound the effects. No country is spared, however: Even high-income countries, especially low-income communities and communities of color within them, are experiencing impacts of fossil fuel-related pollution, climate change and resultant widening inequality and environmental injustice. Global pediatric health is at a tipping point, with catastrophic consequences in the absence of bold action. [EPA-HQ-OAR-2022-0829-0570, pp. 46-47]

Fortunately, technologies and interventions are at hand to reduce and prevent pollution and climate change, with large economic benefits documented or predicted. All cultures and communities share a concern for the health and well-being of present and future children: This shared value provides a politically powerful lever for action. [EPA-HQ-OAR-2022-0829-0570, pp. 46-47]

256 Perera, “Multiple Threats to Child Health from Fossil Fuel Combustion,” op. cit., supra note 114.

Organization: Renewable Fuels Association (RFA)

d. Vehicle weight: Safety concerns and increased PM emissions

It is also well known that higher vehicle weight increases wear and tear on vehicle tires, which causes higher particulate emissions.39 EPA has regulated tailpipe particulate emissions for many years, but there is abundant evidence that wear particles from tires and brakes are at least as important as tailpipe emissions.40 According to one study, “battery weight can result in tire emissions that are almost 400 times greater than real- world tailpipe emissions.”41 But the proposed emissions standards fail to address the large and growing problem of particulate emissions from tires, and instead focus on more stringent tailpipe particulate standards which will add cost without significantly improving air quality. Again, EPA needs to look beyond the tailpipe and create holistic standards that incentivize real improvements. [EPA-HQ-OAR-2022-0829-0602, pp. 18-19]

Organization: Satya Consultores

Satya began its DEP work with the goal of solving the tradeoff between reducing diesel soot and NOX emissions. At higher temperatures, diesel engines achieve more complete combustion, and emit less soot and other fine particulate matter as a result. However, under these conditions NOX emissions increase. In turn, lower engine temperatures result in lower NOX emissions but cause soot emissions to increase. This tradeoff is well known among fuel scientists.1 Both pollutants have significant adverse environmental impacts and health effects. [EPA-HQ-OAR-2022-0829-0687, pp. 2-3]

Satya's DEP resolves this conundrum. We call the resulting fuel "Next Diesel."

1 See, e.g., Narayan et al., Combustion Monitoring in Engines Using Accelerometer Signals, J. VIBROENGINEERING, Sep. 2019, at 4; Tie Li & Hideyuki Ogawa, Analysis of the Trade-Off between Soot and Nitrogen Oxides in Diesel- Like Combustion by Chemical Kinetic Calculation.

In DEP, two proprietary additives are mixed into the diesel fuel. The first additive ("A1") is an ethoxylated fatty acid ester, made with a mixture of stearic and palmitic acid esters of sorbitol and its mono- and dianhydrides. The second additive ("A2") is a complex water-based blend of aromatic solvents with methyl radicals mixed with ethoxylated phenol-derived surfactants. [EPA-HQ-OAR-2022-0829-0687, pp. 2-3]

Diesel fuel flows from a tank at the end of the refining process in a continuous stream through piping to a Shock Wave Power Reactor. En route, A1 is metered into the diesel fuel stream via a Progressive Cavity Injection Pump, and the combination is blended using a static mixer. Once the fuel/A1 mixture is homogenous, A2 is metered in, and that combination is blended in a second static mixer. The resulting diesel fuel/A1/A2 mixture then flows into the Shock Wave Power Reactor where it is subjected to controlled cavitation, a process which creates vapor bubbles in the fuel mixture. As a liquid passes through the SPR it is subjected to "controlled cavitation." The heart of the reactor is a specially designed rotor. The spinning action generates hydrodynamic cavitation in the rotor cavities away from the rotor to prevent damage to metal surfaces. As microscopic cavitation bubbles are produced and collapse, shockwaves are given off into the liquid which can heat and/or mix.2 [EPA-HQ-OAR-2022-0829-0687, pp. 2-3]

2 Hydro Dynamics, Inc. (n.d.). Retrieved from Harnessing the Power of Cavitation: https://www.hydrodynamics.com/cavitation-technology/.

The resulting diesel fuel exhibits improved properties, including significantly improved ignition characteristics. Its electrical conductivity is more than 1,000 times greater than regular diesel fuel, and the lubricity value is more than 100 times greater. These and other upgraded properties of Next Diesel enable more complete fuel combustion, which in turn results in less soot production and also reduces NOX emissions. The corresponding loss of fuel power, if any, is negligible. [EPA-HQ-OAR-2022-0829-0687, pp. 2-3]

The pilot- scale test results, which followed EPA-specified federal test procedures (or "FTPs"), demonstrated significant reductions in soot with accompanying reductions in NOX emissions. All Next Diesel emissions test results were compared to ultra-low sulfur diesel ("ULSD") emissions tests on the same engines. Only the fuels were changed; all other test parameters were identical. All tests were "engine out;" there was no after-treatment or particulate filtering. Combustion map parameters for both Next Diesel and ULSD were the same. [EPA-HQ-OAR-2022-0829-0687, pp. 3-5]

Satya and SwRI compared Next Diesel with ULSD in extensive tests. Two of the many test results illustrate Next Diesel's potential. As illustrated in Figure 1 below, transient cycle tests on a newer model diesel engine, the Navistar N13, documented a 14% reduction in soot emissions and an 8.6% reduction in NOX: [See original attachment for Navistar N13 Transient Tests] [EPA-HQ-OAR-2022-0829-0687, pp. 3-5]

As shown in Figure 2, on an older model DDC Series 60 engine, the reductions in soot were even more dramatic: a 29% reduction of soot, with no increase in NOX emissions. [See original attachment for DDC Series 60 Transient Tests] [EPA-HQ-OAR-2022-0829-0687, pp. 3-5]

The modified fuels produced by this pilot-scale plant conform to physical, mechanical, rheological, thermal, and chemical fuel standards promulgated by the American Society for Testing and Materials ("ASTM"), including ASTM-D975. The fuel has been tested in real-scale heavy duty certification engines. Based on the success of these evaluations, Satya has worked with SwRI and other internationally recognized research organizations to design a production-scale facility. The facility design meets ASTM and American National Standards Institute ("ANSI") standards and would be capable of processing 12,000 barrels of diesel fuel per day, or 150 million gallons per year. SwRI has concluded (Link: https://www.swri.org/press-release/swri-engineers-help-develop-cleaner-burning-diesel-fuels) that DEP and Next Diesel are ready for commercial development. [EPA-HQ-OAR-2022-0829-0687, pp. 3-5]

All of the testing conducted to date by Satya and SwRI has been conducted with ultra- low sulfur diesel ("ULSD") that meets current EPA fuel composition requirements. The introduction of ULSD in 2006 has led to dramatic reductions in particulate matter and NOX emissions from diesel engines, and the diesel engine requirements proposed by EPA in the current rulemaking promise additional reductions. Satya's DEP demonstrates that even more air quality gains are possible with additional diesel fuel controls. [EPA-HQ-OAR-2022-0829-0687, p. 5]

Emissions of pollutants like soot and NOX are generally highest immediately following a cold engine start because after-treatment systems tend to be inefficient during and just after ignition. Next Diesel reduces emissions during and after a cold engine start, and reductions continue to be achieved even after the engine and after-treatment systems reach steady operating temperatures. Engine manufacturers may choose to modify or reprogram new engines to maximize benefits of Next Diesel, but such modifications are not necessary. Next Diesel is an improved fuel that does not require modification of any part of a new or existing engine. [EPA-HQ-OAR-2022-0829-0687, p. 5]

The most obvious benefit of Next Diesel fuel will be its use in the large fleet of existing diesel engines, especially in heavy-duty vehicles, locomotives and other non-road vehicles, and diesel equipment. As EPA notes in the preamble, many of these engines will remain in service in the U.S. and around the world longer than light- and medium-duty gasoline engines. 88 Fed. Reg. at 29400; see also 88 Fed. Reg. at 29191 (most major manufacturers anticipate at least a decade before electrified vehicles dominate sales). DEP has not been tested yet on renewable diesel fuels like biodiesel or on aviation fuels, but Satya expects similar emissions improvements with those fuels. [EPA-HQ-OAR-2022-0829-0687, p. 5]

The reduction of soot achieved by Next Diesel also has benefits for engine operation. The more complete combustion of the soot in Next Diesel fuel increases the energy captured from the fuel. Diesel particulate matter filters can become clogged and fuel has to be diverted from engine operation to burn the collected soot and return the filter to service, resulting in a fuel penalty. [EPA-HQ-OAR-2022-0829-0687, pp. 5-6]

With Next Diesel, less soot generated in the engine translates to less soot that must be captured in the diesel particulate matter filter, and a reduced fuel penalty. Finally, modern diesel engines recirculate gases to reduce NOX emissions, but the particulate matter content causes engine wear and tear. With Next Diesel, less soot means less damage to the diesel engine and longer engine life. [EPA-HQ-OAR-2022-0829-0687, pp. 5-6]

Satya contracted with Baker and O'Brien, Inc. to prepare a Technology and Commercialization Assessment of DEP and Next Diesel. Among other findings, the report estimated significant net health benefits from widespread adoption of Next Diesel. The U.S. alone could see $7.8 billion in health benefits, and similar improvements in Europe and China.3 [EPA-HQ-OAR-2022-0829-0687, p. 6]

3 Baker and O´Brien, Inc., Technology and Commercialization Assessment of Diesel Fuel Technology (January 7, 2020).

To implement the production of Next Diesel, a refinery or fuel distribution terminal would need to install conditioning hardware and acquire the necessary additives. In Satya's commercialization study, the estimated capital hardware cost would be approximately $400,000 for a facility processing 12,000 barrels of diesel fuel per day. The cost of chemicals would be between one and eight cents per gallon. [EPA-HQ-OAR-2022-0829-0687, p. 6]

Organization: South Coast Air Quality Management District

Our region has long suffered from some of the worst air quality in the country and fails to meet Federal standards for ozone and fine particulate matter. Over 80% of the emissions that must be reduced to meet air quality standards are from mobile sources, including light-duty and medium-duty vehicles. As a local air agency, the South Coast AQMD has limited authority to regulate mobile sources. That authority instead rests primarily with the U.S. EPA and the California Air Resources Board (CARB). CARB has taken significant steps to reduce GHG and NOx emissions from light-duty and medium-duty vehicles through the Advanced Clean Cars (ACC) II regulations, which became effective on November 30, 2022. Other states, including a total of 17 other states to- date, have adopted all or part of California's ACC II low-emission and zero-emission vehicle regulations, as allowed by Section 177 of the Clean Air Act. This additional support for the clean vehicle market means that more than 35% of the national new light-duty vehicle sales will meet California's automotive emissions standards. These collective actions will greatly accelerate the adoption of ZEVs in the nationwide fleet, while supporting California's progress towards meeting the national ambient air quality standards. However, more needs to be done and without additional federal action on this and other mobile source sectors our region will be unable to meet air quality standards. The proposed rule offers an opportunity to achieve additional emission reductions so desperately needed in our region – both to assist in attaining national standards, and in supporting our environmental justice communities. [EPA-HQ-OAR-2022-0829-0659, pp. 1-2]

Organization: Southern Environmental Law Center (SELC)

Light- and medium-duty vehicles are also significant sources of criteria pollutants and other air toxics that harm communities and the environment. [EPA-HQ-OAR-2022-0829-0591, pp. 4-5]

In addition to GHG emissions, light- and medium- duty vehicles are a substantial source of harmful "criteria pollutants," like particulate matter (PM), sulfur oxides (SOX), nitrogen oxides (NOX), carbon monoxide (CO), and ozone.31 Light- and medium-duty vehicles account for approximately 20 percent of mobile source NOX emissions and 19 percent of mobile source PM2.5 emissions nationwide.32 Criteria pollutants have damaging effects on our environment and air quality. Among other things, NOX is a central precursor to photochemical smog, harmful ozone, and particulate pollution;33 acid rain results from sulfur dioxide (SO2) and NOX emissions;34 and PM is the primary cause of reduced visibility and regional haze in the United States.35 [EPA-HQ-OAR-2022-0829-0591, pp. 4-5]

35 Particulate Matter Basics, U.S. EPA, https://www.epa.gov/pm-pollution/particulate-matter-pm-basics (last updated July 18, 2022).

These pollutants also negatively impact our health. Due to their detrimental biological effects, each of these criteria pollutants has a health-based National Ambient Air Quality Standard (NAAQS) established by EPA.36 Exposure to ozone and CO, for example, can result in nervous system effects including dementia and cognitive decline, birth defects, and developmental disorders.37 Exposure to PM and NOX can cause respiratory and cardiovascular problems such as an increased incidence of asthma and heart disease, reduced lung function, and exacerbated chronic obstructive pulmonary disease.38 According to a recent study, fine particulate pollution from cars and light trucks in Virginia costs the state $750 million annually and causes approximately 92 deaths, 71 non-fatal heart attacks, and 2,600 child asthma attacks every year.39 [EPA-HQ-OAR-2022-0829-0591, p. 5]

Additionally, light- and medium- duty vehicle pollution contributes to high ambient concentrations of other air toxics, including benzene, 1,3-butadiene, ethylbenzene, formaldehyde, and naphthalene.40 Within the transportation sector, more than 41 percent of these air toxics, collectively known as “volatile organic compounds” (VOCs), are produced by light- and medium-duty vehicles.41 The reaction between pollutants like NOX and CO and VOCs creates harmful fine particulate and smog pollution.42 Not only have VOCs been identified as national and regional cancer risk drivers by EPA,43 but they also cause a range of noncancer health effects such as eye and nose irritation, headaches, nausea, and dizziness.44 [EPA-HQ-OAR-2022-0829-0591, pp. 5-6]

The impacts of criteria pollutants and other air toxics from vehicle tailpipe pollution are widespread, making exposure to this type of pollution a serious public health issue nationwide. Even after decades of NAAQS implementation, 36 percent of Americans—nearly 120 million people—live in areas with unhealthy levels of ozone or particulate pollution.45 Many major metropolitan areas in the United States, including several in the South, continue to suffer from elevated concentrations of these pollutants. Washington, D.C. is currently a nonattainment area for ozone,46 and Augusta, Georgia and Birmingham, Alabama rank among the top 25 cities most polluted by annual PM emissions.47 [EPA-HQ-OAR-2022-0829-0591, pp. 5-6]

Organization: Tesla, Inc.

In addition to light-duty vehicles being one of the largest sources of GHG pollutants that negatively impact public health, they are also one of the largest sources of criteria and air toxic pollutants, including particulate matter (PM) and nitrogen oxides (NOX). To that end, Tesla fundamentally agrees with the agency that: [EPA-HQ-OAR-2022-0829-0792, pp. 9-10]

In 2023, mobile sources will account for approximately 54 percent of anthropogenic NOX emissions, 5 percent of anthropogenic direct PM2.5 emissions, and 19 percent of anthropogenic volatile organic compound (VOC) emissions. Light and medium-duty-vehicles will account for approximately 20 percent, 19 percent, and 41 percent of 2023 mobile source NOX, PM2.5, and VOC emissions, respectively.63 [EPA-HQ-OAR-2022-0829-0792, pp. 9-10]

63 88 Fed. Reg. at 29186.

These emissions contribute to poor air quality in many urban areas, including areas with vulnerable populations, and increased vulnerability and susceptibility for adverse health effects related to air pollution in children.64 [EPA-HQ-OAR-2022-0829-0792, p. 10]

64 Id., at 29211.

The widespread adoption of BEVs is leading to significant benefit from the elimination of tailpipe pollutants and slashing of ambient levels of air pollutants that have been linked to hundreds of thousands of early deaths annually around the world from cardiovascular and respiratory diseases, cancer, and other illnesses.65 Indeed, the public health, climate, and economic benefit from much more stringent, BEV-based GHG emission standards cannot be understated. Air pollution is estimated to cause over 200,000 premature deaths in the U.S. each year; with more than half are caused by transportation emissions.66 Recent findings indicate that the U.S. health care costs of air pollution and climate change exceed $800 billion per year.67 Air pollution impacts with pollutants like PM2.5 that are associated with the transportation sector not only cause premature mortality, cardiovascular disease and respiratory disease but also can affect neurological disorders.68 Other studies suggest that exacerbation of air pollution and heat exposure related to climate change may be significantly associated with risk to pregnancy outcomes in the U.S.69 [EPA-HQ-OAR-2022-0829-0792, p. 10]

Indeed, one recent report estimates that wide-spread transportation electrification across the U.S. translates into $72 billion in avoided health effects. Electrification would save approximately 6,300 lives per year and avoid more than 93,000 asthma attacks, and 416,000 lost workdays annually due to significant reductions in transportation-related pollution.73 Other studies have found dramatic localized air quality and public health benefits can result from vehicle electrification.74 [EPA-HQ-OAR-2022-0829-0792, p. 11]

This could be achieved by electrifying a little over 60,000 MHDVs, about 1% of all the vehicles in greater Houston. By comparison, it would take 3.8 million light duty vehicles to achieve the same amount of NOX reductions. Electrification of MHDVs is the quickest way to take the biggest bite out of greater Houston's NOX emissions).

Organization: Wisconsin Department of Natural Resources

In this proposal, EPA concludes that people who live or attend school near major roadways are more likely to be non-White, Hispanic, or have a low socioeconomic status. As such, these populations are expected to directly benefit from reduced tailpipe emissions of criteria pollutants and mobile source air toxics that would result from these standards. EPA also notes that poorer or predominantly non-White communities can be especially vulnerable to climate change impacts, which these proposed GHG standards would help address. Reducing greenhouse gases, ozone, and particulate matter pollution from on-road vehicles will improve health outcomes throughout Wisconsin. Most importantly, it will take a critical step toward improving air quality in areas overburdened by pollution. [EPA-HQ-OAR-2022-0829-0507, p. 2]

Organization: Zero Emission Transportation Association (ZETA)

a. Reducing Transportation Emissions Protects Public Health

Finalizing stringent emissions standards will save lives, as human interaction with on-road emissions has proven to yield detrimental health outcomes. When inhaled into the lungs, criteria pollutant emissions cause inflammation, chest tightness, shortness of breath, and increased risk of permanent health issues such as asthma.56 Beyond respiratory health, new research also demonstrates that ground level ozone, exacerbated by LMDV tailpipe emissions, leads to worsening coronary disease. A 2023 study shows that "exceeding the World Health Organization ozone limit is associated with substantial increases in hospital admissions for heart attack, heart failure and stroke."57 The study looked at coronary disease over three years and found that increased concentrations of ground-level ozone led to 109,400 of 3,194,577 documented hospital admissions.58 [EPA-HQ-OAR-2022-0829-0638, p. 14]

LMDVs are major contributors to U.S. emissions of particulate matter (PM2.5), nitrogen oxides (NOx), volatile organic compounds (VOCs), and carbon dioxide (CO2).59 Such pollutants are directly linked to long-term respiratory, cognitive, and autoimmune impairment, and the rate of EV deployment is expected to have a direct relationship with improved health outcomes, particularly for millions of individuals living near high traffic areas.60 [EPA-HQ-OAR-2022-0829-0638, p. 14]

60 “PM2.5 polluters disproportionately and systemically affect people of color in the United States,” Science Advances (April 28, 2021) https://advances.sciencemag.org/content/7/18/eabf4491

Despite efforts to curtail emissions through ICEV efficiency improvements and various emissions control technologies, a large portion of the U.S. population remains vulnerable to the dangers of vehicle pollution. In the United States, 45 million people live within 300 feet of a major traffic facility or corridor.61 Proximity to these roadways exposes residents to needless health risks. Replacing combustion engine vehicles with electric alternatives will yield significant public health benefits. According to the American Lung Association, the widespread transition to zero-emission transportation and zero-emission generation over the next 30 years could bring $1.2 trillion in health benefits, save approximately 110,000 lives, prevent more than 2.7 million asthma attacks, and avoid 13.4 million lost workdays.62 Conversely, a recent study concludes that oil and gas consumption leads to negative health impacts totaling $77 billion annually in the U.S. alone.63 [EPA-HQ-OAR-2022-0829-0638, p. 15]

EPA Summary and Response

Summary:

Many of the comments included in this section were supportive of EPA’s proposed program to reduce GHG and criteria emissions from light- and medium-duty vehicles. Commenters note the need for these standards to address air pollution and reduce the impacts of emissions on human health, including specifically impacts on EJ communities, impacts on nonattainment areas, and impacts on children.

As noted above, commenters in this section raised a number of concerns about harm to public health caused by emissions produced by vehicles. These comments primarily focused on combustion-related emissions like particulates, NOx, PAHs and other air toxics. Commenters mentioned that there are health effects below the level of the NAAQS and pointed to specific health effects associated with exposure to PM, like exacerbation of risks from infectious respiratory diseases, and impacts on retinal health. One commenter stated that it is important to critically evaluate the direct correlation between these proposed regulations and substantial improvements in health conditions, suggesting that the relationship between specific regulatory measures and health outcomes is complex and context-dependent. While reducing emissions can have positive effects on respiratory health, it is essential to acknowledge that multiple factors influence overall health outcomes.

Some commenters note that the rapid proliferation of GDI vehicles over the past decade has increased ultrafine particle (UFP) pollution significantly, which along with PAH emissions, have serious health impacts. They describe how the Clean Air Act requires control of such air toxics to the greatest extent achievable using technology which will be available and suggest that EPA could reduce GHGs and air toxics together by taking a systems approach to require simultaneous improvements in both vehicles and fuels. They highlight higher-ethanol blends as a way to increase octane and reduce aromatic content of gasoline and suggest requiring particle filters on all GDI vehicles as a highly effective way to reduce UFP emissions. Commenters also express support for reducing heavy aromatics content in gasoline as an additional way to reduce PM emissions. One commenter described a fuel additive that could reduce NOx and PM emissions from diesel engines.

In addition, some commenters raised concerns about non-combustion sources of emissions from vehicles, like brake and tire wear emissions, that may increase with an increasing number of EVs. Several commenters (American Fuel and Petrochemicals Manufacturers, Donn Viviani, HF Sinclair, John Graham, National Farmers Union and the Renewable Fuels Association) said that electric vehicles would have higher brake and tire emissions than comparable ICE vehicles due to higher weight from batteries and/or higher torque of electric vehicles and should be included in EPA's analysis. Several of these commenters also stated that there would be an increase in roadway dust and some also said that these higher emissions are likely to harm EJ communities. The commenters cite:

American Fuel and Petrochemicals Manufacturers also comments that it "could require a greater number of ZEVs to move the same tonnage of cargo, thus increasing the number of vehicles needed to haul the same amount of freight, vehicle miles traveled, and resulting PM emissions." A commenter, MCS Referral & Resources, pointed out an error in the description of the sources of CO and in the description of diesel exhaust component lifetimes.

Response:

In this RTC section, EPA is focusing on addressing comments related to the criteria and air toxic pollutant impacts associated with the rule. To the extent that these commenters raise other issues, those issues are addressed elsewhere in this RTC or in the preamble for the final rule.

Responses to comments about environmental justice or GHG emissions are included in sections 9 and 10 respectively of this response to comments document. Additionally, responses to comments about criteria pollutant benefits are included in Section 8.5 of this document.

In general, EPA agrees with commenters that actions to control emissions from light- and medium-duty vehicles are necessary to improve public health and welfare. In response to commenters who identify potential health or welfare effects of criteria pollutants from light- and medium-duty vehicles, or other scientific information, views, or analyses that were not specifically incorporated into our discussion in the proposed or final action (such as those noted by CARB, EDF, Jonathan Walker, and others), the EPA notes that the health and welfare impacts associated with exposure to criteria and air toxic pollutants are adequately described in Section II of the preamble that accompanies this rule. The EPA does not interpret these comments as indicating disagreement with the evidence on criteria pollutant health or welfare effects information that was presented in the proposal, but rather understands these comments to suggest that the additional information they provide adds support for finalizing the rulemaking.

The EPA concurs with commenters that there may be additional health outcomes, such as respiratory infections, for which reducing $PM_{2.5}$ concentrations may lead to public health benefits. Within the 2019 PM ISA, the EPA evaluated studies that examined both short- and long-term $PM_{2.5}$ exposure and respiratory infection, and while few studies examined these outcomes, there was some evidence indicating that daily or annual exposures may increase the risk of respiratory infection. In addition, the Supplement to the 2019 PM ISA evaluated recent studies that examined both short- and long-term $PM_{2.5}$ exposure and SARS-CoV-2 infection and COVID-19 deaths and concluded "[w]hile there is initial evidence of positive associations with SARS-CoV-2 infection and COVID-19 death, uncertainties remain due to methodological issues." As the Supplement to the 2019 PM ISA represented a targeted evaluation of the science published since the completion of the 2019 PM ISA, it did not encompass "the full multidisciplinary evaluation presented within the 2019 PM ISA as described in the Preamble to the Integrated Science Assessments that would result in weight-of-evidence conclusions on causality (i.e., causality determinations)."[400] As a result, the evidence for SARS-CoV-2 infection and COVID-19 death were not considered in the context of the causality determination for either short- or long-term PM2.5 exposure and respiratory effects. In addition, the literature cutoff date for the Supplement to the 2019 PM ISA, which included studies of SARS-CoV-2 infection and COVID-19 deaths, was March 2021, which is prior to the publication date of the references provided by the commenter. As such, EPA will consider these references as well as other newly published peer-review studies during the development of the next PM ISA.

EPA acknowledges and agrees with the commenter that noted that the relationship between regulatory measures and health outcomes is complex and context dependent. However, based on our expertise and past experience we anticipate that this rule will have substantial benefits for public health and welfare. As noted in RTC Section 8.5, EPA's analysis is consistent with applicable guidance and best practices for conducting benefit-cost analyses, including OMB Circular A-4 and EPA's Guidelines for Preparing Economic Analyses. We consider our analysis

[400] U.S. EPA. Preamble to the Integrated Science Assessments (ISA). U.S. Environmental Protection Agency, Washington, DC, EPA/600/R-15/067, 2015.

consistent with the guidance, methodologically rigorous, and a best estimate of the projected societal benefits and costs associated with the final program.

Air toxics reductions:

We are finalizing stringent PM standards for gasoline vehicles covering a range of operating conditions, including wintertime temperatures. We expect that manufacturers may choose to comply with these standards through widespread adoption of particulate filters (GPFs) on new light- and medium-duty vehicles by 2031.

Modlin and Detchon cite the requirements for mobile source air toxics standards issued under section 202(l) to reflect the greatest degree of emissions reduction achievable (taking into account several factors specified in the statute) as support for more stringent PAH controls. EPA, however, did not propose to further regulate mobile source air toxics under section 202(l), and new regulation under 202(l) is beyond the scope of this rulemaking. However, EPA anticipates that the PM standards will result in very effective control of PAHs. As discussed in Section III.D.3 of the preamble, emission characterization of GPF-equipped vehicles meeting the PM standards found that filter-based PAHs were reduced by more than 99%. As such, the PM standards are expected to also reduce PAH and other toxics very well. More detailed characterization of GPF benefits is described in Chapter 3.2.6.2 of the RIA. Furthermore, air quality modeling representing the net impacts of the standards on air toxics show average net reductions in all air toxics modeled. EPA will continue to consider the need for, and appropriate means of, further reductions in PAH by continuing to investigate costs and benefits of updated standards for market gasoline that would reduce the content of heavy aromatic compounds (including PAHs) that contribute most potently to PM and PAH emissions (several aspects are described in Section IX of the proposal).

Modlin and Detchon also suggest that EPA could achieve emissions reductions by requiring changes to fuel composition that displace aromatics (including BTEX) with additional ethanol. As discussed in RTC Section 19, such work and changes to fuel controls are beyond the scope of this final rule. Nonetheless, EPA offers some preliminary observations regarding this comment. Imposing limits on gasoline aromatics content would force refiners to reformulate their gasoline to use other high-octane components. Understanding the impact of such reformulations on overall air quality would necessarily include changes in a broad range of vehicle emissions (including refueling and evaporative processes), as well as changes in petroleum refining and increases in ethanol production and agricultural intensity. These things may reduce the overall air quality benefits significantly. We are not aware of any analyses integrating all these pieces at this time. Comments in response to EPA's request for comment on potential future fuel controls are contained in Appendix D to this document and will be further considered for a potential future rulemaking.

Non-exhaust PM:

With regard to non-exhaust emissions, including brake and tire wear, road wear and road dust, EPA did model these emissions for all vehicles, including BEVs, in the proposed rulemaking and for this final rule. However, for the reasons described below, we found it reasonable to assume for modeling purposes that BEVs produce non-exhaust emissions at the same level as their ICE counterparts. More information on modeling brake, tire and other vehicle emissions is available in a memo to the docket.[401]

First, EPA does not agree that increased sales of BEVs would necessarily result in a substantial increase in average vehicle weight. As shown in Table 8-5 of the RIA, the projected increase in weight within vehicle classes is small and is dwarfed by the increase in weight due from the shift from cars to light trucks and SUVs, which is unrelated to the increased sale of EVs.

Second, for brake wear, as one of the commenters noted, it is reasonable to expect BEVs to have lower brake wear emissions than comparable ICE vehicles. Most BEVs are equipped with regenerative braking systems. When a vehicle is using regenerative brakes, some of the kinetic energy from slowing the vehicle is directed to the motor. In a friction braking system, this kinetic energy is normally converted to heat, so there is less material wear and emissions from brakes. This effect is discussed by some of the non-exhaust emission studies cited by the commenters. In fact, a modeling study by Ye Liu et al. found in a literature review that regenerative braking decreases brake wear emissions from EVs by 68 percent. In their modeling, the reduced brake wear emissions offset the increased tire wear, road wear and resuspended road dust emissions associated with the assumed EV weight increase such that EVs have lower non-exhaust $PM_{2.5}$ emissions than comparable gasoline vehicles on urban roads, as can be calculated from Table 3 of their paper.[402]

Still, EPA investigated the possibility of updating our modeling assumptions on brake wear and tire wear emissions from electric vehicles. Updating these non-exhaust PM emission rates specific to BEVs would require having detailed emissions data in which brake wear and tire wear emissions can be calculated in various operating conditions. None of the sources cited by commenters support this level of detailed analysis, nor has EPA identified any sources of data or studies that allow this level of detailed analysis for tire wear. Many sources attempt to compare non-exhaust PM emissions from BEVs directly to ICE vehicles, but they are often modeling studies or studies done under conditions that may not be representative of typical real-world operation in the United States. Tire wear projections for BEVs are also difficult because BEV technologies are evolving rapidly and estimates of tire wear for current BEVs may not be representative of the future vehicle stock, when BEVs are more prevalent across all manufacturers, models, and drivers. In addition, we expect tire design will evolve over time in concert with changes in vehicle design and driving patterns. There are considerable technical difficulties with modeling such uncertainties, so we did not do so.

Overall, EPA is receptive to and appreciates the comments from stakeholders regarding the modeling of tire wear and brake wear. We accounted for brake wear, tire wear, road wear and road dust emissions in the proposal and do so in the final rulemaking. To estimate increased tire wear and road dust emissions from BEVs relative to ICE vehicles, as suggested by the commenters, without a corresponding decrease in brake wear emissions would bias the total

---

[401] Mo, Tiffany, 2024. Revisions to MOVES for Air Quality Modeling to support the FRM for the Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles. Memorandum to Docket EPA-HQ-OAR-2022-0829. February 2024.

[402] Liu, Ye et al. "Exhaust and non-exhaust emissions from conventional and electric vehicles: A comparison of monetary impact values." Journal of Cleaner Production 331 (2022) 129965. https://doi.org/10.1016/j.jclepro.2021.129965

downstream PM inventory impacts. After consideration of the current data sources and literature, we have found that, at this time, there is no study or source of data with sufficient information to improve upon this modeling approach for the FRM.

VMT:

EPA does not agree that an increase in medium-duty ZEVs will result in an increase in overall VMT and associated PM emissions. Manufacturers of medium-duty vehicles have a strong incentive in a competitive market to produce vehicles that are capable of meeting the cargo hauling requirements of commercial owners. As such, EPA's analysis reasonably assumes that manufacturers will maintain the payload of BEVs by increasing GVWR and GCWR to compensate for the additional weight of batteries. EPA projects that most of the medium-duty BEVs will be vans and class 2b pickups, and will therefore not exceed the 14,000lbs GVWR upper limit for medium-duty vehicles under these final standards.

Carbon Monoxide:

After consideration of comments by MCS, clarifying edits have been made to the CO background section to indicate that CO can also be formed by photochemical reactions, as well as being formed by incomplete combustion. In addition, clarifying edits have also been made to the diesel exhaust background section to indicate that lifetimes of components of diesel exhaust can range from seconds to months, rather than seconds to days.

With respect to comments related to CO exposure and health effects, we note that the EPA's statement that "controlled human exposure studies of subjects with coronary artery disease show a decrease in the time to onset of exercise-induced angina (chest pain) and electrocardiogram changes following CO exposure," is based on findings of multiple studies reviewed in the 2010 CO Integrated Science Assessment (ISA).[403]

As the commenter notes, the underlying data for this claim is partially based on results from an HEI multicenter study that investigated the effects of CO exposure in individuals with coronary artery disease. This effort resulted in three peer-reviewed publications, which have been cited more than 250 times: Allred et al 1989a[404], Allred et al 1989b[405], and Allred et al 1991.[406] These studies found that exposures to CO decreased the time to onset of angina during exercise by 4.2% (low exposure group) or 7.1% (high exposure group) and decreased the time to development of ischemic ST-segment changes during exercise by 5.1% (low exposure group) or 12.1% (high exposure group). In addition, several other studies investigating individuals with stable angina also demonstrated that CO exposure during exercise decreases the time to onset of

angina, as well as reduces the duration of exercise and increases ventricular arrhythmias.[407,408,409,410,411]

All ISAs undergo review by an independent Clean Air Scientific Advisory Committee (CASAC), whose members have expertise in a variety of scientific fields relevant to air pollution and air quality issues. In their final Advisory Report for the 2010 CO ISA, CASAC referenced the importance of the above studies ("The most compelling CO-related cardiovascular results remain those from the controlled human exposure studies of Allred et al; Kleinman et al; and Sheps et al.") and expressed support for the related causality determination ("The Panel members concur with the ISA's conclusion that a causal relationship is likely to exist between relevant short-term CO exposure and CV morbidity.").[412]

We have also reviewed the fourteen studies recommended by the commenter. Out of the fourteen studies, none were directly comparable to those discussed above (i.e., controlled human exposure to CO in individuals with coronary artery disease). Three of the recommended studies were review articles,[413,414,415] three were experimental animal studies,[416,417,418] and eight studies

were conducted in humans.[419,420,421,422,423,424,425,426] Out of the eight human studies, two did not investigate a CO exposure (37-38), and one was an epidemiologic study evaluating the effects of acute CO exposures at non-ambient levels(39). The remaining five studies investigated potential cardiovascular effects of CO exposure in healthy individuals (40 - 44), a topic which was discussed in the previous ISA. In reference to effects on exercise-induced angina, the 2010 CO ISA stated that "no such effects have been observed in healthy adults following controlled exposures to CO." Furthermore, it states, "Although some studies have reported CO-induced hemodynamic changes among healthy adults at COHb concentrations as low as 5%, this effect has not been observed consistently across studies."[21] These statements are consistent with the provided studies. Although EPA is not reopening the 2010 CO ISA in this proceeding, we note that these statements are also consistent with the conclusions from the ISA.

The 2010 CO ISA focused on publications from 1999 to May 2009, and no studies were identified which investigated potential carcinogenic effects of CO. The studies which the commenter provides, published from 2012 to 2020, will be considered for inclusion in the next ISA for CO.

11.2 - Upstream and downstream criteria pollutant emissions

Comments by Organizations

Organization: Steven G. Bradbury

Worsening air quality and increasing global carbon emissions. As the EPA touts the environmental benefits it hopes to achieve from the production of more EVs, it ignores the fact that as consumers turn away from new models and the overall U.S. fleet ages, the older cars left on America's highways will produce more smog and other traditional air pollutants that degrade local air quality. And if there truly were an explosion in the sale of EVs, those EVs would need to be charged using electricity produced mostly from fossil-fuel-fired power plants, increasing the national emissions of carbon dioxide.47 EPA largely dismisses this reality based on the wish-

EPA Summary and Response

Summary:

Steven G. Bradbury expressed concerns regarding the potential for the proposed standards to slow adoption of newer, cleaner vehicles leaving older, dirtier vehicles on the road longer thereby producing more smog and pollution. This commenter also argued that an explosion of the sales of EVs would result in more electricity demand produced largely by fossil fueled power plants thereby increasing emissions.

Response:

We respond to fleet turnover and how our OMEGA modeling addresses this issue in Section 12.1.3 of this document. We respond to comments related to increased emissions from power plants in Section 11.3 of this document.

11.3 - Air quality modeling

Comments by Organizations

Organization: Alliance for Automotive Innovation

1. PM Standard Air Quality and Emissions Inventory Impact

EPA is proposing a PM exhaust emission standard of 0.5 mg/mi that is applicable over three test cycles and at cold temperature. The standard is phased-in between the 2027 and 2029 model years, at the same time that CARB's PM 1 mg/mile standard phases in. The current EPA standard is 3 mg/mi, so the 0.5 mg/mi standard represents an 83% reduction in the standard from the current standard. Similarly, EPA's proposed 0.5 mg/mile US06 standard is a 92% reduction from the current standard of 6 mg/mile and 83% lower than the 3 mg/mile US06 standard recently adopted by CARB. [EPA-HQ-OAR-2022-0829-0701, pp. 151-152]

a)PM Emission Inventory Impacts

EPA estimated PM emission reductions from the entire regulatory scenario and went on to evaluate nationwide PM air quality benefits. The emissions inventory benefits are summarized in Figure 41.269 [EPA-HQ-OAR-2022-0829-0701, pp. 151-152]

269 Illustrative Air Quality Analysis for the Light and Medium Duty Vehicle Multipollutant Proposed Rule, Technical Support Document, EPA-420-D-23-002, April 2023, Table 6-1, page 43.

Figure 41: Annual PM2.5 Benefits from the Regulatory Scenario

PM2.5 Source: On-road

2016 Base Year: 104,005

2055 Reference Case: 35,737

2055 LMDV Regulatory Case: 26,833

Reference- LMDV: 8,904 [EPA-HQ-OAR-2022-0829-0701, pp. 151-152]

PM2.5 Source: Upstream

2016 Base Year: 167,795

2055 Reference Case: 92,358

2055 LMDV Regulatory Case: 94,533

Reference- LMDV: -2,174 [EPA-HQ-OAR-2022-0829-0701, pp. 151-152]

PM2.5 Source: Total

2016 Base Year: 271,800

2055 Reference Case: 128,096

2055 LMDV Regulatory Case: 121,365

Reference- LMDV: 6,730 [EPA-HQ-OAR-2022-0829-0701, pp. 151-152]

For on-road vehicles, PM2.5 is reduced by 68,268 tons per year, or 66%, between 2016 and 2055 with existing regulations already in place. EPA estimates that the NPRM standards would reduce PM2.5 by an additional 8,904 tons, or an additional 9%, to 75%. However, upstream emissions increase by 2,174 tons under the NPRM (mainly from electricity generation). When upstream emissions are included with on-road emissions, the emission reduction from 2016 to 2055 with current regulations is 53% and is only an additional 2.5% with the RS. [EPA-HQ-OAR-2022-0829-0701, pp. 151-152]

The on-road PM benefits in Figure 41 are the result of two factors – the replacement of ICE vehicles with BEVs (with zero exhaust PM), and the implementation of the exhaust PM standard for remaining ICE vehicles. We searched the available documentation but were unable to determine how much of the on-road PM reduction was due to either factor. This is an important consideration in determining the overall effectiveness of the proposed exhaust PM standards. EPA should provide more information regarding the relative benefits of the two factors. [EPA-HQ-OAR-2022-0829-0701, pp. 151-152]

b) Air Quality Analysis

EPA's DRIA presents its air quality impacts for its proposal (Chapter 8).271 Section 8.1.1 of the DRIA lists the primary and secondary PM2.5 standards as shown in Figure 43, and indicates that "as of December 31, 2022, more than 19 million people lived in the 4 areas that are designated as nonattainment for the 1997 PM2.5 NAAQS, more than 31 million people lived in the 11 areas that are designated as nonattainment for the 2006 24-hour PM2.5 NAAQS, and more than 20 million people lived in the 5 areas designated as nonattainment for the 2012 annual

PM2.5 NAAQS.272 The report does not indicate what the model predicts as the nonattainment areas in 2055 without the proposal, or at least without the proposed exhaust PM standards. [EPA-HQ-OAR-2022-0829-0701, pp. 152-153]

271 Multi-Pollutant Emission Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles, EPA- 420-D-23-003, Draft Regulatory Impact Analysis, April 2023.

272 Section 8.1.1, page 8-1 of Draft RIA.

Figure 43: EPA's Primary and Secondary PM2.5 Air Quality Standards (µg/m3) [EPA-HQ-OAR-2022-0829-0701, pp. 152-153]

Type: Primary

Annual Average: 12.0

24 Hour: 35.0

Type: Secondary

Annual Average: 15.0

24 Hour: 35.0

[EPA-HQ-OAR-2022-0829-0701, pp. 152-153]

The DRIA goes on to say that the “LMDV regulatory scenario would decrease annual average PM2.5 by 0.1 µg/m3… and that the population-weighted average change in annual average PM2.5 concentrations would be 0.03 µg/m3 in 2055.”273 These impacts are very small, or 0.08% and 0.25% of the annual average primary standard of 12.0 µg/m3. Again, some of the PM air quality impact is due to the replacement of ICE vehicles with BEVs, and some due to the PM standards on ICE vehicles. So, the air quality impact of the PM standards is even smaller than µg/mi in 2055. [EPA-HQ-OAR-2022-0829-0701, pp. 152-153]

273 Page 8-21 of DRIA.

EPA did not consider a viable alternative to its PM proposal – and that is the adoption of the California LEV4 standards for PM. The current Tier 3 PM standard for LDVs and LDTs less than 8500 lbs is 3 mg/mi.274 The California LEVIII standard is 3 mg/mi until model year 2025, when a 1 mg/mi standard is phased-in between model years 2025 and 2028 at 25% per year. 275 The California standard of 1 mg/mi represents a 66% reduction in PM emissions from the current EPA standard of 3 mg/mi. [EPA-HQ-OAR-2022-0829-0701, pp. 152-153]

274 Tier 3 PM regs

275 LEVII regs

c) Light-Duty Vehicle Contribution to PM Inventory

EPA has inadequately considered the exceedingly low contribution of light-duty vehicles to PM emission inventories

The NPRM proposes a PM standard of 0.5 mg/mi standard for the 25 ºC FTP, US06 and -7 ºC FTP. Auto Innovators and our member companies do not believe the air quality benefit warrants the additional development and testing issues that this proposal creates. In particular, even with the EPA proposal to increase in stringency of the PM2.5 NAQQS as low as 8 or 9 μg/m3 from the current 12 μg/m3 earlier this year, EPA has also announced it expects to achieve these levels in most counties except California—a state that chose an FTP PM standard of 1 mg/mi for its environmental benefits and in recognition that resources are more appropriately spent on advancing EV sales. [EPA-HQ-OAR-2022-0829-0701, pp. 153-154]

With that in mind, Toyota contracted Ramboll Environ US Corporation to conduct atmospheric research using similar simulation technology between EPA (CMAQ) and Ramboll (CAMx). Ramboll's results were similar to EPA's in finding that the new PM NAAQS will be broadly met in major regions. Additionally, Ramboll conducted a Source Contribution Study (PSAT) that indicates that the emission category "Other Anthropogenic Sources," which includes prescribed and agricultural fires and other area sources such as residential fuel combustion, solvent utilization (e.g., paint, printing), dry-cleaning, and fugitive dust emissions, are the largest source of PM. Ramboll also found that the LDV sector contribution is far less than 5% of total PM 2.5 emissions in most locations. For details on the Ramboll study, please refer to the presentation attached as "US Air Quality Studies by Toyota." [EPA-HQ-OAR-2022-0829-0701, pp. 153-154]

Organization: American Fuel and Petrochemical Manufacturers

1. EPA overstates the environmental benefits

EPA touts several emissions benefits in the Proposed Rule from shifting the light-duty vehicle fleet to ZEVs. But EPA's analysis is lopsided in favor of its preferred technology. In analyzing environmental costs and benefits, EPA overlooks negative environmental consequences of ZEVs from increased power generation, vehicle usage, ZEV tire wear, the EV manufacturing supply chain, and battery replacements and disposal at the end of their useful life. Notably, EPA fails to assess net emissions. Although EPA modeled changes to power generation anticipated by the Proposed Rule as part of its upstream analysis, EPA does not consider the potential degradation of air quality in areas in the direct vicinity of existing or new power plants.204 [EPA-HQ-OAR-2022-0829-0733, pp. 44-45]

204 Id. at 29,379 (noting that although "[e]missions from upstream sources would likely increase in some cases (e.g., power plants) and decrease in others (e.g., refineries), EPA projects that the Proposed Rule will result in a total decrease in emissions of certain pollutants").

Organization: Delek US Holdings, Inc.

EPA compounds this flaw by making unsupported assumptions regarding total emissions impacts of its proposal as well as broad conclusory assertions not based on sufficient data-based substantiation. For example, EPA asserts that "the air quality analysis does not represent the proposal's regulatory scenario, nor does it reflect the expected impacts of the [IRA]," that while its analysis includes "some increases in ambient pollutant concentrations, as the power sector becomes cleaner over time as a result of the IRA and future policies, these impacts would decrease," and "the specific locations of increased air pollution are uncertain, [EPA] expect[s] them to be in more limited geographic areas."20 The Proposed Rule did not quantify emissions changes associated with producing or extracting crude or manufacturing refined fuels.21 [EPA-HQ-OAR-2022-0829-0527, p. 5]

20 Proposed Rule at 29,361.

21 Proposed Rule at 29,353. EPA concluded that EGU emissions will decrease between 2028 and 2055…[but] the increase in EGU emissions associated with the proposal's increased electricity generation would peak in the late 2030's/early 2040's (depending on the pollutant) and then generally decrease or level off through 2055." Id.

c. BEVs increased demand for power generation will also result in greater emissions of criteria pollutant emissions.

The Proposed Rule predicts net emissions reductions but does not adequately evaluate local ambient air quality impacts from increased power generation spurred by the mass adoption of electric vehicles. Although EPA modeled changes to power generation anticipated by the Proposed Rule as part of its upstream analysis, EPA does not consider the potential degradation of air quality in areas in the direct vicinity of existing or new power plants, especially as the need for baseload generation at times when the sun is not shining and the wind is not blowing rises exponentially with rapid electrification.44 [EPA-HQ-OAR-2022-0829-0527, p. 9]

44 Proposed Rule at 29,361 (describing the illustrative air quality modeling analysis EPA used and conceding that there would be increases in ambient pollutant concentrations but failing to quantify the actual concentrations and volumes or identify the geographic areas impacted).

Organization: Elders Climate Action

EPA performed modeling for the 2022 HD vehicle rule to demonstrate the benefits of the HD rule. That modeling showed that the NOx reductions required by the rule for HD vehicles will not be sufficient to achieve the ozone NAAQS in severe and extreme ozone nonattainment areas. The L/MD vehicle rule does not contain any analysis to determine whether the NOx reductions required by the rule will be sufficient to achieve the NAAQS in the most polluted nonattainment areas. [EPA-HQ-OAR-2022-0829-0737, pp. 5-6]

Without effective action to achieve the emission reductions needed for attainment, many at risk groups will suffer harm. EPA's review of the NAAQS for ozone and particulate matter have identified groups especially at risk from vehicle pollution, including-- [EPA-HQ-OAR-2022-0829-0737, pp. 5-6]

Babies and children, whose bodies are rapidly developing,

Pregnant women who risk increased premature birth and low weight births when exposed to vehicle pollution.

Children who develop asthma.

Children and adults with asthma who suffer asthma attacks.

People with existing respiratory diseases including COPD, COVID-related breathing limitations, long-COVID, and people with active COVID or respiratory infections.

People with lung cancer or other chronic diseases including other cancers. People with or at risk for cardiovascular disease.

Elders (over age 65) who risk premature death with exposure to air pollution.

[EPA-HQ-OAR-2022-0829-0737, pp. 5-6]

The proposed rule fails to achieve the public health benefits that will flow from requiring LD vehicles and MD trucks and buses to emit zero particles, zero NOx and toxic pollutants that cause urban smog, childhood asthma, respiratory and cardiovascular diseases, and premature deaths. Equally objectionable is the failure of EPA to even consider zero emission standards for short-haul L/MDVs, and to evaluate the climate and public health benefits that would follow from the actions needed for attainment in the worst affected nonattainment areas. [EPA-HQ-OAR-2022-0829-0737, pp. 5-6]

Organization: Environmental Defense Fund (EDF) (1of 2)

In addition to the research presented in our previous comments, we are including additional, analyses that further demonstrate the impact of light- and medium-duty vehicle emissions on vulnerable populations and the need for and benefits of zero-emitting solutions, including for light-duty trucks. [EPA-HQ-OAR-2022-0829-0786, p. 6]

A recent study by Calvin Arter et. al. estimated the air quality and health impacts of on-road vehicular emissions from five vehicles classes, including light-duty autos and light-duty trucks, on PM2.5 and O3 concentrations at a 12 × 12 kilometer scale for 12 states and Washington D.C. as well as four large metropolitan statistical areas in the Northeast and Mid-Atlantic U.S. in 2016.2 In the region considered, the research found that light-duty trucks are responsible for the most PM2.5-and ozone-attributable premature mortalities, with 46% of those mortalities from directly emitted primary particulate matter and 80% of those mortalities from ozone-attributable NOx emissions. This study demonstrates the importance and urgent need to address tailpipe emissions from light-duty trucks and supports EPA's proposal to include Class 2b and 3 vehicles in the rulemaking. [EPA-HQ-OAR-2022-0829-0786, p. 6]

2 Calvin A Arter et al Mortality-based damages per ton due to the on-road mobile sector in the Northeastern and Mid-Atlantic U.S. by region, vehicle class and precursor, 2021 Environ. Res. Lett. 16. https://iopscience.iop.org/article/10.1088/1748-9326/abf60b (Attachment B)

Organization: Strong Plug-in Hybrid Electric Vehicle (PHEV)

Allowing Strong PHEV cars and trucks to be eligible in the final regulation brings air quality benefits. [EPA-HQ-OAR-2022-0829-0646, p. 28]

- Strong PHEVs accrue many of the benefits of electrified transportation: they produce no tailpipe emissions during charge-depletion operation (reducing local air pollution), they weigh less than comparable BEVs (reducing non-exhaust particulate emissions from tires), they refuel many fewer times per year than ICEVs (reducing refueling emissions) and address the different types of cold-start emissions. [EPA-HQ-OAR-2022-0829-0646, p. 28]

Organization: Valero Energy Corporation

J. EPA fails to adequately consider the regional air quality impacts associated with the proposed rule.

EPA describes in the Preamble that it conducted an "illustrative air quality modeling analysis of a regulatory scenario" involving LDV and MDV emission reductions and corresponding changes in upstream emission sources.321 EPA goes on to downplay the results of the analysis, explaining that [EPA-HQ-OAR-2022-0829-0707, pp. 58-61]

321 321 EPA's Multi-Pollutant LMDV Proposal at 29361 (emphasis added).

"Decisions about the emissions and other elements used in the air quality modeling were made early in the analytical process for the proposed rulemaking. Accordingly, the air quality analysis does not represent the proposal's regulatory scenario, nor does it reflect the expected impacts of the Inflation Reduction Act (IRA)"322 [EPA-HQ-OAR-2022-0829-0707, pp. 58-61]

322 Id (emphasis added).

…

"While the results of the illustrative analysis include some increases in ambient pollutant concentrations, as the power sector becomes cleaner over time as a result of the IRA and future policies, these impacts would decrease. Although the specific locations of increased air pollution are uncertain, we expect them to be in more limited geographic areas, compared to the widespread decreases that we predict to result from the reductions in vehicle emissions."323 [EPA-HQ-OAR-2022-0829-0707, pp. 58-61]

323 Id.

Despite EPA's claims of uncertainty regarding the upstream emissions inventory,324 peer-reviewed research by Argonne National Laboratory supports the conclusion that BEV adoption can result in increased regional emissions of criteria pollutants, noting that "gasoline vehicles currently have lower total NOx, urban NOx, total PM2.5, and urban PM2.5 in 33%; 15%; 70%; and 10% of states, respectively[, compared with BEV]."325 [EPA-HQ-OAR-2022-0829-0707, pp. 58-61]

The results of the air quality modeling analysis to which EPA is dismissive are actually quite alarming. EPA's modelling of "a regulatory scenario" projects regions of increased annual average concentrations for particulate matter (PM2.5), ozone, nitrogen dioxide, sulfur dioxide (SO2), acetaldehyde, benzene, and formaldehyde, as well as regions of increased annual nitrogen and sulfur deposition.326 Specifically, EPA's modelling projects increased annual average concentrations of criteria or hazardous air pollutants in at least 39 states: Alabama, Arizona, Arkansas, Colorado, Delaware, Florida, Georgia, Idaho, Indiana, Illinois, Iowa, Kansas, Kentucky, Maine, Maryland, Michigan, Minnesota, Mississippi, Missouri, Montana, Nebraska, Nevada, New Hampshire, New Jersey, New Mexico, North Dakota, Ohio, Oklahoma, Pennsylvania, South Carolina, South Dakota, Tennessee, Texas, Utah, Virginia, Washington, West Virginia, Wisconsin and Wyoming.327 [EPA-HQ-OAR-2022-0829-0707, pp. 58-61]

326 DRIA at 8-20 to 8-34.

327 DRIA at 8-24 to 8-34, based on Figures 8-6, 8-8, 8-10, 8-12, 8-14 to 8-17, 8-22 and 8-23.

Of particular interest is EPA's modeling results for annual average SO2 concentrations, which show expansive regions of increased ground-level concentrations, in some areas greater than

0.050 parts per billion.328 Among the regions projected to be impacted are existing SO2 1- hour (2010) non-attainment areas in Arizona, Indiana, Illinois, Iowa, Michigan, Missouri, Ohio, Pennsylvania, Tennessee and Texas.329 [EPA-HQ-OAR-2022-0829-0707, pp. 58-61]

The results of the "illustrative" modeling of "a regulatory scenario" are significant enough to warrant EPA's revisiting the impacts of its actual proposed standards on state and local air quality. [EPA-HQ-OAR-2022-0829-0707, pp. 58-61]

6. Air quality modeling results. EPA should make available, in the docket or website, the complete results of the illustrative air quality modeling it completed for this proposal, including results by individual receptors. This will allow state and local agencies to better understand the potential impacts of this rule on their jurisdictions, especially for ozone and fine particles (PM2.5). [EPA-HQ-OAR-2022-0829-0507, p. 3]

EPA Summary and Response

Summary:

The Alliance for Automotive Innovation (AAI) comments that EPA should provide more information on the fraction of projected onroad PM emissions reductions in the air quality analysis that are due to emission control of ICE vehicles as compared to the fraction of reductions due to electric vehicles. AAI also notes that the impacts on ambient PM from the rule are small. They present results of an air quality modeling analysis, done by Ramboll for Toyota, looking at source contributions to ambient concentrations of $PM_{2.5}$ which shows that light-duty vehicles contribute less than 5% of total $PM_{2.5}$ concentration in most locations.

A commenter, Valero Energy Corporation, noted that the air quality modeling analysis presented in the NPRM projected that the illustrative scenario would result in increases in annual concentrations of pollutants in some areas, and specifically pointed to projected increased ambient SO_2 concentrations. The commenter suggested that EPA should revisit the impacts of the proposal on air quality. Other commenters also noted that the air quality analysis was illustrative and not based on the proposed standards.

Commenters, e.g., Delek US Holdings, Inc. and American Fuel and Petrochemical Manufacturers, asserted that EPA has failed to assess localized air quality impacts due to increased criteria pollutant emissions in areas proximate to EGUs. They also noted that vehicle electrification will increase energy demand and emissions from power plants, and that this increased demand will result in even more emissions from power plants when renewables (wind and solar) are unavailable. And they noted that EPA overlooks negative environmental consequences of increased power generation and ZEV tire wear among others.

The Strong Plug-in Hybrid Electric Vehicle comment notes that allowing Strong PHEV cars and trucks to be eligible in the final regulation brings air quality benefits.

A commenter, WI DNR, noted that EPA should make the complete results of the air quality modeling available to the public, including results by individual receptors, and another commenter, Elders Climate Action, asked how the rule will impact attainment of the ozone and $PM_{2.5}$ NAAQS. Some commenters also noted that this rule is needed to help them meet their NAAQS attainment goals.

Response:

For the final rule, EPA conducted an air quality modeling analysis of the proposed standards (the NPRM action case, rather than an illustrative case) and used an updated version of IPM to project EGU emissions (the 2022 post-IRA version of IPM). EPA also included projected design value concentrations for $PM_{2.5}$ and ozone, see Chapter 7.4 of the RIA for more information. These updates are responsive to comments suggesting that EPA did not model the proposed program, and to comments suggesting that EPA include the impact on projected nonattainment in its analysis.[427] The air quality modeling used a photochemical model, not a source-receptor model, and the outputs of the photochemical model are available at the 12 km grid cell level. EPA docketed the inputs and grid-cell specific outputs to the CMAQ model for the illustrative air quality modeling documented in the NPRM and also has done so for the air quality modeling analysis done for the FRM.[428]
