With regard to the request that EPA provide more information on the portion of the projected PM emission reductions that are due to emissions control of ICE vehicles versus the replacement of ICE vehicles with electric vehicles, EPA has not estimated this value; for purposes of the air quality analyses, we model the impacts of the standards, not of specific technologies that manufacturers may use to comply. We note, moreover, that the final standards do not mandate numbers of ICE vehicles with improved emissions control or of PEVs; rather, each manufacturer can comply with the performance-based standards using a mix of technologies that best suits their business.

EPA believes that the $PM_{2.5}$ emissions standards are adequately justified even without this information (see Section III.D.3 of the preamble and Section 4.1.3 of this document). There is no

[427] Decisions about the emissions and other elements used in the air quality modeling were made early in the analytical process for the final rulemaking. Accordingly, the air quality analysis does not fully represent the final regulatory scenario; however, we consider the modeling results to be a fair reflection of the impact the standards will have on air quality in 2055.

[428] EPA-HQ-OAR-2022-0829-0393 Docket memo modeling input and output files for the IPM runs used in the illustrative AQ and benefits analysis for the LMDV multipollutant proposed rule, EPA-HQ-OAR-2022-0829-0353 Modeling input files for the illustrative air quality and benefits analysis for the LMDV multipollutant proposed rule, and EPA-HQ-OAR-2022-0829-0418 Additional NPRM Illustrative Air Quality Modeling Outputs.

question that the $PM_{2.5}$ standards will yield significant reductions of $PM_{2.5}$ emissions from the light- and medium-duty vehicle fleets and that these reductions are important for public health. Section II of the preamble describes the health and environmental effects associated with exposure to pollutants, including $PM_{2.5}$. Emissions from light- and medium-duty vehicle and upstream sectors contribute to ambient concentrations of $PM_{2.5}$ at the local, regional, and national level, often disproportionally affecting communities of color and low-income populations. As set forth in Sections VI and VII of the final rule preamble, we project that this rule will result in significant reductions of emissions of GHGs, criteria pollutants, and air toxics from the light- and medium-duty vehicle sector. The reduction of emissions associated with vehicles will lead to air quality and health benefits improvements associated with the final rule (see Section VII.C of the final rule preamble).

EPA disagrees with the commenter who notes that the air quality benefit is not enough to warrant the costs of the rule; for responses to comments on the benefit-cost analysis, please see Section 8.5 of this RTC document. The analysis done by Ramboll to assess the contribution of light-duty gasoline vehicles to ambient $PM_{2.5}$ concentration and earlier work done by EPA indicate that light-duty gasoline vehicles contribute to ambient concentrations of $PM_{2.5}$.[429] States with nonattainment areas are required to take action to bring those areas into attainment. Since this rule will reduce onroad light- and medium-duty emissions across the country, this rule could help states and municipal areas in their efforts to attain the $PM_{2.5}$ NAAQS as expeditiously as practicable and may relieve areas with already stringent local regulations from some of the burden associated with adopting additional local controls. The final rule could also assist counties with ambient concentrations near the level of the ozone and $PM_{2.5}$ NAAQS who are working to ensure long-term attainment or maintenance of the ozone and $PM_{2.5}$ NAAQS.

Additionally, to the extent that the information introduced by commenters was intended to advocate for more or less stringent standards, we refer the reader to Sections 3.3 and 4 of this RTC document.

EPA acknowledges and agrees with commenters who note that the air quality analysis models increased energy demand and increased emissions from EGUs. EPA also notes that for this final rule, we modeled the air quality impacts of the proposed standards (not an illustrative scenario), which was a suggestion from a few commenters. Our modeling of projected emissions from the power sector was done using the Integrated Planning Model (IPM), which we note accounts for the fact that renewables are not always available and considers alternative ways that clean power can be supplied during those times. Please see Chapter 7.2.2.1 of the RIA for more information on the IPM modeling used to project emissions from the power sector for the air quality modeling and the EPA Power sector website for more details on the post-IRA 2022 version of IPM (https://www.epa.gov/power-sector-modeling/post-ira-2022-reference-case).

In addition, our air quality modeling finds significant reductions of pollutants across the nation. One commenter specifically mentioned that there were modeled increases in SO_2 concentration presented in the illustrative air quality modeling analysis in the NPRM, see Chapter 8 of the DRIA. The air quality modeling for the final rule (see Chapter 7 of the RIA) projects on average a decrease in annual SO_2 concentration of 0.001 ppb in 2055 and a

---

[429] Zawacki et al, 2018.Mobile source contributions to ambient ozone and particulate matter in 2025. Atmospheric Environment, vol 188. https://doi.org/10.1016/j.atmosenv.2018.04.057

population-weighted average decrease in annual SO_2 concentration of 0.003 ppb. We also project some increases in SO_2 concentration in our final rule air quality modeling analysis, although the increases are smaller and impact fewer locations than the illustrative modeling in the NPRM. Although our air quality modeling is not of sufficient resolution to capture impacts at a smaller than 12 km grid scale, we do expect that increased emissions from EGUs may increase ambient concentrations of some pollutants, including SO_2, in some areas downwind of EGUs. The impact of these increases is limited and dwarfed by the decreases elsewhere in the nation; indeed, we project that more than 99 percent of the population will experience reductions in annual average SO_2 concentrations as a result of this rule. We also expect the power sector to become cleaner over time as a result of the IRA and future policies, which will reduce the air quality impacts of EGUs. Further, none of the grid cells that are projected to have increases in SO_2 concentration are located in nonattainment areas, as was highlighted by this commenter as a concern based on the results of the illustrative analysis described in the NPRM. On average the final rule AQ modeling projects a decrease in annual SO_2 concentration of 0.001 ppb in 2055 and a population-weighted average decrease in annual SO_2 concentration of 0.003 ppb.

Comments related to plug-in hybrids are addressed in Sections 3.1.6 or 12.2.4 of this RTC. Comments related to tire wear are addressed in RTC Section 11.1.

12 - Modeling of compliance pathways, associated costs, and emissions reductions

12.1 - General comments about OMEGA

<u>Comments by Organizations</u>

Organization: American Fuel & Petrochemical Manufacturers

EPA's Proposal fails to evaluate how government credits are embedded in vehicle pricing. For example, neither federal or state governments, or auto manufacturers explain how state ZEV credits, EPA GHG multiplier credits, and NHTSA CAFE EV multiplier credits are accounted for in both ZEV and ICEV vehicle price. There is increasing evidence that regulations which mandate EV sales—along with the cross-subsidies from gasoline and diesel vehicle buyers—are leading manufacturers to abandon sales of the least expensive and higher fuel economy gasoline and diesel vehicles that do not receive similar subsidization.236 Cox Automotive found that "in December 2017, automobile makers produced 36 models priced at $25,000 or less. Five years later, they built just 10," pushing low-income buyers out of the new-car market and into the used-car market. Conversely, in December 2017 automobile manufacturers offered 61 models for sale with sticker prices of $60,000 or higher and in December 2022, they offered 90.237 This is unacceptable. EPA and its sister agencies cannot create credits and then claim they do not affect vehicle price solely because they have not sought to quantify them. [EPA-HQ-OAR-2022-0829-0733, pp. 51-52]

236 Steven G. Bradbury, Distinguished Fellow, The Heritage Foundation, Prepared Statement for the hearing entitled "Driving Bad Policy: Examining EPA's Tailpipe Emissions Rules and the Realities of a Rapid Electric Vehicle Transition," before the Subcommittee on Economic Grown, Energy Policy, and Regulatory Affairs of the U.S. House of Representatives Committee on Oversight and Accountability, at 10

(May 17, 2023) available at https://oversight.house.gov/wp-content/uploads/2023/05/Bradbury-Prepared-Statement-for-17-May-2023-Oversight-Hearing.pdf

237 See Sean Tucker, Are we witnessing the demise of the affordable car? Automobile makers have all but abandoned the budget market (MarketWatch Feb. 28, 2023), available at https://www.marketwatch.com/story/are-we-witnessing-the-demise-of-the-affordable-car-automakers-have-all-but-abandoned-the-budget-market-a68862f0 (last visited May 24, 2023).

Tellingly, EPA never estimates the annual price of a comparable ZEV and ICEV, for each year in which EPA proposes standards. EPA's bias towards EVs is demonstrated by EPA's statement that its OMEGA modeling "now incorporates a consumer choice element. This means that the impacts of, for example, a $40,000 BEV versus a $35,000 ICE vehicle of similar utility (i.e., a 14 percent increase for the BEV) is a much different consideration than a $6,000 incremental BEV cost versus a $1,000 incremental ICE cost (a 500 percent increase for the BEV)."238 In other words, EPA set up its model to show the consumer price (not the actual real-world cost) of EVs have a lower percentage cost increase than the incremental absolute cost of switching from ICEVs to ZEVs. [EPA-HQ-OAR-2022-0829-0733, pp. 51-52]

Organization: Alliance for Automotive Innovation

. We recommend that EPA provide more thorough documentation of the OMEGA input and output files, and descriptions of data used in the final rule. [EPA-HQ-OAR-2022-0829-0701, pp. 66-67]

H. OMEGA Model

EPA introduced OMEGA 2.1.0 to improve the model boundaries by including pre- and post-processing steps to occur within the model, as well as adding an independent policy module, modeling of strategic producer decisions, and a consumer response component. [EPA-HQ-OAR-2022-0829-0701, pp. 137-139]

EPA's OMEGA modeling team provided a helpful tutorial of the model's basic operation and answered numerous manufacturer questions. Despite the assistance, it has been difficult for Auto Innovators and its member companies to figure out how to exercise the model's new features to determine how accurately they replicate reality. Auto Innovators' attempts to maneuver through the model have uncovered information access barriers that make it difficult to understand how key assumptions supporting the proposed standards affect manufacturer compliance and the associated costs and environmental improvements over time. Overall, the model the lacks necessary transparency and user-friendly access needed for stakeholders to evaluate the feasibility claims in the proposal. [EPA-HQ-OAR-2022-0829-0701, pp. 137-139]

The 60-day comment period is insufficient to provide a thorough assessment. With the limited time provided, we have discovered difficulties such as: [EPA-HQ-OAR-2022-0829-0701, pp. 137-139]

- Many complex aspects of the model are not found or clearly stated in the model documentation. [EPA-HQ-OAR-2022-0829-0701, pp. 137-139]

- A baseline fleet of 2021 discussed, but a 2019 fleet appears to have been used. [EPA-HQ-OAR-2022-0829-0701, pp. 137-139]

- There are circular definitions applied to basic terms such as “engine cost.” [EPA-HQ-OAR-2022-0829-0701, pp. 137-139]

- We encountered unreasonable difficulty in creating a technology walk to be able to understand incremental technology penetration and cost to compare to GHG improvements over time. [EPA-HQ-OAR-2022-0829-0701, pp. 137-139]

It is possible, given the limited comment period, that there is some nuance that explains the apparent deficiencies, and we welcome dialogue with EPA on these concerns. [EPA-HQ-OAR-2022-0829-0701, pp. 137-139]

Auto Innovators recommends that the final rule and associated documentation: [EPA-HQ-OAR-2022-0829-0701, pp. 137-139]

- Provide model documentation with clear steps to develop a technology walk. [EPA-HQ-OAR-2022-0829-0701, pp. 137-139]

- Provide a glossary of technology definitions. [EPA-HQ-OAR-2022-0829-0701, pp. 137-139]

- Provide full details on cost assumptions (as in previous rulemakings). [EPA-HQ-OAR-2022-0829-0701, pp. 137-139]

- Provide a straight forward way to identify BEVs, PHEVs, strong hybrids, or conventional ICE technologies in model output files. [EPA-HQ-OAR-2022-0829-0701, pp. 137-139]

We also note that, despite the importance of the OMEGA model in informing its proposed standards, EPA does not appear to have engaged its Science Advisory Board in a review of the model’s structure, inputs, or outputs. [EPA-HQ-OAR-2022-0829-0701, pp. 137-139]

EPA conducted a peer review of the model through its contractor ERG.247 The peer review report describes that four independent reviewers, free from conflicts of interest, were selected by ERG. However, one of the reviewers, Rick Rykowksi, is described as an “Independent Engineering Contractor, Environmental Defense Fund” and is a former EPA employee.248 As EPA staff is well-aware, Environmental Defense Fund (EDF) is a frequent commenter on environmental regulations, including those affecting the automotive industry, generally taking supportive positions on EPA’s proposals and advocating for even more stringent requirements. While Mr. Rykowski may technically be an independent contractor, his close ties to EDF have likely given that organization an unfair advantage relative to other stakeholders in understanding and commenting on the operation of the OMEGA model and its input / output structure as it applies to the NPRM, particularly given the limited comment period. Furthermore, although the OMEGA model is intended to represent potential manufacturer responses to proposed and alternative standards, not a single one of the reviewers selected has recent experience in the automotive industry. [EPA-HQ-OAR-2022-0829-0701, pp. 137-139]

247 U.S. Environmental Protection Agency, External Peer Review of EPA’s OMEGA Model: Final Peer Review Summary Report, EPA-420-R-23-010 (Apr. 2023).

248 Id. at A-59.

We recommend that EPA proactively engage all stakeholders to familiarize them with new and significantly revised models well in advance of their use in rulemaking. EPA should also consider providing notice in the Federal Register of the availability of new modeling tools (again in advance of their formal use) and take public input in addition to limited peer reviews. Finally, for a thorough and appropriate peer review, Auto Innovators recommends that EPA provide an additional peer review now by an independent reviewer with automotive experience and incorporate the peer review input into OMEGA prior to finalizing a rule. [EPA-HQ-OAR-2022-0829-0701, pp. 137-139]

Organization: American Free Enterprise Chamber of Commerce (AmFree) et al.

EPA's Reliance on Its OMEGA Model Is Misplaced

EPA unreasonably relies throughout the proposed rule on a barely tested optimization modeling tool called "OMEGA." All of EPA's projections relat-ing to the number of combustion-engine and electric vehicles in compliant fleets during the relevant period were calculated using OMEGA. See 88 Fed. Reg. at 29,294–95. Those projections in turn inform many aspects of the proposed rule, including feasibility, estimated overall emissions, and the agency's cost-benefit calculation. See, e.g., id. at 29,318 (relying on OMEGA projections to analyze grid reliability); id. at 29,303, 29,347–59 (using OMEGA to estimate emission inventories); id. at 29,370, 29,379, 29,383, 29,385–86, 29,392 (using OMEGA to estimate costs and benefits). If OMEGA is flawed, then so too is the rest of the rule that relies on it. And OMEGA is flawed for multiple reasons. [EPA-HQ-OAR-2022-0829-0683, p. 53]

EPA misleadingly asserts that the model underwent peer review before it was released. See 88 Fed. Reg. at 29,185, 29,294. Rather than granting anony- mous reviewers access to the model and permitting them to pressure-test it and provide comments, EPA contracted with one entity (the Eastern Research Group) to handpick just four reviewers to assess and critique the model. See External Peer Review of EPA's OMEGA Model: Final Peer Review Summary Report, EPA, at 1–2 (Apr. 2023) ("External Review Summary"). EPA does not purport to have distributed the model to any other reviewers. A lack of widespread quality-assessment of the model alone renders the decision to adopt it unrea- soned and arbitrary. [EPA-HQ-OAR-2022-0829-0683, pp. 53-54]

Organization: American Honda Motor Co., Inc.

F. EPA Analysis of Market Impacts

For this proposed rule, EPA utilized an updated and peer reviewed version of their Optimization Model for reducing Emissions of Greenhouse gases from Automobiles (OMEGA 2.0) to model vehicle manufacturer compliance with GHG standards. OMEGA 2.0 builds on the previous version and includes some notable new capabilities:

[T]he updated version of OMEGA extends the prior version's projections of cost-effective manufacturer compliance decisions by also accounting for the relationship between manufacturer compliance decisions and consumer demand and including important constraints on technology adoption. Also, the updated OMEGA allows for evaluation of the influence of other policies beyond the GHG standards being evaluated, such as state-level ZEV policies.43 [EPA-HQ-OAR-2022-0829-0652, pp. 24-25]

43 88 Fed. Reg. 29294 (May 5, 2023)

As in previous rulemakings, the agency has included the OMEGA model and accompanying data files associated with each policy "run" in the regulatory Docket. Although the data files and model documentation were, in our opinion, too opaque for a rulemaking of such significance, Honda found agency staff to be helpful in answering our questions and providing further clarity. Such support was greatly appreciated, particularly for a model with this level of complexity. [EPA-HQ-OAR-2022-0829-0652, pp. 24-25]

Organization: POET, LLC

Future Work, including by EPA

While relatively straightforward to run, the OMEGA model comprises hundreds of inputs and equations across both behavioral, policy, and technological aspects of the LDV market. While the results in this memo demonstrate some salient characteristics of proposed policies, a more thorough evaluation by EPA of these issues are warranted. With additional resources and more time allowed than the short comment period provided by EPA on the proposal, a more comprehensive analysis of LDV policies using the OMEGA module could be performed leading to a more complete understanding of the consequences of this Proposed Rule. [EPA-HQ-OAR-2022-0829-0609, p. 50]

Organization: Valero Energy Corporation

B. Despite feedback from peer reviewers, EPA fails to provide adequate time for stakeholder review of the OMEGA v2.1.0 Model.

OMEGA v1.0 was created to support new LDV GHG standards proposed by EPA in 2011; OMEGA v2.1.0, released to support EPA's proposed standards, reflects "significant changes in the light duty vehicle market including technological advancements and the introduction of new mobility services" in the period since the release of OMEGA v1.0.82 Peer reviewers of the OMEGA v2.1.0 model offered the feedback "OMEGA 2 is not just updated, it is essentially a new model"83 and "OMEGA2 a major expansion of the prior OMEGA model in scope."84 [EPA-HQ-OAR-2022-0829-0707, pp. 16-18]

82 DRIA at 2-2.

83 EPA "External Peer Review of EPA's OMEGA Model Final Peer Review Summary Report" (EPA-420-R-23- 010) at 6, April 2023.

84 EPA "External Peer Review of EPA's OMEGA Model Final Peer Review Summary Report" (EPA-420-R-23- 010) at 22, April 2023.

In the peer review of OMEGA v2.1.0, "the most common category of comments consisted of recommendations for improving the model's documentation by adding further explanations or specifics to enhance the user's understanding."85 Specific comments from peer reviewers include:

85 DRIA at 2-7.

• "'The logical decision-making process in OMEGA2 seems too complex for the necessary level of review (consisting of a review of at least 90+ pages out of total 300+ pages containing some source code of the model documentation besides the model running) due to the limited effort available to reviewers. Some additional documentation would be useful in terms of logical explanation of various iterative producer consumer vehicle choice process (suited to a general non-economist audience) before the public model release."86 [EPA-HQ-OAR-2022-0829-0707, pp. 16-18]

86 EPA "External Peer Review of EPA's OMEGA Model Final Peer Review Summary Report" (EPA-420-R-23- 010) at 3, April 2023.

- "The policy-oriented model seems too complex for a novice user. A professional economics background is necessary for interpretation of model results and so it'd be useful if the model documentation could be made more simpler for the general users."87 [EPA-HQ-OAR-2022-0829-0707, pp. 16-18]

87 EPA "External Peer Review of EPA's OMEGA Model Final Peer Review Summary Report" (EPA-420-R-23- 010) at 4, April 2023.

- "Would be helpful for the novice EPA model users to include a short section on the other EPA complementary ALPHA model with differences between it and OMEGA2 model."88 [EPA-HQ-OAR-2022-0829-0707, pp. 16-18]

88 EPA "External Peer Review of EPA's OMEGA Model Final Peer Review Summary Report" (EPA-420-R-23- 010) at 4, April 2023.

- "Steps for running the model seem not very straight forward to a novice user using the existing model GUI. It was hard to locate some of the listed files in the model documentation. Additional step-by-step flow diagrams including the file listing with a clear indication of necessary user inputs for both necessary preprocessing and post-processing would be useful to be included in User's manual. In addition, a definition glossary of major variables including a data dictionary would be useful."89 [EPA-HQ-OAR-2022-0829-0707, pp. 16-18]

89 EPA "External Peer Review of EPA's OMEGA Model Final Peer Review Summary Report" (EPA-420-R-23-010) at 5, April 2023.

In EPA's response to the peer review comments, EPA generally disagreed with the feedback concerning complexity for the novice user but vowed that it would "continue to look for ways to make the documentation clearer and more useful for a broad range of readers and users."90 While EPA "continues to look for ways" to facilitate the use and understanding of the OMEGA model by its stakeholders, these same stakeholders were granted only 60 days to review the model code, input and output files, run the model themselves, and provide comments to EPA – not enough time, given the scope of changes since the OMEGA v1.0 model and the magnitude and complexity of the model itself. [EPA-HQ-OAR-2022-0829-0707, pp. 16-18]

90 EPA "External Peer Review of EPA's OMEGA Model Final Peer Review Summary Report" (EPA-420-R-23-010) at 4, April 2023.

EPA Summary and Response

The Alliance recommended that EPA provide additional documentation of the OMEGA input and output files, and descriptions of data used in the final rule. In response, EPA has updated the model documentation (https://omega2.readthedocs.io/en/2.5.0/) to provide a description of the model version that was used for the compliance analysis of this final rulemaking. The model documentation also provides a description of the variables in the input and output files, and a description of the data types and file formatting. The input assumptions and values used for this rulemaking's central and sensitivity case analyses are described in the appropriate sections of the Preamble and RIA. For example, consumer modeling inputs are described in RIA Chapter 2.6.3; vehicle powertrain cost inputs in RIA Chapter 2.6.1, and IRA incentive inputs in RIA Chapter 2.6.8. EPA has added a table of OMEGA topics in RIA 2.1 with chapter and section numbers to help guide the reader to the relevant details in the RIA and Preamble.

AmFree was critical of the process used by EPA to have the OMEGA model peer reviewed prior to the NPRM. The commenter describes what in their view was "a lack of wide-spread quality assessment" of the model, and commented that EPA had not distributed the model to other reviewers. The commenter describes an alternative process which involves EPA granting "anonymous reviewers access to the model and permitting them to pressure-test it and provide comments." In response, EPA disagrees with the commenter's view that the review process was deficient. EPA's OMEGA model was subject to a thorough peer-review process that meets the standards outlined by the Peer Review Advisory Group and EPA's Science and Technology Policy Council, as documented in EPA's peer review handbook (https://www.epa.gov/osa/peer-review-handbook-4th-edition-2015). As a result of this thorough peer review process, EPA implemented multiple model revisions and improvements that were incorporated into the version used for the NPRM analysis. In response to the commenter's assertion that the model was not broadly available for comment beyond the formal peer-review, EPA notes that the complete full model and inputs were made available publicly for the NPRM. This includes the model documentation, model code, full peer review report, model inputs and outputs, model executable file, and an introductory video tutorial. Multiple commenters, including AmFree, used the public comment process to submit their observations and recommendations for improving the OMEGA model based on the extensive materials that were available for review.

AmFree commented that EPA's reliance on the OMEGA model is misplaced, since in the commenters view, the model was "barely tested", and is the source for "all of EPA's projections relating to the number of combustion engine and electric vehicles." In response EPA disagrees that the use of the OMEGA model as a tool to project possible compliance pathways is inappropriate. EPA notes that the OMEGA model's compliance logic for this rulemaking is consistent with the modeling for all previous light-duty GHG rulemakings. This logic, to describe briefly, is an optimization approach that applies technologies to comply with GHG standards at the lowest cost. As discussed above, EPA disagrees with the same commenter's assertion that the peer-review process was deficient. It is relevant to the perceived lack of model testing to note that during the formal peer review process, EPA responded to extensive comments on the OMEGA model's optimization algorithm. Additional comments on the same topic were submitted for this rulemaking and are discussed further in RTC Section 12.1.1. The extent and depth of these comments serve to illustrate the intensive review and testing of the model's algorithm. EPA considers that the OMEGA model's refinement is an ongoing process spanning over a decade; the process began with previous rulemakings that utilized OMEGA modeling and continued with development and testing within the Agency over the past several years. Importantly, the process includes the second peer review of OMEGA to which the commenter refers, as well as stakeholder engagement that continues up to and including this current public comment process. Finally, we note that this particular comment regarding EPA's reliance upon OMEGA modeling does not distinguish between the model and the model inputs. The discussion above is in response to the review and testing of the model algorithms and the

OMEGA model itself. It is appropriate to consider input assumptions and values independently, apart from a discussion of model algorithms. Inputs to the OMEGA model are described in RIA Sections 2.4, 2.5 and 2.6, and discussed throughout this RTC Section 12.

AAI commented that it was difficult to navigate through the model and understand how key assumptions were used, while Honda commented that the data files and model documentation were "too opaque for a rulemaking of such significance." These commenters acknowledged that the model, model documentation, and complete input and output files were published and available for public review for the proposal. EPA recognizes that a large volume of materials was posted to the docket, and took several steps to assist stakeholders, including updating and expanding the model documentation based on the peer review and publishing a video tutorial showing how to conduct a run and navigate some of the key output files. One notable step taken by EPA at the time of the NPRM was the establishment of an OMEGA "help desk" in the form of a dedicated email contact for the sole purpose of responding to questions about model operation and interpretation of input and output files. Between April and August of 2023 alone, EPA fielded inquiries on dozens of topics, and shared responses via more than 100 email correspondences. Honda expressed appreciation for these engagement efforts in their comments. Overall, while we agree that it is challenging to navigate a model involving so many inputs and outputs, we believe that the steps taken by EPA to be responsive to requests for clarification and increase transparency were appropriate for providing a sufficient understanding of the modeling during the comment process.

12.1.1 - Producer side modeling

Comments by Organizations

Organization: Alliance for Automotive Innovation

8. Reliance on Credit Trading in Analysis of Compliance Pathways

EPA models a potential compliance pathway for each manufacturer as part of its analysis and justification of proposed GHG standards. Unlike prior rulemakings, EPA has assumed credit trading between manufacturers as part of its central analysis, rather than as a sensitivity case.215 [EPA-HQ-OAR-2022-0829-0701, pp. 117-120]

215 NPRM at 29343.

In EPA's own words,

We have incorporated a 'credit market efficiency' parameter that can be set by the user. A value of '1' represents a perfect credit market; a value of '0' represents no credit trading provisions. Values between 0 and 1 represent imperfect trading, where manufacturers with cost-minimizing compliance pathways that involve the purchase of credits will apply more technology than they would under perfect trading. And as a result, some of the industries credits will expire, unused.216 [EPA-HQ-OAR-2022-0829-0701, pp. 117-120]

216 U.S. Environmental Protection Agency, Final Peer Review Summary Report (Apr. 2023) at 9. ("We have incorporated a 'credit market efficiency' parameter that can be set by the user. A value of '1' represents a perfect credit market; a value of '0' represents no credit trading provisions. Values between 0 and 1 represent imperfect trading, where manufacturers with cost-minimizing compliance pathways that

involve the purchase of credits will apply more technology than they would under perfect trading. And as a result, some of the industries credits will expire, unused.")

By implication, a value of 1 in EPA's model would generally result in a perfect balance of industry performance better and worse than target such that any manufacturer needing to purchase credits would have access to them through a different manufacturer (or multiple manufacturers) that chose to over-comply with the standards. Put another way, a value of 1 would imply that each individual manufacturer has perfect foreknowledge of other manufacturers' product plans and of the distribution of sales for ongoing and future model years, and that they collude in such a manner that they collectively minimize average compliance costs. Such an outcome is clearly not realistic. Automobile manufacturers are highly competitive and do not act in a collective manner in planning products and regulatory compliance.217 Nor is it possible to have perfect knowledge of future sales. [EPA-HQ-OAR-2022-0829-0701, pp. 117-120]

217 Auto Innovators strictly follows all U.S. antitrust laws, and expressly discourages its members from engaging in any collusive or anti-competitive behavior.

For the NPRM, EPA assumed a 'credit market efficiency' of 0.8.218 In other words, that manufacturers would have an 80% ability to act collectively together and predict future markets and sales. Auto Innovators was unable to locate any justification from EPA for its choice of 80% efficiency in collective planning in either the NPRM or RIA, leading us to believe that its choice was completely arbitrary. [EPA-HQ-OAR-2022-0829-0701, pp. 117-120]

218 EPA NPRM OMEGA central analysis batch input file (2023-03-14-22-42-30-ld-central-run-to2055.zip\2023-03-14- 22-42-30-ld-central-run-to2055\batch-expanded_ld_central.csv), parameter "Credit Market efficiency" set to a value of 0.8).

Although we agree that some credit trading is occurring, and thus a 'credit market efficiency' setting greater than 0 may be warranted, the reality is a much more constrained credit market than a credit market efficiency value of 80% would imply. The U.S. auto market and manufacturers are highly competitive. The market for compliance credits is closed, with each participating buyer and seller of credits individually seeking each other out and coming to unique terms. Historically, only three manufacturers have sold any significant quantity of GHG credits, and purchases have been dominated by a single manufacturer with a couple of other manufacturers purchasing significant quantities, and a number of others purchasing relatively small amounts of credit.219 Moreover, EPA's approach in general ignores that most manufacturers prefer to maintain some level of banked credits as insurance against unexpected events that could affect future compliance.220 Maintaining a buffer against unexpected events will likely become increasingly important as standard stringency rapidly increases after MY 2022, and even more-so in the later half of this decade as compliance relies more heavily on electric vehicle market share and its present uncertainties. [EPA-HQ-OAR-2022-0829-0701, pp. 117-120]

219 EPA Trends Report at 119.

220 EPA Trends Report at 122. (A number of manufacturers are maintaining positive credit balances.)

EPA's assumption of 0.8 (or 80%) credit market efficiency is not insignificant. EPA's central analysis of the proposed standards projects two major manufacturers will rely on purchased credits for compliance in most years after MY 2022. Another three major manufacturers are projected to need to purchase credits in at least three years after MY 2022. Despite projections of small volume manufacturers exceeding fleet average BEV market share, they would also need to purchase credits in nearly every year under EPA's projections.221 EPA projects that thirteen manufacturers will generally exceed regulatory requirements, but the two manufacturers with the greatest degree of credit generation would not have enough surplus credit to cover the two manufacturers projected to purchase the most credits.222 Generalizing, it appears that EPA's projected compliance pathways assume virtually all manufacturers participating as buyers or sellers (or both) of credits. Again, these assumptions do not seem realistic, particularly given EPA's lack of support for them. [EPA-HQ-OAR-2022-0829-0701, pp. 117-120]

221 Auto Innovators examination of the proposal central analysis OMEGA [. . .]credit_transactions.csv output files, noting where EPA's analysis results in a "PAST_DUE" result.

222 Auto Innovators examination of the proposal central analysis OMEGA [. . .]credit_transactions.csv output files, noting where EPA's analysis results in an "EXPIRATION" of credits. In other words, credits that would expire unused unless sold to another manufacturer.

Perhaps more important than the intricacies and assumptions of compliance modeling, which is almost always an over-simplified projection of potential future outcomes, are the practical realities that should be considered. [EPA-HQ-OAR-2022-0829-0701, pp. 117-120]

Auto Innovators believes that it is inappropriate to set a standard so stringent as to effectively require many manufacturers to rely on other manufacturers to maintain compliance. [EPA-HQ-OAR-2022-0829-0701, pp. 117-120]

The decision to sell credits, who to sell them to, what price to sell them at, and when to sell them (or to keep them for later use or future value) is a business decision. There is nothing that requires a manufacturer to sell its credits, to sell them to a particular party, or to sell them at a particular price. [EPA-HQ-OAR-2022-0829-0701, pp. 117-120]

Even if a credit-generating manufacturer is willing to sell credits, the credits may be purchased by other parties before other manufacturers can purchase them. Manufacturers engage in multi-year planning. While a small spot purchase of credits might be made to cover an unforeseen gap in a single year, it is just as likely that manufacturers will seek to purchase credits for multiple years. Such behavior is observable in EPA's records of credit transactions. One can clearly identify manufacturers that have purchased more credit than needed in a current model year, that is then used over the course of multiple years. [EPA-HQ-OAR-2022-0829-0701, pp. 117-120]

Setting aside EPA's specific projections, the availability of credits for purchase may also shrink in the future. Standards that rapidly increase in stringency, as do the MY 2023-2026 standards and EPA's proposed standards for 2027 and later, are challenging to comply with, let alone exceed. Available investment capital limits the number of models that can be redesigned and improved or transformed into electric vehicles in a given year. The faster the rate of stringency increase, the more difficult it is to stay ahead of the standard. Also, as the fleet average emission standard is decreased, vehicles above their target become even more of a compliance burden, and vehicles below their target become less of a compliance benefit. Even manufacturers that only sell electric vehicles (such as Tesla) will not generate the same quantity of credits assuming relatively constant production. [EPA-HQ-OAR-2022-0829-0701, pp. 117-120]

Moreover, compliance with EPA's proposed standards is largely premised on rapidly growing EV market share. If EPA's projections are incorrect, and sales of electric vehicles are not as high as expected, many manufacturers are likely to need more credits than projected to maintain compliance with GHG standards. [EPA-HQ-OAR-2022-0829-0701, pp. 117-120]

Auto Innovators recommends that EPA finalize standards that are not premised on projections of readily available purchasable credits. [EPA-HQ-OAR-2022-0829-0701, pp. 117-120]

Organization: American Free Enterprise Chamber of Commerce (AmFree) et al.

EPA misleadingly asserts that the model underwent peer review before it was released. See 88 Fed. Reg. at 29,185, 29,294. Rather than granting anony- mous reviewers access to the model and permitting them to pressure-test it and provide comments, EPA contracted with one entity (the Eastern Research Group) to handpick just four reviewers to assess and critique the model. See External Peer Review of EPA's OMEGA Model: Final Peer Review Summary Report, EPA, at 1–2 (Apr. 2023) ("External Review Summary"). EPA does not purport to have distributed the model to any other reviewers. A lack of widespread quality-assessment of the model alone renders the decision to adopt it unrea- soned and arbitrary. [EPA-HQ-OAR-2022-0829-0683, pp. 53-54]

Worse, even that limited review raised significant concerns about OMEGA's basic functionality that EPA has not addressed. One reviewer pointed out that OMEGA has "limitations that restrict its ability to model some important aspects of policy compliance in practice," including "firm profit- seeking compliance behavior." External Review Summary at 22. That reviewer suggested that EPA "consider implementing functionality" that would permit users to model multiple firms competing for market share. Id. at 24. As he ex- plained, the current version "uses a single monopolist producer with a fleet of products," and that a single producer may respond to a regulation different than a producer that is competing for market share. Id. at 25. Those concerns regard- ing market share and structure have substantial grounding in academic litera- ture. As one scholar has explained, environmental regulation, particularly in industries with few producers and high fixed costs, may have a significant im- pact on new market entrants and overall market structure. See Stephen P. Ryan, The Costs of Environmental Regulation in a Concentrated Industry, 80 Econometrica 1019, 1021 (May 2012). For that reason, by ignoring the effects on competition, EPA's OMEGA model may significantly underestimate the negative effects on consumers of the proposed rule. See id. at 1059. EPA declined to change OMEGA in response to those concerns, see External Review Summary at 22, 24— and it nowhere explains why OMEGA's projections are accurate without hav- ing addressed his comments. [EPA-HQ-OAR-2022-0829-0683, pp. 53-54]

Organization: American Fuel & Petrochemical Manufacturers

EPA requests comment on their approach to determining charging time, as set forth in the DRIA, Chapter 4.155 EPA's analysis is contingent on unsupported assumptions regarding (1) U.S. consumers' adoption of and ability to purchase more expensive ZEVs (see Sections IV.B.2 and IV.E.2.ii); (2) the type of ZEV purchased (used ZEVs or PHEVs compatible with slower charging units or new ZEVs that can use DCFC) (Section IV,B.2 addresses charging times); (3) the availability of critical minerals and metals to expand the supply of reliable and renewable electricity (see Section I.B); and (4) the availability of reliable and affordable charging for all users (see Sections IV.B.4). Given the flaws in EPA's methodology that omits significant data sources and other factors and makes unsupported assumptions, EPA should revise its analysis concerning charging time and continue with promulgating a final rule for future emissions standards, that accounts for the reality of today's automotive market and not the public pronouncements of the automotive industry, a single state or group of states, or other unsupported estimates of future market growth. [EPA-HQ-OAR-2022-0829-0733, pp. 33-34]

155 88 Fed. Reg. at 29,367.

EPA's Proposal fails to evaluate how government credits are embedded in vehicle pricing. For example, neither federal or state governments, or auto manufacturers explain how state ZEV credits, EPA GHG multiplier credits, and NHTSA CAFE EV multiplier credits are accounted for in both ZEV and ICEV vehicle price. There is increasing evidence that regulations which mandate EV sales—along with the cross-subsidies from gasoline and diesel vehicle buyers—are leading manufacturers to abandon sales of the least expensive and higher fuel economy gasoline and diesel vehicles that do not receive similar subsidization.236 Cox Automotive found that "in December 2017, automobile makers produced 36 models priced at $25,000 or less. Five years later, they built just 10," pushing low-income buyers out of the new-car market and into the used- car market. Conversely, in December 2017 automobile manufacturers offered 61 models for sale with sticker prices of $60,000 or higher and in December 2022, they offered 90.237 This is unacceptable. EPA and its sister agencies cannot create credits and then claim they do not affect vehicle price solely because they have not sought to quantify them. [EPA-HQ-OAR-2022-0829-0733, pp. 51-52]

236 Steven G. Bradbury, Distinguished Fellow, The Heritage Foundation, Prepared Statement for the hearing entitled "Driving Bad Policy: Examining EPA's Tailpipe Emissions Rules and the Realities of a Rapid Electric Vehicle Transition," before the Subcommittee on Economic Grown, Energy Policy, and Regulatory Affairs of the U.S. House of Representatives Committee on Oversight and Accountability, at 10 (May 17, 2023) available at https://oversight.house.gov/wp-content/uploads/2023/05/Bradbury- Prepared-Statement-for-17-May-2023-Oversight-Hearing.pdf

237 See Sean Tucker, Are we witnessing the demise of the affordable car? Automobile makers have all but abandoned the budget market (MarketWatch Feb. 28, 2023), available at https://www.marketwatch.com/story/are-we-witnessing-the-demise-of-the-affordable-car-automakers-have-all-but-abandoned-the-budget-market-a68862f0 (last visited May 24, 2023).

Tellingly, EPA never estimates the annual price of a comparable ZEV and ICEV, for each year in which EPA proposes standards. EPA's bias towards EVs is demonstrated by EPA's statement that its OMEGA modeling "now incorporates a consumer choice element. This means that the impacts of, for example, a $40,000 BEV versus a $35,000 ICE vehicle of similar utility (i.e., a 14 percent increase for the BEV) is a much different consideration than a $6,000 incremental BEV cost versus a $1,000 incremental ICE cost (a 500 percent increase for the BEV)."238 In other words, EPA set up its model to show the consumer price (not the actual real-world cost) of EVs have a lower percentage cost increase than the incremental absolute cost of switching from ICEVs to ZEVs. [EPA-HQ-OAR-2022-0829-0733, pp. 51-52]

238 See RIA page 2-42, https://nepis.epa.gov/Exe/ZyPDF.cgi?Dockey=P10175J2.pdf.EPA incorrectly assumes that ZEV owners will pay the national average residential electricity price to charge their vehicles. EPA fails to consider that the majority of ZEVs in the U.S. are located in utility service territories with some of the highest electricity rates in the country and that the average EV owner currently pays a much higher price to charge their ZEV at home than the

national average residential electricity rate. Given that EV penetration has varied widely across the U.S., it would be arbitrary to assume that EVs will, unlike in the past, penetrate uniformly across the U.S. and thus that the average electricity price would be representative of the actual cost electricity. For example, California, which has roughly 40 percent of all registered ZEVs in the U.S., has a residential electricity rate that is roughly double the national average. Considering that EPA is modeling its rule after a California-like approach to mandate ZEVs, it would be more appropriate for EPA to assume similar real-world costs (at a minimum, given California's temperate climate). Moreover, EPA fails to consider that mandating such a high ZEV sales rate will necessarily require exponential increases in commercial ZEV charging at rates that are currently three, four or five times higher than the current national average residential electricity rate, depending on location and charging speed. Those customers who are not homeowners and not able to install their own charging stations and take advantage of charging at low-cost times will be adversely impacted. Instead, EPA uses a residential rate for electricity and does not consider peak power or time of use charges. California electric prices rose 42 percent - 78 percent between 2010 and 2020 and are projected to rise an additional 50 percent by 2030 as shown in Figure 9. [EPA-HQ-OAR-2022-0829-0733, pp. 57-58]

SEE ORIGINAL COMMENT FOR Historic and Forecasted Residential Average Rates Based on Most Recent 5-year Average Rate Increase. Figure 9:

Source: Michael Shellenberger, Twitter (citing California Public Advocate's Office data), April 27, 2021). [EPA-HQ-OAR-2022-0829-0733, pp. 57-58]

Heaping additional demand for EV charging into this market could exacerbate already high electricity prices. This will be especially impactful to lower-income homeowners who may not be able to install dedicated charging units, forcing them to pay more out of pocket for charging during peak demand periods.265 [EPA-HQ-OAR-2022-0829-0733, pp. 57-58]

265 Hardman, Scott, et al., "A Perspective on Equity in the Transition to Electric Vehicles." MIT Science Policy Review, (Aug. 20 2021), available at https://sciencepolicyreview.org/2021/08/equity-transition-electric-vehicles/ (accessed June 29, 2023).

EPA must revise its analysis to account for realistic electricity prices. The proposed ZEV mandate will require an enormous investment in power generation and distribution, resulting in nationwide increases in electricity bills that EPA has not considered. Of course, considering the additional trillions of dollars in costs would paint a clear picture that the costs of forced electrification far exceed even the inflated benefits EPA presented in the Proposed Rule. [EPA-HQ-OAR-2022-0829-0733, pp. 57-58]

Organization: American Fuel & Petrochemical Manufacturers

Ignoring actual ZEV production costs, including credit trading costs, is arbitrary and capricious. [EPA-HQ-OAR-2022-0829-0733, p. 54]

iii. EPA Must Consider Automobile Manufacturer Cross-Subsidies in Determining the Costs of the Proposal

While the purchase price differential between comparable ICEVs and ZEVs may be relevant for forecasting consumer demand, it does not reflect the true costs of the ZEVs required under the Proposed Rule. A ZEV typically costs tens of thousands of dollars more to produce than a comparable ICEV due primarily to the surging costs of critical minerals and resulting high costs of batteries.245 Additionally, the Proposed Rule will force manufacturers to sell an increasing percentage of ZEVs each year that goes far beyond the consumer demand for the product at its true cost. To ensure compliance with the ZEV mandate under the Proposal, manufacturers will be forced to incentivize ZEV purchases through a practice called cross-subsidization. [EPA-HQ-OAR-2022-0829-0733, pp. 53-54]

245 See PCMag, Profit vs. the Planet, (Sept. 26, 2022), Profit vs. the Planet: Here's Why US Automakers Are All-In on Electric Vehicles | PCMag last accessed July 3, 2023 ("EVs are currently more expensive to manufacture than gas-powered vehicles because of spiking battery costs. The cost of lithium, the main ingredient, has skyrocketed since demand far exceeds the number of working mines that can supply it.").

Automobile cross-subsidization is a pricing strategy to spread the high cost of ZEVs across a manufacturer's other product offerings. Under this pricing convention, manufacturers set the prices of certain ICEVs higher than their production costs to generate additional profits that can then be used to offset losses incurred by selling ZEVs below their actual production costs. This operates as a hidden tax on ICEVs and results in the purchasers of ICEVs subsidizing the sale of ZEVs. Without cross-subsidies, ZEV mandates would fail. [EPA-HQ-OAR-2022-0829-0733, pp. 53-54]

While opaque, the magnitude of ZEV cross-subsidies is significant.246 Ford's decision to report EV financial information separately beginning in 2023 provides an additional glimpse into the magnitude of cross-subsidization. Ford lost approximately $58,000 for each ZEV car it sold during the quarter.247 This reported per-vehicle loss is more than an order of magnitude greater than EPA's estimates of the price differential between the two technologies. While cross-subsidization, tax credits, emissions trading, and other EV subsidies may hide the true costs of a ZEV mandate from consumers, EPA has a duty to quantify and present those costs that are attributable to the Proposed Rule. Pursuant to Executive order 12866: [EPA-HQ-OAR-2022-0829-0733, pp. 53-54]

246 EPA's methodology ignores current EPA, DOE, NHTSA, and state regulations that add hundreds of billions of dollars in costs of ICEVs to cross-subsidize buyers of ZEVs. These cost transfers are in the form of: (1) state-mandated ZEV credit payments from ICEV manufacturers (i.e., ICEV buyers) to ZEV manufacturers (i.e., ZEV buyers); (2) current and future potential EPA GHG ZEV multiplier credit payments from ICEV manufacturers (i.e., ICEV buyers) to ZEV manufacturers (i.e., ZEV buyers); and, (3) NHTSA-mandated fuel economy ZEV multiplier credit payments from ICEV manufacturers (i.e., ICEV buyers) to ZEV manufacturers (i.e., ZEV buyers). A NHTSA presentation suggests that NHTSA EV multiplier credits alone subsidize each EV by more than $25,000, increasing the true average cost of every EV sold to over $90,000. See https://www.nhtsa.gov/sites/nhtsa.gov/files/2015sae-powell-altfuels_cafe.pdf; https://www.nhtsa.gov/sites/nhtsa.gov/files/2022-04/Model-Documentation_CAFE-MY-2024-2026_v1-tag.pdf; https://one.nhtsa.gov/cafe_pic/home/ldreports/manufacturerPerformance. Per the NHTSA information above, since MY2017 standards were ~35mpg and MY2017 Tesla FE performance (with multipliers) was 518.7 mpg, and since Tesla sold ~46,979 MY2017 vehicles in the U.S., then Tesla in MY2017 generated 227 million excess credits. If the market-value of these credits is ~$5.50 per 0.1 mpg shortfall per vehicle under the MY2017 CAFE standard of ~35 mpg, then these credits were worth approximately $1.25 billion, or $26,600 per EV that Tesla sold. [Calculation of estimated value: Credits = (518.7 – 35) x 46979 x 10 x CAFE Penalty of $5.50 per 0.1 mpg shortfall per vehicle]. Tesla may have banked, traded, or sold these credits. Tesla MY2022 sales in the U.S. were 484,351 and the CAFE civil penalty is now $15 per 0.1 mpg shortfall per vehicle.

247 See Luc Olinga, TheStreet, Ford Loses Nearly $60,000 for Every Electric Vehicle Sold, (May 2, 2023) available at Ford Loses Nearly $60,000 for Every Electric Vehicle Sold - TheStreet (last accessed July 3, 2023).

EPA is to "assess all costs and benefits of available regulatory alternatives, including the alternative of not regulating. Costs and benefits shall be understood to include both quantifiable measures (to the fullest extent that these can be usefully estimated) and qualitative measures of costs and benefits that are difficult to quantify, but nonetheless essential to consider.248 [EPA-HQ-OAR-2022-0829-0733, pp. 53-54]

248 E.O. 12866, Section 1(a), Sept. 30, 1993.

Astonishingly, EPA makes no attempt to account for these real-world costs, nor to communicate to the public that, as the Proposal mandates a higher percentage of ZEV sales, the cross-subsidies must be paid for by a shrinking number of ICEV buyers and, therefore, must significantly increase the average price of EVs. As EV prices rise, their sales and ICEV fleet turnover will slow, reducing environmental benefits and creating a significant drag on the economy. [EPA-HQ-OAR-2022-0829-0733, pp. 54-55]

Organization: American Honda Motor Co., Inc.

Of particular interest to Honda when evaluating the model was OMEGA's new capability of assessing consumer-producer interactions, described by the agency below:

Among the key new features of OMEGA is the representation of consumer-producer interactions when modeling compliance pathways and the associated technology penetration into the vehicle fleet. This capability allows us to project the impacts of the producer and consumer incentives contained in the IRA and BIL legislation. Compared to the previous model version, the updated version of OMEGA has extended capability to model a wider range of GHG program provisions, and it has been critical in the assessment of various policy alternatives that were considered for this proposal.44 [EPA-HQ-OAR-2022-0829-0733, pp. 53-54]

44 88 Fed. Reg. 29294 (May 5, 2023)

In addition to being able to model incentives such as those offered as part of the IRA, OMEGA also models (within user-specified bounds, and market classes) the price adjustments (incentives and disincentives) placed on vehicles by producers to reach an equilibrium between ICE and BEV sales share, also known as a cross subsidized price. This new aspect of the model provides fascinating insight into the agency's logic of optimized OEM compliance, and the broader impact of regulatory policies on both industry and consumers. By examining OMEGA model output files associated with the agency's official regulatory proposal, one can ascertain which vehicles and market classes the agency reasonably believes would require discounts in order to drive greater sales in support of the proposal's compliance goals and, conversely, which vehicles would be expected to shoulder the burden of offsetting those discounts by means of increased prices. [EPA-HQ-OAR-2022-0829-0733, pp. 53-54]

When aggregating the agency's output data by powertrain technology type (ICE, HEV and BEV), a clear pattern emerges. For the agency proposal, which includes an assumption that IRA provisions for both battery production and consumer tax credits will see near-full utilization, the model's optimized solution set suggests BEVs are the logical cost-effective technology pathway. In fact, during the regulation's years in which incentives are assumed to be in effect (MY2027-2032), OMEGA assumes that BEVs will shoulder a modest cost increase (of about $650 per vehicle, on average) to cross-subsidize reductions in ICE and hybrid vehicle prices required to reach a producer and consumer equilibrium. [EPA-HQ-OAR-2022-0829-0733, pp. 53-54]

Beginning in MY2033, however – when IRA provisions are no longer available – the agency's modeling results show a staggeringly different calculus. While BEVs are still needed to meet the agency's stringent emissions standards, the phase-out of 45X and sudden loss of consumer purchase incentives means that the non-subsidized price of EVs suddenly become much higher relative to the gasoline vehicle equivalent, and are no longer economically viable for consumers at the mix shares predicted by the compliance model just one year prior. In order to maintain the high levels of producer EV penetration achieved to date, the model assumes that a sudden and substantial cross-subsidization occurs from ICE and HEV models (i.e., the producer increases the prices of ICE and HEV vehicles and applies that additional revenue to accommodate a price reduction on EVs). [EPA-HQ-OAR-2022-0829-0733, pp. 53-54]

The levels of cross-subsidization required for EVs absent IRA 45X and 30D are not small. The agency's own model calculates that in order to support the sales mix of EVs required by the proposed rule, $10-14 billion per year in price subsidies would be required in MYs 2033-2035. These BEV price subsidies would need to be offset by higher costs of an ICE fleet that is, by the agency's own design, dwindling in size. According to OMEGA model outputs, this amounts to an increase (relative to 2032) of between $2,626 and $3,368 for every ICE and HEV vehicle sold in MYs 2033-2035, as shown in Figure 4. Moreover, should the agency's optimistic forecasts about future battery costs not materialize as envisioned by the agency, these costs will be even higher. It is unclear whether the agency considered these costs – which will ultimately be borne by consumers – in its regulatory analysis, or whether 2033-2035 is being considered "outside the scope" of the 2027-2032 regulatory window. [EPA-HQ-OAR-2022-0829-0733, pp. 53-54]

SEE ORIGINAL COMMENT FOR GRAPH of Figure 4. OMEGA 2.0 annual producer cross subsidization results for ICE (includes conventional and hybrid vehicles) under EPA's Proposed Scenario. Positive numbers indicate price increases to subsidize BEV technologies; negative numbers indicate decreases in prices. [EPA-HQ-OAR-2022-0829-0733, pp. 53-54]

Not surprisingly, the situation would become even more problematic if IRA provisions do not pan out in a manner consistent with the agency's expectant predictions. To investigate this, Honda created two custom OMEGA runs, both of which are based on EPA's Proposed Regulatory Scenario stringency and retain all other EPA proposal assumptions except for those relating to 45X and 30D. One scenario reduces the agency's assumed amount of utilized IRA 45X and 30D incentives by 50 percent. The other scenario eliminates the 45X and 30D incentives entirely. [EPA-HQ-OAR-2022-0829-0652, pp. 25-26]

The cumulative cross subsidization impacts for these two OMEGA 2.0 runs for MYs 2027-2035 are shown in Figure 5 below. Unlike the agency's Proposed Scenario shown in Figure 4, in which the IRA provisions buoy the high costs of electric vehicles through 2032, these alternate scenarios illustrate that BEV technology would need to be cross-subsidized by ICE technology from year one of the regulation, reaching extraordinary cumulative amounts by the mid-2030s. While there could be some additional application of emissions reduction technology to ICE vehicles, the severity of the standards still dictates large-scale adoption of BEVs. As such, the OMEGA 2.0 model cross subsidization outputs (which are, incidentally, bounded and thus conservative) show that partial or full loss of IRA incentives under the agency's proposed standards would drive a "regulatory premium" of $632-$1,461 for every ICE and HEV vehicle sold in 2027, and $1,025-$2,344 for every ICE and HEV vehicle sold in 2032.45 It is important to note that these runs retain the agency's battery cost assumptions (with the exception of IRA

45X incentives) which, as noted in our comments above, we believe to be optimistic for a number of reasons. As such, Honda believes the numbers output by OMEGA and reflected in this chart represent a conservative estimate. [EPA-HQ-OAR-2022-0829-0652, pp. 26-28]

45 The range reflects OMEGA 2.0 results in which IRA provisions are cut in half vs. eliminated.

SEE ORIGINAL COMMENT FOR GRAPH of Figure 5. Cumulative OMEGA 2.0 cross subsidization for BEV models under three scenarios: EPA's Proposal, a "50% IRA" scenario, and a "No IRA" scenario. Positive values indicate a subsidization of BEVs by other technologies. [EPA-HQ-OAR-2022-0829-0652, pp. 26-28]

It is critical that the impact of a potentially significantly higher new vehicle transaction price on total sales be accounted for by the agency. Unfortunately, the agency's analysis is extremely limited, as their sensitivity cases are independently analyzed and omit the possibility of IRA being weakened. Honda attempted to quantify the impact that a "stacking" of uncertainties would have on average new vehicle price. We examined average new vehicle price from OMEGA 2.0 under EPA's proposal (shown in light blue in Figure 6, below), as well as the resulting increase in price that would occur under two additional stacked scenarios: (1) elimination of IRA incentives, and (2) EPA's high battery cost assumptions. As shown in Figure 6, the cumulative impact of these two uncertainties could increase the average new vehicle price by more than $8,600 (a 25% increase) in 2030, relative to the agency's proposal. [EPA-HQ-OAR-2022-0829-0652, pp. 26-28]

Qualitatively, one would assume that such a significant increase in price would have a noticeable quelling effect on new vehicle sales. Strangely, the agency's OMEGA output files show very little impact on overall sales, despite the significant price increase. The agency's modeled sales impacts show a long run demand elasticity of just -0.21, notably different than values cited in EPA's Draft RIA as well as by other industry experts.46 47 As shown in Table 3 below, the implication of a different demand elasticity has a significant impact on the magnitude of overall new vehicle sales. If actual demand elasticities are closer to -0.40 (EPA estimate) or -0.61 (CAR estimate), loss of sales due to a 25% price increase would be between 1.5 million and 2.3 million new vehicle sales annually. One can speculate on the potential impact that such a loss of sales would have both on the industry and the economy, as well as the impact on consumer choice, vehicle affordability and equity. [EPA-HQ-OAR-2022-0829-0652, pp. 26-28]

Available online at https://www.cargroup.org/wp-content/uploads/2017/02/The-Potential-Effects-of-the-2017_2025-EPANHTSA-GHGFuel-Economy-Mandates-on- the-US-Economy.pdf

While one could argue these are merely modeling outputs, and that automakers would pursue countermeasures to minimize such impacts, the fact remains that the agency is predicating its proposed standards on this very same model. This model confirms that the economic viability of the agency's proposal rests heavily – one might argue entirely – on a suite of policy incentives that nobody, including the agency, can guarantee will exist through 2032. It is these considerations of uncertainty and risk that manufacturers must take into account when developing future products and, similarly, that the agency must consider when developing future regulations. In our opinion, the agency has not adequately addressed this uncertainty. [EPA-HQ-OAR-2022-0829-0652, pp. 26-28]

SEE ORIGINAL COMMENT FOR GRAPH Figure 6. Average new vehicle price from OMEGA 2.0 under proposal and two alternate scenarios. [EPA-HQ-OAR-2022-0829-0652, pp. 26-28]

Table 3.Magnitude of new vehicle sales impacts caused by higher battery cost and loss of IRA incentives. Calculations were performed using OMEGA 2.0. For comparison, sales impacts with alternate demand elasticities are shown. [EPA-HQ-OAR-2022-0829-0652, pp. 26-28]

Market Conditions: OMEGA 2.0: High Battery Cost & No IRA

Avg. New Vehicle Price Change Relative to Proposal: +25%

Elasticity of Demand: -0.21

New Vehicle Market Sales Change Relative to Proposal: (372,194) [EPA-HQ-OAR-2022-0829-0652, pp. 26-28]

Market Conditions: Impact assuming Demand Elasticity of -0.4

Avg. New Vehicle Price Change Relative to Proposal: +25%

Elasticity of Demand: -0.40 a

New Vehicle Market Sales Change Relative to Proposal: (1,511,130) [EPA-HQ-OAR-2022-0829-0652, pp. 26-28]

Market Conditions: Impact with Demand Elasticity of -0.61

Avg. New Vehicle Price Change Relative to Proposal: +25%

Elasticity of Demand: -0.61 b

New Vehicle Market Sales Change Relative to Proposal: (2,304,473) [EPA-HQ-OAR-2022-0829-0652, pp. 26-28]

Recommendation: Should the agency continue to set standards based on an inclusion of IRA and BIL incentives, the agency should similarly provide a mechanism for alternate standards subject to their removal or weakening. [EPA-HQ-OAR-2022-0829-0652, pp. 26-28]

1. The Lead Time and Costs of Applying Zero-Emission Technologies Are Adequate and Reasonable

As EPA observes, its modeling anticipates auto manufacturers will meet the proposed standards primarily through increased application of zero-emission technologies and secondarily through application of certain advanced combustion technologies. 88 Fed. Reg. at 29,329-30. Thus, the majority of the proposed standards' costs are likely attributable to EPA's projected increase of electric vehicle penetration rates in model-year 2032 from 39% in the no-action case to 67% under the Proposal. EPA's analysis properly accounts for the key challenges in applying zero- emission technologies on this scale—especially the need to build out critical mineral, battery, and chip supply chains—by simulating likely constraints on auto manufacturers' electric vehicle production in its modeling. Id. at 29,295; Draft RIA, at 3-22 to 3-26. EPA's approach to mineral supply constraints appropriately incorporates the effect the battery component supply chain has on its standards without asserting authority over sectors outside its regulatory purview. [EPA-HQ-OAR-2022-0829-0746, pp. 33-34]

First, EPA assumes that auto manufacturers will produce electric vehicles to comply with standards in a "purely cost-minimizing" way. 88 Fed. Reg. at 29,296. As EPA acknowledges, however, auto manufacturers have planned for far higher rates of electric vehicle sales in response to both policies that recognize the significant role of the internal combustion engine in the climate crisis and the surging demand for electric vehicles. Id. A model of industry behavior that minimizes costs without accounting for these other drivers of electric vehicle adoption likely understates electric vehicle penetration in a no-action scenario.186 And, given that respected organizations like Bloomberg New Energy Finance are estimating battery electric vehicle penetrations rates near 52% by 2030 even without considering EPA's proposed standards,187 EPA's no-action scenario projection of 40% penetration is likely an underestimation. See 88 Fed. Reg. at 29,329 (Table 81). [EPA-HQ-OAR-2022-0829-0746, pp. 33-34]

186 See Consumer Reports Amicus Brief, Doc. No. 1988445 in Texas v. EPA, Case No. 22-1031 (D.C. Cir. Mar. 3, 2023), at 4-15.

187 Ira Boudway, More Than Half of US Car Sales Will Be Electric by 2030, Bloomberg (Sep. 20, 2022), available at https://www.bloomberg.com/news/articles/2022-09-20/more-than-half-of-us-car-sales-will- be-electric-by-2030.

Organization: Clean Fuels Development Coalition et al.

And the real costs will be far higher than EPA projects. As the comment will show, EPA's cost analysis is flawed in at least a dozen ways. Most egregiously, EPA assumes without support—and with scarcely a mention in the proposed rule or Draft Regulatory Impact Analysis (DRIA)—that baseline vehicle manufacturing costs it uses to determine all future costs are two-thirds of a vehicle's current MSRP. But EPA knows this is not true. As far as commentors can tell, every electric vehicle currently on the market costs significantly more to make than it sells for. Ford, for example, loses about $60,000 on every electric vehicle it sells. If EPA used accurate vehicle manufacturing costs in its projections, compliance costs would rise proportionately, and the cornerstone of EPA's feasibility analysis would crumble. Fixing just the underestimated vehicle technology costs would raise the proposal's price tag to more than $4,700 per ton of CO_2, while making EPA's projected electric vehicle penetration rates, and thus proposed standards, unachievable. [EPA-HQ-OAR-2022-0829-0712, p. 2]

These aggregate costs include:

- Real electric vehicle costs. Not what manufacturers sell their vehicles for, but the actual cost to build these vehicles. EPA incorrectly assumes that there is currently no cross subsidization between electric vehicles and internal combustion engine vehicles, despite relying on California's Advanced Clean Cars programs which create subsidies of at least $3,500 per electric vehicle through ZEV credits. See Cristian Agatie, Tesla Sits on a Billion dollar Chest of ZEV Credits That Other Carmakers Are Keen to Buy, Auto Evolution (Sep. 12, 2022), https://www.autoevolution.com/news/tesla-sits-on-a-billion-dollar-chest-of-zev-credits-that-other-carmakers-are-keen-to-buy-198418.html ("To give you an idea, Tesla posted $2.1 billion in revenue from ZEV credit sales in 2021 and Q1 2022 combined. Automotive News estimates Tesla sold its ZEV credits at an average of $3,500.") Most vehicles receive 3 or 4 credits. [EPA-HQ-OAR-2022-0829-0712, pp. 5-6]

A. The proposed rule underestimates the current manufacturing cost of electric vehicles, skewing future vehicle technology costs.

All of EPA's projections for vehicle sales were calculated using the OMEGA model. See 88 Fed. Reg. 29,294–95. The OMEGA model takes as input a bevy of information about vehicles currently sold by every manufacturer and uses this to project how each manufacturer can update its current fleet with by adding new technologies to meet EPA's proposed standards most cost-effectively. These projections are the basis of all of EPA's calculations about the rule: feasibility, vehicle costs, emissions reductions, etc. [EPA-HQ-OAR-2022-0829-0712, pp. 15-16]

Crucial to OMEGA's projections is its simulation of the adoption of new vehicle technologies. See OMEGA 2.1.0 Documentation (last accessed July 5, 2023), https://omega2.readthedocs.io/en/latest/. The model assumes that every vehicle on the road has some baseline manufacturing costs. These manufacturing costs change as auto manufacturers add new technologies to existing vehicles to reduce emissions as they seek to comply with the standards. Every new technology comes with some "cost curve," which represents the added cost of using this new technology over time. Id. When a vehicle adopts a new technology, this cost curve is added to a vehicle's baseline manufacturing cost, which the model then uses to project the vehicle price or MSRP. Id. This means that future projections of vehicle prices are critically dependent on an accurate picture of current vehicle manufacturing costs. If the model underestimates current manufacturing costs, all future manufacturing costs—and thus future MSRP's—will be underestimated proportionately. [EPA-HQ-OAR-2022-0829-0712, pp. 15-16]

But OMEGA cannot accept vehicle manufacturing cost as an input. Instead, the model uses "the base year vehicle's MSRP value as the [manufacturing cost] for the base year" making the assumption that current MSRPs are just "a marked up value of direct manufacturing costs using a 1.5X retail price equivalent (RPE) multiplier." Email of Kevin Bolon, EPA, to Taylor Myers, Boyden Gray & Associates (June 27, 2023) (Attached as Appendix A). EPA acknowledges that "there may be existing cross subsidies that are already inherent in the empirical MSRP values," i.e., manufacturers may raise the MSRPs of internal combustion engine vehicles while lowering those of electric vehicles to meet regulations while sustaining overall profitability. Id. But because the agency "cannot observe" these cross subsidies, it has designed the OMEGA to assume a "cross_subsidy_multiplier of 1.0 for all vehicles" in the baseline year. Id. [EPA-HQ-OAR-2022-0829-0712, pp. 16-17]

This is an unreasonable assumption. There is overwhelming evidence that the manufacturing costs for electric vehicles far exceed their current MSRPs and that current prices are the result of (large) cross subsidization. For example, Ford recently split its electric vehicle sales off from its internal combustion engine sales for accounting purposes: Ford e Segment sells the former while Ford Blue sells the latter. The company's 2023 Q1 SEC filings show the revenue and costs per unit for both types of vehicles. See Ford Motor Company, Form 10-Q, 2023 Q1, https://s201.q4cdn.com/693218008/files/doc_financials/2023/q1/ford-q1-2023-10-q-report.pdf. The filing shows that while the company as a whole was profitable, Ford e Segment was not. ICE vehicles returned a profit of about $3,700 per vehicle, or about 10 percent of average vehicle revenue. By contrast, electric vehicles lost $60,000 per vehicle, meaning that each vehicle represented a more than 100 percent loss. Id. [EPA-HQ-OAR-2022-0829-0712, pp. 16-17]

Figure 1: Ford's electric vehicles cost $60,000 more to make on average than they were sold for.

Ford Blue (ICE)

Units: 706,000

Revenue: $ 25,124,000,000

EBIT: $ 2,623,000,000

Revenue per unit: $ 35,586

Cost per unit: $ 31,871

Profit per unit: $ 3,715

Ford e Segment (EV)

Units: 12,000

Revenue: $ 707,000,000

EBIT: $ (722,000,000)

Revenue per unit: $ 58,917

Cost per unit: $ 119,083

Profit per unit: $ (60,167)

[EPA-HQ-OAR-2022-0829-0712, pp. 16-17]

Other companies' statements confirm similar losses. Chrysler Automobiles CEO Sergio Marchionne explained that while the electric Fiat 500e has an MSRP of about $33,000, the company is losing about $20,000 per car on each sale: a 60 percent loss. Matthew DeBord, FCA Loses a Staggering $20,000 on Every One of Its All Electric Cars, Business Insider (Oct. 2, 2017), https://www.businessinsider.com/fca-loses- 20000-on-every-one-electric-car-2017-10. General Motors' Chevrolet Volt and Bolt EV both lost approximately $16,000 per unit. [EPA-HQ-OAR-2022-0829-0712, pp. 17-18]

Manufacturers are willing to sustain a high loss on electric vehicles because, under EPA, NHTSA, and California's regulatory schemes, these vehicles are helpful (and now, necessary) to meet fleet standards.10 As Marchionne explained, the company is willing to sell each vehicle for a loss because electric vehicles like the "500e also ha[ve] value as [ ] 'compliance vehicle[s],' helping FCA meet government-mandated fuel-economy requirements for [an] automaker's fleet." Id. [EPA-HQ-OAR-2022-0829-0712, pp. 17-18]

10 Historically, the benefit of EVs towards compliance obligations has been largely due to the prevalence of unlawful "EV multipliers," discussed infra.

These losses are accepted because of the value of the regulatory cross subsidies. An automaker charges less for an electric vehicle—expecting to take a loss—so it can sell more of them, and take advantage of their favorable regulatory treatment to com ply with federal standards. But to ensure that it is not losing money as a whole, the manufacturer simultaneously raises prices—and thus profits—on its internal combustion engine vehicles to offset the electric vehicle losses. And because electric vehicles are treated more favorably in all relevant regulations, these cross subsidies always go one way: from internal combustion engine vehicles to electric vehicles. [EPA-HQ-OAR-2022-0829-0712, pp. 17-18]

EPA acknowledges that cross subsidization has a real impact. The OMEGA model expects manufacturers to cross subsidize into the future to encourage sales of lower emitting, but more expensive, technologies. Figure 2 below shows the cross- subsidization multiplier, or what multiple of a natural, unsubsidized MSRP it expects the vehicles to sell for. The OMEGA modeling used in the proposal arbitrarily limits this cross-subsidization multiplier to values of between 0.9 and 1.1, or 10 percent. It also unreasonably permits manufacturers to cross subsidize internal combustion engine vehicles with electric vehicles, a result that would never be logical because electric vehicles are always treated more favorably by the regulations. [EPA-HQ-OAR-2022-0829-0712, pp. 17-18]

SEE ORIGINAL COMMENT FOR Figure 2: The cross-subsidization multiplier for all electric vehicles calculated in the proposal. [EPA-HQ-OAR-2022-0829-0712, pp. 17-18]

Even more unreasonably, EPA assumes that current vehicles are not cross subsidized at all. While the exact magnitude of cross subsidies may be difficult to calculate precisely, EPA knows that at minimum each electric vehicle is cross subsidized by in an amount equivalent to the number of California ZEV Credits it earns. California's ZEV mandate requires automobile manufacturers to acquire a minimum number of ZEV credits either by producing ZEVs for sale in California or purchasing credits from another auto manufacturer who has done the same. Of all the manufacturers, Tesla had earned the most credits in California. Simon Alvarez, Tesla's ZEV Credits in the United States are Poised to Become Even More Valuable, Teslarati (Sep. 12, 2022), https://www.teslarati.com/tesla-zev-credits-usa-more-valu- able-inflation-reduction-act/. At the end of 2020, Tesla had logged a stockpile of 752,445 credits, with each new vehicle sold qualifying for between 3 and 4 credits. Id. "Tesla booked about $2.1 billion in revenue from credit sales in 2021 and Q1 2022. And while the value of a ZEV credit could be flexible depending on demand, it appeared that Tesla averaged about $3,500 each." Id. In other words, every Tesla was subsidized by at least $10,500. [EPA-HQ-OAR-2022-0829-0712, pp. 18-20]

Based on the above information, reasonable estimates of cross subsidies for electric vehicles must be between $10,500 and $60,000 per electric vehicle sold. These cross subsidies are equivalent to the difference between EPA's estimated vehicle manufacturing costs and the true vehicle manufacturing costs. While EPA is free to—and obligated to—conduct its own (perhaps different) analysis of the precise magnitude of cross subsidization, it cannot ignore it. Accounting for these cross subsidies results in a much higher new vehicle manufacturing costs for electric vehicles.11 When these overlooked manufacturing costs are applied to each of the additional 15 million electric vehicles EPA projects its proposal to require between 2027 and 2032,12 vehicle technology costs rise by between $160–915 billion over the compliance period. See Figure 3. [EPA-HQ-OAR-2022-0829-0712, pp. 18-20]

11 The same cross subsidization also implies a lower new vehicle manufacturing cost for internal combustion engine vehicles, which the proposal also ignores.

12 This assumes 13.7 million cars sold per year and electric vehicle penetrations for the no action case and the proposal to follow Tables 129 and 80 of the proposal, respectively.

SEE ORIGINAL COMMENT FOR Figure 3: Projected additional manufacturing costs EPA missed as a result of overlooking cross subsidization. [EPA-HQ-OAR-2022-0829-0712, pp. 18-20]

Accounting for cross subsidization is critical for the feasibility analysis because it will have a direct impact on future vehicle prices. As EPA forces electric vehicles to grow from 6 percent to 67 percent of light-duty sales, automakers will lose the ability to accommodate large cross subsidies in electric vehicle price with small increases across conventional vehicle prices because there will no longer be 12 times as many internal combustion engine vehicles as electric vehicles, but instead 2 times as many electric vehicles as internal combustion engine vehicles. If, for example, it continues to cost Ford $120,000 to manufacture an electric vehicle, EPA's proposed fleet would raise the average Ford vehicle price from around $36,000 today to $92,000 in 2032. Like all Ponzi schemes, EPA's plan will inevitably hit a wall. [EPA-HQ-OAR-2022-0829-0712, pp. 20-21]

Failing to account for these costs, and how cross subsidization will become less feasible as the fleet is electrified, papers over the most important aspect of the problem. EPA must make these calculations when projecting the feasibility of the rule. [EPA-HQ-OAR-2022-0829-0712, pp. 20-21]

Organization: Environmental. and Public Health Organizations

2. The OMEGA2 model produces unlikely results for combustion vehicles.

As noted above, the OMEGA2 model suffers from significant shortcomings in terms of capturing the potential improvement available from technologies applicable to combustion vehicles. However, there is also a problem with the way in which the OMEGA2 model assumes manufacturers then apply those technologies: not only can manufacturers add new technology, but they can remove it. The level of so-called "decontenting" that occurs in the OMEGA2 model is neither unrealistic, and it drastically underestimates the improvements from combustion vehicles that would likely be deployed for a given PEV scenario. [EPA-HQ-OAR-2022-0829-0759, p. 40]

In the Proposal modeling, 40% of the combustion vehicle models have worse 2-cycle tailpipe GHG emissions in 2032 than in 2022. On average, that 40% of the fleet has increased its emissions by 13%, or 27 g/mi. For reference, this decline in emissions performance approximates a return to 2016 levels of tailpipe emissions for those vehicles (i.e., those vehicles would achieve no net progress over a 16-year period). Of course, the remaining combustion vehicle fleet sees plenty of backsliding in this time as well. While manufacturers may not have fully slipped back to 2022 levels, OMEGA2 modeling finds that through the course of the 2022-2032 period, manufacturers are more than twice as likely to make the direct CO2 emissions from a combustion vehicle worse year-to-year, increasing year-to-year emissions 22% of the time, keeping them unchanged 69% of the time, and reducing emissions just 9% of the time. And this percentage increases dramatically between the years governed by the current standards and the

Proposal: the modeling shows that manufacturers are much more likely to decrease the emissions of a combustion vehicle to achieve compliance with the MY 2023-2026 standards (15%, compared to 9% for the proposed MY 2027-2032 standards), and are 6 times more likely to decontent a combustion vehicle in the 2027-2032 period than in the 2023-2026 period. [EPA-HQ-OAR-2022-0829-0759, p. 41]

Notably, the modeling of manufacturer behavior described above does not distinguish between the magnitudes of the reduction/increase in emissions. On average, emissions reductions from the combustion vehicle fleet under the existing standards greatly outweigh the average increases, since improving combustion vehicles is a significant compliance mechanism for the current standards. Interestingly, the magnitude of the average increase vs. decrease does not vary substantially over the entire decade (2022-2032). Instead, the disparity in outcome (combustion vehicles increasing, rather than decreasing, emissions) is entirely driven by the massive increase in decontenting that begins to occur in the modeling in the post-2026 period. [EPA-HQ-OAR-2022-0829-0759, p. 41]

EPA provides no explanation for this rapid shift in modeled manufacturer behavior in the documentation for the rule, and such behavior makes little sense, particularly when examining cases of decontenting that occur in the modeled compliance for the Proposal. To the extent that manufacturers may consolidate engine platforms as they reduce the number of available combustion vehicles, that consolidation is not likely to happen on the oldest, lowest technology options but rather on the newest engine platforms, in order to avoid accelerated depreciation of new investments. While there may be some simplification, it is more likely that the simplification would be elimination of a lower-volume technology package, such as a high-performance (and higher emission) option, which again would not result in increases in emissions. Below we present two examples to illustrate the unrealistic aspects of the compliance model for technology content, in consideration of industry behavior. [EPA-HQ-OAR-2022-0829-0759, p. 41]

a. Example: Volvo S60

The Volvo S60 is available in multiple configurations and is represented by three different vehicles in the OMEGA2 model: two conventional vehicles (one of which is a high-performance trim with greater horsepower), and one strong hybrid (incidentally utilizing the Miller cycle engine benchmarked by EPA). The modeled technology packages for these vehicles are illustrated in Table VI.A-1. In 2026, the first redesign opportunity is available for the model. The vehicles undergo one major change to the platform (a shift from steel to aluminum cuts a significant amount of weight), and then the three engines move to the same exact configuration, a 48V mild hybrid with a high compression ratio (HCR) engine utilizing discrete cylinder deactivation. The power output for the former-hybrid and the high-performance trim are virtually identical, which is why the emissions numbers are so similar in 2026, effectively reducing the trims available to two. This type of consolidation could happen, though eliminating the high-tech Miller cycle engine (part of one of the most efficient technology packages implemented by EPA) from the vehicle after just one product cycle is unlikely. And, at least in this case, on net the former-hybrid vehicle still sees a reduction in emissions due to the weight reduction. [EPA-HQ-OAR-2022-0829-0759, pp. 41-42]

Table VI.A-1: Comparison of technology packages, fuel economy, and emissions for the Volvo S60 at each redesign

Volvo S60 T8 (313 hp)

Year: 2021

Tech package: SHEV-PS, Miller cycle

Body Material: Steel

Tailpipe CO2 (lab) [g/mi]: 194

Label Fuel Economy [mpg]: 35.4

Year: 2026

Tech package: MHEV (P0), HCR + continuous cyl. deac., advanced 8-speed AT

Body Material: Aluminum

Tailpipe CO2 (lab) [g/mi]: 181

Label Fuel Economy [mpg]: 38.9

Year: 2031

Tech package: HCR + continuous cylinderdeactivation, 5-speed AT

Body Material: Steel

Tailpipe CO2 (lab) [g/mi]: 236

Label Fuel Economy [mpg]: 33.5

Volvo S60 T5 (316 hp)

Year: 2021

Tech package: Start-stop, Turbo, advanced 8-speed AT

Body Material: Steel

Tailpipe CO2 (lab) [g/mi]: 225

Label Fuel Economy [mpg]: 32.7

Year: 2026

Tech package: MHEV (P0), HCR + continuous cyl. deac., advanced 8-speed AT

Body Material: Aluminum

Tailpipe CO2 (lab) [g/mi]: 183

Label Fuel Economy [mpg]: 38.2

Year: 2031

Tech package: HCR + continuous cylinder deactivation, 5-speed AT

Body Material: Steel

Tailpipe CO_2 (lab) [g/mi]: 268

Label Fuel Economy [mpg]: 30.7

Volvo S60 T4 (250 hp)

Year: 2021

Tech package: Start-stop, Turbo, advanced 8-speed AT

Body Material: Steel

Tailpipe CO_2 (lab) [g/mi]: 206

Label Fuel Economy [mpg]: 34.4

Year: 2026

Tech package: MHEV (P0), HCR + continuous cyl. deac., advanced 8-speed AT

Body Material: Aluminum

Tailpipe CO_2 (lab) [g/mi]: 170

Label Fuel Economy [mpg]: 40.1

Year: 2031

Tech package: HCR + continuous cyl. deac., 5-speed AT

Body Material: Steel

Tailpipe CO_2 (lab) [g/mi]: 237

Label Fuel Economy [mpg]: 32.2

In 2031, however, the vehicle platform reverts from aluminum back to steel, gaining weight in the process. All three vehicles drop the mild hybrid configuration but introduce three completely distinct engine technologies, again less efficient than the prior offerings, and now paired with a 2007-era 5-speed transmission instead of the advanced 8-speed transmission of the previous generation. To summarize, under EPA's modeling, the S60 in 2031 will: 1) revert to an old body platform and an ancient transmission; 2) adopt engine technology that will reduce fuel economy for consumers by 8 mpg, below what the vehicle started at in 2022 for all configurations; and 3) not do anything to consolidate engines or platforms, or do anything else that could justify decontenting, because there remain three distinct engine offerings. There is little reason to suppose that Volvo (or any other manufacturer) would be able to find consumers for a combustion vehicle, such as the modeled S60, that gets notably worse over time. [EPA-HQ-OAR-2022-0829-0759, p. 43]

b. Example: Jeep Cherokee

A similar trajectory is observed in the case of the Jeep Cherokee (Table VI.A-2). In this case, the modeled vehicle does not correspond directly to each of the real vehicle's trims but is instead averaged into a high- and low-throughput engine option for the 2WD and 4WD versions.126 However, the pattern of vehicle change in the modeling is the same: each vehicle is first upgraded and then downgraded, with 3 of the 4 model variants ending up worse than they started a decade prior. [EPA-HQ-OAR-2022-0829-0759, p. 43]

126 While Jeep has since dropped the 2WD version of the Cherokee, this is not reflected in EPA's model due to the use of a 2019 baseline fleet.

SEE ORIGINAL COMMENT FOR Table VI.A-2: Comparison of technology packages, fuel economy, and emissions for the Jeep Cherokee at each redesign [EPA-HQ-OAR-2022-0829-0759, pp. 43-44]

What makes this behavior particularly unrealistic in the case of the Jeep Cherokee is that the parent company (Stellantis) is, according to the model, purchasing credits from other manufacturers in order to comply with the standards after the 2029 model year (Figure VI.A-3). In other words, the model projects that it is in Stellantis' interest to increase emissions from its combustion-powered vehicles (even though there is no concurrent improvement in performance-related vehicle attributes), and this strategy results in the manufacturer falling short of its regulatory requirements, which then forces the company to purchase credits from its competitors. [EPA-HQ-OAR-2022-0829-0759, p. 44]

SEE ORIGINAL COMMENT FOR Figure VI.A-3: Year-over-year average certification for Stellantis (formerly FCA), from EPA's Proposal modeling run [EPA-HQ-OAR-2022-0829-0759, p. 45]

In all years modeled, Stellantis is reliant upon banked credits in order to comply with the standards, as indicated by the difference between the target curve (blue dots) and the calendar year certification (red circles). Stellantis is able to use its own banked credits (indicated through credit transactions via arrows) in order to comply with the standards through the 2026 model year, indicated by the overlap between the model year certification (orange line) and target curve. However, beginning with the 2026 model year, those credits (including credits carried back from the 2029 model year) are no longer sufficient for Stellantis to meet its requirements. Therefore, Stellantis is required to make up the remaining gap between model year and target year curves with credits purchased on the general market (not modeled explicitly by the Agency). [EPA-HQ-OAR-2022-0829-0759, p. 45]

3. In allowing combustion vehicles to backslide, the OMEGA2 model fails to capture readily achievable emissions reductions; adjusting these features would further support the feasibility of stronger standards.

By allowing combustion vehicles to backslide in its modeling, EPA fails to consider a significant pathway for potential emissions reductions. By 2032, this backsliding results in nearly a 10% increase in tailpipe emissions from the fleet. In terms of feasibility, it is beyond question that the decontented combustion vehicle technologies can be deployed in the timeframe of the rule, since these technologies had previously been on those vehicles. Since manufacturers will not incur any new costs for research and development and will simply be elongating the period for which they can utilize their investments, it would be more reasonable for the model to assume that manufacturers would not remove such technologies, thus preserving emissions levels already achieved. [EPA-HQ-OAR-2022-0829-0759, pp. 45-46]

We urge EPA to take this "no backsliding" approach in its modeling for the final rule. The impact would be significant: if manufacturers simply adopted a strategy of not removing technology from their combustion vehicle fleet, they could nearly achieve the more stringent Alternative 1 standards with no increase in ZEV sales as compared to ZEV sales in the modeling supporting the Proposed Rule (Figure VI.A-4). [EPA-HQ-OAR-2022-0829-0759, p. 46]

SEE ORIGINAL COMMENT FOR Figure VI.A-4: Fleet-wide average certification levels, as modeled compared to a scenario where manufacturers do not remove technology from combustion vehicles[EPA-HQ-OAR-2022-0829-0759, p. 46]

4. Summary of available improvement for combustion vehicles

By leaving a significant amount of available and feasible combustion vehicle emission reduction technologies on the table—including technology improvements EPA identified in prior rulemakings—the Agency has underestimated the potential emissions reductions available to the fleet. This problem is compounded because the Agency's compliance model assumes that a large share of the combustion vehicle fleet will get worse over time, even for manufacturers that the model projects will fall short of compliance and therefore will be dependent upon purchasing credits from their competitors. [EPA-HQ-OAR-2022-0829-0759, pp. 46-47]

By adjusting its modeling to reflect the full range of combustion vehicle technology improvements available to manufacturers, and by aligning its modeled manufacturing behavior with a strategy that reflects continued deployment of the technologies already available and incorporated into vehicles instead of allowing backsliding, EPA's modeling would better capture the full range of emissions reductions pathways that are feasible. Improving the OMEGA2 modeling in this way will affirm that manufacturers can easily achieve a standard at least as stringent as Alternative 1, with little to no increase in ZEV penetration compared to the model runs supporting the Proposal. [EPA-HQ-OAR-2022-0829-0759, p. 47]

Organization: International Council on Clean Transportation (ICCT)

As explained above and shown in the table, the ICE fleet emits more in 2032 than in 2027. In fact, based on analysis of OMEGA results, the car fleet has higher 2-cycle tailpipe emissions in MY2032 than in MY2022, with its lowest 2-cycle emissions levels occurring in MY2027.108 Similarly, the truck fleet shows its lowest GHG emissions levels in MY2028, with a net increase in 2-cycle emissions by MY2032. Much of this backsliding is explained by individual ICE models getting worse over time. Of all the 719 ICE models, 438 show higher emissions in MY2032 than in MY2027, and 333 show worse emissions in MY2032 than in MY2022. This modeling result presented in EPA's proposal highlights the risk that backsliding on GHG emissions could occur in real-world compliance with EPA's standards. If BEV penetration occurs faster than modeled by EPA, there is risk of further ICE backsliding on GHG emissions. ICCT recommends EPA include in its regulation a mechanism to prevent the backsliding of new ICE vehicles or the new ICE fleet. [EPA-HQ-OAR-2022-0829-0569, pp. 40-43]

108 Based on analysis of 2023_03_14_22_42_30_central_3alts_20230314_Proposal_vehicles.csv.

Organization: Steven G. Bradbury

Finally, the $1,200-per-vehicle cost figure touted by EPA is simply borrowed and carried over from the EPA's 2021 rulemaking without additional substantive analysis.32 It is not reasonable to assume that the per-vehicle cost of the current proposal for model years 2027 through 2032 would be anywhere close to the same as the estimated cost figure for the 2021 rule covering model years 2023 through 2026 (even if the figure was accurate for the 2021 rule). The current proposal is far more expansive and involves much more dra- conian reductions in emissions limits. [EPA-HQ-OAR-2022-0829-0647, pp. 13-14]

32 See 86 FR 74434, 74497, https://www.federalregister.gov/documents/2021/12/30/2021-27854/revised-2023-and-later-model-year-light-duty-vehicle-greenhouse-gas-emissions-standards.

The true per-vehicle technology costs of the proposed rules must be far higher than the figure thrown out by EPA. Even accepting the thoroughly implausible "no action" base- line that EPA has posited for future EV sales, EPA is projecting that the regulatory force of the current proposal, considered in isolation, will by itself cause the overall percentage of EV sales nationally to go from 39 percent to 67 percent—a huge increase, nearly a doubling in EV production and sales. Notably, based on EPA's own assumptions, this regu- lation-forced increase would have to come after all the early adopters have already pur- chased their EVs. Such an industry-wide transformation in production volumes and sales of EVs to non-early-adopters would involve a massive capital investment and marketing surge, and all the costs associated with that transformation would be attributable to the EPA's administrative rule, if the rule were indeed expected to be the forcing action. [EPA-HQ-OAR-2022-0829-0647, pp. 13-14]

Organization: Tesla, Inc.

Third, the agency's production modelling underestimated BEV production levels on several fronts. Foremost, the modeling significantly underestimates Tesla vehicle sales and projects them out at less 100,000 vehicles per year. See Figure 5. EPA's Under Projections of Tesla's Implied U.S. Sales MY 2027-2032. This under projection is inexplicable, unjustified, and needlessly undermines the stringency of the rule, as the Tesla Model Y was just recognized as the world's best-selling vehicle, and second to only the Ford F-150 in the U.S.120 In 2022, Tesla's U.S. sales already approached 500,000 vehicles.121 Further, at Tesla's 2022 shareholder meeting, the company has established a goal of producing 20M vehicles globally by 2030.122 While this goal does not speak to Tesla's annual U.S. sales, the agency's modelling already vastly underestimates Tesla's current and future sales. This data should be updated to recognize both Tesla's current market status and the ambition of Tesla's future ramp of U.S. sales during the MY 2027-2032 timeframe. To address this under projection, Tesla has confidentially provided production and sales estimates to EPA. See Appendix I, submitted as CBI. [EPA-HQ-OAR-2022-0829-0792, p. 18]

4. The analysis fleets modeled by OMEGA are highly implausible, and EPA fails to account for the actual costs to produce such fleets. [EPA-HQ-OAR-2022-0829-0707, pp. 5-6]

As described in Section 9.2 of the DRIA, when running the OMEGA model, EPA starts with a "base year fleet" that represents a comprehensive list of vehicles sold in MY 2019.28 OMEGA then "produces a fleet of new light-and medium-duty vehicles for each analyzed model year."29 [EPA-HQ-OAR-2022-0829-0707, pp. 5-6]

28 DRIA at 9-1.

29 DRIA at 2-1.

Starting in MY 2021, OMEGA creates a BEV "clone" of every ICEV, HEV and PHEV in the base year fleet, and the BEV clones enter into production when the vehicle ID reaches its next redesign year.30 Ultimately OMEGA phases all of the BEV clones into production over MY 2021- 2028, with the original ICEVs, HEVs and PHEVs remaining in production alongside the BEV clones. This means that between the base year and MY 2028, the number of vehicle IDs in the OMEGA LDV analysis fleet essentially doubles, growing from 740 to 1,459. [EPA-HQ-OAR-2022-0829-0707, pp. 5-6]

30 EPA LMDV OMEGA GHG Compliance Modeling Runs (Document ID EPA-HQ-OAR-2022-0829-0486), "vehicles.py" in 2023-03-25-11-46-49-ld-central-compliance-run.zip. This approach is adopted for every modeled scenario (e.g., "No Action" as well as proposed and alternate scenarios). No clone vehicles are created for the BEVs and FCVs in the base year fleet.

[See original for graph titled "Figure 1 – LDV Models by Powertrain in OMEGA Analysis Fleet"] [EPA-HQ-OAR-2022-0829-0707, pp. 5-6]

EPA's approach to modeling future LDV fleets in OMEGA is disingenuous and inconsistent with the cost analysis presented in the rulemaking. Doubling the number of LDV models available for sale in the U.S. would entail a significant increase in vehicle design, engineering, production, and assembly costs,31 to support flat-to-declining LDV sales numbers. The loss in economies of scale would be staggering, dropping from an average of 22,000 new vehicle sales per production model in the base year to 10,000 new vehicle sales per production model in MY 2028.32 EPA does not account for this in its analysis of vehicle costs associated with the proposed rule. [EPA-HQ-OAR-2022-0829-0707, pp. 5-6]

31 DRIA at 2-84. EPA notes that it "did not specifically impose a limit on vehicle assembly capacity."

32 EPA LMDV OMEGA GHG Compliance Modeling Runs (Document ID EPA-HQ-OAR-2022-0829-0486), "vehicles.py" in 2023-03-25-11-46-49-ld-central-compliance-run.zip. For the base year, new LDV sales totaled 16,149,471 vehicles ("vehicles_ldv_20221017_cleanedredesigne.csv"), spanning 740 vehicle IDs (0 to 739) ("2023_03_25_11_46_49_ld_central_compliance_run_Proposal_vehicles.csv"). For MY

2028, new LDV sales projected to total 14.8 million vehicles across 1,459 vehicle IDs (calculated from “2023_03_25_11_46_49_ld_central_compliance_run_Proposal_vehicles.csv).

EPA fails to present a feasible compliance scenario to accompany its proposed MY 2027-2032 standards, and it fails to adequately quantify the impacts of the compliance scenario that it does present. [EPA-HQ-OAR-2022-0829-0707, pp. 5-6]

Organization: Zero Emission Transportation Association (ZETA)

The case for emissions standards more stringent than Alternative One is even stronger when considering the agency’s apparent omission of ZETA member Rivian from its analysis. [EPA-HQ-OAR-2022-0829-0638, p. 26]

Specifically, OMEGA’s Manufacturers File, an input file listing vehicle producers considered as distinct entities for GHG compliance, does not list Rivian.128 Even the agency’s survey of manufacturer commitments, presented as Table 1 in the NPRM, does not include the company.129 Omitting Rivian from the agency’s analysis could affect EPA’s analysis and proposal. EPA should update its model inputs to account for Rivian’s sales and revise its evaluation of the alternatives accordingly. [EPA-HQ-OAR-2022-0829-0638, p. 26]

128 Purpose and description of the Manufacturers File per https://omega2.readthedocs.io/en/2.1.0/index.html#document-1_overview. List of producers found in the “manufacturers.csv” in the OMEGA zip file.

129 See 88 FR 29192 (May 5, 2023)

ZETA notes that EPA’s modeling appears to show a decline in BEV sales in the MD pickup segment in the early model years covered by these proposed standards.136 EPA should establish standards stringent enough to drive increasing electrification across all MD vehicle categories. The technology can meet the needs of many duty cycles performed by MD pickups, including those involving towing, but the rapid uptake of BEVs in the van fleet coupled with credit multipliers in the early years of the program could pad credit banks and allow BEV development and sales in the MD pickup category to stall. EPA should evaluate the feasibility of even stricter emissions requirements. [EPA-HQ-OAR-2022-0829-0638, p. 28]

136 See DRIA at 13-53

As in the LDV segment, EPA’s modeling appears to omit ZETA member Rivian. Yet, Rivian’s order book includes 100,000 all-electric Class 2b-3 vans, several thousand of which already operate on U.S. roads. The agency should assess to what extent the addition of 100,000 BEV vans to the national fleet by MY 2030 could support a lower fleet average emissions target. [EPA-HQ-OAR-2022-0829-0638, p. 28]

EPA Summary and Response

The Alliance commented that EPA’s assumption of credit trading in the central analysis is a departure from the approach taken in previous rulemakings, and that it is “inappropriate to set a standard so stringent as to effectively require many manufacturers to rely on other manufactures to maintain compliance.” The commenter also asserted that the choice of an 80 percent value for modeling credit market efficiency is “completely arbitrary.” In response, EPA disagrees that the approach used for modeling credit trading for the NPRM and for this final rulemaking analysis is either inappropriate or unjustified. The justification for the analytical assumptions for EPA's modeling of credit trading was outlined in the NPRM Preamble RIA Chapter 2.6.4.4, and is explained further here. On this topic, the primary difference between the 2012 rulemaking and this one is that we now have over a decade of observations upon which to base our trading assumptions, compared to no GHG credit trading evidence at the time the earlier rulemakings were promulgated in 2010 and 2012. For more recent rulemakings, including the 2020 and 2021 light-duty GHG rules, the primary difference is capability of the available modeling tools. EPA has continued to refine the OMEGA model, including as described in RTC Section 12.1 above. The version of OMEGA used for this rulemaking analysis has, for the first time in any GHG rulemaking, the capability to model the expiration of a portion of credits. The analytical question is then what portion of credits should EPA assume will be allowed to expire. The empirical evidence from the prior decade of credit trading would suggest a value of zero. In other words, consistent with EPA's observation that to-date, no GHG credits have expired unused. Conversely, EPA also recognizes that manufactures might choose to generate and bank at least some additional credits through technology application to act as a buffer against uncertainty. Other program flexibilities, such as credit carry-forward and carry-back within a company, serve the same purpose, but EPA concluded that it was reasonable to assume that, to some extent, manufacturers would incorporate a buffer against uncertainties into decisions about credit trading between firms. The value of 80 percent chosen by EPA means that for companies with cost-minimizing compliance plans where GHG targets are not met entirely through the application of technology (i.e., plans that involve the purchase of credits), 20 percent of credits would act as a buffer against uncertainty, and would be expected to expire unused. EPA acknowledges that there is not any historical evidence or studies that would indicate what the future credit efficiency and associated compliance buffer will likely be (apart from the supporting evidence for 100 percent mentioned above). In lieu of empirical studies on this specific topic, EPA approximated a compliance buffer that is analogous to the five-year credit carry forward provision, where a manufacture might accumulate a 20 percent credit buffer in each year for five years to address an unexpected case in the future where no credits can be procured for any reason. Notably, this idea of a compliance buffer is also identified by the commenter as a potential business strategy. EPA does not agree with the commenter's assertion that these standards "effectively require many manufacturers to rely on other manufacturers to maintain compliance." While the central case does assume some level of credit purchases (with a level of imperfect trading defined by the "Credit Market Efficiency" parameter of 20 percent, as described in RIA Chapter 2.6.4.4), other compliance pathways and sensitivities analyzed for this rulemaking demonstrate that it is feasible for manufactures to comply without a reliance on credit purchases at still reasonable, although higher, costs than in the central case. (See preamble Section IV.F.5. "no credit trading case").

CARB, ICCT, and Environmental and Public Health Organizations commented that in EPA's compliance modeling of the proposed standards, individual ICE vehicles were projected to have higher tailpipe GHG emissions in 2032 than they did in 2022. In response, EPA acknowledges these observations that some modeled ICE vehicles exhibited emissions "backsliding" as a result of EPA's approach of modeling producer decisions to seek the most cost-effective compliance pathway. Although EPA accounted for various constraints in vehicle production, for the proposal we did not apply any restriction on the removal of emission-reducing technology from ICE vehicles. However, we agree with the commenters that it is not likely that there will be a wide-spread removal of technologies that have been previously developed, produced, and implemented, and we do not anticipate manufacturers spending money towards development and integration of higher GHG-emitting powertrains on a widespread level – for this reason, we have prevented increases in tailpipe emissions from base year vehicles in the version of OMEGA for the final rulemaking. Furthermore, the fleet averaging standards ensure that if even if backsliding were to occur in a few isolated models, those vehicles would need to be offset with additional cleaner technologies so that the fleet would achieve the GHG reduction performance called for by the standards.

AmFree, [and others] commented on the OMEGA model's optimization logic or the choice of the objective function used to define the model's optimization problem. AmFree commented that by not accounting for the strategic decisions of firms in an oligopoly, the peer-reviewed version of the OMEGA model may underestimate the negative effects of the proposed rule on consumers. The example provided from the academic literature was based on a model an oligopoly in the U.S. Portland cement industry, where firm decisions to enter and leave the market were simulated, along with the resulting effect on consumer welfare. However, the U.S. Portland cement industry is an entirely different industry than the motor vehicle industry, with different market characteristics. EPA does not believe that there is a sufficient basis upon which such a model could be constructed for this rulemaking's analysis of the light- and medium-duty vehicle markets. Also, and most significantly, EPA does not draw any conclusion from existing studies of firm behavior, including the one given by the commenter, that these final regulations will tend to increase the cost of entry for new firms in the light- and medium-duty vehicle market. Among the auto manufacturers that submitted comments on the proposed standards, the most strongly supportive comments were from the newest entrants into the market which specialize in the production of low-emission PEV models. For these reasons, the OMEGA model does not attempt to simulate the strategic decisions of firms to leave or enter the vehicle market.

EPA acknowledges comments from the California Attorney General's office that EPA's modeling properly accounts for constraints on BEV manufacturing such as that automakers must account for, such as critical material supply for battery production. EPA responds to comments about the availability of critical minerals in RTC Section 15.

The Clean Fuels Development Coalition asserted that EPA's BEV cost estimates for the NPRM were under stated, and that "the real costs will be far higher than EPA projects." The commenter's assertion appears to be based on the incorrect presumption that EPA's future incremental costs (Action case minus No Action case) are influenced by existing BEV prices. The commenter contends that because BEV's prices are, in some cases, significantly discounted today, any incremental cost between an ICE and existing BEV would be lower than the real costs. This is an incorrect characterization of OMEGA's costing methodology, and in general, EPA does not agree that the approach used for the NPRM and this final rulemaking analysis will tend to underestimate incremental costs. In actuality, EPA's approach does not use MSRP to determine the incremental costs between technologies (e.g. ICE vs BEV). Instead, the incremental costs are based on the bottom-up cost estimations of powertrain costs and vehicle structure costs, which are informed by the engineering analyses and contracted vehicle teardowns that have been the foundation of EPA's cost estimates over multiple previous rulemakings. The commenter refers to MSRP, but in our analysis that is only relevant for the estimation of the non-structural glider costs. And because those costs are determined individually for each base year vehicle, and carried forward unchanged into future years and across policy scenarios, it has no influence on incremental costs. In other words, the average incremental vehicle manufacturing cost presented in our analysis is influenced only by our estimates for technology costs (i.e. powertrain, battery, structure material). And while vehicle price, MSRP, and cross subsidies are relevant for the consumer demand modeling within OMEGA, those values do not factor into the incremental vehicle manufacturing costs.

Valero commented that EPA's projection of future new vehicle production is implausible, and that we failed to account for the actual costs to produce such fleets because we overestimated the number of vehicles with both a BEV and ICE variant. EPA disagrees. EPA's OMEGA model does, as the commenter describes, create "clones" of base year vehicles to act as potential placeholder options for ICE, PHEV, of BEV powertrain variants. However, the presence of those placeholder vehicles does not automatically mean that the model is projecting production volumes for those vehicles, beyond the placeholder value of 1 vehicle. EPA vehicle production projections are representative of an aggregation of vehicles which, in reality, would have many individual differences in options, and trim levels. The level of aggregation we have chosen, at the manufacturer and model type level, is appropriate for this rulemaking since it allows enough differentiation for emissions performance and incremental cost as a result of the analyzed polices, while avoiding extraneous details that would not help to inform questions about compliance costs and feasibility. EPA notes that our marked up production costs account for vehicle design, development and manufacturing overhead, so even if our modeled results generate more variants than will be produced in the future, as the commenter suggests, the costs of producing those variants is appropriately considered in our overall cost estimates.

Steven G. Bradbury commented that EPA simply carried over the $1,200 cost estimate in the Proposal from the 2021 rulemaking, and that the actual costs would be higher. In response, EPA disagrees with this comment. We did not carry over the incremental cost estimates from the prior rulemaking. The Preamble and RIA provide extensive explanations for the modeling tools, inputs and assumptions that were developed and applied specifically for this rulemaking.

Zero Emission Transportation Association commented that EPA's analysis for the proposal excluded Rivian from the manufacturers represented in the base year vehicle fleet. Tesla similarly commented that the MY 2019 base year fleet used in the NPRM has lower volumes for their vehicles than today. In response, EPA notes that we have updated the base year fleet for this final rulemaking analysis, consistent with our general practice of using the most recent data whenever possible. The MY 2022 base year fleet used for the updated analysis now includes Rivian vehicles, and Tesla production volumes (and volumes of other manufacturers) that represents MY 2022 instead of the MY 2019 base year used for the NPRM analysis.

12.1.2 - Consumer side modeling

Comments by Organizations

Organization: Alliance for Automotive Innovation

B. Comparison of EPA's Projected U.S. BEV Market Share to Other Projections

EPA projects that manufacturers can reach 60% BEV U.S. market share by 2030 and 67% share by 2032. In context, for all light-duty auto sales in 2022, less than 6% were BEV (or just over 7% when including PHEVs). Effectively, EPA's proposed BEV requirements would be roughly ten times higher than 2022 levels. [EPA-HQ-OAR-2022-0829-0701, pp. 28-29]

Given the degree of electrification that EPA projects in association with its proposed standards, it is helpful to compare EPA's projections to those of industry analysts. EPA does provide some third-party projections of U.S. BEV market share, but does so only in the context of supporting its finding that demand for BEVs is rapidly increasing.22 [EPA-HQ-OAR-2022-0829-0701, pp. 28-29]

22 NPRM at 29189.

Auto Innovators compares EPA's projections23 to those of the U.S. Energy Information Agency (EIA),24 S&P Global Mobility,25 Bloomberg,26 Benchmark Minerals Intelligence (BMI),27 and the International Council on Clean Transportation (ICCT)28 in Figure 1. EPA's projections exceed those of other government agencies (EIA) and of the industry and financial analysts (S&P Global Mobility, Bloomberg, and BMI). The only projection close to EPA's is that from ICCT (a well- known non-governmental organization that advocates for stronger standards), but EPA's projections still exceed even those of ICCT. While projections can and certainly do vary based on input assumptions, EPA has not adequately explained how increasing GHG standards in and of itself would enable greater BEV-only market share than those projected by multiple other analyses that include both BEVs and PHEVs. [EPA-HQ-OAR-2022-0829-0701, pp. 28-29]

23 For this assessment, Auto Innovators used EPA's projected BEV market share from the ACC II sensitivity case for the proposed standards. (NPRM at 29335, Table 108.)

24 U.S. Energy Information Administration, Annual Energy Outlook 2023, High Uptake of the IRA side case, Table 38. (Market share calculated by Auto Innovators based on EV sales and total sales of light-duty vehicles.)

25 S&P Global Mobility, U.S. light vehicles sales forecast by propulsion system design (Jan. 2023). Obtained via personal correspondence. Used with permission.

26 Bloomberg NEF, Electric Vehicle Outlook 2023 (Jun. 2023) at 22 (Figure 30; reflects BloombergNEF economic transition scenario). Data obtained via BloombergNEF subscription.

27 Benchmark Minerals Intelligence, 1Q2023 model for Auto Innovators (proprietary).

28 The International Council on Clean Transportation, Analyzing the Impact of the Inflation Reduction Act on Electric Vehicle Uptake in the United States (Jan. 2023) at 27. (Table A5, IRA Moderate with increased state ACC II adoption scenario.)

The projection from S&P Global Mobility, a well-respected third-party analyst of the automotive industry, suggests approximately 47% EV market share (including PHEVs) in 2030 and 59% in 2032. In comparison, EPA projects a BEV-only market share of 61% by 2030 and 67% in 2032 under its proposed standards. The projection from Bloomberg is very similar to that of S&P Global Mobility, reaching 51% combined EV sales in 2030 and 60% combined EV sales by 2032. The S&P Global Mobility and Bloomberg projections are generally consistent with Auto Innovators belief that 40-50% EV market share by 2030 is an aspirational, yet achievable goal if suffcient complementary policies are in place. [EPA-HQ-OAR-2022-0829-0701, pp. 28-29]

[See original comment for Figure 1: Comparison of EPA-projected BEV market share under the proposed standards to projections from EIA, S&P Global Mobility, Bloomberg, and ICCT.] [EPA-HQ-OAR-2022-0829-0701, pp. 28-29]

4. Modeling the geographic diffusion of BEVs is important for accurately gauging the customer acceptance of the national standards.

The OMEGA least-cost compliance modeling suggests that, by model year 2032, 67% of new vehicle sales will be BEVs, a remarkably different figure than the 8% BEV share observed in the U.S. in early 2023. [EPA-HQ-OAR-2022-0829-0701, pp. 284-285]

Modeling a highly segmented and geographically dependent market as a single entity is spurious. The agency's assumption that all consumers will respond with the same elasticity of demand pegged to the same diffusion of innovation curve is simplistic and not appropriate. As we know, there are many factors outside of the relative price of powertrains that come into play when purchasing a new vehicle. These include the robustness of the charging ecosystem, inclement weather, relative price of fuels, and even political affiliation. [EPA-HQ-OAR-2022-0829-0701, pp. 284-285]

It is crucial that EPA model accurately the diffusion of BEVs into different parts of the country, since the pattern of spatial diffusion influences key issues in this rulemaking: [EPA-HQ-OAR-2022-0829-0701, pp. 284-285]

-the amount of electricity required to support BEVs in different areas;

-the degree of grid investments and public-charging investments required to support BEVs;

-the amount of emissions from the electric utility sector (as some regions are more carbon intensive than others);

-and the prospects for customer acceptance of BEVs (as regions vary in attitudes toward BEVs, the pace of the public charging build out, cold weather climates, and the availability of state incentives and public outreach to facilitate BEV deployment). [EPA-HQ-OAR-2022-0829-0701, pp. 284-285]

In its analysis EPA adapts a "vehicle adopter model" (VAM) developed by the National Renewable Energy Laboratory. The model includes some plausible predictor variables such as income, housing type, housing tenure, population density, and rural vs urban location. The authors also acknowledge the model omits crucial variables relevant to predicting whether a household will purchase or lease a BEV such as environmental attitudes, interest in advanced technology, whether the household has a place at home or at work to charge their BEV, commuting distance, and long-trip frequency. The model explained little of the variation in BEV ownership in the sample (R-square = 0.04). The authors explain that the model seemed to perform better statistically at the county level, but with so many omitted variables it seems doubtful the model coefficients are useful for prediction. A deeper problem is that the data set included only 224 households that owned at least one BEV, about 6% of the sample, and it is not clear whether the sample is representative of the U.S. Since the 224 households are, as the authors note, early BEV adopters, it seems unlikely that information about them will be relevant in predicting which households adopt BEVs as the technology diffuses from 8% of new vehicle purchasers in early 2023 to 67% in 2032. For the purposes of the rulemaking, it is more important to model carefully, for example, those who are open to a BEV but have not yet purchased one. The authors were careful to state that their results have limited utility [EPA-HQ-OAR-2022-0829-0701, pp. 284-285] :

The absolute values of the estimates and the predictive capability of the model are not the priorities for this purpose—instead, we emphasize the relative scale of these coefficients (for example, how much influence housing type has on PEV adoption compared with income). [EPA-HQ-OAR-2022-0829-0701, pp. 284-285]

EPA then decided to use the absolute coefficients to forecast PEV adoption, exactly contrary to what the authors suggested. [EPA-HQ-OAR-2022-0829-0701, pp. 284-285]

Auto Innovators appreciates that EPA may have been inclined to use this survey because the results can be linked to the IPM model of the electric utility sector. Unfortunately, the survey and modeling have so many weaknesses for use in this rulemaking that a different modeling strategy is required [EPA-HQ-OAR-2022-0829-0701, pp. 284-285].

In the long run, Auto Innovators suggests that EPA develop an improved BEV adopter model.

Organization: American Fuel & Petrochemical Manufacturers

EPA requests comment on their approach to determining charging time, as set forth in the DRIA, Chapter 4.155 EPA's analysis is contingent on unsupported assumptions regarding (1) U.S. consumers' adoption of and ability to purchase more expensive ZEVs (see Sections IV.B.2 and IV.E.2.ii); (2) the type of ZEV purchased (used ZEVs or PHEVs compatible with slower charging units or new ZEVs that can use DCFC) (Section IV,B.2 addresses charging times); (3) the availability of critical minerals and metals to expand the supply of reliable and renewable electricity (see Section I.B); and (4) the availability of reliable and affordable charging for all users (see Sections IV.B.4). Given the flaws in EPA's methodology that omits significant data sources and other factors and makes unsupported assumptions, EPA should revise its analysis concerning charging time and continue with promulgating a final rule for future emissions standards, that accounts for the reality of today's automotive market and not the public pronouncements of the automotive industry, a single state or group of states, or other unsupported estimates of future market growth. [EPA-HQ-OAR-2022-0829-0733, pp. 33-34]

155 88 Fed. Reg. at 29,367.

EPA's Proposal fails to evaluate how government credits are embedded in vehicle pricing. For example, neither federal or state governments, or auto manufacturers explain how state ZEV credits, EPA GHG multiplier credits, and NHTSA CAFE EV multiplier credits are accounted for in both ZEV and ICEV vehicle price. There is increasing evidence that regulations which mandate EV sales—along with the cross-subsidies from gasoline and diesel vehicle buyers—are leading manufacturers to abandon sales of the least expensive and higher fuel economy gasoline and diesel vehicles that do not receive similar subsidization.236 Cox Automotive found that "in December 2017, automobile makers produced 36 models priced at $25,000 or less. Five years later, they built just 10," pushing low-income buyers out of the new-car market and into the used- car market. Conversely, in December 2017 automobile manufacturers offered 61 models for sale with sticker prices of $60,000 or higher and in December 2022, they offered 90.237 This is unacceptable. EPA and its sister agencies cannot create credits and then claim they do not affect vehicle price solely because they have not sought to quantify them. [EPA-HQ-OAR-2022-0829-0733, pp. 51-52]

236 Steven G. Bradbury, Distinguished Fellow, The Heritage Foundation, Prepared Statement for the hearing entitled "Driving Bad Policy: Examining EPA's Tailpipe Emissions Rules and the Realities of a Rapid Electric Vehicle Transition," before the Subcommittee on Economic Grown, Energy Policy, and Regulatory Affairs of the U.S. House of Representatives Committee on Oversight and Accountability, at 10 (May 17, 2023) available at https://oversight.house.gov/wp-content/uploads/2023/05/Bradbury- Prepared-Statement-for-17-May-2023-Oversight-Hearing.pdf

237 See Sean Tucker, Are we witnessing the demise of the affordable car? Automobile makers have all but abandoned the budget market (MarketWatch Feb. 28, 2023), available at https://www.marketwatch.com/story/are-we-witnessing-the-demise-of-the-affordable-car-automakers-have-all-but-abandoned-the-budget-market-a68862f0 (last visited May 24, 2023).

Tellingly, EPA never estimates the annual price of a comparable ZEV and ICEV, for each year in which EPA proposes standards. EPA's bias towards EVs is demonstrated by EPA's statement that its OMEGA modeling "now incorporates a consumer choice element. This means that the impacts of, for example, a $40,000 BEV versus a $35,000 ICE vehicle of similar utility (i.e., a 14 percent increase for the BEV) is a much different consideration than a $6,000 incremental BEV cost versus a $1,000 incremental ICE cost (a 500 percent increase for the BEV)."238 In other words, EPA set up its model to show the consumer price (not the actual real-world cost) of EVs have a lower percentage cost increase than the incremental absolute cost of switching from ICEVs to ZEVs. [EPA-HQ-OAR-2022-0829-0733, pp. 51-52]

238 See RIA page 2-42, https://nepis.epa.gov/Exe/ZyPDF.cgi?Dockey=P10175J2.pdf.EPA incorrectly assumes that ZEV owners will pay the national average residential electricity price to charge their vehicles. EPA fails to consider that the majority of ZEVs in the U.S. are located in utility service territories with some of the highest electricity rates in the country and that the average EV owner currently pays a much higher price to charge their ZEV at home than the national average residential electricity rate. Given that EV penetration has varied widely across the U.S., it would be arbitrary to assume that EVs will, unlike in the past, penetrate uniformly across the U.S. and thus that the average electricity price would be representative of the actual cost electricity. For example, California, which has roughly 40 percent of all registered ZEVs in the U.S., has a residential electricity rate that is roughly double the national average. Considering that EPA is modeling its rule after a California-like approach to mandate ZEVs, it would be more appropriate for EPA to assume similar real-world costs (at a minimum, given California's temperate climate). Moreover, EPA fails to consider that mandating such a high ZEV sales rate will necessarily require exponential increases in commercial ZEV charging at rates that are currently three, four or five times higher than the current national average residential electricity rate, depending on location and charging speed. Those customers who are not homeowners and not able to install their own charging stations and take advantage of charging at low-cost times will be adversely impacted. Instead, EPA uses a residential rate for electricity and does not

consider peak power or time of use charges. California electric prices rose 42 percent - 78 percent between 2010 and 2020 and are projected to rise an additional 50 percent by 2030 as shown in Figure 9. [EPA-HQ-OAR-2022-0829-0733, pp. 57-58]

Heaping additional demand for EV charging into this market could exacerbate already high electricity prices. This will be especially impactful to lower-income homeowners who may not be able to install dedicated charging units, forcing them to pay more out of pocket for charging during peak demand periods.265 [EPA-HQ-OAR-2022-0829-0733, pp. 57-58]

265 Hardman, Scott, et al., "A Perspective on Equity in the Transition to Electric Vehicles." MIT Science Policy Review, (Aug. 20 2021), available at https://sciencepolicyreview.org/2021/08/equity-transition-electric-vehicles/ (accessed June 29, 2023).

EPA must revise its analysis to account for realistic electricity prices. The proposed ZEV mandate will require an enormous investment in power generation and distribution, resulting in nationwide increases in electricity bills that EPA has not considered. Of course, considering the additional trillions of dollars in costs would paint a clear picture that the costs of forced electrification far exceed even the inflated benefits EPA presented in the Proposed Rule. [EPA-HQ-OAR-2022-0829-0733, pp. 57-58]

iii. Review of Annual Energy Outlook (AEO) data and projections.

EPA's BEV projections differ significantly from other federal agencies and reflect that EPA is improperly mandating that a significant proportion of new LDV and MDV must be powered by electric drivetrains and setting unrealistic tailpipe emission standards. The EIA published market share projections for light-duty BEV and PHEV sales in its Annual Energy Outlook35 2023 (AEO 2023). The AEO 2023 Reference Case modeling includes laws, such as the IRA and the BIL, and other adopted regulations in its analysis. The AEO 2023 incorporates the IRA by adjusting EV purchase prices to account for the Clean Vehicle Credit using offcial estimates of vehicles that will be eligible for tax credits. In addition to the Reference Case, the AEO conducts a range of scenario modeling, that considers different assumptions and uncertainties. Across the range of modelled scenarios in AEO 2023, EIA36 concluded that sales of BEVs and PHEVs do not exceed 29% and the share of the on-road light-duty vehicle stocks comprised of BEVs and PHEVs did not exceed 26%, over the projection period to 2050. [EPA-HQ-OAR-2022-0829-0641, pp. 13-14]

35 U.S. Energy Information Administration. "Annual Energy Outlook 2023." March 2023. https://www.eia.gov/outlooks/aeo/.

36 U.S. Energy Information Administration. "Incentives and lower costs drive electric vehicle adoption in our Annual Energy Outlook." Today in Energy. Accessed May 15, 2023. https://www.eia.gov/todayinenergy/detail.php?id=56480.

Analysis of BEV-only37 sales data from the AEO 2020 (pre-COVID) and 2023 (most recent) editions indicate BEVs sales are projected to increase in comparison to the respective Reference Cases. For example, in 2032, BEV sales are projected to reach 13% in the AEO 2023 Reference Case up from 5% in the AEO 2020 Reference Case. Increased BEV sales in AEO 2023 compared to AEO 2020 likely reflect emerging trends, technological improvements, relative manufacturing costs and purchase prices, subsidies, consumer behavior, and other factors. Also, minimum projections for BEV sales in the AEO 2023 are nearly identical to the AEO 2020 Reference Case (see chart below). However, projections for maximum BEV sales in AEO 2023 reach only 23% in2032. Figure 1 below illustrates BEV sales across a wide range of scenarios as projected by EIA. [EPA-HQ-OAR-2022-0829-0641, pp. 13-14]

37 Transportation supplemental tables for AEO 2020 and AEO 2023 can be found here: https://www.eia.gov/outlooks/aeo/.

BEV sales projected by EPA,38 under a scenario to meet the proposed standards and a "no action" scenario, are included in the chart. BEV sales required to meet EPA's proposed standards or "no action" scenario are significantly higher than any scenario projected by EIA in its AEO 2023 analysis. Differences in trajectories between EPA's proposed standards and the AEO projections illustrate EPA selecting and essentially forcing one technology over others and setting an unrealistic stringency for tailpipe emission standards. Although EIA has projected BEV sales to increase (i.e., AEO 2023 vs. AEO 2020) because of recently enacted federal subsidies and expenditures (i.e., BIL and IRA), along with technological advancements, 2032 BEV sales are projected to reach to only 13% in the AEO 2023 Reference Case compared to EPA's proposed standard at 67%. This is a significant difference in projected BEV sales and the agency has not provided adequate information to explain this major difference. EPA must explain why its projections differ so significantly from its sister agency with far more expertise in such projections than EPA. [EPA-HQ-OAR-2022-0829-0641, pp. 13-14]

2. EPA's consumer demand module isn't explained and leads to strange results

EPA's analysis includes an estimate of consumer demand of vehicles by powertrain, which it describes as "the share weight parameter changes over time to account for factors that are not included in the generalized costs, such as greater access to charging infrastructure or greater availability and awareness BEVs". EPA does not explain how they built their S curve or how it behaves and relies on a single paragraph in its draft RIA to describe this approach (it reserves conversation of the 'cost' metrics for a different section of the RIA). More importantly, EPA does not explain why consumer demand increases because of their proposal across the alternatives when their proposal shouldn't impact these considerations. EPA's proposal does not increase the amount of chargers available or reduce range anxiety. If these things are assumed to change because of EPA's rule, the explanation should be clear in EPA's analysis, and EPA should also carry the costs of forcing increases to the grid and charger access as a cost to their rule. [EPA-HQ-OAR-2022-0829-0565, p. 3]

In considering costs, EPA states "consumers assume that approximate annual VMT is 12,000 miles, annual non-fuel ownership costs for BEVs are $1,600, and annual non-fuel ownership costs for ICE vehicles are $2,000" but does not explain where those assumptions come from and deprives commenters from being able to meaningfully comment and contribute. This basis of non-fuel costs for ICE vehicles being higher by 20% leads to ICE vehicles being disadvantaged. [EPA-HQ-OAR-2022-0829-0565, p. 3]

EPA analysis also seems to gloss over range anxiety which is a leading consideration for many consumers in whether to purchase a BEV (https://www.caranddriver.com/news/a40119553/survey-range-anxiety-evs/#:~:text=The%20bad%20news%3F,list%20their%20top%20three%20concerns) or the time it takes to charge a vehicle, in their analysis of consumer demand. These oversights seriously undermine the value of EPA's model. [EPA-HQ-OAR-2022-0829-0565, p. 3]

Ironically, EPA also assumes 0% rebound for BEVs. Rebound is a sign that consumers value driving a vehicle more and will do so as cost decreases. However, EPA's assumption assumes that there is no additional value to driving a BEV as it becomes more efficient. So on the one hand, BEVs confer the same or better benefits to their drivers, on the other, consumers do not value additional BEV miles. [EPA-HQ-OAR-2022-0829-0565, p. 3]

Organization: International Council on Clean Transportation (ICCT)

The notion that MDV have different use cases than LDV also suggests that consumer and manufacturer purchase and production decisions may differ between MD and LD. As MDV are generally used in commercial applications, consumers likely consider the purchase of MDV as a business decision. Consequently, MDV purchasers are more likely than LD purchasers to consider the full cost of ownership when making such a decision. In particular, MDV buyers may fully value the fuel savings from efficiency technologies or BEVs. Because of this full valuation of fuel savings, ICCT recommends EPA model MDV consumers as valuing at least 5 years of fuel savings (double the 2.5 years of fuel savings currently used for both LD and MD164). According to ICCT's 2022 MD EV cost study, over the first 5 years of ownership, before 2030 both MD BEV pickups and vans are expected to cost less to own and operate than their diesel and gasoline counterparts.165 [EPA-HQ-OAR-2022-0829-0569, pp. 62-64]

164 According to producer_generalized_cost-body_style_20220613.csv—used in both the LD and MD central analyses

Organization: Jeremy Michalek et al.

The EPA assesses the potential for future demand for electric vehicles by first simulating a "No Action" scenario, representing a future scenario without the proposed policy but accounting for other policies such as the IRA. They then simulate a future scenario that includes the additional effects of the proposed policy. In both cases, the consumer demand model's parameters (the "share weights," which we refer to as alternative specific constants to be consistent with the discrete choice literature) are calibrated so that future shares in the "No

Action" scenario match those projected in an IHS report (Fiske et al., 2021), resulting in the projections summarized in Figure 1. We compare these projections to new results from our research based on an empirical investigation of (1) past trends in consumer preferences and (2) expected technology trends. [EPA-HQ-OAR-2022-0829-0705, p. 4]

[See original for graph titled "Graphical summary of EPA's assessment of expected BEV adoption by vehicle class in the proposed rule (US Environmental Protection Agency, 2023)"] [EPA-HQ-OAR-2022-0829-0705, p. 4]

1.1 Cars and SUVs

In an attached study, published this year in Proceedings of the National Academy of Sciences, we compare results from a discrete choice survey experiment conducted with over 1500 people in 2020-2021 with those of a similar survey conducted in 2012-2013 (Forsythe et al., 2023a). This experiment importantly investigates the likelihood of mainstream U.S. new vehicle consumers choosing BEVs, where our sample is weighted to be representative of the U.S. new car and SUV buying population across household income, age, education, gender, marital status, and household size. We find that technological improvements in battery elec-tric vehicles (BEVs) - particularly increasing range of these vehicles - have driven increases in consumers' likelihood of choosing these vehicles over their conventional gasoline vehicle counterparts. We find that the consumer preference parameters defining what consumers want in vehicle characteristics and what they are willing to pay for have not changed (in to- day's dollars) enough to identify statistically significant trends over this 8 year period. This implies that consumer preferences (independent of technology improvements) have been rel-atively static. The findings suggest that consumers are buying more electric vehicles today because the technology has improved, and that as BEV technologies continue to improve in the future, it will further increase consumer likelihood of choosing BEVs over conventional vehicle counterparts. [EPA-HQ-OAR-2022-0829-0705, p. 4]

Using the consumer preferences estimated from the choice experiment, we examine con-sumers' likelihood of purchasing a BEV when choosing between two vehicles: one that has a conventional gasoline powertrain and one that has a battery electric powertrain, but oth-erwise have very similar characteristics (such as the BMW i4 and the BMW BMW 4-Series Gran Coupe, and the Nissan Leaf and the Nissan Versa). We find that, if consumer prefer-ence parameters continue at today's values and if the technology for range and cost improve to levels predicted by the National Academies (NASEM, 2021), then consumers will become roughly indifferent, on average, between electric and gasoline versions of several car and SUV models by 2030 (see Figure 2 from Forsythe et al. (2023a)). [EPA-HQ-OAR-2022-0829-0705, p. 5]

We further simulate market shares for BEVs across the full U.S. new car and new SUV markets. We find that in a case where BEVs are equally available as conventional gasoline vehicles (every conventional gasoline vehicle has a counterpart BEV with the same body style, brand, and other characteristics important to consumers), BEV technology improvements follow those projected by the National Academies (NASEM, 2021), and consumer preference parameters remain steady at today's values, we find that simulated BEV market shares of both new cars and new SUVs would be approximately 50% by 2030 (see Figure 3 from (Forsythe et al., 2023a)). [EPA-HQ-OAR-2022-0829-0705, p. 5]

Our findings support that large increases in consumer demand for BEVs in the near future is feasible. The research suggests that mainstream consumer demand for BEVs is likely to sharply increase due to expected BEV technology improvements alone. It also supports that BEV demand could grow high enough by 2030 so that BEVs become the majority of new passenger cars, and SUVs nearly the majority, through expected BEV technology improvements and equal availability of BEVs and conventional vehicles. It is important to note that these findings do not incorporate the reduced cost of maintenance and repair or the cost of at-home charger installation. If the net balance of these provides cost savings to consumers as the EPA predicts, then we would expect consumer demand for BEVs would be even larger than predicted in our study. [EPA-HQ-OAR-2022-0829-0705, p. 5]

The proposed EPA rule may further increase consumer demand for BEVs trends by (1) encouraging automakers to shift price margins to encourage more BEV sales, (2) encouraging automakers to reduce gasoline vehicle offerings in favor of increasing BEV offerings, (3) encouraging automakers to invest in electrification technology advancement, potentially exceeding National Academy projections, (4) triggering network effects, such as vehicle buyers being more likely to purchase a BEV as they know more friends and family who own them, and (5) encouraging other efforts - including adver- tising, dealership practices, and other actions - that would increase consumers' likelihood of purchasing BEVs over conventional vehicles. [EPA-HQ-OAR-2022-0829-0705, p. 5]

Recommendation 1. We recommend that EPA pursue (internal and/or external) re- search to develop models for future versions of OMEGA such as the one we present here that are capable of explicitly modeling improvements in BEV characteristics that drive consumer choices, such as range, so that alternative assumptions beyond the IHS projections can be investigated in future OMEGA model versions and so that trends can be more explicitly and transparently investigated and communicated. [EPA-HQ-OAR-2022-0829-0705, pp. 5-7]

[See original for Figure 2, titled "Car and SUV head-to-head comparisons over time.] [EPA-HQ-OAR-2022-0829-0705, pp. 5-7]

[See original for Figure 3:, titled "Hypothetical share of BEV cars and SUVs for model year 2020 and 2030 if all gasoline cars and SUVs offered a BEV option and technology trends followed those predicted by the National Academies (NASEM, 2021). From (Forsythe et al., 2023a)"] [EPA-HQ-OAR-2022-0829-0705, pp. 5-7]

In a working paper, we conducted a similar discrete choice experiment of 52 pickup truck owners across the U.S. to characterize their preferences. This sample represented a range of pickup truck consumer household incomes, ages, education, gender, and household size and was weighted to be representative of the U.S. new pickup truck buying population. We find that most pickup truck owners (78%) are open to purchasing electric pickup trucks if the technology provides sufficient performance attributes, including range, operating cost, towing capacity and payload capacity. We find that the largest group, representing 43% of our consumers, choices between a BEV or conventional gasoline pickup truck are driven primarily by what the vehicle can do, rather than its powertrain type (we call this group "tech indifferent" because the don't value the powertrain technology in and of itself, only what it can deliver). Another group, representing an additional 13% cared about payload capacity and operating cost, but did not otherwise value the powertrain technology in and of itself. 17% of pickup truck owners were "BEV enthusiasts" who were willing to pay significantly more for a BEV pickup truck than a conventional gasoline pickup truck, even if they had identical characteristics (including operating costs, towing, payload, and brand). We find that 22% of pickup truck owners are strongly opposed to all types of electrification, including hybrid, plug-in hybrid and battery electric pickup trucks. For this group, a substantial change in consumer preferences would be necessary for the group to opt for electric pickup trucks over gasoline pickup trucks. [EPA-HQ-OAR-2022-0829-0705, p. 8]

We simulate market shares for BEVs across the full U.S. new pickup truck market. We find that in a case where BEV pickup trucks are equally available and diverse as conventional gasoline pickup trucks (every conventional gasoline and diesel truck has a counterpart BEV with the same towing, payload, brand, and other characteristics important to consumers), BEV technology improvements follow those projected by the National Academies (NASEM, 2021), and consumer preference parameters remain steady at today's values, where all gaso- line or diesel pickup trucks offer a BEV powertrain option and technology trends match those suggested by the National Academies (NASEM, 2021), we estimate that, despite the notable group opposed to electrification of pickup trucks, over half of pickup truck owners would choose the electric powertrain by 2030 (Figure 4), exceeding EPA's assessment of expected BEV pickup truck adoption in 2030 (Figure 1). [EPA-HQ-OAR-2022-0829-0705, p. 8]

Implications for EPA. Our findings support that large increases in consumer demand for BEV pickup trucks in the near future is feasible. The research suggests that mainstream consumer demand for new BEV pickup trucks is likely to sharply increase due to expected BEV technology improvements in the future. It also supports that, although some pickup truck owners are strongly opposed to purchasing BEV pickup trucks, the majority of pickup truck owners value BEV pickup trucks equally to conventional gasoline pickup trucks as long as they have sufficient performance characteristics. The research supports that consumer de- mand for BEV pickup trucks may exceed EPA's scenario of BEV pickup truck adoption in 2030. It is important to note that our study does not incorporate the reduced cost of main- tenance and repair or the cost of at-home charger installation. If the net balance of these [EPA-HQ-OAR-2022-0829-0705, pp. 8-9]

[See original for Figure 4, titled "Hypothetical share of BEV pickup trucks for model year 2020 and 2030"] [EPA-HQ-OAR-2022-0829-0705, pp. 8-9]

provides cost savings to consumers as the EPA predicts, then we would expect consumer demand for BEVs would be even larger than predicted in our study. The proposed EPA rule may further increase consumer demand for BEV trucks by (1) encouraging automak- ers to shift price margins to encourage more BEV sales, (2) encouraging automakers to reduce gasoline pickup truck offerings in favor of increasing BEV pickup truck offerings, (3) encouraging automakers to invest in electrification technology advancement, potentially ex- ceeding National Academy projections for pickup trucks, (4) triggering network effects, such as pickup truck buyers being more likely to purchase a BEV as they know more friends and family who own them, and (5) encouraging other efforts - including advertising, dealership practices, and other actions - that would increase consumers' likelihood of purchasing BEV pickup truck over conventional trucks. [EPA-HQ-OAR-2022-0829-0705, pp. 8-9]

We show in the attached report that the GCAM-based demand model formulation used to compute vehicle choice shares, described on pg. 4-5 of the Draft Regulatory Impact Analysis (DRIA), is mathematically equivalent to a multinomial logit model. This means that the demand model fits within the random utility model (RUM) paradigm used in the scientific literature and is grounded in expected utility theory, which has a long history of use in economics and the decision sciences (McFadden, 1972; von Neumann et al., 1944). It also means that the parameters EPA uses in the demand model are directly interpretable using expected utility theory. We find that increases in the ”share weight” parameter of BEVs relative to conventional vehicles represents consumer utility of BEVs associated with factors other than generalized cost (including but not limited to BEV range, styling, towing capability, and other factors consumers consider during the purchasing decision). [EPA-HQ-OAR-2022-0829-0705, p. 10]

Specifically, we find that the formulation used in EPA’s proposed rule is equivalent to a multinomial utility model with a consumer utility function composed of the log of generalized cost plus an alternative specific constant (ASC). We show in the attached report how the GCAM ”share weight” parameter maps to the ASC in the standard logit form. The logit model falls within the class of random utility discrete choice models, which all assume the following (Train, 2009): [EPA-HQ-OAR-2022-0829-0705, p. 10]

1. Consumers choose the alternative in a choice set that provides them the highest utility [EPA-HQ-OAR-2022-0829-0705, p. 10]

2. Utility is partly observable to the modeler, modeled as a function of the product’s attributes [EPA-HQ-OAR-2022-0829-0705, p. 10]

3. Utility is partly unobservable to the modeler, modeled as a random variable [EPA-HQ-OAR-2022-0829-0705, p. 10]

Upon reviewing over 200 automotive demand model studies in the scientific literature and government reports, we found random utility discrete choice models to be the dominant paradigm for modeling automotive demand, with the logit model and its variants most commonly used. Thus, EPA’s demand model follows the dominant paradigm and inherits the properties of random utility discrete choice models. [EPA-HQ-OAR-2022-0829-0705, p. 10]

The equivalence of GCAM and the logit model implies several important properties of EPA’s choice model, which we summarize in this section and the sections below. The logit model, and, by extension, the GCAM model form used by EPA, has a well-known property called Independence from Irrelevant Alternatives (IIA) that restricts the kinds of substitution patterns the model can represent (Train, 2009). IIA implies that when a new alternative is introduced or when an existing alternative is improved, it will draw consumer choice share proportionally from the other alternatives. Figure 5 shows an illustrative example, where a gasoline vehicle and an electric vehicle are valued equally by consumers with equal observable utility v and therefore equal choice shares of 1/2 each. If an additional electric vehicle were introduced that is effectively identical to the first, then all three alternatives would have equal choice shares, resulting in 1/3 of consumers choosing gasoline vehicles and 2/3 of consumers choosing one of the two electric vehicle options. This example (a variation on the classic “red-bus blue-bus problem” (Train, 2009)), illustrates why predictions made with models that exhibit the IIA property can be sensitive to how the choice set is modeled. [EPA-HQ-OAR-2022-0829-0705, p. 11]

[See original for Figure 5: Substitution Patterns Implied by the GCAM logit model's Independence of Irrel- evant Alternatives (IIA) Property] [EPA-HQ-OAR-2022-0829-0705, p. 11]

In EPA's current OMEGA implementation, as we understand it, the GCAM logit model is used in scenarios that predict demand independently for the sedan/wagon, CUV/SUV, and pickup truck markets as separate markets. In each of these demand simulations, consumer demand is determined between an aggregate representation of conventional gasoline vehicles and an aggregate representation of BEVs. Based on the fact that GCAM is equivalent to a RUM, we believe that this representation is equivalent to representing two ”composite” vehicles, one representing the portfolio of conventional vehicle offerings, and one representing the portfolio of BEV offerings (see (Yip et al., 2021)), as shown in Figure 6. When there are only two alternatives in a choice set (e.g., only BEV or a conventional vehicle), the IIA property is not relevant. Therefore, we do not believe that the IIA property causes concerns in EPA's current simulations. [EPA-HQ-OAR-2022-0829-0705, pp. 11-12]

The IIA property may cause concerns when simulations include choice sets with more than two alternatives that do not compete proportionally. In these cases, the model produces substitution patterns among the vehicle offerings that are determined by implicit assumption from the model form rather than empirical evidence and has the potential to produce un- realistic predictions. Issues could arise if future versions of OMEGA were to include choice sets with more than two alternatives, such as by: [EPA-HQ-OAR-2022-0829-0705, pp. 11-12]

1. Combining sedan/wagon, CUV/SUV, and pickup truck markets into a single choice set with 6 alternatives (BEV and conventional for each body style) [EPA-HQ-OAR-2022-0829-0705, pp. 11-12]

2. Adding additional technology alternatives to the existing choice set, such as a PHEV [EPA-HQ-OAR-2022-0829-0705, pp. 11-12]

3. Including disaggregated vehicle alternatives or less coarse composite vehicles [EPA-HQ-OAR-2022-0829-0705, pp. 11-12]

Recommendation 2. If EPA considers model variations that involve larger vehicle choice sets, EPA should carefully consider the implications of the IIA property of the GCAM logit model and/or augment the model to relax the IIA restriction. Potential options for relaxing the GCAM logit IIA restriction include:

1. Modeling heterogeneity of consumer preferences, such in latent class logit models (sum of demand from multiple consumer groups with distinct demand model parameters) or mixed logit models (sum of demand from a set of consumers drawn from a population distribution of demand model parameters); or [EPA-HQ-OAR-2022-0829-0705, pp. 11-12]

2. Making alternative assumptions about the unobserved consumer utility error term, such as in the nested logit or probit models. [EPA-HQ-OAR-2022-0829-0705, pp. 11-12]

We expect that modeling heterogeneity is possible within the GCAM framework; it could be achieved by modeling multiple different consumer groups and determining demand as the sum across these consumer groups. This would require specifying the variation of consumer preferences across the consumer population. We present an example of empirical data below that could potentially be used to specify these parameters. [EPA-HQ-OAR-2022-0829-0705, p. 12]

In contrast, we expect that alternative assumptions about the error term would require models that deviate from the GCAM model form (but remain within the broader RUM framework). Therefore, relaxing the IIA property through consumer heterogeneity may be more feasible than relaxing it through alternative assumptions of the error term. [EPA-HQ-OAR-2022-0829-0705, p. 12]

Finally, we note that there is no single “right” way to model consumer demand – all models have assumptions and limitations. Among possible model forms, it is important to select models whose properties are appropriate for the application. The GCAM logit form’s IIA property is not restrictive for EPA’s current implementation predicting demand among two alternatives. However, if applied to larger choice sets in the future or in response to other comments on the proposed rule, it may overly restrict predicted substitution patterns among different vehicle types to ones that are based purely on the assumptions of the model form and may not accurately represent consumer substitution behavior. [EPA-HQ-OAR-2022-0829-0705, p. 12]

Because the GCAM logit model is a special case of the logit model, it effectively assumes that the only source causing different consumers to make different choices is random noise captured in the error term of the discrete choice model. There are two advantages to expand- ing the demand model in future iterations of OMEGA to model systematic heterogeneity:

[See original for Figure 6: Illustration of the 3 independent markets, each with 2 composite vehicles, in EPA’s OMEGA model] [EPA-HQ-OAR-2022-0829-0705, pp. 12-13]

1. Capturing systematic heterogeneity in consumer preference parameters, such as with a latent class logit or mixed logit model, relaxes the IIA substitution pattern restrictions of the logit model, enabling the ability to capture alternative substitution patterns driven by data rather than modeling assumptions. [EPA-HQ-OAR-2022-0829-0705, pp. 12-13]

2. Capturing systematic heterogeneity in consumer preference parameters allows assess- ment of differential effects across consumer groups, potentially allowing assessment of equity implications. [EPA-HQ-OAR-2022-0829-0705, pp. 12-13]

While future adaptations of EPA’s demand model to incorporate consumer heterogeneity would bring these advantages, it is important that the representation of consumer hetero- geneity appropriately represents consumer behavior. Ideally, the consumer parameters would be estimated based on empirical data and peer reviewed. [EPA-HQ-OAR-2022-0829-0705, pp. 12-13]

Recommendation 3. We recommend that EPA not modify the GCAM logit model to capture heterogeneity when finalizing the proposed rule (provided that only two alternatives remain in each of the demand simulations as described above) because doing so may introduce additional complications and take substantial time to execute correctly with peer review. We recommend that EPA begin internal and/or external research to advance the consumer de- mand model so that future iterations of OMEGA have the potential to incorporate consumer heterogeneity. [EPA-HQ-OAR-2022-0829-0705, pp. 12-13]

2.1.3 Share weights and alternative-specific constants

We show in the attached report and mathematical proof that the share weights in the GCAM model are equivalent to well-established alternative-specific constants (ASCs) in the logit model.1 This means that they represent the average utility of all unobserved attributes (such as BEV range, towing capability, accessories, aesthetics, etc.) that are considered by consumers in their purchasing decisions but are not included in the generalized cost. ASCs, and therefore share weights, have the following properties: [EPA-HQ-OAR-2022-0829-0705, pp. 13-14]

1 More precisely, the log of the share weight of vehicle j is equal to the alternative specific constant, $\ln(\alpha j) = \xi j$, where the alternative-specific constant, ξj, represents the average utility associated with all other attributes of the vehicle not represented by xj in the logit consumer utility, $uij = \beta jxj + \xi j + ?ij$.

1. ASCs (and therefore share weights) are only interpretable in relative terms. The value of an ASC has no meaning in and of itself; it can only be interpreted in relation to another ASC (e.g., if one vehicle's ASC is larger or smaller than another's and by how much). A common practice in estimating ASCs is to normalize the value of one alternative, which will act as a reference, and all other ASCs will be interpreted relative to that reference. [EPA-HQ-OAR-2022-0829-0705, pp. 13-14]

Implications for EPA:

Implications for EPA. In the draft regulatory impact analysis (DRIA), share weights are interpreted as being a measure of "consumer acceptance of the technology" (DRIA, p.4-5). The language in the DRIA implies that the interpretation is in absolute, rather than relative terms. This language should be modified to clarify the correct interpre- tation of the share weights. [EPA-HQ-OAR-2022-0829-0705, p. 14]

Specifically, the DRIA states "A constant share weight of 1 reflects the long-established nature of ICE technology in the light-duty vehicle market and the expectation that consumer attitudes toward ICE vehicles is stable," (DRIA, p.4-5). This does not have to be the case. Setting a share weight (ASC) to 1 for the ICE vehicles is a normalization, where the ASC of the BEV is measured relative to this baseline. This normalization is arbitrary (it could be set to any value), and it does not imply or reflect the idea that preferences for ICEVs are stable. What matters for model predictions is only the difference in ASCs (and thus share weights) between the ICE vehicle and the BEV. [EPA-HQ-OAR-2022-0829-0705, p. 14]

Recommendation 4. Revise model documentation to interpret share weights as interpretable only in relative terms. An increase in the BEV share weight relative to the ICEV share weight over time means that consumer utility for BEVs (due to factors other than generalized cost) is improving over time. [EPA-HQ-OAR-2022-0829-0705, p. 14]

2. ASCs (and therefore share weights) that change over time relative to the ref- erence represent the combined effect of changing technology and changing consumer preferences: ASCs (and therefore share weights) are lumped parameters representing the consumer utility associated with all other factors influencing their pur- chasing decisions that are not otherwise captured in the utility equation. This includes all other vehicle attributes as well as external considerations, such as ease of finding charging stations, network effects, and other factors influencing consumer preferences for BEVs relative to ICEVs. [EPA-HQ-OAR-2022-0829-0705, pp. 14-15]

Implications for EPA: The increasing share weights for BEVs relative to ICEVs over time represents improvements in BEV attributes other than generalized cost and/or improvements in consumer preferences for BEVs due to other factors than the ve- hicle's attributes. EPA's calibration of ASCs to IHS's share projections implicitly follows IHS's assumptions of the reasons why BEV market shares may increase over time. These are not explicitly described. We find evidence that consumer likelihood of purchasing BEVs could increase in the future if BEV range increases as expected and BEVs are as widely available across the market as ICEVs (Forsythe et al., 2023a) (see Appendix). We did not find evidence that consumer preferences for BEVs indepen- dent of the vehicle's technology improvements statistically significantly changed over a recent 8 year period. As we describe above in Section 1, it is possible that network effects and other factors could increase consumer preferences for BEVs in the future, but our study suggests that technology improvements were the larger factor over the past 8 years. [EPA-HQ-OAR-2022-0829-0705, pp. 14-15]

Recommendation 5. A more transparent approach of justifying increases in BEV share weights over time relative to ICEV share weights would be to use projected im- provements in vehicle attributes from a credible source, like the National Academies. We recommend that in future versions of OMEGA, EPA consider revising the calibra- tion of the share weights combining projected BEV improvements and credible estimates of how these changes would affect consumer willingness to pay for BEVs relative to ICEVs. We discuss such an example in Section 1. [EPA-HQ-OAR-2022-0829-0705, pp. 14-15]

2.2 Choice set

In the demand model used in the proposed rule, as we understand it, EPA models three independent markets (sedan/wagon, CUV/SUV, pickup truck) assumed not to interact. In each market, an aggregated representation of two different types of vehicles compete. This type of demand model is referred to as using ”composite” alternatives Yip et al. (2021). In EPAs model, consumer share is predicted for two composite vehicle types: an internal combustion engine vehicle (ICEV) and a battery electric vehicle (BEV), as illustrated in Figure 6. We discuss, in turn, implications of assuming independent markets, implications of using composite vehicle representations, and potential issues that may arise if the choice sets were changed. [EPA-HQ-OAR-2022-0829-0705, p. 15]

2.2.1 Implications of independent markets

The assumption that these markets are independent restricts substitution patterns, by assuming exogenously that a policy regulating cars and trucks differently will not shift con- sumers from one vehicle class to the other. In practice, policy may induce consumers to shift among these classes. [EPA-HQ-OAR-2022-0829-0705, p. 15]

Recommendation 6. We think EPA's decision to model these markets as independent is a reasonable simplification. We make similar assumptions in our work, described in Sec- tion 1. We do not recommend changing this assumption in the proposed rule because allowing markets to interact can introduce other kinds of substitution pattern issues, such as IIA, and substantial time, critique and peer review would be needed to successfully implement such a generalization. EPA's current assumptions are simple and transparent. However, we do recommend that EPA begin internal and/or external research on choice models that may be capable in future iterations of OMEGA of modeling the potential for policy intervention to induce consumers to shift across vehicle classes. [EPA-HQ-OAR-2022-0829-0705, p. 15]

2.2.2 Implications of composite vehicles

EPA's use of composite vehicle representations of ICEV and BEV offerings has two key advantages:

1. It avoids potential problems from substitution pattern restrictions from the IIA property of the GCAM logit model, as discussed in Section 2.1.1.

2. It reduces the search space so that the grid-search approach used by OMEGA is computationally tractable. [EPA-HQ-OAR-2022-0829-0705, p. 16]

However, the use of composite vehicles carries important implications. Yip et al. (2018) show that using composite vehicles with sales-weighted average attributes can produce substan- tially different choice share predictions than modeling all disaggregated vehicle alternatives (e.g.: make-model-trim), which we call the "elemental" alternatives. Two correction factors, one capturing the number of offerings represented by each composite and another captur- ing the heterogeneity of those offerings, can be used in a model with composite vehicles to recover the choice probabilities of the elemental-level choice set (Yip et al., 2018). [EPA-HQ-OAR-2022-0829-0705, p. 16]

The use of ASCs calibrated to market share data, as used by EPA, can eliminate the discrepancy between composite level choice sets and elemental level choice sets for some, but not all, counterfactual scenarios. Figure 6 of Yip et al. (2018) shows that ASCs eliminate the discrepancy in a baseline scenario and in a counterfactual scenario where BEV and PHEV subsidies are removed (price change only), whereas, without correction factors, models with composite level choice sets predict different choice shares than models with elemental level choice sets for counterfactual scenarios where BEV battery cost is reduced and/or the number of BEV offerings increases. This suggests that the use of composite vehicles can induce changes in predictions for certain counterfactual scenarios relevant to the proposed rule. [EPA-HQ-OAR-2022-0829-0705, p. 16]

Importantly, it is difficult to know the "right" level to model vehicle alternatives to most accurately represent consumer choices. Choice share predictions with the elemental level choice set need not necessarily imply a better match with reality than more aggregated vehicle alternatives. However, modelers should be aware that the use of composites introduces modifications to choice predictions in some counterfactual scenarios. These differences can also affect which vehicle design and pricing decisions are optimal (Yip et al., 2021). [EPA-HQ-OAR-2022-0829-0705, p. 16]

Recommendation 7. Because the current version of OMEGA uses the GCAM logit model, which has the IIA property substitution pattern restriction, we do not think an elemental level vehicle choice set would provide better estimates, and we do not recommend using correction factors to adjust the composite choice set choice shares. However, we do recommend that EPA begin (internal and/or external) research on how future versions of OMEGA that may examine larger choice sets should account for the implications of the use of composite vehicle representations on outcomes, including the potential use of correction factors described in Yip et al. (2018) and other sources. [EPA-HQ-OAR-2022-0829-0705, p. 16]

When using composite vehicle representations with correction factors, increases in the number of vehicles (e.g., different vehicle models) the composite is representing and the heterogeneity of these vehicle offerings increase the consumer utility of the composite. [EPA-HQ-OAR-2022-0829-0705, p. 17]

Recommendation 8. If the proposed rule induces automakers to increase BEV offerings, those increased offerings would increase the ASC (and therefore the share weight) for the BEV composite via composite correction factors, which would increase consumer demand for BEVs further than the simulations currently imply. We recommend that EPA avoid quantitatively accounting for this possibility unless there is credible evidence or justification of the magnitude that the proposed rule may have on vehicle offerings. We recommend that EPA note qualitatively that the proposed rule could increase BEV adoption more than estimated in the model by inducing new vehicle offerings, because new offerings would increase the composite's share weight. We also recommend that EPA begin (internal and/or external) research to investigate the implications of composites and policy-induced vehicle offerings for future versions of OMEGA that may model such effects. [EPA-HQ-OAR-2022-0829-0705, p. 17]

2.2.3 PHEVs

EPA's analysis focuses on internal composition vehicles and battery electric vehicles, ignoring plug-in hybrid electric vehicles (PHEVs) that use electricity for short trips and gasoline for long trips. We expect PHEVs to represent a substantial portion of the fleet mix over the period of the proposed rule. [EPA-HQ-OAR-2022-0829-0705, p. 17]

Recommendation 9. While we do think it would be valuable to assess the implications of PHEVs, we do not recommend doing so with the current automotive choice model ap- proach except potentially as a sensitivity case. The reason is that if a composite PHEV were added to each of the markets in Figure 6, the IIA property substitution pattern restrictions discussed in 2.1.1 would imply that PHEVs compete proportionally with ICEVs and BEVs. Unless there is evidence to support such substitution patterns, we would be concerned that modeled implications of the proposed policy would be partly driven by this substitution pat- tern restriction and could be misleading. Instead, we recommend that EPA pursue (internal and/or external) research described in Section 1 toward developing a future OMEGA model to support future rules that avoids this restriction and informs substitution patterns more directly from empirical data, rather than model assumption. [EPA-HQ-OAR-2022-0829-0705, p. 17]

2.3 Data

As we understand it, EPA's GCAM logit model effectively has three parameters:

1. The discount rate

2. The gamma parameter (which we show in the attached report is equivalent to the utility coefficient for log generalized cost in a logit model)

3. The share weight (which we show is equivalent to a function of the vehicle's alternative- specific constant in a logit model) [EPA-HQ-OAR-2022-0829-0705, pp. 17-18]

Of these parameters, the share weight parameters are calibrated to exogeneous projections from IHS to define the baseline, while the discount rate and gamma parameters are as- sumed exogeneously and determine the consumer response to changes in vehicle efficiency and purchase price induced by the proposed policy. We discuss each in turn and provide recommendations:

1. The discount rate defines the relative importance of purchase cost vs. annual costs (fuel, maintenance, etc.) paid in the future. EPA assumes it to be 10%. This is within the range of empirical estimates that appear in the literature [CITE], and it is consistent with the kinds of opportunity cost opportunities that many consumers have (e.g.: opportunity to pay down loans, credit card debt, etc.). [EPA-HQ-OAR-2022-0829-0705, pp. 17-18]

Recommendation 10. EPA's assumption for discount rate is reasonable and con- sistent with theory and empirical evidence, though a range of equally reasonable as- sumptions could be made. Because the effect of the proposed rule on consumer demand outcomes depends on the discount rate parameter assumption, we recommend that EPA conduct sensitivity analysis to alternative assumptions for the discount rate that are consistent with empirical estimates. Specifically, we recommend testing assumptions x and y because [CITE rationale in literature]. [EPA-HQ-OAR-2022-0829-0705, pp. 17-18]

The gamma parameter defines how much generalized cost weighs in consumer de- cisions relative to the unobserved attributes captured in the ASC (share weight) term. In extremes, if $\gamma = 0$ we expect consumers to choose only due to unobserved attributes in the ASC and for demand to be unaffected by vehicle price, fuel cost, and other costs. As $\gamma \rightarrow \infty$ we expect consumers to deterministically select the alternative with the lowest generalized cost. EPA is using $\gamma = 0.8$, but it is not clear from the model documentation how EPA selected this value or what empirical basis it has. [EPA-HQ-OAR-2022-0829-0705, p. 18]

Recommendation 11. Provide justification for the value of the gamma parameter and conduct sensitivity analysis to determine the degree to which variation in this parameter may change predictions of policy implications. [EPA-HQ-OAR-2022-0829-0705, p. 18]

The share weight, which maps directly to alternative-specific constants (ASCs) in a logit model, represent the utility of all attributes not otherwise captured by generalized cost (e.g., range, accessories, aesthetics, etc.).2 EPA calibrates these ASCs so that the model's resulting choice shares match those predicted by IHS in a baseline ”No Action” scenario: “We calibrated absolute shareweight values so that the overall BEV shares produced by the OMEGA model would align with an external projection of BEV sales published by IHS Markit (IHS Markit 2021)” (EPA, p. 4-8). We reviewed the IHS projects and found that, although IHS states that “the forecast combines both a top down and bottom up approach for transparency, flexibility and traceability”3, the modeling assumptions behind these projections are not fully in the public domain: “The Light Vehicle Sales Forecast and most modules are delivered via AutoInsight, a proprietary web application.”4 ... . Because all vehicle attributes outside generalized cost are captured in the ASC term, which includes potential improvements in vehicle attributes and potential future changes in consumer preferences separate from the vehicle's attributes, there is limited transparency about what kinds of vehicle and consumer changes could produce these outcomes. Our work suggests that consumer preferences may be relatively stable and that some attributes unobserved in EPA's model, like BEV range, may be critical to driving adoption (Forsythe et al., 2023a). The current approach assumes that the proposed policy does not affect unobserved attributes such as by incentivizing automakers to increase BEV range or trade off performance or cargo capacity. [EPA-HQ-OAR-2022-0829-0705, pp. 18-21]

2 More precisely, the log of the share weight of vehicle j is equal to the alternative specific constant, ln(αj) = ξj, where the alternative-specific constant, ξj, represents the average utility associated with all other attributes of the vehicle not represented by xj in the logit consumer utility, uij = βjxj + ξj + ?ij.

3 IHS Markit Automotive Advisory, Slide 11

4 IHS Markit Light Vehicle Sales Forecast, Page 6

Recommendation 12. We recommend that EPA begin (internal and/or external) research to develop consumer choice models based on empirical choice data to charac- terize consumer responses to attributes beyond generalized cost so that future versions of OMEGA can be more transparent in the implied assumptions of the share weight calibration. We provide an example in Section 1. We do not recommend that EPA pursue such a model change for the current rule, since it takes substantial time to de- velop a high quality model, and such models should be subjected to critique and peer review before use. We view EPA's current OMEGA 2.0 model as reasonable for in- forming the current rule. We recommend EPA examine how the model could be further improved in future versions of OMEGA to more clearly justify the assumptions of the share weight callibration. [EPA-HQ-OAR-2022-0829-0705, pp. 18-21]

EPA Summary and Response

The consumer module of OMEGA and RIA Chapter 4.1 have been revised for the FRM and now address many of the comments received on this topic. Before we list those revisions and respond to comments, we note that comments on consumer side modeling allude to consumer demand, PEV acceptance, projected technology shares, third party estimates, heterogeneity among consumers, and technology diffusion. We respond to those comments here only to the extent that they are related to modeling structure, assumptions, and inputs. See Section 13 of this RTC for more on those topics. For example, we discuss the calibration of shareweight parameters here and discuss the factors influencing consumer acceptance that underlie shareweight parameter estimation in Chapter 13. In addition, where commenters make additional recommendations not directly relevant to consumer side modeling such as electricity price, grid reliability, and charging, we refer readers to respective sections of the Preamble, RIA, and this RTC.

Revisions to consumer side modeling and corresponding RIA text include the following:

- EPA has revised vehicle choice sets to include PHEVs.
- EPA has estimated re-calibrated shareweights to include PHEVs, recent research of PEV acceptance, and recent third party-projections of PEV market shares that include BIL and IRA.
- EPA has assumed that consumers include in their purchase decision estimated annual vehicle miles traveled equal to 15,000 miles.
- EPA has revised RIA Chapter 4 text to reflect the correct value of the logit parameter and describe the rationale behind the value of the logit parameter.
- EPA has revised RIA Chapter 4 text to provide additional information on the annual non-fuel ownership costs consumers incorporate into their purchase decision.
- EPA has revised Chapter 4 text to include reasons for increases in BEV and PHEV shareweights over time, while reference case shareweights for ICE vehicles remain static.

These revisions, documented in RIA Chapter 4, address most of the comments on consumer side modeling. We discuss comments in more detail below. Note that commenters Jeremy Michalek et al. provided a comprehensive description of EPA's consumer side modeling in their comments. We refer readers to their excellent exposition. In addition, they situated EPA's consumer side modeling in the broader context of "random utility discrete choice models" and their own review of "over 200 automotive demand model studies in the scientific literature and government reports." Importantly, they state "random utility discrete choice models to be the dominant paradigm for modeling automotive demand, with the logit model and its variants most commonly used. Thus, EPA's demand model follows the dominant paradigm and inherits the properties of random utility discrete choice models." For those reasons, and because Jeremy Michalek et al. very clearly highlight the comments that require response (i.e., what they call recommendations), we employ the structure they provide to organize our response to all comments relevant to consumer side modeling. Importantly, we exclude the recommendations for future research and future rulemakings.

"Recommendation 2. If EPA considers model variations that involve larger vehicle choice sets, EPA should carefully consider the implications of the Independence of Irrelevant Alternatives (IIA) property of the GCAM logit model and/or augment the model to relax the IIA restriction." In response, EPA has included PHEVs in vehicle choice sets, representing consumer choice among three technology options – BEVs, PHEVs, and ICE vehicles.[430] We have effectively made "alternative assumptions about the unobserved consumer utility error term." In lay terms, we have assumed in the absence of evidence to the contrary, that consumers view BEV, PHEVs, and ICE vehicles as three distinct choices. In other words, when it comes to choosing a vehicle, PHEVs are in a category of their own, just like BEVs and ICE vehicles are..

"Recommendation 3. We recommend that EPA not modify the GCAM logit model to capture heterogeneity when finalizing the proposed rule (provided that only two alternatives remain in each of the demand simulations as described above) because doing so may introduce additional complications and take substantial time to execute correctly with peer review." In response, EPA has not modified the logit model to capture heterogeneity (despite adding a third alternative) because current PEV sales and registration data are not sufficiently representative of mainstream consumers to adequately support a model that captures heterogeneity. Relatedly, the Alliance for Automotive Innovation suggests that modeling the geographic diffusion of BEVs is important for accurately gauging the customer acceptance of the national standards. In response, we disagree. Empirical evidence is insufficient to support a modeling endeavor of that granularity, nor is it imperative. As Jeremy et al. points out and every good modeler knows, models require are a simplifications, and there are pros and cons to every modeling approach. EPA has opted for an approach that is well-situated as the dominant paradigm and chosen a level of granularity that is consistent with available data.

"Recommendation 4. Revise model documentation to interpret share weights as interpretable only in relative terms. An increase in the BEV share weight relative to the ICEV share weight over time means that consumer utility for BEVs (due to factors other than generalized cost) is improving over time." In response, EPA has revised the corresponding text accordingly.

"Recommendation 5. A more transparent approach of justifying increases in BEV share weights over time relative to ICEV share weights would be to use projected improvements in vehicle attributes from a credible source, like the National Academies." In response, EPA has revised RIA Chapter 4 text to include reasons for increases in BEV and PHEV shareweights over time due to increased awareness and access, while reference case shareweights for ICE vehicles remain static.

"Recommendation 6. We think EPA's decision to model these markets [i.e., model consumer decision making within body style] as independent is a reasonable simplification. …We do not recommend changing this assumption in the proposed rule." In response, EPA continues to model consumer choice within body styles.

[430] Note that the producer module includes a larger choice set of technology to choose from in meeting the standards, including different levels of non-plug-in hybrid technology. These are combined into "ICE" for the purposes of consumer choice in the consumer module.

"Recommendation 7. Because the current version of OMEGA uses the GCAM logit model, which has the IIA property substitution pattern restriction, we do not think an elemental level vehicle choice set would provide better estimates, and we do not recommend using correction factors to adjust the composite choice set choice shares." In response, EPA continues to use composite vehicles and does not use correction factors.

"Recommendation 8. If the proposed rule induces automakers to increase BEV offerings, those increased offerings would increase the ASC (and therefore the share weight) for the BEV composite via composite correction factors, which would increase consumer demand for BEVs further than the simulations currently imply. We recommend that EPA avoid quantitatively accounting for this possibility unless there is credible evidence or justification of the magnitude that the proposed rule may have on vehicle offerings. We recommend that EPA note qualitatively that the proposed rule could increase BEV adoption more than estimated in the model by inducing new vehicle offerings, because new offerings would increase the composite's share weight." In response and consistent with Recommendation 4, EPA has revised RIA Chapter 4 text to include reasons for increases in BEV and PHEV shareweights over time due to increased awareness and access, where "access" includes the availability of PEVs with desired body style.

Recommendation 9. While we do think it would be valuable to assess the implications of PHEVs, we do not recommend doing so with the current automotive choice model approach except potentially as a sensitivity case" due to concerns related to Independence from Irrelevant Alternatives. In response, EPA disagrees. As stated in response to Recommendation 2, In response, EPA has included PHEVs in vehicle choice sets, representing consumer choice among three technology options – BEVs, PHEVs, and ICE vehicles. We have assumed in the absence of evidence to the contrary, that consumers view BEV, PHEVs, and ICE vehicles as three distinct choices. In other words, PHEVs are not any more like a BEV than they are like an ICE vehicle. We have also recalibrated shareweights to be consistent with moderate third-party projections of technology market shares.

"Recommendation 10. EPA's assumption for discount rate is reasonable and consistent with theory and empirical evidence, though a range of equally reasonable assumptions could be made. Because the effect of the proposed rule on consumer demand outcomes depends on the discount rate parameter assumption, we recommend that EPA conduct sensitivity analysis to alternative assumptions for the discount rate that are consistent with empirical estimates." In response, EPA appreciates that Jeremey Michalek et al. state that our assumption for discount rate is reasonable and consistent with theory and empirical evidence. As a result, we did not conduct sensitivity analysis of the discount rate.

"Recommendation 11. Provide justification for the value of the gamma parameter and conduct sensitivity analysis to determine the degree to which variation in this parameter may change predictions of policy implications." In response, we have corrected RIA Chapter 4 text to show that the logit parameter is -8. The negative sign of the logit parameter reflects that alternatives are represented with costs (i.e., lower cost items are generally preferred) and the magnitude of the logit parameter regulates the degree to which relative costs affect choice among battery electric, plug-in hybrid electric, and ICE vehicle technologies. In our modeling, the magnitude of the logit is specified to allow for market penetration of lower and higher priced vehicles which is consistent with other models and with shareweight parameters.

This concludes the consumer side modeling comments provided by Jeremy Michalek et al.

In addition, ICCT recommends EPA model MDV consumers as valuing at least 5 years of fuel savings. In response, EPA offers a clarification. In OMEGA, the consumer purchase decision for MDV is not modeled the same way as it is for LD consumers. LD consumers' purchase decisions differ from producers' assumptions about consumers' purchase decision, however MDV consumers incorporate fuel savings exactly as producers assume they do, which is set to 2.5 years for this analysis. We appreciate the logic of ICCT's argument. We also note that there is no consensus around the role of fuel consumption in vehicle purchase decisions, and the evidence discussed in RIA Chapter 4.4.1.1 states that automakers "perceive that typical consumers would pay upfront for only one to four years of fuel savings." Thus, EPA finalized this rule assuming 2.5 years of fuel savings are incorporated into MDV purchase decisions. See RIA Chapter 4.4 or RTC Section 14 for more information on the choice of 2.5 years of fuel savings in purchase decisions.

Commenters suggested that the estimates of PEV market shares are too high and offer comparisons to, for example, U.S. Energy Information Administration.[431] Annual Energy Outlook 2023, S&P Global Mobility, Bloomberg, Benchmark Minerals Intelligence (BMI), and the International Council on Clean Transportation (ICCT). In response, we note that we have revised OMEGA projections since the NPRM (See RIA Chapter 8) and demonstrated several compliance pathways. We have also updated consumer side modeling to include PHEVs in addition to BEVs, hybrids, and ICE vehicles and re-calibrated shareweight parameters accordingly. In addition, we have re-calibrated PEV acceptance parameters, taking into account recent third-party studies that include the BIL and IRA (See RIA Chapter 4.1.2). As a result, we conclude that projections of PEV market shares in the FRM central case are reasonable estimates of vehicle technology market shares. Our parametrization of PEV acceptance is based on the scientific literature on consumer acceptance, and the resulting central case estimate of future PEV market shares is consistent with moderate third-party estimates (See RIA Chapter 4.1.2). Importantly, we reviewed lower and higher third-party estimates of PEV market shares, and calibrated to the moderate cases. Furthermore, we acknowledge the uncertainty inherent in any estimate, and as a result, we have projected PEV market share for slower and faster PEV acceptance. These sensitivities, along with others shown in RIA Chapter 12, lead us to conclude that compliance can be achieved under a broad range of PEV acceptance and adoption rates. (See RIA Chapter 4.1.3 and RIA Chapter 12.1.4).

12.1.3 - Effects/emissions reductions modeling

Comments by Organizations

Organization: American Free Enterprise Chamber of Commerce (AmFree) et al.

EPA's Analysis Of Net Emissions Is Flawed

[431] Some commenters characterize EPA estimates of technology market shares as "assumptions" To be absolutely clear, EPA has not assumed growth in PEV adoption. Rather, we have estimated vehicle technology adoption usingt OMEGA. PEV adoption estimates are model outputs that follow from several modeling inputs, including acceptance, technology costs, and consumer costs. They also follow from the modeled interaction of producer and consumer decision making. See RIA Chapters 8.1, 8.2, and 8.3.

EPA estimates that the proposed rule will result in a net reduction of GHG, criteria air pollutant, and air toxic emissions in 2055. See 88 Fed. Reg. at 29,198. That estimate is dubious. In numerous ways, EPA has underestimated the up- stream emissions—i.e., those that do not come from the vehicle itself but can still be attributed to its manufacture and operation—that will result from a widespread shift to electric vehicles. [EPA-HQ-OAR-2022-0829-0683, pp. 55-56]

First, EPA improperly cabins its upstream analysis to only those emissions caused by electricity generating units ("EGUs") and refineries. See 88 Fed. Reg. at 29,198, 29,347, 29,353, 29,355; Draft RIA at 9-32–33. But the emissions as- sociated with powering a vehicle—whether by electricity from an EGU or fuel from a refinery—are far from the only ones reasonably attributed to its opera- tion. Depending on the vehicle, there are also emissions associated with pro- ducing, recycling, and disposing of batteries; operating charging infrastructure; and extracting, refining, transporting, and storing petroleum fuels. These emis- sions can be substantial and, when considered together, may undermine EPA's assumption that swapping internal-combustion-engine vehicles for electric ones will necessarily result in an environmental good. [EPA-HQ-OAR-2022-0829-0683, pp. 55-56]

The International Energy Agency's discussion of emissions from mining il- lustrates this point. According to the IEA, "the production and processing of energy transition minerals are energy-intensive" and involve "relatively high emission[s]." Role of Critical Minerals at 15, 130; see also Charging Infrastructure Challenges for the U.S. Electric Vehicle Fleet, Am. Transp. Rsch. Inst., https://ti- nyurl.com/3ktjd85v ("Mining and processing produce considerable CO2 and pollution issues."). For this reason, producing an electric vehicle is a more car- bon-intensive process than producing a conventional one. Role of Critical Miner- als at 194. [EPA-HQ-OAR-2022-0829-0683, pp. 55-56]

EPA never explains why emissions from EGUs and refineries are the only ones relevant to the analysis. Instead, it acknowledges that "[t]he upstream emissions inventory does not account for all upstream sources related to vehicles, fuels, and electricity generation, such as charging infrastructure, stor- age of petroleum fuels, battery manufacture, etc." Draft RIA at 8-14. But EPA makes no attempt to justify that selective, incomplete approach. [EPA-HQ-OAR-2022-0829-0683, pp. 55-56]

Moreover, EPA's current position marks a change from settled agency prac- tice. In earlier GHG and criteria-pollutant rulemakings, the agency did con- sider additional upstream sources in assessing net emissions. See SAFE Vehicles Rule for Model Years 2021-2026 Passenger Cars and Light Trucks, 85 Fed. Reg. 24,174, 24,872 (Apr. 30, 2020) (noting that emissions "model accounts for up- stream emissions" from "extraction, transportation, refining, and distribution of . . . fuel"); Greenhouse Gas Emissions Standards and Fuel Efficiency Standards for Medium- and Heavy-Duty Engines and Vehicles, 76 Fed. Reg. 57,106, 57,301 (Sept. 15, 2011) ("To project these impacts, EPA estimated the impact of reduced pe- troleum volumes on the extraction and transportation of crude oil as well as the production and distribution of finished gasoline and diesel."); Greenhouse Gas Emissions and Fuel Efficiency Standards for Medium- and Heavy-Duty Engines and Vehicles—Phase 2, 81 Fed. Reg. 73,478, 73,852 (Oct. 25, 2016) ("To project these impacts, Method B estimated the impact of reduced petroleum volumes on the extraction and transportation of crude oil as well as the production and distribution of finished gasoline and diesel."). The agency has not acknowl- edged its change in position here, let alone explained "why the new approach" of ignoring these upstream emissions "better comports with . . . the provisions that Congress enacted." Am. Fed'n of Gov't Emps. v. FLRA, 25 F.4th 1, 12 (D.C. Cir. 2022). That is reason enough to conclude that "the [agency] has not, in fact, engaged in reasoned decisionmaking." Id. (internal quotation marks and brackets omitted). Nor could EPA offer a valid explanation for its change. Up- stream emissions are more important in the current rulemaking than they were in previous regulations given that EPA, for the first time, intends to effectively mandate widespread adoption of electric vehicles, which (as explained above) produce emissions primarily through upstream sources. [EPA-HQ-OAR-2022-0829-0683, p. 56]

Second, EPA's assessment of EGU emissions is flawed. EPA assumes that emissions associated with increased demand for electricity will decrease over time because of projected changes in the future generation mix, including "in- creasing use of renewables." 88 Fed. Reg. at 29,303–04, 29,198, 29,353. That expectation is based on speculation that various provisions of the IRA will sub- stantially alter the power-generation mix. See id. at 29,303–04; Draft RIA at 5-9–10. But even if the power-generation mix changes in the way EPA predicts— i.e., even if EGUs alter the sources they use to power their base loads in the way EPA anticipates—analysis of EGU emissions must also account for the pro- spect that EGUs will switch to other sources to address peak loads, including those that will inevitably occur if the proposed rule is adopted. [EPA-HQ-OAR-2022-0829-0683, pp. 56-58]

Providing electricity to meet peak loads can have a disproportionately high impact on emissions, which cannot be adequately captured by looking at "av- erage emissions" (i.e., carbon intensity) across the electricity sector. Stephen P. Holland et al., Why Marginal CO2 Emissions Are Not Decreasing for US Electricity: Estimates and Implications for Climate Policy, Nat'l Acad. of Scis., at 1 (2022). For example, according to a recent study, changes in the electricity sector have caused EGUs to rely increasingly on coal to meet demand that exceeds their typical capacity. Id. ("More recently, however, changes in the electricity sector have pushed coal, which has the greatest CO2 intensity, to more frequently be used as the marginal fuel for generation, thereby increasing marginal emissions."). "[E]stimates of marginal emissions" thus "are needed to accurately evaluate the impacts of policies or behaviors that cause changes in the demand or supply of electricity." Id. at 2. [EPA-HQ-OAR-2022-0829-0683, pp. 56-58]

The authors of the study demonstrated the importance of this point in the context of electric vehicles. They analyzed the Biden Administration's goal to make half of new vehicle purchases electric by 2030 and concluded that, when taking marginal emissions into account, "the increase in electricity sector CO2 emissions . . . would undo more than half of the reductions from reducing the number of gasoline-fueled, light-duty vehicles." Holland et al., Why Marginal CO2 Emissions Are Not Decreasing, supra, at 2. By contrast, if they had instead looked only at average emissions, "the emissions reductions would [have been] overestimated by somewhere between 27% and 114%." Id. [EPA-HQ-OAR-2022-0829-0683, pp. 56-58]

EPA does not explain whether or how it takes marginal emissions into ac- count when estimating EGU emissions. Although the agency indicates that its power-sector modeling shows an increase of renewables, it makes clear that, even under its predictions, renewables will not entirely displace coal or natural gas. See 88 Fed. Reg. at 29,303–04 (explaining that its "[p]ower sector modeling results showed that the increased use of renewables will largely displace coal and (to a lesser extent) natural gas EGUs" (emphases added)). Neither the notice of proposed rulemaking nor the draft regulatory impact analysis discusses the marginal-emissions concept, and stakeholders were denied an opportunity to study the agency's complicated modeling given the exceedingly short window for public comment. [EPA-HQ-OAR-2022-0829-0683, pp. 56-58]

Given the importance of this issue, EPA should clearly explain whether it considered marginal emissions. If it has, EPA should explain how it analyzed that aspect of the problem and how it affects EPA's projection of reduced emis- sions. If EPA has not considered the issue, it should do so, or at a minimum, explain why it believes that omission to be justified.6 [EPA-HQ-OAR-2022-0829-0683, pp. 56-58]

6 EPA does not even address the impact that hydrogen production—necessary for powering fuel-cell vehicles—would have on net emissions.

Finally, EPA may be substantially overestimating the decrease in refinery emissions. The agency's "central analysis estimates that . . . reduced liquid fuel demand results in reduced domestic refining." 88 Fed. Reg. at 29,358; see also id. at 29,198, 29,353. But at the same time, EPA "recognize[d] that there is significant uncertainty in the impact on refinery emissions due to decreased demand." Draft RIA at 8-12. Indeed, there is a distinct "possibility that reduced domestic demand for liquid fuel would have no impact on domestic refining." 88 Fed. Reg. at 29,358 (emphasis added); see Draft RIA at 8-12 ("If refineries do not decrease production in response to lower domestic demand" and "in- crease exports" instead, total upstream emissions "would be higher," not lower. (emphasis added)). EPA must explain the basis for its assumption that refiner- ies will decrease production before it factors these sizeable reductions into the calculation. See Int'l Harvester Co. v. Ruckelshaus, 478 F.2d 615, 645 (D.C. Cir. 1973) (explaining that EPA must "support its methodology as reliable" with more than "speculation"). [EPA-HQ-OAR-2022-0829-0683, p. 58]

In sum, EPA's analysis of upstream emissions rests on unfounded assump- tions and methodological choices that are skewed in favor of the proposed rule. EPA should withdraw its proposal and conduct a more thorough assessment of the ways in which a widespread shift to electric vehicles will impact overall emissions.7 [EPA-HQ-OAR-2022-0829-0683, p. 58]

7 EPA's superficial analysis of upstream emissions also undermines its discussion of "the envi- ronmental justice impacts of [its] proposal." 88 Fed. Reg. at 29,393; see id. at 29,199, 29,393–97. Although the agency acknowledges that upstream emissions can negatively affect certain populations, it improperly discounts those negative effects by failing to consider emissions as- sociated with anything other than EGUs and refineries, speculating that the emissions from EGUs will decrease over time due to changes in the future generation mix, and overestimating the decrease in refinery emissions.

Organization: American Fuel & Petrochemical Manufacturers

1. EPA overstates the environmental benefits

EPA touts several emissions benefits in the Proposed Rule from shifting the light-duty vehicle fleet to ZEVs. But EPA's analysis is lopsided in favor of its preferred technology. In analyzing environmental costs and benefits, EPA overlooks negative environmental consequences of ZEVs from increased power generation, vehicle usage, ZEV tire wear, the EV manufacturing supply chain, and battery replacements and disposal at the end of their useful life. Notably, EPA fails to assess net emissions. Although EPA modeled changes to power generation anticipated by the Proposed Rule as part of its upstream analysis, EPA does not consider the potential degradation of air quality in areas in the direct vicinity of existing or new power plants.204 [EPA-HQ-OAR-2022-0829-0733, pp. 44-45]

204 Id. at 29,379 (noting that although "[e]missions from upstream sources would likely increase in some cases (e.g., power plants) and decrease in others (e.g., refineries), EPA projects that the Proposed Rule will result in a total decrease in emissions of certain pollutants").

EPA assumes the power sector is expected to shift over time to using significantly more wind/solar generation and electricity storage (i.e., batteries), but ignores the environmental impacts of the overall increase in critical minerals demand for electrical grid storage and how that compounds the stress on critical minerals for the ZEVs themselves. But the expansion of electrical grids—even ignoring the Proposed Rule's increased demand—requires a large amount of earth minerals and metals. Copper and aluminum, which are both needed for ZEVs, are also the two main materials in wires and cables and, as described above, higher prices could have a major impact on future grid investments and EV costs.205 The need for expanded grid capabilities simultaneous to expanded ZEV production places a more pressing demand on materials like copper and aluminum thereby increasing extraction and refining efforts throughout the global market. [EPA-HQ-OAR-2022-0829-0733, pp. 44-45]

205 IEA Report 2022.

EPA's Proposal unreasonably relies on comparing ICEV's and ZEV's performance based on EPA's own vastly different fuel economy testing procedures for these two different technologies and incorrectly assumes it is an apples-to-apples comparison. This error significantly undermines EPA's estimates of potential environmental benefits. EPA has cherry- picked the data underlying its analysis to boost the estimated environmental benefits from EVs compared to ICEVs by a significant percentage. EPA's proposal is based on performance data estimates of ICEV fuel economy using EPA's "5-cycle method", i.e., Federal Test Procedure-75 ("FTP") at regular and cold temperatures, Highway Fuel Economy Test ("HWFET") and High- Speed Driving (US06) and Use of Air Conditioning (SC03). EPA's proposal is also based on performance data estimates of ZEV fuel economy that (unlike the testing for ICEVs) never account for EVs operating: above a top speed of 60 mph (whereas ICEVs are tested at 80 mph), above an acceleration rate of 3.2 mph/sec (whereas ICEVs are tested at 8.46 mph/sec); in real world temperatures (ZEVs are tested at optimal battery performance temperatures of approximately 75 degrees F, while ICEVs are tested at 20 degrees F and 95 degrees F); with air conditioning and heating (EPA assumes ZEVs never used air conditioning or heating). See AFPM Comments on the Department of Energy Petroleum-Equivalent Fuel Economy Calculation and Petition for Rulemaking, 88 Fed. Reg. 21525 (April 11, 2023) (Attachment 3) [EPA-HQ-OAR-2022-0829-0733, pp. 46-47]

These discrepancies are unreasonable and arbitrary. If EPA's analysis were based on real-world fuel economy testing of ZEVs, it would show they use vastly higher amounts of electricity to travel the same distance, with a corresponding increase in power sector emissions and ZEV maintenance and battery replacement and associated environmental impacts. EPA must account for these differences and environmental impacts. [EPA-HQ-OAR-2022-0829-0733, pp. 46-47]

EPA incorrectly assumes that ZEV owners will pay the national average residential electricity price to charge their vehicles. EPA fails to consider that the majority of ZEVs in the U.S. are located in utility service territories with some of the highest electricity rates in the country and that the average EV owner currently pays a much higher price to charge their ZEV at home than the national average residential electricity rate. Given that EV penetration has varied widely across the U.S., it would be arbitrary to assume that EVs will, unlike in the past, penetrate uniformly across the U.S. and thus that the average electricity price would be representative of the actual cost electricity. For example, California, which has roughly 40 percent of all registered ZEVs in the U.S., has a residential electricity rate that is roughly double the national average. Considering that EPA is modeling its rule after a California-like approach to mandate ZEVs, it would be more appropriate for EPA to assume similar real-world costs (at a minimum, given California's temperate climate). Moreover, EPA fails to consider that mandating such a high ZEV sales rate will necessarily require exponential increases in commercial ZEV charging at rates that are currently three, four or five times higher than the current national average residential electricity rate, depending on location and charging speed. Those customers who are not homeowners and not able to install their own charging stations and take advantage of charging at low-cost times will be adversely impacted. Instead, EPA uses a residential rate for electricity and does not consider peak power or time of use charges. California electric prices rose 42 percent - 78 percent between 2010 and 2020 and are projected to rise an additional 50 percent by 2030 as shown in Figure 9. [EPA-HQ-OAR-2022-0829-0733, pp. 57-58]

SEE ORIGINAL COMMENT FOR Historic and Forecasted Residential Average Rates Based on Most Recent 5-year Average Rate Increase. Figure 9:

Source: Michael Shellenberger, Twitter (citing California Public Advocate's Office data), April 27, 2021). [EPA-HQ-OAR-2022-0829-0733, pp. 57-58]

Heaping additional demand for EV charging into this market could exacerbate already high electricity prices. This will be especially impactful to lower-income homeowners who may not be able to install dedicated charging units, forcing them to pay more out of pocket for charging during peak demand periods.265 [EPA-HQ-OAR-2022-0829-0733, pp. 57-58]

265 Hardman, Scott, et al., "A Perspective on Equity in the Transition to Electric Vehicles." MIT Science Policy Review, (Aug. 20 2021), available at https://sciencepolicyreview.org/2021/08/equity-transition-electric-vehicles/ (accessed June 29, 2023).

EPA must revise its analysis to account for realistic electricity prices. The proposed ZEV mandate will require an enormous investment in power generation and distribution, resulting in nationwide increases in electricity bills that EPA has not considered. Of course, considering the additional trillions of dollars in costs would paint a clear picture that the costs of forced electrification far exceed even the inflated benefits EPA presented in the Proposed Rule. [EPA-HQ-OAR-2022-0829-0733, pp. 57-58]

As previously mentioned, EPA did not fully consider the impact of the rule on fleet turnover. The Agency is aware that the higher purchase price of new ZEVs will keep older cars and trucks on the road longer and that new ZEVs will increase particulate matter ("PM") emissions through increased tire and road wear.

Organization: American Honda Motor Co., Inc.

Marginal abatement cost of shifting from 1.0 mg/mi to 0.5 mg/mi is exceedingly high

Using EPA's own cost estimate for a GPF, one can compute a marginal abatement cost of PM emissions. On a per-vehicle basis, improving from 1.0 mg/mi (Honda's suggested alternative of aligning with California's LEV IV program nationwide) to 0.5 mg/mi will result in an additional emissions savings of 0.0001075 metric tons over the life of a vehicle. As shown in Table 2 below, EPA estimates $128.60 per GPF, a conservative estimate as that excludes any costs associated with testing, development or updating of laboratory hardware. In spite of this, the agency's estimated GPF costs still amount to a marginal abatement cost of approximately $1.2 million per metric ton of PM2.5. This number stands in stark contrast to the $160,000/ton maximum marginal abatement cost threshold for control strategies which EPA set for their December 2022 PM 2.5 NAAQs rulemaking.28 Comparatively, the PM2.5 marginal abatement cost being considered for this multipollutant rule is nearly 7.5 times as high. [EPA-HQ-OAR-2022-0829-0652, p. 16]

Organization: California Air Resources Board (CARB) (Part 1 of 5)

Maintaining reductions from conventional vehicles

While CARB notes the tremendous benefits associated with ZEV deployment, it is also important to continue to reduce GHG emissions across the fleet. Due to the inherent flexibility of a performance standard, U.S. EPA's proposal does not specify or require manufacturers to meet any particular technology mix to comply with the fleet average standards so long as a manufacturer's calculated compliance values can meet the fleet average; manufacturers are not limited in the emission rates of any individual vehicle model as long as their overall sales-weighted fleet average does not exceed the standard. Indeed, combining the estimated BEV penetration rates U.S. EPA's model projects with its proposed GHG standards, the standards allow for the GHG emission rates for the remaining non-BEVs to increase from approximately 240 g/mi in 2027 to approximately 250 g/mi in 2032 with the fleet overall still achieving compliance with the standards. [EPA-HQ-OAR-2022-0829-0780, pp. 13-15]

To understand this potential increase, CARB analyzed U.S. EPA's modeled fleet results for the 2022 through 2032 MYs. To remove the possibility that the higher average emissions in the later years is simply a result of the types or sizes of vehicles remaining as conventional vehicles, this analysis evaluated only the vehicles that U.S. EPA's model projected to remain as internal combustion engine vehicles from the 2022 through 2032 MYs (approximately 33 percent of the 2032 MY sales). As shown in Figure 1, the projected sales-weighted average tailpipe emissions from this subset of vehicles initially declines to approximately 240 g/mi by the 2028 MY but then increases to 255 g/mi by the 2032 MY. 9 Although not all of the individual vehicle models in this subset display this trend, the average trend is not driven by a few high-volume models; the individual emission profiles of the majority of vehicle models decrease and then increase to a higher emission rate in 2032 than in earlier MYs. Furthermore, this projected increase in emission rates is not trivial. Three-quarters of the vehicles in this subset increase their emissions by more than 20 g/mi, with some models increasing by as much as 80 g/mi. These increases represent roughly a 10 to 40 percent increase in emissions from their lowest levels. Such a finding indicates that GHG-reducing technologies would be removed from the vehicles at scheduled redesign intervals for cost savings or other reasons. [EPA-HQ-OAR-2022-0829-0780, pp. 13-15]

9 The 255 g/mile emission level represents the 2-cycle tailpipe emission levels before any credits, which is most reflective of the technologies installed on the vehicles. The 250 mg/mi figure mentioned above represents the certification value after accounting for credits used for compliance.

[See original for graph titled "Figure 1: Average GHG Tailpipe Emission Values for Internal Combustion Vehicles in U.S. EPA Proposal"] [EPA-HQ-OAR-2022-0829-0780, pp. 13-15]

While some may suggest this is an artifact of the model solving for the lowest-cost method to comply and that any increased emissions are offset by additional more cost-effective reductions on other vehicle models, the proposed standards allow for such a backsliding by manufacturers as they implement increased levels of BEVs. And, to the extent that a manufacturer implements even more BEVs than U.S. EPA has modeled, the increase in GHG emission levels from the remaining conventional vehicles could be even larger. Although removing or undoing certain emission control strategies may involve additional costs that would prevent an auto manufacturer from actually decontenting as the model projects, there are some that would be relatively easy, such as replacing an aluminum hood with a steel one. Additionally, manufacturers could eliminate some of the lower-emitting model variants and instead offer variants that would effectively result in greater emissions over time. The complementary, proposed Tier 4 criteria pollutant standards would not provide any protections against such changes due to different control technologies and strategies used for controlling different pollutants. [EPA-HQ-OAR-2022-0829-0780, pp. 13-15]

While the fleet average approach ensures that this portion of the fleet getting dirtier is offset by other portions of the fleet getting cleaner, there currently is no guard against a backwards step in GHG emission levels on a significant portion of vehicles. At a time where every GHG reduction feasible needs to be considered, there should be additional protections against vehicles redesigning in later years to remove cost-effective technologies and emit at higher levels. Simply because those technologies are superseded in cost-effectiveness by BEVs does not mean they are no longer cost-effective themselves, especially relative to more costly emission reductions outside of the light-duty vehicle sector. Additionally, there is a risk of increased real-world GHG emissions not accounted for in the regulatory impact analysis of the proposed standards if those who continue to purchase conventional vehicles (while most new vehicle offerings are ZEVs) drive more miles than U.S. EPA estimates. [EPA-HQ-OAR-2022-0829-0780, pp. 13-15]

If non-ZEVs were required to stay at their lowest levels throughout the regulatory period, manufacturers could meet a more stringent fleet average standard than U.S. EPA's proposal without increasing the projected ZEV share. Maintaining these lowest emission levels would also provide consumer benefits; as U.S. EPA has analyzed in its proposal, operating cost- savings are an important metric in assessing emission standards and these savings are generally expected to be higher for lower-emitting vehicles. Furthermore, to the extent that conventional vehicles are purchased by lower-income households, operating cost-savings associated with lower-emitting conventional vehicles may be especially beneficial given that transportation costs are typically a larger share of their household budgets. [EPA-HQ-OAR-2022-0829-0780, pp. 13-15]

Organization: Clean Fuels Development Coalition et al.

B. The proposed rule misstates emissions benefits because it neglects upstream electric generating unit emissions, among others.

In addition to underestimating costs, the proposal also overstates benefits. The most egregious of these comes from the way EPA accounts for upstream emissions for electric generating units ("EGU"). See DRIA 8-10, 11. To realize substantial reductions in GHG emissions—and thus benefits from such emissions—the rule relies on the decrease in emissions from petroleum-fueled vehicles replaced by electric vehicles. But these vehicles are themselves still responsible for emissions from the electricity that powers them. Current electricity GHG emissions factors are approximately 442,000 U.S. Tons of CO2 / Terawatt-Hour. How much carbon dioxide is produced per kilo watt hour of U.S. electricity generation, Energy Information Administration, https://www.eia.gov/tools/faqs/faq.php?id=74&t=11 (last accessed July 5, 2023). [EPA-HQ-OAR-2022-0829-0712, pp. 34-35]

This is unrealistic. Emissions reduction on the U.S. electric grid have thus far come primarily from natural gas replacing coal. To continue to lower CO2 emissions in this manner would require an almost complete conversion to low carbon sources. But barriers to wind, solar, and nuclear adoption will not enable these changes on EPA's timeframe. Furthermore, researchers estimate that the 350 million EVs required to decarbonize the fleet in 2050 could use as much as half of US national electricity demand. Thea Riofrancos et al., Achieving Zero Emissions with More Mobility and Less Mining, U.C. Davis Climate + Community Project (Jan. 2023), https://sub- scriber.politicopro.com/eenews/f/eenews/?id=00000185-e562-de44-a7bf-ed7751a00000. [EPA-HQ-OAR-2022-0829-0712, pp. 34-35]

These costs also ignore that realizing these reductions requires the installation of new solar and wind generation, which itself has a cost. Without additional wind and solar generation, upstream emissions from electricity generating units will not decrease as much as EPA expects, diminishing those benefits. In addition to the direct costs of this generation, the proposal also ignores the greenhouse gas emission associated with manufacturing more, less dense, remotely located intermittent generation sources, and the battery back-up; transmission, substation, and transformer investment to integrate these technologies into the power grid; and natural gas peaking capacity necessary to sustain their intermittency. These emissions are significant and must be accounted for in the calculation of any benefits of the proposed rule. [EPA-HQ-OAR-2022-0829-0712, pp. 34-35]

Organization: Donn Viviani

Also not addressed is evidence that the increased weight of BEVs com- pared to comparable ICE vehicles, because of battery weight, will result in nonexhaust emissions (NEE) of particulate matter (PM) that will significant- ly lessen or even may exceed the proposal's anticipated reductions. While there is controversy as to whether NEE PM is as large as exhaust PM, with evidence on both sides. What is known for certain however, is that heavier vehicles produce more NEE PM and BEVs are significantly heavier than in-ternal combustion vehicles17. While it is true BEVs regenerative braking removes most brake-NEE, the greater torque of BEVs will cause some ag- gressive drivers to produce increased NEE PM18. This needs to be ac- knowledged and to the extent practicable included in the benefit assess- ment. In my view, the potential climate benefits of the necessary transi- tion to EVs is too important to risk with an inadequate analysis as to other effects. [EPA-HQ-OAR-2022-0829-0546, pp. 5-6]

II. MODELING ANALYSIS

To estimate the emission reduction benefits of the regulatory approach that we ask EPA to adopt, we have performed modeling using Emfac to quantify the emission reductions that would be achieved in the South Coast and San Joaquin Valley (SJV) Air Quality Management Districts (AQMDs). [EPA-HQ-OAR-2022-0829-0737, pp. 8-10]

CARB has developed estimates of the NOx reductions needed for attainment in South Coast and SJV AQMDs. CARB has identified emissions from federally regulated transportation source sectors as the primary cause of nonattainment after the implementation of stationary and area source measures included in the draft ozone SIP. These source sectors include out-of-state (OOS) trucks traveling into and through California, commercial shipping and aircraft operations in CA. [EPA-HQ-OAR-2022-0829-0737, pp. 8-10]

In these comments we fault EPA for not identifying the degree of emission needed to help states achieve the emission reductions needed for ozone and PM2.5 attainment. To address that objection, we have prepared modeling analyses of two scenarios to estimate the contribution to attainment in the two most polluted ozone NAs in the U.S. where 20 million Americans are at risk from exposure to frequent (more than 100 days per year) daily violations of the ozone NAAQS, that include the most extreme daily peak concentrations measured in the U.S. [EPA-HQ-OAR-2022-0829-0737, pp. 8-10]

The two scenarios we test are the emission reductions achieved by applying the proposed NOx standards for L/MDVs in Option 1 to OOS trucks operating in the AQMDs, and a scenario that reduces emissions from those trucks to zero based on a zero emission standard. [EPA-HQ-OAR-2022-0829-0737, pp. 8-10]

III. CLIMATE CRISIS REQUIRES ZERO EMISSION STANDARDS TO ACCELERATE TRANSITION TO ZERO GHG ECONOMY

The science is clear: stabilizing the climate before it becomes too hot to support human civilization is another reason beyond attaining the ozone NAAQS in all of America's 230 nonattainment counties why GHG emissions from on-road vehicles must be reduced to zero as soon as possible. In his Climate Executive Order President Biden declared that the policy of the United States is to "put the United States on a path to achieve net-zero emissions, economy-wide, by no later than 2050."1 [EPA-HQ-OAR-2022-0829-0737, pp. 8-10]

1 Executive Order to Tackle Climate Change (January 27, 2021). Sec. 201. Policy. Even as our Nation emerges from profound public health and economic crises borne of a pandemic, we face a climate crisis that threatens our people and communities, public health and economy, and, starkly, our ability to live on planet Earth. Despite the peril that is already evident, there is promise in the solutions— opportunities to create well-paying union jobs to build a modern and sustainable infrastructure, deliver an equitable, clean energy future, and put the United States on a path to achieve net-zero emissions, economy-wide, by no later than 2050. We must listen to science — and act. We must strengthen our clean air and water protections. We must hold polluters accountable for their actions. We must deliver environmental justice in communities all across America. The Federal Government must drive assessment, disclosure, and mitigation of climate pollution and climate-related risks in every sector of our economy, marshaling the creativity, courage, and capital necessary to make our Nation resilient in the face of this threat. Together, we must combat the climate crisis with bold, progressive action that combines the full capacity of the Federal Government with efforts from every corner of our Nation, every level of government, and every sector of our economy. It is the policy of my Administration to organize and deploy the full capacity of its agencies to combat the climate crisis to implement a Government-wide approach that reduces climate pollution in every sector of the economy; increases resilience to the impacts of climate change; protects public health; conserves our lands, waters, and biodiversity; delivers environmental justice; and spurs well-paying union jobs and economic growth, especially through innovation, commercialization, and deployment of clean energy technologies and infrastructure. Successfully meeting these challenges will require the Federal Government to pursue such a coordinated approach from planning to implementation, coupled with substantive engagement by stakeholders, including State, local, and Tribal governments.

The President's declared policy responds to and is supported by the science which makes clear that the climate will continue to heat up so long as humanity continues to increase GHG levels in the atmosphere. The global mean temperature reached 1.2 o C above the pre-industrial baseline in 2020 [2] which has produced massive damage and destruction to property and natural systems, and caused hundreds of deaths, displacement, homelessness and loss of livelihoods for tens of thousands of Americans from extreme floods, drought, wildfires, hurricanes and tornadoes. [EPA-HQ-OAR-2022-0829-0737, pp. 8-10]

2 World Meteorological Organization, State of the Global Climate, 6 (April 2021); available at doc_num.php (wmo.int). WMO uses the “1850–1900 baseline as an approximation of pre-industrial levels.” Id.

Organization: Energy Innovation

Alternative 1 projects a fleet-wide CO2 target that is 10 g/mile lower on average than the proposed rule targets, representing a 67 percent reduction in average GHG emissions targets, from the MY 2026 standards, compared with the projected 56 percent reduction for the proposed rule.27 While the stringency in Alternative 1 does not represent a huge jump from the proposed rule, the adjustment from the proposed rule would boost BEV penetration rates from 67 to 69 percent in the year 2032. See Table 96 below from the proposed rule.28 [EPA-HQ-OAR-2022-0829-0561, pp. 11-12]

27 U.S. EPA, 29331.

28 U.S. EPA, 29332-3.

[See original attachment for Table 96 – Fleet BEV Penetration Rates, by Body Style, Under Alternative 1] [EPA-HQ-OAR-2022-0829-0561, pp. 11-12]

According to the EPA’s modeling, Alternative 1 will also further reduce GHG emissions and other pollutants, compared with the proposed rule and other alternatives.29 See Tables 8 and 9 from the proposed rule below. As the EPA aptly states, “[r]educing GHG emissions, including the three GHGs (CO2, CH4, and N2O) affected by this program, will contribute toward the goal of holding the increase in the global average temperature to well below 2[degrees]C above pre-industrial levels, and subsequently reducing the probability of severe climate change related impacts including heat waves, drought, sea level rise, extreme climate and weather events, coastal flooding, and wildfires.”30 Similarly, Alternative 1 would result in greater reductions in criteria pollutants and air toxics, which would result in greater public health benefits and improvements to air quality. [EPA-HQ-OAR-2022-0829-0561, pp. 11-12]

29 U.S. EPA, 29350-3.

Organization: Marathon Petroleum Corporation (MPC)

Renewable liquid fuels can play a critical role in a multifaceted solution for reducing carbon emissions, particularly those from the transportation sector. The renewable liquid fuel industry is well-positioned to produce the renewable fuels needed to help attain the EPA’s emissions goals.

However, EPA has ignored the emission-reduction benefits provided by renewable liquid fuels in its proposed vehicle emissions standards because EPA did not account for the assumption that the CO2 emissions from renewable liquid fuel combustion are zero. [EPA-HQ-OAR-2022-0829-0593, pp. 1-2]

Organization: POET, LLC

EPA should leverage all available technologies to begin reducing carbon emissions from LDVs as promptly as is technologically feasible. This position is consistent with EPA's own statements. The Proposed Rule explains "EPA's rules have historically not required the use of any particular technology" and EPA sets standards "without a priori limiting its consideration to a particular set of technologies."13 [EPA-HQ-OAR-2022-0829-0609, p. 7]

13 See id. at 29232.

Yet EPA contradicts its own stated approach by proposing a rule that effectively requires one technology for LDVs—BEVs. POET engaged OnLocation to use EPA's own OMEGA model to determine what might happen if the auto industry falls short, even by a little, of EPA's optimistic predictions for BEV adoption. OnLocation's modeling, set out in its report attached to this letter as Attachment 1, shows that "no amount of technological improvements for ICE vehicles incorporated by EPA for their supporting analysis with the OMEGA model for ICE vehicles can compensate for even a relatively small reduction in the penetration rate of BEVs."14 OnLocation also finds that, when one accounts for the upstream emissions from BEVs, the Proposed Rule's target of 86 grams per mile in 2032 cannot be met. If BEV deployments drop only a few percentage points below EPA's very aggressive projections, and if BEV upstream emissions are accounted for, the proposed standards are impossible to meet, even with BEVs. Given this microscopic margin for error, EPA must not omit other technologies, such as renewable fuels, and in particular, bioethanol, that can immediately begin to dramatically reduce LDV emissions on a lifecycle basis. [EPA-HQ-OAR-2022-0829-0609, p. 7]

14 Attachment 1, OnLocation Report, at 3 (June 30, 2023).

B. EPA Has Relied on Unreasonable and Unsupported Assumptions in Its Assessment of GHG Emissions Reductions.

The Trinity report also addresses certain unfounded assumptions in EPA's assessment of GHG emissions reductions and has identified the following flaws. [EPA-HQ-OAR-2022-0829-0609, pp. 24-25]

First, EPA ignores upstream emissions from BEVs other than emissions from electricity generation.105 EPA's assessment assigns 710 metric tons of GHG emissions from the increased electricity needed to power BEVs incentivized by the Proposed Rule. However, the Trinity report demonstrates that EPA's assessment significantly undercounts those emissions. The report cites a recent study showing that between "56 to 494 kilograms of CO2eq emissions per kWh of battery pack capacity which translates to between about 5 and 50 metric tons of GHG emissions per 100 kWh battery pack."106 Using this study and EPA's estimate of 80 million BEVs on the road by 2055, Trinity calculates additional upstream emissions between 400 and 4,000 metric tons.107 That is in addition to the 710 metric tons EPA calculates for electricity generation. [EPA-HQ-OAR-2022-0829-0609, pp. 24-25]

V. OMEGA Modeling Highlights the Feasibility Challenges of EPA's Proposed Rule and How Biofuels Could Make the Rule More Workable.

After conducting a series of runs using EPA's OMEGA model, OnLocation in the attached report concludes that EPA's Proposed Rule on light-duty vehicle emissions "has significant shortcomings in achieving its stated goal of reducing GHG emissions."111 OnLocation finds that compliance with the Proposed Rule "can only be achieved through a narrow range of BEV vehicle penetration pathways."112 While EPA relies on BEV penetrations around 67% of new light-duty vehicle sales in 2032, OnLocation finds that if a production limit of 60% is imposed on BEVs in that general timeframe, compliance with the target emission goals is prevented through 2034.113 When a BEV production limit of 50% is similarly imposed, compliance is generally not achieved throughout the timeframe covered by the Proposed Rule and not even through the year 2050.114 Furthermore, ICE vehicles cannot make up the difference in GHG emissions reductions.115 This result occurs because EPA does not consider the lifecycle benefits of biofuels while artificially assigning zero emissions to BEVs (ignoring the upstream emissions of BEVs), and for other reasons that may include EPA assigning unduly low battery costs to BEVs. [EPA-HQ-OAR-2022-0829-0609, p. 26]

111 Attachment 1, at 2, 16.

112 Id. at 1.

113 Id. at 7 & Fig. 4.

114 Id. 4 & Fig. 1.

115 OnLocation found "no amount of technological improvements for ICE vehicles incorporated by EPA for their supporting analysis with the OMEGA model for ICE vehicles can compensate for even a relatively small reduction in the penetration rate of BEVs." See id. at 3.

Introduction

Peter Whitman and Michael Schaal of OnLocation ("Authors") have been asked to review the assumptions and modeling in support of the U.S. Environmental Protection Agency's ("EPA's") proposed "Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles," under Docket ID No. EPA–HQ–OAR–2022–0829–0451 ("Proposed Rule"), that addresses standards for criteria pollutants and greenhouse gases (GHG) for light-duty vehicles and Class 2b and 3 (''medium-duty'') vehicles for model years 2027 through 2032. [EPA-HQ-OAR-2022-0829-0609, pp. 35-36]

OnLocation's Analysis

In this analysis, we reviewed EPA's assumptions and then we performed a series of test scenarios to observe the robustness of the results obtained using EPA's OMEGA (Optimization Model for reducing Emissions of Greenhouse Gases from Automobiles) model. This OMEGA model is the same model that EPA used in the Proposed Rule for its analysis of compliance scenarios.1 [EPA-HQ-OAR-2022-0829-0609, pp. 35-36]

1 Available at https://www.epa.gov/regulations-emissions-vehicles-and-engines/optimization-model-reducing-emissions- greenhouse-gases

EPA's Assumptions

We focus on two interrelated aspects of the rulemaking: using only tailpipe emissions for compliance with the MY 2027 – 2032 standards and only a narrow range of BEV penetration trajectories that will allow compliance to be achieved. [EPA-HQ-OAR-2022-0829-0609, pp. 35-36]

Our key insight is that compliance can only be achieved through a narrow range of BEV vehicle penetration pathways. We demonstrate this through a set of runs using EPA's OMEGA model described below. [EPA-HQ-OAR-2022-0829-0609, pp. 35-36]

In addition, we note that upstream emissions are a significant contributor to GHG emissions and ignoring them has implications for aligning the incentives for compliance to the Proposed Rule with its intent, reductions in GHG emissions. This leads to the following observations:

- Should upstream emissions for all fuels, including electricity, be incorporated in compliance, projections of grid carbon emissions vary widely, and according to our modeling using the OMEGA model, EPA's proposed standard of 86 grams/mile in 2032 cannot be met when using EIA's projected electric grid carbon intensities. [EPA-HQ-OAR-2022-0829-0609, pp. 35-36]

- Upstream manufacturing emissions are an important differentiator between vehicles but are not accounted for. Using only tailpipe emissions provides inconsistent incentives between BEVs and ICE vehicles, while EPA's optimistic projections for the grid carbon intensity and BEV penetration could reduce the effectiveness of the Proposed Rule in reducing carbon. [EPA-HQ-OAR-2022-0829-0609, pp. 35-36]

- Because upstream emissions are ignored in the Proposed Rule, the shape of the GHG footprint-based compliance curve depends on the assumed BEV penetration, even though it is only applicable to ICE vehicles. If BEVs penetration is different than EPA projections, then EPA's proposed compliance curves are likely to be inconsistent with the analysis used in their development and penalize larger footprint vehicles. [EPA-HQ-OAR-2022-0829-0609, pp. 35-36]

Per the Summary at the end of this report, our analysis of the EPA's Proposed Rule on light-duty vehicle emissions finds it has significant shortcomings in achieving its stated goal of reducing GHG emissions. [EPA-HQ-OAR-2022-0829-0609, pp. 35-36]

Uncertainty in BEV Penetration Rate

In its proposal, EPA forecasts almost 70% BEV penetration will occur in MY 2032 across the light duty categories (passenger car, crossover/SUV, and light truck), or over 10 million BEVs. In addition, this compliance pathway would require almost 40% BEV penetration in the medium-duty van and pickup truck categories. By comparison, EIA projects approximately 1.5 million BEVs in 2050, with only 1.2 million in 2032.2 Thus, EPA's projections of sales of approximately 11 million BEVs are almost nine times higher than those of EIA, the leading U.S. governmental source for independent energy statistics and analysis.3 [EPA-HQ-OAR-2022-0829-0609, p. 36]

2 Annual Energy Outlook (AEO) 2023 Reference Table 38, https://www.eia.gov/outlooks/aeo/tables_ref.php

3 Regarding BEV sales in EPA's analysis, EPA finds 15,834,010 total light duty vehicle sales in 2032 (Draft Regulatory Impact Analysis Table 4-18) multiplied by 70% BEV penetration (Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles Fact Sheet, EPA-420-F-23-009 pg. 5).

Battery production is a key constraint in the EV penetration rate. Supporting material on the battery production from S&P Global and Argonne National Laboratories5 are based on battery manufacturing plant announcements rather than more definitive metrics such as plants under construction. EPA has focused on lithium as the constraining critical material for battery production, and growth in domestic lithium production is based on infrastructure that has not yet been built. None of the studies referenced directly incorporate the level of U.S. EV penetration proposed in the Proposed Rule. The assumptions underlying EPA's proposed path merit further analysis by EPA and call into question the robustness of EPA's assumptions regarding future EV penetration rates. [EPA-HQ-OAR-2022-0829-0609, p. 36]

5 "Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles," Federal Register Vol. 88, No. 87, pg. 29317

OnLocation's analysis using OMEGA

OnLocation executed numerous runs of the OMEGA model to test the boundaries of its domain and the robustness of the supporting analysis. We describe the model and then the scenarios executed to illustrate some of the limitations of the modeling and the lack of robustness of the Proposed Rule to changes in market assumptions. [EPA-HQ-OAR-2022-0829-0609, p. 37]

About the OMEGA Model

The OMEGA model was designed by the EPA to visualize the future of the car industry and its environmental effects. OMEGA can produce predictions about a wide range of the light-duty vehicle (LDV) market. Within OMEGA, there are different parameters that act as preset events, of which those specified in the Proposed Rule are used for this investigation. The specific outputs of importance for this project are the emissions (CO_2g/mi) per vehicle class (pickup, sedan, crossover, and SUV) and the market share of battery electric vehicles (BEVs) versus internal combustion engines (ICE). [EPA-HQ-OAR-2022-0829-0609, p. 37]

Description of Scenarios Using the OMEGA Model

In order to demonstrate the fairly narrow set of conditions that would allow compliance with the Proposed Rule, we executed the following runs of the OMEGA model to test the robustness of the Proposed Rule:

Scenario 1: 50% Market Share Production Limit on BEVs

Scenario 2: Relaxed (60%) Market Share Production Limit on BEVs Scenario 3: Modified Battery Cost Learning [EPA-HQ-OAR-2022-0829-0609, p. 37]

These scenarios demonstrate that no amount of technological improvements for ICE vehicles incorporated by EPA for their supporting analysis with the OMEGA model for ICE vehicles can compensate for even a relatively small reduction in the penetration rate of BEVs. [EPA-HQ-OAR-2022-0829-0609, p. 37]

Finally, we look at three scenarios showing the effect of upstream emissions and low-carbon fuels on meeting the Proposed Rule.

Scenario 4: Adding Upstream Emissions to the Compliance Values Scenario 5: 10% Reduction in Carbon Intensity of Gasoline, Scenario 6: 75% Reduction in Carbon Intensity of Gasoline [EPA-HQ-OAR-2022-0829-0609, p. 37]

The first three OMEGA runs show a narrow range of BEV penetration pathways will allow sufficient reductions to support compliance with the Proposed Rule, and that reductions in BEV market share cannot be compensated for by ICE technology improvements. The latter three runs show that low carbon fuels could potentially play an important role in GHG emission reductions. [EPA-HQ-OAR-2022-0829-0609, p. 37]

Testing the Robustness of the Proposed Rule using OMEGA

OnLocation executed numerous runs of the OMEGA model to test the boundaries of its domain and the robustness of the supporting analysis. The following scenarios explore some of the limitations of the modeling and the lack of robustness of the Proposed Rule to changes in market assumptions. [EPA-HQ-OAR-2022-0829-0609, pp. 37-41]

Scenario 1: Production Limit on BEV Production

[See original attachment for Figure 1 Compliance Path with Production Limit] [EPA-HQ-OAR-2022-0829-0609, pp. 37-41]

[See original attachment for Figure 2 Market Shares] [EPA-HQ-OAR-2022-0829-0609, pp. 37-41]

In Scenario 1, only tailpipe emissions were included for compliance purposes, while potential BEV penetration was limited to 30% in 2025, 40% in 2030, and 50% from 2035 onwards. Figure 1 shows the effects of BEV production limits. From 2027 through 2051, the target is not reached. Figure 2 below shows the evolution of the market share of different vehicle categories for this scenario, where the BEV production limits are binding at 30%, 40%, and then 50%. It is clear that the BEV penetration constraints limit the ability of manufacturers to meet the target, as the fuel efficiency improvements available for ICE vehicles are insufficient to compensate for the zero tailpipe emissions of the BEV vehicles. [EPA-HQ-OAR-2022-0829-0609, pp. 37-41]

In Figure 1 and in each of the following figures labeled “Compliance Path,” the blue line indicates the target emissions while the red line indicates achieved emissions. Yellow circles indicate banked credits from previous periods, while the green lines indicate inter-temporal credit trades. The red circles indicate fleet does not reach compliance in that year. [EPA-HQ-OAR-2022-0829-0609, pp. 37-41]

Scenario 2: Relaxed Production Limit on BEV Production [EPA-HQ-OAR-2022-0829-0609, pp. 37-41]

[See original attachment for Figure 3 Compliance Path with Relaxed Production Limit] [EPA-HQ-OAR-2022-0829-0609, pp. 37-41]

[See original attachment for Figure 4 Market Shares with Relaxed Production Limit] [EPA-HQ-OAR-2022-0829-0609, pp. 37-41]

Scenario 2 follows the CO2 targets in the Proposed Rule, with no upstream emissions. In this scenario, production limits on BEVs were relaxed relative to Scenario 1. BEV penetration was initially limited to 40%, rising to 50% in 2030 and 60% in 2035 for the remainder of the scenario. Even these relaxed production limits on BEV market penetration were binding throughout the simulation (Figure 3), preventing compliance with the target emission goals through 2034 (Figure 4). [EPA-HQ-OAR-2022-0829-0609, pp. 37-41]

Scenario 3: Modified Learning Coefficient

[See original attachment for Figure 5 Compliance Path with Modified Learning Coefficient] [EPA-HQ-OAR-2022-0829-0609, pp. 41-42]

[See original attachment for Figure 6 Market Shares with Modified Learning Coefficient] [EPA-HQ-OAR-2022-0829-0609, pp. 41-42]

Scenario 3 involves modifying the battery learning curve (i.e., the extent to which EPA projects battery costs will decline) by setting the learning equation to be constant. As shown in Figure 5 and Figure 6, BEV market share collapses after 2025 to the 2021 level, and emissions are far from the target level even as total costs over the model horizon (e.g., through 2055) are over $2.5 trillion dollars more expensive than in the Proposed Rule. [EPA-HQ-OAR-2022-0829-0609, pp. 41-42]

However, we believe this is an artifact of model inputs, not likely to be representative of slow learning for batteries. Nonetheless, the significance of this potential impact merits a thorough evaluation of this issue by EPA, and an updated analysis of the impacts of learning curve rates on costs in in its OMEGA model. [EPA-HQ-OAR-2022-0829-0609, pp. 41-42]

The effect of low-carbon fuels

The first three scenarios all identified the risks of developing a new set of rules which are highly dependent on a high BEV market share being achieved. In the next three scenarios, we examine the effect of upstream emissions and low-carbon fuels in achieving the targets of the Proposed Rule. The first scenario evaluated in this regard follows on the next page. [EPA-HQ-OAR-2022-0829-0609, pp. 42-44]

Scenario 4: Adding Upstream Emissions

[See original attachment for Figure 7 Compliance Path with Upstream Emissions] [EPA-HQ-OAR-2022-0829-0609, pp. 42-44]

[See original attachment for Figure 8 Market Shares with Upstream Emissions] [EPA-HQ-OAR-2022-0829-0609, pp. 42-44]

In Scenario 4, upstream emissions were added to the compliance calculations for gasoline, diesel, and electricity (these upstream emissions for BEVs include grid impacts, but BEV battery manufacturing impacts are not included). The AEO2023 EIA Reference Scenario was used to calculate upstream emissions of grid electricity. As shown in Figure 7 and Figure 8, with the addition of upstream emissions, the BEV market share rises to over 80%, much greater than the 67% market share in the central case of the Proposed Rule. To achieve this BEV market share, the domestic infrastructure would have to grow at an accelerated rate. [EPA-HQ-OAR-2022-0829-0609, pp. 42-44]

This figure shows that using the OMEGA model, EPA's proposed standard of 86 grams/mile in 2032 cannot be met if upstream emissions are also included. Furthermore, actual BEV lifecycle emissions would be even higher if battery manufacturing impacts are considered. [EPA-HQ-OAR-2022-0829-0609, pp. 42-44]

In this scenario, the LDV fleet does not reach the modelled target emission until 2036, and compliance is intermittent throughout the model forecast. EPA's having such stringent target emission goals. which rely to such a degree on the implementation of BEVs into the market, ignores the importance of upstream emissions, as model runs indicate upstream emissions generally render any achievable fleet of BEVs and ICE vehicles (within the current technology packages of the model, which don't include biofuels carbon intensity reductions) out of compliance with EPA's proposed standard. [EPA-HQ-OAR-2022-0829-0609, pp. 42-44]

Scenario 5: Low Carbon Fuel

[See original attachment for Figure 9 Compliance Path with Low Carbon Fuel (gasoline with 10% lower Carbon Intensity)] [EPA-HQ-OAR-2022-0829-0609, pp. 45-46]

[See original attachment for Figure 10 Market Shares with Low Carbon Fuel] [EPA-HQ-OAR-2022-0829-0609, pp. 45-46]

In Scenario 5, starting in 2030, gasoline combustion emissions were reduced by 10% to represent the introduction of low-carbon biofuels such as bioethanol. No upstream emissions were included within the model. This scenario effectively provides compliance flexibility for the Proposed Rule, leading to a 0.2% to 0.4% reduction in the absolute market share of BEVs from 2035-2050. Greater reductions in the need for high BEV shares could potentially result if the model is revised to (i) assess a broader range of battery learning curve algorithms, and (ii) the "zero emissions" treatment assigned to BEVs is refined. Further evaluation of these issues is warranted by EPA to ensure that small changes in BEVs under this scenario 5 (e.g., lower carbon intensity gasoline) are not a result of artifacts of the modelling. [EPA-HQ-OAR-2022-0829-0609, pp. 45-46]

Scenario 6: Adding Low Carbon Fuel and Upstream Emissions

[See original attachment for Figure 11 Compliance Path with Low Carbon Fuel and Upstream Emissions] [EPA-HQ-OAR-2022-0829-0609, pp. 47-48]

[See original attachment for Figure 12 Market Shares with Low Carbon Fuel and Upstream Emissions] [EPA-HQ-OAR-2022-0829-0609, pp. 47-48]

Scenario 6 presents a 75% reduction in fuel carbon intensity for gasoline, though including upstream emissions including those for BEVs. Figure 11 and Figure 12 show that using the model compliance with the Proposed Rule's targets still could be achievable, though outside of 2027 – 2032 timeframe when considering both upstream emissions and the impact if biofuels reduce ICE vehicle carbon intensity by 75%. In this scenario, the market share of BEVs only changes slightly from the Proposed Rule, however in the model greater total emission reductions (i.e., those that consider upstream emissions) are achieved by deploying low-carbon ICE vehicles. This scenario shows that with lower-carbon ICE fuels (such as low carbon bioethanol), and considering upstream emissions, compliance within the range of EPA's proposed target is possible. [EPA-HQ-OAR-2022-0829-0609, pp. 47-48]

2. Similarly, U.S. EPA has used assumptions to estimate the GHG reductions associated with the Proposed Rule that are unreasonable and unsupported. These lead to the benefits of the Proposed Rule being overstated. [EPA-HQ-OAR-2022-0829-0609, p. 53]

Review of U.S. EPA's Assessment of Reductions in GHG Emissions Due to BEVs

At a high level, the U.S. EPA's assessment of the reductions in GHG emissions due to the Proposed Rule, presented in Chapter 9 of the DRIA, is straightforward. The agency uses its MOVES emissions inventory model to estimate GHG emissions from conventional vehicles and then subtracts the GHG emissions associated with the electricity used to power BEVs. The methodology used to estimate emissions from electricity generation is presented in Chapter 5.2 of the DRIA. In estimating GHG emissions associated with electricity, U.S. EPA assumes that all BEVs will be charged using grid electricity. Unfortunately, while the basic approach used in the assessment is straightforward there are a number of concerns resulting from the way it was implemented by U.S. EPA. [EPA-HQ-OAR-2022-0829-0609, p. 62]

The first of these concerns is that U.S. EPA has ignored upstream sources of GHG emissions other than electricity generation. This is of particular concern given that there are significant upstream emissions associated with the manufacturer of batteries for BEVs that do not occur with conventional vehicles. A paper published by ICCT4 notes that estimates of these GHG emissions range from 56 to 494 kilograms of CO2eq emissions per kWh of battery pack capacity which translates to between about 5 and 50 metric tons of GHG emissions per 100 kWh battery pack. Using U.S. EPA's assumption that the Proposed Rule will result in an additional 80,000,000 BEVs on the road in the U.S. by 2055 relative to the no[1]action case, and these estimates of GHG emissions from battery production, the cumulative increase in GHG emissions by would be between 400 and 4000 metric tons. This value can be compared to U.S. EPA's 710 metric ton estimate of the cumulative GHG emissions increase due to electricity generation for BEVs and the 8,000 ton reduction from conventional vehicles (see DRIA Table 9-21) to show the importance of accounting for battery production emissions. U.S. EPA might respond by noting that they have not accounted for upstream GHG emissions associated with the production of gasoline and diesel, but those are small compared to the GHG emissions from fuel combustion and accounting for them would assume a net global reduction in the use of those fuels which would likely, even with the Proposed Rule, still be used in other parts of the developing world. [EPA-HQ-OAR-2022-0829-0609, p. 62]

The next concern is with U.S. EPA's assumptions regarding the mix of electricity generation sources which are shown in DRIA Figure 5-8. This figure is reproduced below and compared to similar projections prepared by EIA as part of AEO 2023.5 The EIA projections reflect the impacts of the IRA for several cases including a "high uptake" (e.g. most optimistic case) case of solar and wind generation technologies which are depicted in yellow and green, respectively that can be compared directly to the green portion of the bars in Figure 5-8. By 2050, EIA estimates maximum amounts of solar and wind generation that are about 20% less than U.S. EPA's estimates with the difference being made up by coal and natural gas generation. What this means is that U.S. EPA is overstating the contribution of low emissions generation (solar and wind) and thereby underestimating the magnitude of upstream GHG emissions that will result from BEV operation. [EPA-HQ-OAR-2022-0829-0609, p. 62]

Continuing, U.S. EPA uses the emission factor equations presented in DRIA Table 9-12 to estimate GHG from electricity generation as a function of time over the period from 2020 through 2050. These equations predicted that emissions of CO2, methane, and nitrous oxide due to electricity generation will decline by 89, 96, and 98% respectively over the 2020 to 2050 period and if extrapolated to 2054 that there will be no emissions in the U.S. occurring from Power Plants. Even accounting for the increase in demand for electricity over the period, U.S. EPA claims that GHG emissions from electricity generation will be reduced by about 80% from 2020 through 2030 compared to EIA's forecast of about 50%. At a minimum, U.S. EPA should explain in detail the reasons why their forecast of future GHG emissions from electricity generation are so much lower than those generated by EIA and more appropriately perform a sensitivity analysis to quantify the GHG reductions associated with the Proposed Use using EIA's emission forecasts. [EPA-HQ-OAR-2022-0829-0609, pp. 62-63]

[See original attachment for U.S. net electricity generation by fuel] [EPA-HQ-OAR-2022-0829-0609, pp. 62-63]

[See original attachment for Figure 5-8: 2028 through 2055 power sector generation and grid mix] [EPA-HQ-OAR-2022-0829-0609, pp. 62-63]

The U.S. EPA Emission Inventory analysis in Chapter 9 also overstates the GHG reductions associated with the Proposed Rule by failing to account for the fact that conventional vehicles operate on fuels that are a mixture of fossil and low-carbon renewable fuels – including ethanol, renewable diesel fuel and biodiesel fuel. Based on data from EIA,6 the average ethanol content of gasoline sold in the U.S. is expected to increase from about 10% to 12% between now and 2050 while the average content of the combination of renewable and biodiesel is expected to increase from about 7% to 10% over the same range. Although the actual impact of proper accounting for renewable fuels on CO2 emissions from the Proposed Rule will be slightly smaller than the percentages listed above, they should clearly be accounted for by U.S. EPA. It is also important to note that use of ethanol and other renewable fuels capable of reducing GHG emissions from both new and in-use HD vehicles could be increased through incentives like those that have been provided to electricity and hydrogen through the IRA and the structure of the Proposed Rule. In addition, the magnitude of GHG reductions due to the use of ethanol and other renewable fuels could be increased by greater use of carbon capture and storage during their production, which would further lower their carbon intensity. [EPA-HQ-OAR-2022-0829-0609, p. 64]

6 https://www.eia.gov/outlooks/aeo/data/browser/#/?id=11-AEO2023&cases=ref2023&sourcekey=0.

Taken together, all of the concerns discussed above suggest that GHG emission benefits of the Proposed Rule are likely to be substantially less than claimed by U.S. EPA. [EPA-HQ-OAR-2022-0829-0609, p. 64]

Organization: Strong Plug-in Hybrid Electric Vehicle (PHEV)

We believe the uncertainty in CARB's report on 2045 fuel neutrality26 argues for EPA to be broad minded and nimble in adopting regulations, plans and incentives to reach the 2045 carbon neutrality goal and implies long-term use of low carbon fuels with Strong PHEVs. In addition, reaching very high levels of ZEV sales in the next decade frees up large amounts of biofuels for use in spark-ignited and compression-ignited engines such as the strong PHEVs allowed in the proposed rule. [EPA-HQ-OAR-2022-0829-0646, p. 26]

26 E3 report for CARB at 11. “ Many key uncertainties remain around the achievement of carbon neutrality in California. One of these uncertainties is the optimal use and deployment of zero-carbon fuels in hard-to-electrify sectors, including certain high temperature industrial processes, heavy-duty long-haul trucking, aviation, trains and shipping. These fuel uses may be met with a combination of fossil fuels, hydrogen, synthetic zero-carbon fuels or biofuels. It is still uncertain how the relative costs of these technologies will evolve over time. As the cost of wind and solar decline, the cost of renewable hydrogen production is also falling, making hydrogen a more attractive solution than biofuels for some applications. The market for sustainable biofuels remains nascent, making it uncertain how much sustainable biomass supply will be available, and what the best uses for these biomass resources will be through mid-century.” See https://ww2.arb.ca.gov/resources/documents/achieving-carbon- neutrality-california-final-report-e3

Organization: Toyota Motor North America, Inc.

6.2. Technology Assessments Should Incorporate Critical Mineral Supply and Lifecycle Emissions

The modeling should also include a sensitivity analysis of BEV/PHEV mix on critical mineral usage for any assumed overall PEV penetration. PHEVs can make the most efficient use of the limited battery supply and constrained infrastructure network forecast through the period of the rulemaking. The below example compares different vehicle powertrain emissions for a mid-size SUV using peer-reviewed data from carghg.com. The same amount of lithium in the battery of one 300-mile plus BEV can be used for up to six PHEVs –or more than eighty conventional hybrids. See Figure 10 for the CO2 saved from replacing a mid-sized SUV powered by a conventional gasoline engine with electrified alternatives under a constrained lithium supply. This analysis assumes average US electric grid emissions for BEVs and the electric operation of PHEVs. [EPA-HQ-OAR-2022-0829-0620, pp. 31-32]

[See original for attachment for Figure 10 CO2 Saving from Replacing ICEs Under Constrained Mineral Supply] [EPA-HQ-OAR-2022-0829-0620, pp. 31-32]

PHEVs can rival the emissions performance of BEVs under many real-world operating conditions. PHEVs are not always the best-performing option but can have as good or better lifecycle performance because of lower manufacturing emissions for smaller batteries and lower well-to- tank emissions while still covering a significant fraction of daily trips in electric drive. Given most average daily trips are under 50 miles, this results in a significant portion of all-electric miles like a BEV. [EPA-HQ-OAR-2022-0829-0620, pp. 31-32]

Organization: Valero Energy Corporation

2. The charging efficiencies adopted by EPA for purposes of this proposed rule are arbitrarily inconsistent with other contemporaneously proposed rules.

EPA adopts the following charging efficiency rates for use in this rulemaking:13: [EPA-HQ-OAR-2022-0829-0707, p. 3]

13 EPA LMDV OMEGA GHG Compliance Modeling Runs (Document ID EPA-HQ-OAR-2022-0829-0486), 2023-03-25-11-46-49-ld-central-compliance-run.zip, “onroad_fuels_20220325.csv”

[EPA-HQ-OAR-2022-0829-0707, p. 3]

fuel_id	start year	unit	Refuel efficiency	Transmission efficiency

US electricity	2020	kWh	0.9	0.935

The EV charging efficiencies used by EPA in this rulemaking are inconsistent with those used in other proposed rulemakings: [EPA-HQ-OAR-2022-0829-0707, p. 3]

- In the "Draft Regulatory Impact Analysis: RFS Standards for 2023-2025 and Other Changes," to support the generation of eRINs, EPA used an EV charging efficiency of 85% and a line loss factor of 5.3%, yielding a total loss rate of 19.5%.14 [EPA-HQ-OAR-2022-0829-0707, p. 3]

14 EPA "Draft Regulatory Impact Analysis: RFS Standards for 2023-2025 and Other Changes" (EPA-420-D-22-003) at 329, November 2022.

- EPA's Greenhouse Gas Emissions Standards for Heavy-Duty Vehicles – Phase 3 15 assume charging efficiencies ranging from 88.0 to 89.25% across MY 2027-2032, failing to account for transmission line losses. [EPA-HQ-OAR-2022-0829-0707, p. 3]

15 EPA "Greenhouse Gas Emissions Standards for Heavy-Duty Vehicles: Phase 3 Draft Regulatory Impact Analysis" (EPA-420-D-23-001) at 227, April 2023.

- Here, EPA proposes a third distinct set of charging efficiency and line loss. [EPA-HQ-OAR-2022-0829-0707, p. 3]

EPA provides no explanation for why the efficiency values should differ among the three proposed rules. [EPA-HQ-OAR-2022-0829-0707, p. 3]

7. The upstream emission factor that EPA uses for transportation electricity is not consistent with other EPA sources and does not represent full lifecycle emissions from electricity generation. [EPA-HQ-OAR-2022-0829-0707, p. 10]

EPA's OMEGA modeling uses the following GHG emission factors for electricity:42 [EPA-HQ-OAR-2022-0829-0707, p. 10]

42 EPA LMDV OMEGA GHG Compliance Modeling Runs (Document ID EPA-HQ-OAR-2022-0829-0486), 2023- 03-25-11-46-49-ld-central-compliance-run.zip, "policy_fuels_20220722.csv."

fuel_id	start year	unit	direct_co2e_grams_per_unit	upstream_co2e_grams_per_unit
Electricity	2020	kWh	0	325 [EPA-HQ-OAR-2022-0829-0707, p. 10]

EPA explains the origin of the 325 gCO2e/kWh upstream emissions factor with the note "20220722 electricity upstream set at midpoint of high BEV 353 g/mi and low BEV 297 g/mi effects values."43 But the correct units for this emission factor are gCO2e/kWh – not g/mi – so the origin note does not make sense. [EPA-HQ-OAR-2022-0829-0707, p. 10]

43 EPA LMDV OMEGA GHG Compliance Modeling Runs (Document ID EPA-HQ-OAR-2022-0829-0486), 2023- 03-25-11-46-49-ld-central-compliance-run.zip, "policy_fuels_20220722.csv."

By contrast, EPA's 2021 eGRID reports a U.S. grid average 857.0 lbsCO2e/MWh, which is equivalent to 389 gCO2e/kWh. However, this factor represents emissions from electricity generation only and does not account for line losses or for the "well-to-power plant" GHG emissions associated with the extraction and processing of the power plant fuel. [EPA-HQ-OAR-2022-0829-0707, p. 10]

EPA must correct the emission factor adopted for transportation electricity and adequately explain any discrepancies with other EPA sources. [EPA-HQ-OAR-2022-0829-0707, p. 10]

8. EPA must update its gasoline emission factors to reflect a Tier 3 E10 certification fuel.

EPA's OMEGA modeling uses the following GHG emission factors for electricity:44

44 EPA LMDV OMEGA GHG Compliance Modeling Runs (Document ID EPA-HQ-OAR-2022-0829-0486), 2023- 03-25-11-46-49-ld-central-compliance-run.zip, "policy_fuels_20220722.csv."

fuel_id	start_year	unit	direct_co2e_grams_per_unit	upstream_co2e_grams_per_unit
gasoline	2020	gallon	8887	2478

[EPA-HQ-OAR-2022-0829-0707, p. 10]

The direct emission factor of 8,887 gCO_2e/gallon of gasoline is based on Tier 2 E0 gasoline.45 However, EPA is proposing in this rulemaking to update the gasoline certification fuel to a Tier 3 E10 gasoline, so it must update the direct CO_2e emissions accordingly. [EPA-HQ-OAR-2022-0829-0707, p. 10]

45 75 Fed. Reg. 25330 (May 7, 2010).

Organization: Wisconsin Department of Natural Resources

3. Compliance flexibilities. Throughout the rule, EPA proposes a variety of compliance flexibilities (e.g., allowing several compliance pathways and proposing changes to the compliance factor adjustment) that are intended to facilitate implementation of the standards and encourage earlier emissions reductions. EPA should carefully assess those flexibilities to ensure they do not unintentionally reduce the stringency of the rule or result in real world emissions that would exceed the standards. [EPA-HQ-OAR-2022-0829-0507, p. 2]

EPA Summary and Response

Summary:

Commenters argued that EPA's estimated emissions reductions were wrong because they ignore vehicle production, recycling, and disposing of batteries; mining and processing of battery minerals; operating charging infrastructure; extracting, refining, transporting, and storing petroleum fuels; etc., and considering these emissions may undermine EPA's assumption that swapping ICE for BEV will necessarily result in an environmental good (AmFree, American Fuel & Petrochemical Manufacturers, POET).

Commenters also expressed concern over peak loads and the impact of peak load demands on EGU emissions. Commenters encouraged EPA to consider marginal emissions, i.e., those occuring from high peak loads that might be supplied via coal, rather than considering only average emissions, i.e., those occuring from routine power generation (AmFree).

Commenters provided feedback to EPA on which upstream emissions sources were modeled and how that affects the modeled net emission impacts of the final standards. They also noted that this reflects a change in how EPA has modeled upstream emissions for previous GHG rules and argued that EPA may be overestimating the decrease in refinery emissions since it is possible that refinery throughput will not change as evidenced by EPA's own statements in the NPRM (AmFree).

Commenters stated that EPA had not considered the impacts of changes in power generation on the potential degradation of air quality in areas around power plants (American Fuel & Petrochemical Manufacturers).

Commenters argued that EPA was treating ICE vehicles and BEVs differently with respect to real world fuel and energy consumption by considering 5-cycle, cold temperatures and air conditioning use when estimating ICE real world fuel consumption but considering only 2-cycle energy consumption in estimating BEV real world energy consumption (American Fuel & Petrochemical Manufacturers). Commenters argued that this underestimated power sector demand and emissions as a result (American Fuel & Petrochemical Manufacturers).

Commenters argued that EPA should not have used the national average electricity price in estimating charging costs (American Fuel & Petrochemical Manufacturers). Commenters argued that the majority of BEVs are in areas with the highest electricity rates in the country and that EPA failed to consider peak rates of time of use charges (American Fuel & Petrochemical Manufacturers).

Commenters also argued that EPA did not consider the impact of the rule on fleet turnover suggesting that the higher purchase price of new electrified vehicles will keep older cars and trucks on the road longer thus increasing particulate matter emissions through increased tire and road wear (American Fuel & Petrochemical Manufacturers).

Commenters argued that the marginal abatement cost of shifting from 1.0 mg/mi to 0.5 mg/mi is exceedingly high (American Honda).

Commenters expressed concern about ICE vehicles increasing their emissions as more BEVs enter the fleet (CARB). Comments stressed the importance of continuing to reduce GHG emissions across the fleet and to not allow the penetration of electrified vehicles to be offset by ICE vehicles whose GHG emissions increase which could be possible given the fleet average nature of the standards (CARB).

Commenters argued that EPA had neglected upstream EGU emissions (Clean Fuels Development Coalition et al.). Commenters also argued that the 350 million EVs required to decarbonize the fleet in 2050 could use as much as half of US national electricity demand (Clean Fuels Development Coalition et al.). Commenters argued that EGU emissions can only decrease if EPA considers the costs of installing new solar and wind generation and the emissions of such remote and less dense generating sources, back up storage and transmission along with peak capacity generation must be considered (American Fuel & Petrochemical Manufacturers, Clean Fuels Development Coalition et al.).

Commenters stated that BEVs, being heavier, will result in more PM emissions associated with increased brake and tire wear (Donn Viviani).

Commenters faulted EPA for not identifying the degree of emission reduction needed to help states achieve ozone and PM2.5 attainment (Elders Climate Action).

Commenters expressed support for the NPRM's Alternative 1 since it provided greater emissions reductions (Energy Innovation).

Commenters argued that EPA had failed to consider efficiency improvements that were possible with hybrid architectures even at small costs (John Graham). Commenters also argued that renewable liquid fuels can play a role in reducing carbon emissions (Marathon Petroleum Corporation, POET).

Commenters argued that, if one accounts for upstream emissions from BEVs, the Proposed Rules' target of 86 grams per mile in 2032 cannot be met (POET). If BEV deployments drop only a few percentage points below EPA's very aggressive projections, and if BEV upstream emissions are accounted for, the proposed standards are impossible to meet, even with BEVs (POET).

Commenters claimed that EPA uses its MOVES emissions inventory model to estimate GHG emissions from conventional vehicles and then subtracts the GHG emissions associated with the electricity used to power BEVs (POET). Commenters expressed concerns over EPA's assumption that all BEVs will be charged using grid electricity with one concern being ignoring other sources of upstream emissions similar to comments already summarized above and another being EPA's mix of generation sources which were different than those projected by AEO even though the AEO projections include impacts of the IRA (POET).

Commenters argued that EPA's emission factor equations presented in Chapter 9 of the DRIA implied that there will be no EGU emissions by 2054 and that EPA had failed to consider that conventional vehicles operate on fuels that are a mixture of fossil and low-carbon renewable fuels – including ethanol, renewable diesel fuel and biodiesel fuel (POET).

Commenters argued that EPA's modeling should include a sensitivity analysis of BEV/PHEV mix on critical mineral usage for any assumed overall PEV penetration (Toyota). PHEVs can make the most efficient use of the limited battery supply and constrained infrastructure network forecast through the period of the rulemaking (Toyota). The same amount of lithium in the battery of one 300-mile plus BEV can be used for up to six PHEVs–or more than eighty conventional hybrids (Toyota).

Commenters argued that EPA was using charge efficiency estimates that were inconsistent with an RFS NPRM and the recent heavy-duty GHG NPRM (Valero). Commenters argued that EPA had used an EGU emission rate inconsistent with other sources and that the rate did not account for the full life-cycle emissions from electricity generation (Valero). Commenters also argued that EPA should update the CO2/gallon factor for gasoline in compliance modeling to be consistent with Tier 3 test fuel (Valero).

Commenters encourage EPA to carefully consider compliance flexibilities to ensure that they do not unintentionally reduce the stringency of the rule or result in real world emissions that would exceed the standards (Wisconsin Department of Natural Resources).

<u>Response:</u>

We respond more fully to comments regarding life cycle analysis in Section 19.2 of this document. We respond to comments regarding tire wear and brake wear in Section 11.1 of this document. We respond to issues specific to air quality in Section 11.3 of this document. We respond to issues related to electricity prices in Section 17 and 18 of this document. We respond to comments regarding critical minerals and battery production in Section 15 of this document. We respond to comments regarding our power sector modeling efforts in Section 18 of this document.

Regarding comments related to the production of a BEV being more carbon intensive than production of an ICE vehicle, one commenter pointed to the study "The Role of Critical Minerals in the Clean Energy Transitions."[432] Page 194 of this study has the heading, "Emissions from minerals development do not negate the climate advantages of clean energy technologies." On page 192, the study does point out that, "if poorly managed, mineral development can lead to a myriad of negative consequences," but the key to this warning is the management of this development. Also on page 192, the study points to companies having a clear business case to address the risks and consumers and investors demanding that companies do so. We note that similar risks apply to the production of fossil fuels; for example, improper management at petroleum refineries can cause oil spills and enormous harm to the environment. We further respond to comments about life cycle emissions in RTC Section 19.2.

Regarding EPA not including emissions associated with elements of both the BEV and ICE supply chain (transportation, storage, charging infrastructure, etc.), EPA acknowledges that there are other potential emissions further upstream than those EPA included in our analysis. EPA has not historically modeled most of the upstream sources listed by AmFree et al. We expect some of the emissions sources they listed (for example, the operation of charging infrastructure and the transportation of petroleum fuels) to have only marginal impacts on the magnitude of the net emission impacts. This is discussed throughout this RTC section, and more discussion of the consideration of life cycle emissions in setting standards can be found in Section 19.2 of this RTC document.

AmFree et al. also commented that the upstream sectors included in the analysis for this rule represents a change in how EPA has modeled upstream emissions for previous GHG rules. In this comment, they are referring to EPA's modeling for the SAFE and HD GHG Phase 2 rules, which included the extraction and transportation of crude oil and distribution of finished gasoline and diesel.

It is true that, as discussed in RIA Chapter 8.6, EPA's analysis of upstream emissions is limited to EGUs and refineries. EPA's judgment is that this approach represents a reasonable balance between considering indirect effects of the rule on emissions and limiting that consideration to reasonably proximate and predictable effects. Because we lack the data and capacity to predict every indirect effect of the rule throughout the supply chain and the broader economy, we judge that by examining the upstream emissions of EGUs and refineries we have taken into consideration the most significant indirect effects of the rule on air quality, such that our analysis is sufficiently complete for consideration in the rulemaking. In addition, EPA's OMEGA modeling of upstream emission impacts from the final standards includes the three most significant sectors in terms of understanding the impact of the standards on overall GHG and CAP/HAP emissions (downstream, EGUs, and refineries). In the NPRM illustrative air quality modeling analysis, we did consider impacts on crude production wells and pipeline pumps, and natural gas production wells and pipeline pumps. The NPRM air quality modeling

[432] "The Role of Critical Minerals in Clean Energy Transitions," International Energy Agency, https://iea.blob.core.windows.net/assets/ffd2a83b-8c30-4e9d-980a-52b6d9a86fdc/TheRoleofCriticalMineralsinCleanEnergyTransitions.pdf, accessed January 30, 2024.

analysis suggests that emission reductions from crude production wells and pipeline pumps are partially offset by increases from natural gas production well and pipeline pumps. The net oil and gas sector emissions changes are therefore small relative to those of the onroad and power sectors.

EPA also notes that accounting for further upstream emission processes in the context of an increase in PEV production while failing to do equivalent accounting for a reduction in the production of other vehicles, including ICE with a range of electrification, would unreasonably skew the emission impacts estimates. Many of the same metals that are in demand for PEV production would also be in demand for ICE production, so whether the standards would truly result in an increase in all mining, resource extraction, and production emissions is not clear. And, because such a broad accounting of these emission processes for the range of vehicles would include emissions from around the world, accounting for these emissions presents scope challenges.

In addition, modeling EGU and refinery emissions is balanced in considering the operation of ZEV versus ICE vehicles. For both vehicle types, our analysis considers the emissions and energy consumption of the vehicle itself plus the production of the fuel it uses, be it refined liquid fuels for ICE vehicles or electricity for ZEVs. It would skew the emission results if EPA calculated reduced transport of fuels caused by a reduction in ICE vehicle usage but no corresponding increase in the transport of fueling sources, such as natural gas, used to power the increased electric vehicle usage. Similarly, EPA does not assess comparable emissions associated with refinery waste generation and management (many of those wastes are listed as hazardous under the RCRA subtitle hazardous waste program, 40 CFR Part 261 hazardous wastes K 048-052).

There were also technical and practical reasons, in OMEGA, for EPA to model upstream emissions only from EGUs and refineries. EPA has available tools that are well suited to modeling the impacts of the standards on EGUs (i.e., IPM) and on refineries (i.e., a combination of the emissions modeling platform and EIA’s Annual Energy Outlook to generate emission factors for refineries). Both the CAFE model and EPA’s spreadsheet model used in previous GHG rules incorporated upstream emission factors from GREET. These emission factors from GREET were process-level emission factors and often encompassed several upstream emissions sources together, such as both crude extraction and transport. EPA finds that this approach may not be adequate to capture the complexities associated with major shifts in transportation fuels. Furthermore, matching GREET's emission factors to more specific emissions and activities estimates from EPA's detailed models, including the emissions modeling platform, would introduce additional uncertainty. EPA determined that other modeling tools, in particular GREET and EPA’s previous upstream modeling tool for emissions from previous GHG rules, did not have the same advantages as our chosen methodology for the purposes of modeling quantitative and detailed upstream emission impacts from the final standards.

While EPA included fewer upstream emission sources for this rule than some previous GHG rules, it’s important to note that this modeling is more detailed and rigorous, for the purposes of this rulemaking, than if we had used the same approach as we did for previous rules. Neither EPA’s spreadsheet tool nor GREET are dynamic models, in which projections of future time periods depend on the simulation of prior time periods. IPM, however, is a dynamic model. Because of its dynamic nature, the inclusion of rule-specific IPM runs allows for a better understanding of how the standards (especially possible ZEV adoption driven by the standards) impact the full U.S. energy system.

Nevertheless, EPA does not dispute the utility of other upstream emissions modeling tools, especially GREET, for other purposes. Also, there is ongoing work to develop the capability to capture upstream and cross-sector impacts in more detail, including the use of multi-sector modeling tools such as EPA's GLIMPSE framework.[433]

Regarding EPA's estimated real world fuel and energy consumption, EPA disagrees with the commenter's assertion that ICE and BEV onroad energy consumption and associated emissions are calculated using different drive cycles. EPA uses the same onroad drive cycle assumptions for both BEV and ICE vehicles in the effects calculations. These weighted onroad cycles include a significant portion of the higher speed US06 cycle, as described in Chapter 8.5.1 of the final RIA.

Regarding use of average EGU emissions rather than marginal emissions, we have done so because the expectation is that transportation charging will be closely monitored and most charging will be done at times during which grid loads are low (i.e., overnight, see Figure 5-5 in Chapter 5.1.1 of the RIA for example load profiles). Several strategies exist to alleviate the concerns associated with peak demand (see Chapter 5.3 and 5.4 of the RIA).

Regarding refinery emissions, EPA has updated the analysis and calculation methodology for the final analysis and has also updated the estimates of impacts on imports and exports with much more detail supporting our estimates (see Chapter 8 of the final RIA).

Regarding electricity prices, we have updated our effects modeling and no longer rely on AEO national average retail electricity prices to estimate costs associated with charging electrified vehicles. We respond in greater detail in Section 17 of this document.

Regarding fleet turnover, EPA disagrees that our OMEGA modeling does not reflect any shift towards older vehicles relative to the No Action scenario. EPA projects changes in new vehicle sales as a result of the standards and associated changes in new vehicle purchase prices. EPA also accounts for the distributions of vehicle age and VMT across the vehicle stock. The net effect of the analysis approach is that the slight reduction in new vehicle sales tend to increase the portion of miles driven by older vehicles, and therefore tend to increase their overall impacts relative to a case where there is no change in new sales. Our modeling includes a consumer choice element that considers out-of-pocket expenses when purchasing a new vehicle, projected operating savings, and incentives available by the IRA. While our modeling normalizes total sales to projections in AEO, the producer-consumer interaction elements of OMEGA determine the share of BEVs to PHEV to ICE. In other words, OMEGA is not forcing a level of BEV penetration. Rather, it is determining a level based on producer requirements to meet standards and consumer desire to purchase their preferred vehicle. As a result, while we do not model delayed scrappage per se, OMEGA will show an increased number of older vehicles in the event that new vehicle sales decrease in response to a policy, and those vehicles will drive more total miles than driven by older vehicles in the No Action scenario; this shifting of VMT distribution

[433] U.S. EPA. "GLIMPSE – A computational framework for supporting state-level environmental and energy planning". February 1, 2024. Available online: https://www.epa.gov/air-research/glimpse-computational-framework-supporting-state-level-environmental-and-energy

across the vehicle stock has the same practical effect as changing the scrappage rates of older vehicles.

Regarding Honda's comment that the marginal abatement costs for the new PM standard are exceedingly high, we disagree with their assessment. EPA is moving from a higher current Federal standard to the new Federal standard, so a marginal impact relative to the CARB standard is not relevant. The CARB ACC II program includes both PM reductions from more stringent PM standards from ICE-based vehicles and PM reductions from a ZEV mandate. As noted in RTC Section 4.1, EPA is not adopting a ZEV mandate, as the CARB standards use; instead, EPA is setting performance-based standards for both criteria pollutants and GHG emissions. EPA believes it would not be appropriate to project CARB's ACC II program emission reductions across the entire country, including a ZEV mandate, and then attempting to calculate the marginal benefits of EPA's final PM standard. In addition, EPA projects that the PM standard in this FRM will result in the adoption of control technologies which are effective over the broadest range of environmental and vehicle operating conditions, in other words, EPA anticipates that PM controls adopted as the result of this rulemaking will be effective both on-cycle and off-cycle. CARB, on the other hand, has adopted standards which are focused on on-cycle PM emissions conducted at 25°C. Finally, because at the time of this final rulemaking EPA has not yet granted a waiver to California for the ACC II program, the agency believes it would be inappropriate to prejudge the outcome of the waiver request process and project PM emission reductions and benefits incremental to a program that is still under consideration by the Administrator.

Regarding backsliding of conventional ICE vehicles as more electrified vehicles enter the fleet, EPA does not believe that it is likely to happen in any significant manner. See comments from other commenters, specifically Consumer Reports in Section 12.3.1 of this document where they state, "Consumer demand for EVs is rapidly increasing, and technology improvements will mean that the remaining gasoline powered vehicles will have to compete with better and better EV offerings. In order to continue to find buyers for their remaining gasoline powered vehicles, automakers will need to make them better, not worse." Also, such an outcome, if it were to happen, is inherent in any performance standard. Provided performance is achieved, the standard is met. And there is no indication that the higher GHG vehicles will be driven more miles as hypothesized by the commenter. Our long-standing practice of setting performance-based fleet average GHG standards gives the industry the flexibility to achieve emissions reductions in the most cost-effective and efficient manner. If we set requirements for specific technologies, it would eliminate manufacturers' flexibility to identify and apply potentially more cost-effective compliance solutions.

Regarding claims that EPA had failed to consider EGU emissions, this is incorrect. See Sections VI and VII of the preamble. We did and continue to estimate emission impacts associated with power generation. Extensive modeling efforts have been undertaken to estimate charge demand and power sector emissions and those efforts are reflected in our analysis. We respond to more comments regarding our power sector modeling efforts in Section 18 of this document. Importantly, we have not estimated full fleet conversion to BEV (presuming that was the meaning behind the mention of 350 million vehicles by 2050). Indeed, none of the many pathways that EPA has modeled reflects 100% fleet conversion to BEV by 2050. In contrast, we project, under just one potential pathway, that roughly 48 percent of the light- and medium-duty fleet will be BEV with roughly an additional 5 percent being PHEV by 2030. Further, our EGU modeling suggests that light- and medium-duty electricity demand will be roughly 12 percent of U.S. generation in 2050 (see Table 5-3 of the RIA).

Regarding the expectation that EPA would identify the level of emissions needed to achieve compliance with the NAAQS, we respond to this in Section 2.

We appreciate comments from Energy Innovation regarding the NPRM's Alternative 1 and address this comment in Section 3.3.1 of this document.

Regarding EPA's failure to consider some technologies, specifically efficiency improvements available in hybrid architectures, we recognize that manufacturers may develop and apply additional efficiency improvements in hybrid vehicles. We take the comment to suggest that our NPRM analysis was conservative since it failed to consider some cost-effective technologies that could have been used toward compliance. Importantly, our analysis should be viewed as identifying a set of possible pathways toward meeting the standards and we have included additional pathways in our sensitivity analysis presented in Sections IV.F and IV.G of the preamble. Our analysis should not be viewed as an endorsement of specific technologies and, if the commenter is correct that hybridization can be used more widely and more cost-effectively than our analysis has estimated, the auto makers are free to choose such technologies. The same is true of PHEVs. Similarly, renewable liquid fuels may be another means of reducing carbon emissions and nothing in this final rule precludes Marathon or other fuels producers from providing those fuels. However, setting standards that would require such fuels is outside the scope of this action.

Regarding inclusion of upstream emissions for BEVs, we presume that this comment is directed at the issue of including upstream emissions in the compliance determination because we have, in fact, included upstream emissions in our effects calculations (i.e., emissions inventory impacts). The inclusion of upstream emissions in the compliance determination and the possibility that it makes the standards infeasible even for BEVs is not relevant because we are not including those emissions in the compliance determination. See Section 3.1.5 of this RTC.

Regarding the infeasibility of the standards should BEV penetrations fall short of EPA projections, we note that we have conducted several analyses showing different possible pathways to compliance including one that involves no additional BEV penetration beyond current levels in the U.S. market. We present these in Sections IV.F and IV.G of the preamble.

Regarding the claim that we had subtracted the GHG emissions associated with electricity used to power BEVs from the emissions inventory associated with conventional vehicles, this claim is incorrect. We account for vehicle emissions (note that BEVs have tirewear and brakewear emissions) and add to those the EGU emissions. Regarding other upstream sources, we addressed that issue earlier in this response. Regarding the mix of generation sources in the EPA modeling compared to that in AEO, we note that part of the reasons we continued to rely on IPM modeling, as we did in the NPRM, was our disagreement with the AEO projections and the way that AEO had characterized the impact of the IRA (i.e., AEO 2023 projected very little BEV penetration). We stand by the IPM modeling we have conducted and the expertise of those behind that model. We discuss our IPM modeling in Chapter 5 of the final RIA and we respond to comments regarding use of IPM over AEO in Section 18 of this document.

Regarding comments related to the EGU emission rates presented in Chapter 9 of the RIA, we note that the emission rates presented there were used only through calendar year 2050 with the rates held constant at the 2050 rate thereafter. This is done because the IPM modeling results for the next to last year modeled (in this case 2050 since the last year modeled was 2055) are considered the last set of results for use. Importantly, for the final analysis, we have revised our approach to estimating EGU emission rates and, instead of using emission rate curves as done in the NPRM, we now use the IPM results directly with linear interpolations between years (IPM results are done for several but not all calendar years up to 2055). As done in the NPRM, the IPM results beyond 2050 are not used and the EGU emission rates beyond 2050 are kept at the 2050 rates. One result of this change is that, while the NPRM analysis held rates constant beyond 2050 thereby ensuring that rates never went negative, our final rates give no impression that perhaps rates could go negative.

Regarding claims that EPA had failed to consider that gasoline consumed in the U.S. contains both fossil and renewable fuels like ethanol, we disagree. We do adjust for the ethanol and biodiesel content of retail or pump gasoline when calculating our emissions inventory and fuel consumption effects. See Chapter 8.5.3 of the RIA. We have improved the transparency of the calculation approach since the NPRM.

Regarding Valero's claim that EPA had used an inconsistent EGU emission rate, this is a misunderstanding on the part of the commenter. The emission rate noted by the commenter—325 grams CO_2e—is meant only for possible use in compliance determinations. Note that the commenter found the file containing the 325 value in a set of compliance modeling runs. Because upstream emissions are not included in the compliance determination of any vehicles, that 325 value is not used. We do not use that value in calculating the upstream inventories associated with EGUs and instead use the emission rates described in Chapter 8.6.1 of the RIA which are based on the IPM modeling described in Chapter 5 of the RIA.

Regarding Valero's comment about inconsistent charge efficiencies across EPA analyses, we note that the final RFS rule did not make use of the value noted by the commenter and slightly different efficiencies for the light-duty and heavy-duty markets (90 percent in light-duty and 88 percent to 89.25 percent in the heavy-duty NPRM) is not inappropriate from our perspective given differences in the markets.

Regarding the gasoline CO_2/gallon factor used in compliance modeling, this value is not actually used and we apologize for any confusion. Importantly, all of the response surface equations used in estimating gasoline vehicle CO_2/mile and used for determining gasoline vehicle compliance within OMEGA were generated using characteristics of in-use retail gasoline (i.e., pump gasoline containing ethanol). Since the CO_2/gallon value noted by the commenter is not actually used, this comment is essentially moot.

Regarding compliance flexibilities, EPA has carefully considered those flexibilities in the context of determining the final standards. We present those flexibilities and the rationale behind them in Section III of the preamble and further respond to comments in Sections 3.1.3 and 3.1.4 of this RTC.

Organization: American Honda Motor Co., Inc.

Base Year Fleet

The proposed rule and supporting documentation make numerous references to a MY2021 base year fleet, suggesting that agency modeling of low-carbon technology pathways "builds upon" an automaker's MY2021 fleet. As we have noted in previous sets of comments to the agency, it is Honda's belief that selection of the base year fleet can have meaningful impact on modeling results, at least at an OEM-based level of granularity. As Honda noted in comments submitted to the agency in September 2021:

Fundamentally, the base year defines the sets of technologies already applied in the market, and therefore sets constraints regarding "technology walks" to further emissions reductions. In other words, it defines the low-hanging fruit that are available for providing further improvement to the fleet. By selecting an overly dated base year fleet, the agency's modeling could erroneously assume application of technology that, in reality, did not occur. Use of [an older] base year permits the modeling to apply "imagined" technology to model years that have already passed, ignoring actual technology application decisions and potentially widening the gap between simulated results and what is achievable with the current vehicle fleet.53 [EPA-HQ-OAR-2022-0829-0652, pp. 31-32]

53 American Honda Motor Co., Inc. comments on Revised 2023 and Later Model Year Light-Duty Vehicle Greenhouse Gas Emissions. September 27, 2021. Docket ID No. EPA–HQ–OAR–2021–0208.

Honda was encouraged by the references to a MY2021 base year fleet in the agency's proposal and supporting documentation. Upon closer examination of the OMEGA 2.0 computer model, however, it is clear that the agency is not using a MY2021 base year, but rather is using a MY2019 fleet. For the reasons noted above, we request that the agency update its model assumptions to reflect a more up-to- date and accurate base year fleet. [EPA-HQ-OAR-2022-0829-0652, pp. 31-32]

Recommendation: Honda respectfully requests that the agency use the most up-to-date and accurate base year fleet available as part of its modeling activities. [EPA-HQ-OAR-2022-0829-0652, pp. 31-32]

Organization: Institute for Policy Integrity at New York University School of Law

C. EPA Should Update the Baseline to Ensure Full Consideration of the Inflation Reduction Act

In regulatory impact analysis, the baseline refers to "the best assessment of the way the world would look absent the proposed action."90 Developing an accurate baseline is important for conducting benefit-cost analysis, but challenging when baseline conditions are in flux. That is the case here given last year's passage of the Inflation Reduction Act (IRA). [EPA-HQ-OAR-2022-0829-0601, pp. 15-16]

90 Circular A-4, supra note 86, at 15.

To model the baseline for the Proposed Rule, EPA adopts key variables from the Annual Energy Outlook 2021 (AEO 2021), such as fleet size, new vehicle sales shares, fuel prices, electricity prices, and vehicles miles traveled.91 However, AEO 2021 was developed before the IRA's passage and thus does not include the effects of that law. While it was reasonable for EPA to rely on AEO 2021 in this proposal, it should consider adjusting the baseline in the final rule to fully incorporate the IRA's impacts. In particular, according to the 2023 version of Annual Energy Outlook (AEO 2023), the IRA will decrease both short-run and long-run electricity prices relative to the no-IRA case.92 AEO 2023 also projects that the IRA will decrease long-run gas prices, with a minimal short-run impact.93 Gasoline and electricity prices are important modeling inputs, as they affect the relative cost of ownership between ICE vehicles and BEVs and thereby influence the sales of these vehicles. These prices also affect the fuel-cost savings, the rebound effect, and related environmental impacts. [EPA-HQ-OAR-2022-0829-0601, pp. 15-16]

91 See RIA at 9-1.

92 See infra p. 30 fig.2 (difference between AEO 2023 with IRA (solid-blue line) and AEO 2023's "No IRA" case (dotted-blue line)).

93 See infra p. 30 fig.1 (difference between AEO 2023 with IRA (solid-blue line) and AEO 2023's "No IRA" case (dotted-blue line)).

There are several potential options for EPA to consistently account for the IRA across modeling inputs. One option is for EPA to adopt AEO 2023 for parameters where it currently uses AEO 2021. This would presumably also entail updating future BEV penetration, which, although EPA models separately, is based in part on parameters from AEO 2021. If EPA updates its baseline to incorporate AEO 2023, it should beware that AEO 2023 models only certain aspects of the IRA but does not include the producer-side battery tax credit.94 To blunt the resulting potential underestimate of the IRA's full impact, EPA should consider using the "High uptake of the IRA" sensitivity case provided in AEO 2023. [EPA-HQ-OAR-2022-0829-0601, pp. 15-16]

94 U.S. Energy Information Administration, Transportation Demand Module Assumptions 26 (Mar. 2023), https://www.eia.gov/outlooks/aeo/assumptions/pdf/TDM_Assumptions.pdf.

If updating the baseline to AEO 2023 is infeasible, a more feasible alternative may be for EPA to continue to use AEO 2021 as its baseline and then add the IRA's impact on other parameters on top of that. Data within AEO 2023 enables this type of assessment, as AEO 2023 provides sensitivity analysis in which it models the world with and without the IRA.95 This enables a direct comparison to assess the IRA's effect on key parameters, including electricity prices and gas prices.96 As noted above, EPA should consider adopting the "High uptake of the IRA" sensitivity case in AEO 2023 for comparison purposes.97 [EPA-HQ-OAR-2022-0829-0601, pp. 15-16]

95 See Projection Tables for Side Cases, Annual Energy Outlook 2023, https://www.eia.gov/outlooks/aeo/tables_side_xls.php (providing tables for "No IRA" case).

96 EPA acknowledges that it has estimates of future retail electricity prices that account for the IRA and that these estimates exhibit lower prices compared to a scenario without the IRA. But due to the absence of corresponding information on gasoline price estimates under the IRA and a desire for consistency across variables and model components, EPA opts not to use these estimates. RIA at 2-84.

97 See Projection Tables for Side Cases, supra note 95 (providing tables for “High uptake of the IRA” case).

This modeling adjustment could have meaningful effects (though it’s unclear whether this would increase or decrease net benefits overall, and it would almost certainly not change the sign or ordering of net benefits). According to projections from AEO 2023, the retail electricity price for transportation could be lower by an average of 0.45 cents per kWh from 2027 to 2032 under a high-IRA uptake scenario compared to a scenario without the IRA. This could translate to a decrease of about $50 in the “generalized cost,” 98 i.e. the purchase price net of vehicle ownership and operation costs.99 The lower cost of operating an electric vehicle would translate to greater BEV uptake than EPA projects in its baseline fleet. This suggests, among other implications, that the Proposed Rule’s compliance costs may be lower than EPA projects, since automakers may already be closer to complying with the proposed standards under the baseline than EPA recognizes. [EPA-HQ-OAR-2022-0829-0601, pp. 15-16]

98 Considering the average EV efficiency at 3 miles per kWh, a reduction of 0.45 cent per kWh equates to a savings of 0.15 cents per mile. Incorporating EPA’s assumptions for consumer fuel-cost calculations in their purchase decision—with an annual mileage of 12,000 miles, a 2.5-year fuel-cost valuation period, and a fueling efficiency factor of 0.9—this saving translates to around $50 = 2.5(years) ×{0.15(¢/mile)×12,000(miles/year)÷100(¢/$)}÷0.9.

99 Both producers and consumers use this metric in their decisionmaking processes. See RIA at 4-2 to 4-4.

The Appendix below includes four figures illustrating the data presented in this section. [EPA-HQ-OAR-2022-0829-0601, pp. 15-16]

Organization: Rivian Automotive, LLC

EPA Does Not Appear to Account for Rivian’s Production

The case for Alternative 1 is even stronger when considering the agency’s apparent omission of Rivian from its analysis. Specifically, OMEGA’s Manufacturers File, an input file listing vehicle producers considered as distinct entities for GHG compliance in the model, does not list Rivian.16 Even the agency’s survey of manufacturer commitments, presented as Table 1 in the NPRM and reproduced below, does not include the company.17 [EPA-HQ-OAR-2022-0829-0653, pp. 2-7]

16 List of producers found in the file, “manufacturers.csv.” Purpose and description of the Manufacturers File per U.S. Environmental Protection Agency, “OMEGA 2.1.0 Documentation (rev. 5/8/2023)” (May 8, 2023), available at https://omega2.readthedocs.io/en/2.1.0/index.html#document-1_overview.

17 Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles, 88 Fed. Reg. 87 (May 5, 2023) (revising 40 C.F.R. Parts 85, 86, 600, 1036, 1037, and 1066), Table 1, 29,192.

See original attachment for: Figure 3. EPA’s Table 1 reports stated manufacturer EV commitments but does not include Rivian. In calendar year 2022, Rivian produced approximately 25,000 EVs. We have a planned annual production capacity for later this decade of 600,000 units. [EPA-HQ-OAR-2022-0829-0653, pp. 2-7]

Rivian produced and sold four distinct vehicle models in MY22 as recorded in EPA’s “Certified Vehicle Models” data.18 Over the course of calendar year 2022, we produced approximately 25,000 units across all our product lines. The R1T was the tenth bestselling EV in the U.S. that year.19 We expect to double production in 2023 as we build toward our planned production capacity of over half a million units annually across two manufacturing facilities. Rivian would be pleased to meet directly with the agency to discuss our historical production volume and plans, and to address any related questions, concerns, or data availability. [EPA-HQ-OAR-2022-0829-0653, pp. 2-7]

18 U.S. Environmental Protection Agency, "Annual Certification Data for Vehicles, Engines, and Equipment," available at www.epa.gov/compliance-and-fuel-economy-data/annual-certification-data-vehicles-engines-and-equipment. See "Certified Vehicle Models (Model Years: 2014 – Present) (xlsx)."

19 Mark Kane, InsideEVs, "US: Top Selling BEVs in 2022 Were Long Range Ones," April 18, 2023, available at www.insideevs.com/news/663012/us-top-selling-bevs-2022-long-range/.

We believe omitting Rivian from the agency's analysis could have material implications for EPA's findings of feasibility and the final regulatory proposal. EPA should update its model inputs to account for Rivian's sales and revise its evaluation of the alternatives accordingly. [EPA-HQ-OAR-2022-0829-0653, pp. 2-7]

Update the Baseline Fleet

We have concerns about EPA's reliance on MY19 as the base year fleet for its analysis, a baseline now several years in the past during a time of rapid change in the industry.20 Most significantly for purposes of this rulemaking and EPA‘s analysis, the EV sales share grew from just 1.7 percent in MY19 to 4.4 percent in MY21.21 Preliminary data show the sales share roughly doubling in MY22 to approximately 8 percent.22 In previous regulatory proceedings, the agency stated that the vintage of the base year will "not normally have a significant impact" but that certain broad shifts in the market, such as the average vehicle power- to-weight ratio, can affect the incremental cost-effectiveness of technology application in the modeling.23 The significant growth in the EV market in recent years—a trend not yet visible in the MY19 data—would seem to constitute a "broad market shift" with potential impacts on the OMEGA model runs. For example, could greater BEV volumes in the base year fleet could affect credit-trading and technology application decisions in the model? If nothing else, greater EV volumes in the base year fleet would imply greater growth potential and higher penetrations of this technology by the end of the regulation window and could support greater stringency than currently proposed. Finalized compliance data through MY21 were available during the analysis and development phase. We encourage incorporation of the most recent base year data available for the final rule in accordance with best practice.24 [EPA-HQ-OAR-2022-0829-0653, pp. 7-8]

24 EPA "will often attempt to utilize the most recent base year data," per Revised 2023 and Later Model Year Light- Duty Vehicle Greenhouse Gas Emissions Standards, 86 Fed. Reg. 151, 43,769 (Aug. 10, 2021) (revising 40 C.F.R. Parts86 and 600).

Organization: The Heritage Foundation (Kevin Dayaratna and Diana Furchtgott-Roth)

EPA has selected an arbitrary vehicle range, 300 miles, as the standard for the Omega model. This is carried over into the cost analysis since the analysis is based on $/kWh and the range of a BEV or PHEV is linked to battery capacity along with other factors. [EPA-HQ-OAR-2022-0829-0674, pp. 8-9]

The mileage regularly advertised is in best-case scenarios, such as flat highway driving conditions. The introduction of terrain, adverse weather, traffic, excess drag, or load from something such as a trailer can have a significant negative effect on the advertised range. This is not acknowledged and is detrimental to the EPA proposal in several ways. [EPA-HQ-OAR-2022-0829-0674, pp. 8-9]

First, for Americans to maintain their current type of usage of their vehicles—including professional and recreational activities such as landscaping, construction, hotshot trucking, equestrian sports, boating, camping, road trips, etc.—battery packs will need to become much larger. This renders the EPA's cost per vehicle analysis invalid. [EPA-HQ-OAR-2022-0829-0674, p. 9]

Second, larger packs will mean more weight and potentially more aerodynamic drag and therefore less efficiency. Unlike an internal combustion engine vehicle, the weight is not reduced upon energy consumption. The F150 Lightning is a perfect example of a 300-mile EV that struggles to tow a lightweight camper 100 miles.35 [EPA-HQ-OAR-2022-0829-0674, p. 9]

35 Tingwall, Eric. "Tow No! The Ford F-150 Lightning Struggled in Our Towing Test."MotorTrend, 12 July 2022, www.motortrend.com/reviews/ford-f150-lightning-electric-truck-towing-test/ (accessed 5 July 2022).

As a rudimentary example of comparison, consider the scenario of a diesel truck pulling a trailer a short distance of 150 miles. The truck has a tank size of 36 gallons and achieves 12.5 MPG during the trip. This equates to 12 gallons of burned diesel, well within the no-stop capability of the truck. With modern diesel engines having an efficiency of just over 40%, and diesel having 37.95 kWh/gal of energy, the minimum energy required for a no-stop trip is 182.16 kWh. [EPA-HQ-OAR-2022-0829-0674, p. 9]

With an optimistic motor efficiency of 94% the battery pack must have 193.79 kWh of usable energy. With high-performance batteries capable of 95% usable capacity this means that for the battery pack to make this short trip without stopping it must be no less than 203.99 kWh. With GM's Ultium battery cells having a capacity of 0.1157 kWh per pound, the battery cells alone for this scenario would weigh in excess of 1700 pounds. While the diesel can complete this task nearly three times before refueling, the EV must have a 200 kWh battery, twice the size of the EPAs chosen capacity, to complete the task even once. [EPA-HQ-OAR-2022-0829-0674, p. 9]

Organization: Valero Energy Corporation

I. EPA's OMEGA modeling does not support the proposed standards.

EPA relies on an Optimization Model for reducing Emissions of Greenhouse Gases from Automobiles ("OMEGA") to model manufacturer compliance with the proposed tailpipe emission standards for light-and medium-duty vehicles by "finding cost-efficient pathways for manufacturers to achieve compliance with desired emissions standards."1 The model projects producer and consumer behavior in response to policies and their physical and cost effects. While EPA relies on the modeling results to conclude that the proposed emission standards can be attained in a range of scenarios, the model inputs are riddled with errors and unreasonable assumptions. Further, although EPA notes that the model was peer-reviewed, important qualifications from the peer reviewers were inappropriately dismissed. [EPA-HQ-OAR-2022-0829-0707, p. 1]

1 EPA "Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles Draft Regulatory Impact Analysis" ("DRIA"), April 2023, at 2-1.

A. EPA's modeling of technological suitability based on hypothetical future light and medium duty (LMD) BEVs is significantly compromised by pervasive unreasonable assumptions in the modeling inputs. [EPA-HQ-OAR-2022-0829-0707, p. 1]

The highly complex OMEGA model relies on a multitude of user inputs, upon which the model results are highly sensitive.2 Notwithstanding this high degree of sensitivity to specific inputs, EPA applies numerous unsupported, unreasonable, and in some cases plainly incorrect assumptions in the model. Consequently, the results of the model are arbitrary and provide an unsuitable basis for concluding that the proposed standards are feasible. [EPA-HQ-OAR-2022-0829-0707, p. 1]

2 EPA's Multi-Pollutant LMDV Proposal at 29295 to 29297.

1. The EVSE (charging infrastructure) installation costs adopted by EPA are unrealistic. [EPA-HQ-OAR-2022-0829-0707, pp. 1-3]

2. The charging efficiencies adopted by EPA for purposes of this proposed rule are arbitrarily inconsistent with other contemporaneously proposed rules. [EPA-HQ-OAR-2022-0829-0707, p. 3]

3. EPA arbitrarily excludes viable LMDV technologies from its compliance modeling. [EPA-HQ-OAR-2022-0829-0707, pp. 3-4]

4. The analysis fleets modeled by OMEGA are highly implausible, and EPA fails to account for the actual costs to produce such fleets. [EPA-HQ-OAR-2022-0829-0707, pp. 5-6]

5. EPA overstates BEV adoption and associated benefits by failing to calibrate model projections to reflect current vehicle offerings.

In the OMEGA modeling to support the proposed rulemaking, EPA adopts a MY 2019 base year fleet, from which the OMEGA model then produces an analysis fleet for each subsequent year.33 At the time that EPA published the proposed standards in May 2023, the base year fleet adopted by EPA for this rulemaking was already four years old. Between the outdated base year fleet and EPA's lack of calibration of the OMEGA inputs and algorithms, the MY 2023 analysis fleet generated by OMEGA is wildly inaccurate, as demonstrated below for just one auto manufacturer. [EPA-HQ-OAR-2022-0829-0707, pp. 7-8]

33 DRIA at 9-1 and 2-1.

The MY 2023 Ford fleet generated by OMEGA includes 13 vehicle IDs with a BEV powertrain, spanning six distinct body styles and size classes. By comparison, Ford's actual MY

2023 light-duty vehicle offerings include only the 2023 Mustang Mach-E® and the 2023 F-150 Lightning®. [EPA-HQ-OAR-2022-0829-0707, pp. 7-8]

[See original for table titled "OMEGA MY 2023 analysis fleet for Ford] 34 35 [EPA-HQ-OAR-2022-0829-0707, pp. 7-8]

34 EPA LMDV OMEGA GHG Compliance Modeling Runs (Document ID EPA-HQ-OAR-2022-0829-0486), 2023- 03-25-11-46-49-ld-central-compliance-run.zip, "2023_03_25_11_46_49_ld_central_compliance_run_Proposal_vehicles.csv," Columns A, C, I and V.

35 Ford Showroom, https://shop.ford.com/showroom#/, accessed on April 27, 2023. The 2023 Ford E-Transit has a maximum GVWR of 9,500 lbs and is not a light-duty vehicle, per https://www.ford.com/commercial-trucks/e- transit/models/cargo-van/, accessed April 27, 2023.

While it is understood that OMEGA is intended to be an analytical tool and not a prognostication, in recognition of the significant impact that the OMEGA analysis fleets have on future tailpipe standards, EPA has the responsibility to calibrate the OMEGA model and true-up the legacy analysis fleets using the most current vehicle offerings and attributes. Otherwise, EPA is knowingly using inaccurate data to support the rulemaking, and in the case of Ford, overestimating BEV production and the associated benefits of the proposed rule. [EPA-HQ-OAR-2022-0829-0707, pp. 7-8]

Peer reviewers of the OMEGA v2.1.0 model commented to EPA "[i]t'd be good to have a model calibration/validation, if not already done so," to which EPA responded "[c]alibration/validation of inputs unique to the user's analysis are the responsibility of the user."36 As EPA is the "user" of the OMEGA modeling performed to support the proposed standards, EPA has the responsibility to appropriately calibrate and validate its inputs. [EPA-HQ-OAR-2022-0829-0707, pp. 7-8]

36 EPA "External Peer Review of EPA's OMEGA Model Final Peer Review Summary Report" (EPA-420-R-23- 010) at 4, April 2023.

6. EPA's application of price modifications is inconsistent with the Inflation Reduction Act ("IRA") and IRS's proposed implementation of 26 U.S.C. §30D and §45W. [EPA-HQ-OAR-2022-0829-0707, p. 9]

7. The upstream emission factor that EPA uses for transportation electricity is not consistent with other EPA sources and does not represent full lifecycle emissions from electricity generation. [EPA-HQ-OAR-2022-0829-0707, p. 10]

8. EPA must update its gasoline emission factors to reflect a Tier 3 E10 certification fuel. [EPA-HQ-OAR-2022-0829-0707, p. 10]

9. EPA fails to account for the rising cost of electricity over the regulatory period. [EPA-HQ-OAR-2022-0829-0707, p. 10]

10. EPA's baseline and sensitivity analysis is flawed. [EPA-HQ-OAR-2022-0829-0707, pp. 11-12]

EPA Summary and Response

The Heritage Foundation commented that EPA's choice of a 300 mile range for BEVs was arbitrary, and that real world driving often does not achieve the advertised range. EPA disagrees that this choice of range is arbitrary. EPA considers this to be representative of today's BEVs and a good "middle ground" for the typical range of BEVs going forward (see Section 3.1.1 of the final RIA). Importantly, when we size batteries within OMEGA, we size them for 300 miles of onroad operation, not 300 miles of test cycle operation. Additionally, the choice of BEV range in OMEGA impacts battery sizing and ultimately, the cost of the battery. The range does not impact our results calculations. All vehicles of a given body-style and model year and age will operate the same number of non-rebound miles regardless of powertrain. For ICE vehicles, all of those miles are driven using the ICE powertrain. For BEVs, all miles are driven by the BEV powertrain, but it would be the same number of miles driven within a body-style, model year, age cohort regardless of the range.

Valero asserted that a number of EPA's modeling inputs are unreasonable or incorrect, and consequently the results of the model provide an unsuitable basis for concluding that the proposed standards are feasible. EPA's discussion and response to these comments is provided throughout the RTC in the relevant topic sections as follows. Topic 1: EVSE installation cost comments are discussed in RTC Chapter 17, Topic 2: charging efficiencies are discussed in RTC Section 17, Topic 3: the exclusion of LMDV technologies from compliance modeling is discussed in RTC Section 12.2.4, Topic 4: analysis fleet and number of vehicle variants is discussed in RTC Section 12.1.1, Topic 5: base year fleet is discussed immediately below, Topic 6: IRA incentive modeling is discussed in RTC Section 12.4, Topic 7: electricity upstream emissions factor is discussed in RTC Section 12.1.3, Topic 8 gasoline emissions factor is discussed in RTC Section 12.1.3, Topic 9: electricity prices are discussed in RTC Section 8.3, and Topic 10: modeling of the No Action case is discussed in RTC Section 12.5.6.

Several commenters (Honda, Rivian, and Valero) suggested that EPA should update its base year fleet for the final rule analysis. For example, Valero commented that EPA's use of a MY 2019 base year fleet was already four years old at the time of the NPRM issuance in 2023. The commenter provided an example where the projected number of BEV models for a vehicle manufacturer in MY 2023 differed from the actual number of models in that same year. In response, EPA notes that there will necessarily be some delay between when the vehicle specifications and end-of-year production volume data becomes available and when the analysis is conducted. EPA agrees with the underlying point of the comment, which is that it is normally preferable to use the latest data possible. For this final rulemaking analysis, EPA has updated the base year fleet to MY 2022, which is the latest available, allowing time to process the data and quality check the resulting modeling inputs. EPA notes that even though the first Rivian model was introduced for MY 2022, the certification data for that model year was not available. As a result, the relatively small volume of Rivian vehicles produced for MY 2022 are not included in EPA's updated base year fleet for this final analysis.

12.2 - Battery/electrification technologies

12.2.1 - Battery costs

Comments by Organizations

Organization: Alliance for Automotive Innovation

F. Lithium-ion Battery Cost

The high cost of batteries, a crucial component, contributes to the affordability challenge of EVs. EPA has made ambitious assumptions on future battery raw material and manufacturing costs for battery packs that include aggressive learning rates that have not been proven with the new and rapidly evolving technology and manufacturing. From the Proposed Rule and Draft Regulatory Impact Analysis82 (DRIA), it appears that the agency's basis for setting stringent standards, which in turn drive significant levels of BEV adoption, is an assumption that battery costs will be substantially less expensive in the coming years. Given the fundamental importance of battery costs projections in this rulemaking, we examine the agency's assessment more closely, below. [EPA-HQ-OAR-2022-0829-0701, pp. 47-48]

82 U.S. Environmental Protection Agency, Draft Regulatory Analysis: Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium Duty Vehicles, EPA-420-D-23-003 (Apr. 2023). Hereinafter "DRIA".

EPA uses Argonne National Laboratory's BatPaC 5.0 model as the basis for battery pack costs, developing a baseline cost of $120/kWh for an exemplar 75 kWh battery in 2022, based on a per factory production rate of 250,000 packs/year and NMC811-G battery chemistry among other features.83 EPA then applies a learning factor based on cumulative battery production without consideration for the cost of raw materials.84 EPA also assumes that by 2027 all automotive batteries sold in the U.S. will qualify for IRA 45X credits totaling $45/kWh and that the savings associated with them will pass through to consumers. The modeling inputs and assumptions EPA makes culminate in unrealistically low battery costs. In fact, in combination with additional assumptions regarding IRA 30D/45W EV purchase incentives, EPA's analysis leads to implied negative battery costs in a number of years of the rulemaking. [EPA-HQ-OAR-2022-0829-0701, pp. 47-48]

83 DRIA at 2-44 et seq. (Base year battery cost estimation).

84 DRIA at 2-49 (Development of battery pack cost reduction factors for future years).

1. Comparison of EPA's Base Cost (2022) to Third-Party Sources

EPA compares its base 2022 battery cost of $120/kWh to only one third-party source, Bloomberg New Energy Finance (BNEF), which documented a current average BEV pack price of $138/kWh,85 15% higher than EPA's projected cost. EPA promptly dismisses the BNEF value as too difficult to compare to their analysis based on speculation of potential differences before concluding, "EPA believes that our proposed battery cost estimates are reasonable based on the record at this time."86 [EPA-HQ-OAR-2022-0829-0701, pp. 48-49]

85 NPRM at 29301.

86 Ibid.

The article cited by EPA with the BNEF cost projection87 is based on BNEF's 2022 Lithium-Ion Battery Price Survey.88 More detailed data in that report suggests EPA's assessment of a base battery cost of $120/kWh in 2022 is even more dubious than it appears in comparison to the BNEF-reported average BEV pack price of $138. BNEF reports an average price of NMC-based packs (the same type of cell chemistry that EPA used in its modeling) of $184/kWh (53% higher than EPA's estimate), with a range of $139 to $523/kWh (Figure 12). EPA described concerns that it is diffcult to know for sure how closely average costs match its specific assumptions for production, pack size, specific chemistry, etc.89 However, using even the minimum $139 cost reported by BNEF for NMC packs, EPA's base price in 2022 appears to be about 15% too low. [EPA-HQ-OAR-2022-0829-0701, pp. 48-49]

87 Id. at 29301, FN 561.

88 Bloomberg New Energy Finance, 2022 Lithium-Ion Battery Price Survey (Dec. 6, 2022).

89 NPRM at 29301.

Figure 12: BNEF 2022 Battery Price Survey Pack Volume-Weighted Price by Chemistry90 [EPA-HQ-OAR-2022-0829-0701, pp. 48-49]

90 Bloomberg New Energy Finance, 2022 Lithium-Ion Battery Price Survey (Dec. 6, 2022) at 9 (Figure 10). Available via Bloomberg New Energy Finance subscription. Used with permission.

Moreover, data from the same BNEF price survey provides an average U.S. battery pack price of $157/kWh91 (31% higher than EPA's estimate of $120/kWh). Regardless of whether the current average pack matches EPA's specific assumptions, EPA should be concerned that its specific assumptions fail to align to known, current data. [EPA-HQ-OAR-2022-0829-0701, pp. 48-49]

91 BloombergNEF (Dec. 6, 2022), Lithium-ion Battery Pack Prices Rise for First Time to an Average of $151/kWh, available at https://about.bnef.com/blog/lithium-ion-battery-pack-prices-rise-for-first-time-to-an-average-of-151- kwh/. (Battery pack cost of $127/kWh; U.S. prices 24% higher implies $157/kWh U.S. pack price.)

Data from Benchmark Minerals Intelligence (BMI) also contrasts sharply with EPA's base pack price assessment of $120 in 2022. BMI estimates the current cost of NMC811-G cells at a cost of $120-130 per kWh.92 Pack costs would be higher, $150 to $163 per kWh assuming cell cost is approximately 80% of pack cost. [EPA-HQ-OAR-2022-0829-0701, pp. 49-50]

92 BMI Study at 28.

EPA also relies on data from EDF/ERM to provide a qualitative comparison to its projected battery price curves.93 That data indicates as pack price of $135/kWh in 2022,94 12.5% higher than EPA's $120 projection. It is unclear how EPA could use this data to justify its own projection of uncertain future costs, yet completely ignore it for comparison to base costs in 2022. [EPA-HQ-OAR-2022-0829-0701, pp. 49-50]

93 DRIA at 2-51 et seq.

EPA's projections also diverge from those of Argonne National Laboratory (ANL). Using the same model as EPA, ANL estimates a 2022 battery pack cost of $130/kWh for an NMC811-G battery of 94 kWh, 8% higher than EPA's estimate for a smaller pack size.95 Battery pack costs tend to decrease as pack size increases, so ANL's modeling would likely yield a slightly higher pack cost for a 75 kWh battery. Although EPA discusses its modeling inputs and attempts to justify them, EPA's analysis ignores the inputs chosen by ANL, the developer of the model used by EPA, for the same battery chemistry and year. No explanation is given for the differences in assumptions, or why ANL's inputs are not appropriate in EPA's view. EPA makes no mention of ANL's estimate. Similar to EPA's analysis, the ANL analysis is based on a specific chemistry, and the broader question of interest is the alignment of EPA's modeling to known data such as BNEF's and BMI's. [EPA-HQ-OAR-2022-0829-0701, pp. 49-50]

94 Environmental Defense Fund, Electric Vehicle Market Update (Sep. 2022) at 27. Available at https://blogs.edf.org/climate411/wp-content/blogs.dir/7/files/2022/09/ERM-EDF-Electric-Vehicle-Market-Report_September2022.pdf.

95 Ahmed, S., et al., 2022. Estimated Cost of EV Batteries 2018-2022. Online slide presentation available at htps://www.anl.gov/cse/batpac-model-sotiware. Retrieved June 28, 2023. (Slide 6.)

The trend is clear. Third-party sources for current battery pack prices, including those cited for other purposes by EPA, and those developed by a national laboratory using the same model as EPA, all agree that the cost of a battery pack in 2022 is higher than that estimated by EPA. The inescapable conclusion is that EPA's modeling of base battery pack cost is incorrect and yields too low of a value even before EPA starts adding additional modifiers to it. EPA must reconsider its assessment of base battery pack costs for the final rule. [EPA-HQ-OAR-2022-0829-0701, pp. 50-51]

Figure 13 shows the more accurate 2022-2023 U.S.-specific battery pack cost (about $153/kWh based on BNEF's and Benchmark Minerals Intelligence industry survey data) compared to EPA's battery cost projections in its central and high battery cost cases. The BNEF/BMI data is approximately 33% higher than EPA's Central Case 2022 battery costs and is 10% higher than even the High Battery Cost Sensitivity Case. If future years are adjusted according to today's higher pricing, it would affect 2030-2032 battery pack-level costs similarly, about 33% higher. This makes it abundantly clear that EPA's reference 2022 battery cost96 and its Central Case 2022-2032 costs are clearly far too low. As shown, EPA's "High Battery Cost Case" is a much more representative (but still too low) reflection of actual current and projected future battery costs than EPA's Central Case battery costs. [EPA-HQ-OAR-2022-0829-0701, pp. 50-51]

96 DRIA at 2-53 (Figure 2-26).

[See original comment for Figure 13: Table of Battery Pack Direct Costs] [EPA-HQ-OAR-2022-0829-0701, pp. 50-51]

Furthermore, this deeper exploration of EPA's battery analysis examined the associated cell-level battery costs that relates to the above pack-level battery costs, and similarly shows that EPA's assumed battery costs are far too low. Auto Innovators could not locate EPA's projected cell-level battery costs, which are critical in vetting the accuracy of their projections against the leading research and industry battery cost estimates. As a result, Auto Innovators assumes, based on general industry and research data, that cell-level costs are equivalent to 80% of battery pack-level costs97 in order to estimate EPA's implied cell-level cost. [EPA-HQ-OAR-2022-0829-0701, pp. 51-52]

97 Cost-to-pack ratios differ by battery technology. In the absence of clarity on EPA's assumption, we assume that the U.S. automotive industry average battery cell cost is 80% of the overall pack cost, which is the approximate average of the last two years of BNEF industry surveys. See htps://about.bnef.com/blog/lithium-ion-battery-pack-prices- rise-for-first-time-to-an-average-of-151-kwh/ and htps://about.bnef.com/blog/battery-pack-prices-fall-to-an- average-of-132-kwh-but-rising-commodity-prices-start-to-bite/.

A key cell-level data source in this regard is Benchmark Minerals Intelligence, which rigorously assesses supply chain and commodity dynamics and prices. Benchmark finds significantly higher battery prices than what the EPA is assuming. For example, as illustrated in Figure 14 below, industry-wide North America 2022 battery cell-level prices are around $130 per kilowat-hour.98 Figure 14 shows NCM811, a representative battery technology for batteries that meet the technical and market specifications in the U.S. market. The real-world estimated industry cost that the auto industry experiences are substantially higher than EPA's assumed reference battery cost. Comparing Benchmark Minerals Intelligence data to EPA's estimated 2022 cost, considering cell-level costs are approximately 80% of pack-level costs, EPA's reference Central Case 2022 battery cell-level cost is approximately $92/kWh (or approximately 8% too low). [EPA-HQ-OAR-2022-0829-0701, pp. 51-52]

98 Simon Moores, Benchmark Minerals Intelligence (Feb 2023). Benchmark prismatic NCM811 cell price, htps://twiter.com/sdmoores/status/1627979954892816384/photo/1

Figure 14: Benchmark Prismatic NCM811 Cell Price Figures [EPA-HQ-OAR-2022-0829-0701, pp. 51-52]

Critically, we observe a key oversight in EPA's research into future battery costs. The EPA regulatory analysis fails to incorporate what appears to be the most rigorous and representative peer-reviewed research on the applicable dynamics with battery innovations, battery chemistries, and critical mineral prices from Mauler et. al (2022).99 The Mauler study more comprehensively analyzes the associated dynamics for lithium, nickel, manganese, cobalt, and graphite than EPA or any of the underlying data that EPA cited. [EPA-HQ-OAR-2022-0829-0701, pp. 52-53]

99 Mauler, L., Lou, X., Duffner, F., Leker, J. (2022). Technological innovation vs. tightening raw material markets: falling battery costs put at risk. Energy Advances. Issue 3: 136-145. htps://pubs.rsc.org/en/content/articlelanding/2022/ya/d1ya00052g

From our analysis of EPA's data, the BNEF and BMI baseline 2022 data, and the Mauler research, we compare cell-level battery costs in Figure 15 below. In the figure we convert EPA's projected pack-level costs to cell-level costs by multiplying by 0.80. BNEF and Benchmark indicate 2022 (and likely 2023) U.S. cell-level costs are approximately $125 per kWh. Mauler et al (2022) cell- level estimates for 2030 are shown, including its lowest ($77) and highest ($104) presented values, as well as the midpoint ($90). As indicated, EPA's implied Central Case direct manufacturing battery cost for 2030 (at $62/kWh) is 32% lower than the Mauler midpoint, and 20% lower than the Lowest value in Mauler (2022). Considering the Mauler et al (2022) analysis more accurately and rigorously accounts for the technology and market dynamics related to batteries, we recommend that EPA revisit its battery cost analysis and align its 2027-and-later projections with Mauler analysis. [EPA-HQ-OAR-2022-0829-0701, pp. 52-53]

[See original comment for Figure 15: Battery Cell Direct Costs] [EPA-HQ-OAR-2022-0829-0701, pp. 52-53]

Based on this analysis into the underlying research literature, for the final rule's central analysis, we recommend that EPA increase its reference direct manufacturing battery pack cost per kilowat-hour for 2022 and 2023 to be approximately $153 per kilowat-hour. Further, we recommend that EPA adjust its central case battery projection through 2032 to match the midpoint of the Mauler et al (2022) analysis (i.e., $90/kWh cell-level, approximately equal to $113/kWh at a pack-level in 2030). To better reflect these key inputs, we also recommend that the final rule's low battery case sensitivity analysis go no lower than the "Lowest" value in Mauler et al 2022 (i.e., $77/kWh cell-level, approximately equal to $96/kWh at a pack-level in 2030). This adjustment better matches the U.S.-specific battery characteristics as seen by U.S. automakers and tailored for the U.S. market, better reflects the actual underlying data that EPA references for battery costs, and incorporates research that was not cited in EPA's NPRM and DRIA. In addition, we recommend EPA clearly present its EV sales-weighted $/kWh values in pack-level and cell-level estimates for all model years 2022-2032 to transparently allow comparisons between EPA's projections and the applicable research literature and industry estimates. [EPA-HQ-OAR-2022-0829-0701, pp. 52-53]

Argonne National Laboratory's BatPaC model itself has reflected increased materials costs over the past few years, directionally consistent with Auto Innovators' understanding of the market. For example, between 2021 and 2022, updates to BatPaC reflect a 14% increase in the $/kg cost of cathode active material and a 50% increase in the $/kg cost of positive binder.100 While Auto Innovators appreciates EPA's use of the most recent version of BatPaC to reflect the latest information regarding material costs, these recent cost increases are a further indication that – contrary to EPA's assumptions – costs are unlikely to remain static at 2022 levels for the next decade. It is unreasonable for EPA to assume that a site, regulation-driven ten-fold increase in demand for critical minerals in a tight, volatile and geopolitically sensitive global market would have no impact on electrode and other materials costs beyond levels assessed in 2022. EPA should consider supply / demand impacts in a volatile and still-developing mineral commodities market for batteries. [EPA-HQ-OAR-2022-0829-0701, pp. 53-54]

100 Ahmed, S., et al., 2022. Estimated Cost of EV Batteries 2018-2022. Online slide presentation available at htps://www.anl.gov/cse/batpac-model-sotiware.

2. Battery Pack Production Rate Assumptions

Battery pack production rates are an important consideration in estimating the cost of a battery. Generally, as production rates increase, the cost per kWh of batteries produced decreases due to economies of scale. [EPA-HQ-OAR-2022-0829-0701, p. 54]

EPA chooses to model batteries for all manufacturers and all years of its analysis based on a battery plant production rate of 250,000 packs/year.101 EPA's entire reasoning is provided in a single sentence: "The annual volume of 250,000 is similar to that being produced in the largest plants today, such as those of Tesla, and also is appropriate for the purpose of causing the BatPaC model to calculate costs applicable to a production plant of 30 to 40 GWh capacity, which is a common plant capacity among the largest manufacturers today."102 [EPA-HQ-OAR-2022-0829-0701, p. 54]

101 DRIA at 2-46. ("The equation for a production volume of 250,000 packs was then used as an input to OMEGA to represent a base year cost . . .")

102 Ibid.

The source of EPA's assertion that 30-40 GWh battery manufacturing plant capacity is common among the largest manufacturers is unclear. Whether or not this is the case, EPA's own descriptions make clear that this assumption applies to "the largest" plants and "the largest" manufacturers. No consideration is given that there will likely be a range of battery plant production capacities, nor that smaller automotive manufacturers may only utilize a portion of a larger plant's total capacity for cells and packs built to their individual specifications. Likewise, this assumption fails to contemplate the production efficiencies of new battery plants versus those that have been fully operational for years, including variations in battery chemistry. [EPA-HQ-OAR-2022-0829-0701, p. 54]

To the extent that some manufacturers begin to vertically integrate and technically differentiate on battery systems, Auto Innovators encourages EPA to consider costs and specifications that are reasonable for the industry as a whole to inform policy analysis, and not to assume that intellectual property and proprietary production processes that have been the result of billions of dollars of research and development paid by one manufacturer will be readily available to all manufacturers. In the BatPac model, production volume can affect direct manufacturing cost estimates, and Auto Innovators points out that many battery cells vary (size, shape, chemistry) to suit the application. Even battery packs that share cells may require different housings and assembly processes, requiring separate production lines, resulting in economies of scale lower than would be projected if all these parts were the same. Total industry volumes of BEVs are not an appropriate volume assumption for BatPac. [EPA-HQ-OAR-2022-0829-0701, pp. 54-56]

Furthermore, EPA's battery cost modeling and application in its OMEGA compliance model implicitly assumes a 100% capacity, 250,000 pack per year production rate from a battery plant's initial start of production. As shown in Figure 16, the vast majority of anticipated North American battery cell manufacturing capacity is yet-to-be built. [EPA-HQ-OAR-2022-0829-0701, pp. 54-56]

[See original comment for Figure 16: Benchmark Mineral Intelligence assessment of N. American battery cell manufacturing capacity, 2020-2032, and country of ownership.] [EPA-HQ-OAR-2022-0829-0701, pp. 54-56]

Such a production ramp-up is unrealistic. For example, Tesla's gigafactories have a decade of experience. It took Tesla three years to build its first gigafactory, then another three years to reach a production capacity of 35 GWh per year (Figure 17).103 [EPA-HQ-OAR-2022-0829-0701, pp. 54-56]

103 htps://www.tesla.com/sites/default/files/blog_atachments/gigafactory.pdf

[See original comment for Figure 17: Gigafactory Projected Timeline] [EPA-HQ-OAR-2022-0829-0701, pp. 54-56]

Auto manufacturers also need to consider machine makers for battery facilities and the lack of a trained workforce. Auto manufacturers need to be careful with ramp-up rates because a manufacturing defect equates to a potential safety recall which in turn could result in billions of dollars of unplanned losses. [EPA-HQ-OAR-2022-0829-0701, pp. 54-56]

For the final rule, EPA should adjust its estimated battery pack production rate to account for average (instead of largest) battery manufacturers, the potential split of total capacity into multiple cell variants, and production ramp-up associated with all-new manufacturing plants. [EPA-HQ-OAR-2022-0829-0701, pp. 54-56]

1. Consideration of Labor Costs in Battery Cost Projections

EPA uses default BatPaC model labor costs. Presumably those costs reflect global production of batteries today. Yet given the agency's assumption that all batteries in all electric vehicles sold in the United States will be domestically produced, it seems likely that default labor values currently hard coded into the BatPaC model would need some degree of reconsideration. Neither of these issues, nor other potential issues pertaining to default assumptions applied elsewhere in the model, are addressed, or even acknowledged by the agency in its proposal. [EPA-HQ-OAR-2022-0829-0701, p. 56]

2. Consideration of Critical Mineral Costs in Battery Cost Learning Curve

EPA's use of effectively static 2022 material costs from BatPaC 5.0 is problematic. EPA does not appear to make any upward adjustments to the core BatPaC material costs to account for the current cost of critical minerals, nor for potentially elevated prices during the timeframe of the rulemaking due to the exponential expansion in supplies that are needed to support global electrification goals. We believe these are gross oversights that likely result in an underestimation of true vehicle electrification costs. [EPA-HQ-OAR-2022-0829-0701, pp. 56-57]

Why is this so important? According to Argonne National Laboratory, the NMC811-G, graphite, separator, and electrolyte add up to 86% of material costs.104 Material costs, in turn, represent about 68% of battery pack costs.105 And as the agency is well aware, batteries represent the largest cost associated with an electric vehicle. To put it more plainly, as go material costs, so go electric vehicle costs. Poorly or improperly forecasted future battery costs have a very real potential of yielding directionally different conclusions regarding the economic viability of vehicle electrification at the market share project for the NPRM. [EPA-HQ-OAR-2022-0829-0701, pp. 56-57]

104 Ahmed, S., et al., 2022. Estimated Cost of EV Batteries 2018-2022. Online slide presentation available at htps://www.anl.gov/cse/batpac-model-sotiware. Retrieved June 28, 2023. (Slide 11.)

105 Ahmed, S., et al., 2022. Estimated Cost of EV Batteries 2018-2022. Online slide presentation available at htps://www.anl.gov/cse/batpac-model-sotiware. Retrieved June 28, 2023. (Slide 9.)

The agency's consideration of the critically important topic of battery costs is inadequate. Of the 688-page DRIA, EPA devotes precisely three paragraphs to this issue, in which it generically points to two recent forecasts to justify its position. Additionally, it is difficult for stakeholders to provide feedback on one of those forecasts (Wood Mackenzie), as the agency has excluded it from the docket on grounds that it is a paid subscription service and not licensed for publication.106 The other forecast (EDF/ERM), commissioned by Environmental Defense Fund, an environmental advocacy group that has long supported stringent vehicle standards and electric vehicle mandates, simply observes that "supply chain disruptions have affected EV and battery pricing,"107 and does not at all contemplate the potential impact of a more than 10-fold increase in demand over the next eight years. [EPA-HQ-OAR-2022-0829-0701, pp. 56-57]

a) Need for Two-Stage Learning Curve to Address Critical Mineral Costs

As EPA notes, average lithium-ion battery prices declined by 85-90% from 2010 to 2020, paving the way for the spillover of lithium-ion batteries from consumer electronics to automotive. In fact, the National Research Council in 2021 – based on data before the unexpected events of 2021-2022 – was naively forecasting an annual 7% decline in battery prices from 2022 to 2030.108 Other sources were predicting that, due to rapid declines in battery prices, electric vehicles would be cheaper to produce than gasoline vehicles by the early part of the 2020-2030 period. [EPA-HQ-OAR-2022-0829-0701, pp. 57-58]

108 National Academies of Sciences, Engineering, and Medicine 2021. Assessment of Technologies for Improving Light-Duty Vehicle Fuel Economy 2025-2035. Washington, DC: The National Academies Press. https://doi.org/10.17226/26092.

In 2019, an MIT report cautioned that it is naïve to believe that battery prices will continue to fall steadily through 2030 as they fell in the previous decade.109 The reason is that, according to Benchmark Minerals Intelligence, raw materials accounted for about 70% of the cost of a lithium-ion battery in 2022, up from 40% in 2015 and less than 20% in 2010. Over half of the materials costs are for the cathode alone. As economies have been achieved in manufacturing of batteries, the costs of raw materials have become relatively more important. Some of the learning factors that apply in battery manufacturing (e.g., economies of scale) are not applicable – or apply with less potency -- in the raw materials sector. Instead of the one stage model used by EPA, the MIT report illustrates a two-stage model where the first stage covers “battery production” (e.g., cell production, battery assembly, and battery-pack assembly) and the second stage covers “materials synthesis” (e.g., mining of raw materials, immediate processing for use by component producers). The MIT report estimates that the learning curve is 4.7 times larger in the battery production phase than in the materials synthesis stage. They also show that the costs of materials synthesis place a floor on learning in the battery production stage. Using the two-stage model, the MIT report concludes that it is “unlikely” that battery prices will fall below $100 kWh by 2030. [EPA-HQ-OAR-2022-0829-0701, pp. 57-58]

3. Jacky Wong. Commodity Prices Are Risk for EV Batteries. Wall Street Journal. July 23, 2021, B12. [EPA-HQ-OAR-2022-0829-0701, pp. 57-58]

4. Scott Patterson. Metal Price Surge Threatens EV Growth. Wall Street Journal. February 7, 2022, B4. [EPA-HQ-OAR-2022-0829-0701, pp. 57-58]

The events of 2021-2022 were a shock to the battery industry and have given credence to the technical concern raised in the MIT report. The decade-long decline in lithium-ion battery prices stopped for 2021 and 2022. Indeed, battery prices rose 7% in 2022, primarily due to an explosive surge in the prices of raw materials that support cathode and battery-cell production. Since battery producers cannot instantly switch the materials used in their cathodes and battery cells, higher materials prices flowed through to battery prices. As a result, stunned forecasters have been busily delaying their forecasts of when battery prices would fall below $100/kWh. [EPA-HQ-OAR-2022-0829-0701, pp. 58-59]

In our comments on the model year 2023-2026 light-duty rulemaking, Auto Innovators urged EPA to begin modeling the raw materials synthesis stage separately from battery production, building on the insight from the MIT report. In response to our comments on the final rule, EPA acknowledged the key role of raw material costs:

EPA agrees that mineral and other material costs are a large component of the cost of the currently prevailing family of lithium-ion chemistries . . . [and those chemistries] may not have the potential to reach as low a cost as suggested by other commenters. . . and these costs might decline more slowly or increase if supply fails to meet demand in a timely manner.110 [EPA-HQ-OAR-2022-0829-0701, pp. 58-59]

110 86 Fed. Reg. 74478 (Dec. 30, 2021).

Auto Innovators was therefore disappointed to read the 2021 final rule's treatment of battery prices (for MY 2023 to 2026) as well as the current NPRM for model years 2027 to 2032. EPA continues to lump the raw materials synthesis stage with battery production, thereby producing highly optimistic forecasts for battery prices. [EPA-HQ-OAR-2022-0829-0701, pp. 58-59]

What EPA needs is a model of the materials synthesis stage – a separate model from the BatPaC model, which focuses on battery manufacturing. The materials model would forecast which battery chemistries will be implemented each year, the required amounts of specific materials for each battery design, and the prices for specific materials. The prices should reflect a global sub-model of supply and demand for specific materials since those prices are determined in global commodity markets. This materials synthesis model, and the inputs used in the model, should be subject to independent expert peer review. The explicitness and transparency of such a model would subject EPA's analysis of raw materials to accountability over time. [EPA-HQ-OAR-2022-0829-0701, pp. 58-59]

3. Other Considerations for Battery Cost Analysis

a) Omitted Upward Pressures on Battery Prices

One of the obvious biases in EPA's battery-price analysis is that they emphasize factors that might contribute to a continuing fall in battery prices but omit consideration of several factors – beyond materials prices -- that are working to keep battery prices high. Here are some key factors working to increase battery prices:

-Increased energy density to enhance driving range – automakers and their suppliers are under increasing market pressure to produce batteries with higher energy density, especially for the large SUV and pickup truck segments to provide adequate range for buyers. [EPA-HQ-OAR-2022-0829-0701, pp. 59-60]

-Improved safety systems and designs to minimize the risk of battery fires, as several automakers have experienced NHTSA investigations as well as stigmatizing and costly recalls. [EPA-HQ-OAR-2022-0829-0701, pp. 59-60]

-New battery designs that can accommodate, without battery degradation, frequent use of DC fast chargers (150 kWh to 350 kWh), which provide higher charging speeds and greater convenience to consumers. [EPA-HQ-OAR-2022-0829-0701, pp. 59-60]

-Improved battery management systems that can help protect the battery pack under extremely cold and hot outdoor temperatures. [EPA-HQ-OAR-2022-0829-0701, pp. 59-60]

-Adherence to responsible sourcing guidelines that establish environmental, social and governance standards for an auto maker's supply chains, including third-party validation of compliance with those standards. [EPA-HQ-OAR-2022-0829-0701, pp. 59-60]

-Expectations to source raw materials, processing, component facilities and battery production in the United States, or at least in North America or with free-trade partners, even though the lowest cost suppliers in the EV supply chain may be based in China or in other countries that have no free-trade agreement with the United States. [EPA-HQ-OAR-2022-0829-0701, pp. 59-60]

Given the competing pressures on battery prices between now and 2032, Auto Innovators is not confident that a net decrease in battery prices will occur; an increase in battery prices is a distinct possibility due to global demand for limited resources. [EPA-HQ-OAR-2022-0829-0701, pp. 59-60]

b) Electricity Price Impacts on Costs of Battery Production

Electricity prices have an indirect effect on the cost of producing EVs because the supply chain of an EV is much more energy-intensive than the supply chain for an ICE vehicle. At battery manufacturing facilities, for example, large furnaces are required to evaporate the solvents from the coated electrodes; since battery cells are sensitive to moisture, cell assembly must occur in a dry room, which incurs high electricity costs. [EPA-HQ-OAR-2022-0829-0701, pp. 60-61]

State and national policies are shifting electricity generation from fossil fuels and nuclear power to renewables, especially wind and solar. At low levels of renewables, the effect on electricity prices may be minimal. Moreover, the cost disadvantages of renewables are declining over time, but the renewables transition may increase electricity prices at higher levels of renewables penetration and will likely raise them further when investments are made (e.g., in grid-scale energy storage solutions) to address the intermittent nature of wind and solar. [EPA-HQ-OAR-2022-0829-0701, pp. 60-61]

It is difficult to estimate how much electricity prices will rise in a precise time frame (e.g., 2024- 2026) because they are often determined in utility rate-setting processes in each of the 50 states, and the EIA forecasts of future electricity prices do not account for all the policy changes that are underway or will soon be adopted to promote or compel increased use of renewables. [EPA-HQ-OAR-2022-0829-0701, pp. 60-61]

One way for the agencies to bound the potential magnitude of rising electricity prices is to undertake a scenario analysis where all of the U.S. – residences and businesses – face the higher electricity prices now experienced by Germany or the State of California, both jurisdictions that have made determined efforts to boost renewables and phase out coal and nuclear power. Germany has the highest household electricity prices in Europe, about $0.30 per kWh. In May 2021, the average price of residential electricity in California was $0.21 per kWh, about 7% higher than the price in May 2020. In the U.S. as a whole, the average residential electricity price is about $0.13-0.14 per kWh. [EPA-HQ-OAR-2022-0829-0701, pp. 60-61]

The electricity prices paid by businesses need to be analyzed separately, as they tend to be higher than the residential rates (in part due to demand charges). The business rate for electricity is appropriate to use when computing the energy costs in the supply chain of battery production. [EPA-HQ-OAR-2022-0829-0701, pp. 60-61]

c) Electrolyte Costs in BatPac 5.0

Finally, it appears that the version of BatPaC 5.0 utilized for this rulemaking may contain errors. The version of BatPaC utilized in the rulemaking and included by EPA in the docket assumes an electrolyte cost of $10/L for 2022. Materials price assumptions presented by Argonne National Laboratory in October 2022 and included on the anl.gov website show a $15/L cost for electrolyte in 2022.111 We assume this is an oversight, and request that the agency investigate and address this discrepancy. [EPA-HQ-OAR-2022-0829-0701, pp. 61-62]

111 Ahmed, S., et al., 2022. Estimated Cost of EV Batteries 2018-2022. Online slide presentation available at htps://www.anl.gov/cse/batpac-model-sotiware.

6. Battery Cost Conclusion

As EPA points out, including references to automakers' direct public statements, the automobile industry is absolutely focused on making the transition to EVs. However, it is critical that EPA also acknowledge the auto industry's direct statements about EV and battery costs, as well as related comments addressing the consumer, supply chain, and charging and refueling infrastructure challenges. Auto Innovators views the NPRM analysis as fundamentally flawed. EPA needs to update its modeling to align with current battery costs and future critical mineral costs in its analysis for the final rule. Relatedly, we also recommend that the EPA show a full cost-benefit analysis for each of its sensitivity cases, including for high and low battery cost cases, and also for varying assumptions on IRA tax credit eligibility, phase-out, or elimination. [EPA-HQ-OAR-2022-0829-0701, p. 67]

Organization: American Coalition for Ethanol (ACE)

Among the rosy forecasts are battery costs. EPA states that "battery costs continue to decline," but this is not true. Battery costs increased in 2022 and have been generally stagnant over the last four years.6 [EPA-HQ-OAR-2022-0829-0613, pp. 2-3]

6 Lithium-ion Battery Pack Prices Rise, Bloomberg NEF (Dec. 6, 2022). https://about.bnef.com/blog/lithium-ion-battery-pack- prices-rise-for-first-time-to-an-average-of-151-kwh/.

Organization: American Free Enterprise Chamber of Commerce (AmFree) et al.

As for battery costs, EPA elsewhere concedes that those costs have actually increased—not decreased—in recent years. See 88 Fed. Reg. at 29,301. Bloom- berg recently released a report showing that "the global average price for lith- ium-ion battery packs . . . climbed by about 7 percent in 2022." Id. EPA dis- misses this study by asserting that the survey respondents are "likely to include both large and small purchasers of diverse battery packs," while EPA's own modeling looks to "a specific class of pack design manufactured in large quan- tities at a large manufacturing facility[] to fulfill large orders for a major [origi- nal equipment manufacturer]." Id. But as major original-equipment manufac- turers have noted, as recently as a few months ago, high battery prices are the key factor standing in the way of price parity. The CEO of the Renault

Group, for example, says that prices for electric vehicles are unlikely to match those of internal-combustion-engine vehicles "anytime soon" because "of the ever in- creasing cost of batteries." Charette, Convincing Consumers. Likewise, the Chief Technology Officer of Mercedes notes that he "does not see . . . price parity" between electric and internal-combustion-engine vehicles given "the battery chemistry we have today." Id. [EPA-HQ-OAR-2022-0829-0683, p. 25]

Organization: American Fuel & Petrochemical Manufacturers

While we have not had sufficient time to fully analyze EPA's cost analyses, we have been able to identify several significant deficiencies, each of which understates the true costs of the Proposal: (1) EPA significantly understated the costs of batteries required by the rule; [EPA-HQ-OAR-2022-0829-0733, pp. 48-49]

i. Battery costs

We start with a discussion of EPA's analysis of battery costs because it has significant impacts on ZEV production, operating, and disposal costs. EPA "substantially underestimates the costs of batteries,"223 providing an inadequate analysis and ignoring the cost and long-term affordability of battery production. In the DRIA, EPA states that "despite recent short-term fluctuations in price, the price of lithium is expected to stabilize at or near its historical levels by the mid- to late-2020s, suggesting that the elevated battery costs being reported today will not persist."224 [EPA-HQ-OAR-2022-0829-0733, pp. 49-50]

223 AAI Comments at iv.

224 DRIA at 2-51.

This analysis misses the mark. Between January 2021 and March 2022, the cost of lithium increased by 738 percent.225 2022 battery costs were $153 per kWh,226 and cost reduction curves have already begun to flatten out. Indeed, battery costs rose 7 percent in 2022. With EPA's and other developing nations' push to electrify transportation and the concomitant need to deploy utility-scale batteries, the demand for lithium (and other critical minerals) is expected to grow exponentially. Even so, EPA assumes declining battery costs will reach $120 per kWh in 2032.227 [EPA-HQ-OAR-2022-0829-0733, pp. 49-50]

225 See Canada Energy Regulator, "Market Snapshot: Critical Minerals are Key to the Global Transition" (Jan. 18, 2023), available at https://www.cer-rec.gc.ca/en/data-analysis/energy-markets/market-snapshots/2023/market-snapshot-critical-minerals-key-global-energy-transition.html.

226 Dept. of Energy, "Electric Vehicle Battery Pack Costs in 2022 Are Nearly 90% Lower than in 2008, according to DOE Estimates," (Jan. 9, 2023) available at https://www.energy.gov/eere/vehicles/articles/fotw-1272-january-9-2023-electric-vehicle-battery-pack-costs-2022-are-nearly.

227 DRIA at 2-46 (resulting 75kWh battery).

EPA's reliance on an ICCT study to justify its estimate of falling battery costs is misplaced. ICCT ignored literature that PHEVs depreciate with certain models and makes losing greater value than others, like Tesla, especially those with long-range features. A May 2023 CBS article highlighted a statement from Kelley Blue Book, an automotive research company, that PHEVs generally depreciate faster than ICEVs.228 Kelley Blue Book said that three-year-old PEVs hold 63 percent of their value compared to 66 percent for ICEVs.229 Additionally, ICCT's battery cost curve does not account for the potential of rising PEV-related metal prices which can cause the price of battery packs to increase, as seen in 2022 and 2023. If ICCT's estimates of PEV battery pack costs were revised to be higher, PEVs are likely to be priced at a substantial premium compared to ICEVs. [EPA-HQ-OAR-2022-0829-0733, pp. 49-50]

228 Joe D'Allegro, What to know about buying a used electric vehicle as more hit the auto sales market, CNBC (May 21, 2023), https://www.cnbc.com/2023/05/21/what-to-know-about-buying-a-used-ev-as-more-hit-the-car-market.html. See also AAA Survey Shows EV Owners Should Be Concerned About Depreciation (insideevs.com).

229 Id.

While prices have since declined, price volatility should be expected to continue. Despite these very public findings, EPA asserts that "battery costs have continued to decline."230 EPA points to the IRA as a mechanism to reduce battery prices, yet this law simply extended the existing battery subsidy and even limited its applicability through domestic sourcing and income requirements. Thus, EPA is relying on an existing program for the proposition that it will lower battery prices in the future. EPA is simultaneously ignoring that the increase in demand for batteries will raise their price. [EPA-HQ-OAR-2022-0829-0733, pp. 49-50]

230 Proposed Rule at 29,188.

Further complicating the projection of future battery prices is the fact that battery raw materials are not commodities, they are classified as specialty chemicals. As such pricing will not follow traditional commodity pricing structures, especially because these supplies are geographically concentrated in areas with geopolitical instabilities. Each OEM, cathode or anode producer, and battery manufacturer have their own specifications for the materials, and thus the raw materials must be refined and tested to meet their bespoke specification. Spot markets for battery materials are virtually non-existent and unlikely to develop in the near term. For example, most lithium contracts are written as long-term agreements, which are based on Fastmarkets' lithium index and a discount, and sometimes with a floor/ceiling mechanism to hedge against pricing volatility. [EPA-HQ-OAR-2022-0829-0733, p. 50]

Ultimately, the volatility of material pricing will directly affect whether certain battery projects even materialize. And if they do, OEMs will need to increase their prices to ensure a steady supply. Morgan Stanley estimates ZEV makers will need to increase prices by 25 percent to account for rising battery prices.231 EPA must consider these data and correct this aspect of its cost-benefit analysis. [EPA-HQ-OAR-2022-0829-0733, pp. 50-51]

231 James Thornhill, Bloomberg, "Morgan Stanly Flags EV Demand destruction as Lithium Soars" (Mar. 24, 2022), Chart 7, available at https://www.bloomberg.com/news/articles/2022-03-25/morgan-stanley-flags- ev-demand-destruction-as-lithium-soars#xj4y7vzkg.

EPA ignores that battery prices have begun to rise due to limited supply of minerals.240 [EPA-HQ-OAR-2022-0829-0733, pp. 52-53]

240 BLOOMBERGNEF "Lithium-ion Battery Pack Prices Rise for First Time to an average of $151/kWh" (Dec. 6, 2022) available at https://about.bnef.com/blog/lithium-ion-battery-pack-prices-rise-for-first-time-to- an-average-of-151-kwh/

Organization: American Honda Motor Co., Inc.

A. Battery Cost Projections

The agency's rationale for setting stringent standards – achieved through significant levels of battery electric vehicle (BEV) adoption – appears to be driven largely by an assumption that BEV prices will significantly decrease. These modeled consumer price decreases rest largely on agency findings that batteries will be substantially less expensive in the coming years. The accuracy of this claim is perhaps the most important aspect of the entire proposed regulation, one that will determine whether or not this program and transformation of the auto industry ultimately occurs on the timeline suggested by the agency. Regulatory stringencies set using a reasonably accurate forecast of future battery costs would result in standards that are both feasible in achievement and effective in decarbonizing the transportation fleet. Conversely, stringencies set using inaccurate (overly optimistic) forecasts of future battery costs would likely result in unachievable compliance obligations and ultimately an ineffective regulatory program [EPA-HQ-OAR-2022-0829-0652, p. 7]

Surprisingly, the agency did not appear to consider one of the few peer-reviewed papers that does speak to this issue, Technological innovation vs. tightening raw material markets: falling battery costs put at risk, by Mauler et al., published in the journal Energy Advances. This important paper notes that cell cost reductions expected to occur between 2020 and 2030 (akin to those anticipated by the agency) "could be significantly slowed down," or potentially even "fully vanish": [EPA-HQ-OAR-2022-0829-0652, p. 8]

The combined impact of material-specific price increases on cell cost in 2030…ranges from +6.9 to +34.3 $ kW h−1, meaning that cell cost reductions from technological innovations could be significantly slowed down or, under the most pessimistic raw material price expectations, fully vanish in 2030.13 [EPA-HQ-OAR-2022-0829-0652, p. 8]

13 Mauler et al., 2022. Technological innovation vs. tightening raw material markets: falling battery costs put at risk. Energy Advances. https://pubs.rsc.org/en/content/articlelanding/2022/YA/d1ya00052g

In our view, the NPRM would benefit from a more meaningful consideration of battery material costs. Of the near 700-page Draft Regulatory Impact Analysis (RIA), EPA devotes only a few paragraphs to this issue, highlighting two recent forecasts to justify its position. Upon closer examination, one of those forecasts (Wood Mackenzie) was found to not even be made available in the Docket, as the agency has excluded it on grounds that it is a paid subscription service and not licensed for publication.11 The other forecast (EDF/ERM), commissioned by Environmental Defense Fund, an environmental advocacy group that has long supported stringent vehicle emissions standards, is available in the Docket, but falls well short of an analysis upon which one could make a reasonable decision that materials costs will not meaningfully climb in the 2027-2032 timeframe. The EDF/ERM forecast was conducted recently enough to acknowledge that "supply chain disruptions have affected EV and battery pricing,"12 but it does not contemplate the potential impact of a meaningful expected increase in battery demand over the next eight years. [EPA-HQ-OAR-2022-0829-0652, p. 8]

11 Safoutin, M. 2022. Agency memorandum. https://www.regulations.gov/document/EPA-HQ-OAR-2022-0829- 0316

12 EDF/ERM 2022. Electric Vehicle Market Update: Manufacturer Commitments and Public Policy Initiatives Supporting Electric Mobility in the U.S. and Worldwide. https://www.regulations.gov/document/EPA-HQ-OAR- 2022-0829-0154

The very real possibility that battery material costs will climb during the window of this regulation needs to be considered by the agency. According to Argonne researchers, the NMC811, graphite, separator and electrolyte add up to 86% of material costs.14 Poorly or improperly forecasted future battery costs can result in directionally different conclusions regarding the viability of vehicle electrification. [EPA-HQ-OAR-2022-0829-0652, pp. 8-9]

14 Ahmed, S., et al., 2022. Estimated Cost of EV Batteries 2018-2022. Online slide presentation available at https://www.anl.gov/cse/batpac-model-software

As we have witnessed over the past few years, numerous critical minerals used in EV and plug-in hybrid- electric vehicle (PHEV) batteries have seen significant price volatility. Even BloombergNEF, known for its optimistic (low price) forecasts of battery cost, recently acknowledged that pack costs will see increases in price, at least in the near term, due in part to supply chain issues and higher demand for critical minerals. The BatPaC model has also noted increased materials costs over the past few years. Between 2021 and 2022, for example, updates to BatPaC resulted in a 14% increase in the $/kg cost of cathode active material and a 50% increase in the $/kg cost of positive binder.15 While we appreciate EPA's use of the most recent version of BatPaC to reflect the latest material cost assumptions, these cost increases are a further indication that – contrary to EPA's assumptions – costs are unlikely to remain at 2022 levels for the next decade. For EPA to assume that a swift, regulation-driven exponential increase in demand for critical minerals in a tight, volatile and geopolitically sensitive global market would have no impact on electrode and other battery materials costs calls into question the fundamental validity of the agency's analysis. [EPA-HQ-OAR-2022-0829-0652, p. 9]

15 Ahmed, S., et al., 2022. Estimated Cost of EV Batteries 2018-2022. Online slide presentation available at https://www.anl.gov/cse/batpac-model-software

Recommendation: Honda strongly urges the agency to revise its battery price forecasts used in the Final Rule to include the impact of increased global demand on materials costs. Specifically, Honda requests that the agency rely on impartial sources of information, including the peer-reviewed paper by Mauler et al., to support its position. [EPA-HQ-OAR-2022-0829-0652, p. 9]

Use of default costs

The agency notes in its proposal that "default costs provided in BatPaC for electrode powders and other constituents were used."16 Based on our read of the proposal and Draft RIA, it is not clear where these cost assumptions came from. Are they predicated on a certain set of assumptions, such as a globally- sourced mining/refining/production supply chain? If so, such assumptions should be revisited and adjusted accordingly, since EPA also assumes in this proposed rule that OEMs will significantly utilize IRA tax incentives, some of which have particular content and sourcing requirements that may limit their utility (depending on the outcome of yet-to-be-released IRS guidance). [EPA-HQ-OAR-2022-0829-0652, p. 9]

16 EPA, 2023. Draft RIA, p. 2-45. Available online at https://nepis.epa.gov/Exe/ZyPDF.cgi?Dockey=P10175J2.pdf

Recommendation: Honda respectfully requests that EPA revisit all default values with Argonne National Laboratory's materials cost experts to ensure that cost estimates extrapolated from the BatPaC model are factually consistent with other IRA-based assumptions being made by EPA in this rulemaking. [EPA-HQ-OAR-2022-0829-0652, p. 9]

Lack of transparency regarding BatPaC inputs

EPA claims that "the BatPaC spreadsheet models used to develop the costs for BEVs, HEVs, and PHEVs are available in the Docket…and fully describe the BatPaC inputs."17 Honda respectfully disagrees. Investigation into the BatPaC model revealed that numerous key inputs and default values utilized by the agency were in fact undocumented numbers, hard coded into the model. Investigation into key battery cost assumptions (as noted above) required separate examination outside of the Docket to better understand the agency's analysis. This should not be required. EPA's lack of transparency on this potentially critical topic of model assumptions, particularly given the short 60-day comment period provided by the agency, undermines stakeholders' abilities to provide meaningful feedback on the agency's proposal. [EPA-HQ-OAR-2022-0829-0652, p. 10]

17 EPA, 2023. Draft RIA, p. 2-45. Available online at https://nepis.epa.gov/Exe/ZyPDF.cgi?Dockey=P10175J2.pdf

Recommendation: Honda respectfully requests that the Final Rule include greater transparency regarding BatPaC-based values used in its rulemaking. [EPA-HQ-OAR-2022-0829-0652, p. 10]

Projecting future battery material and labor costs

The agency assumes that the IRA 45X tax credits will be fully utilized by all OEMs through MY2032 (subject to phase-down in the final years of the program) and applies those reductions to the overall cost of batteries in EPA's OMEGA modeling. This has resulted in profoundly low battery cost estimates, for example, below $40/kWh in 2029.10 The agency does not, however, appear to make any upward adjustments to the core Argonne National Laboratory BatPaC 5.0 material costs to account for exponential growth in critical minerals demand that will occur during this time frame, or to the increased labor cost associated with domestically produced packs. We believe these are significant oversights that likely result in a meaningful underestimation of true vehicle electrification costs. [EPA-HQ-OAR-2022-0829-0652, pp. 7-8]

10 EPA, 2023. Draft RIA, Figure 2-27. Available online at https://nepis.epa.gov/Exe/ZyPDF.cgi?Dockey=P10175J2.pdf

Organization: American Petroleum Institute (API)

Battery Cost Modeling

The NPRM includes several citations112 of battery cost analysis used by the EPA in developing the technical feasibility of the regulation based on Argonne National Laboratory's BatPaC Model Software. This software includes an analysis of several different battery chemistries and a breakdown of the individual costs for various components needed to manufacture an automotive battery at scale.113 Argonne's assessment of the 2022 battery cost concludes that 63% of the total battery cost is from raw materials on the anode and cathode of the individual cells. This is an important fact for EPA to consider in the assessment of long-term battery cost modeling as the model for parts and raw materials are fundamentally different. [EPA-HQ-OAR-2022-0829-0641, pp. 43-46]

112 40 CFR Parts 85, 86, 600, 1036, 1037, and 1066 [EPA–HQ–OAR–2022–0829; FRL 8953–03– OAR] pages 29295, 29299, 29301, 29302.

113 https://www.anl.gov/cse/batpac-model-software.

The NPRM then applies a modeling equation to these initial cost/kWh values to develop long-term costs on a year-by-year basis. This model is detailed in the DRIA in section 2.5.2.1.3.114 [EPA-HQ-OAR-2022-0829-0641, pp. 43-46]

114 Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles - Draft Regulatory Impact Analysis (EPA-420-D-23-003, April 2023).

1) Calculate the cumulative GWh needed by BEVs placed into the analysis fleet through the last model year. [EPA-HQ-OAR-2022-0829-0641, pp. 43-46]

2) Calculate the cost reduction factor due to learning:

factor = 4.1917 × (cumulative ?W ? through last year) −0.225 [EPA-HQ-OAR-2022-0829-0641, pp. 43-46]

3) Calculate battery cost in the base year, as a function of pack kWh, according to the equation in RIA 2.5.2.1.2: $/????? = 261.61 × (gross ?????) −0.184 [EPA-HQ-OAR-2022-0829-0641, pp. 43-46]

4) Multiply the result of Step 3 by the result of Step 2.

This model makes several unrealistic assumptions:

- No lower bound with increasing volume – at some point in the future, the real cost of battery cells will be $0.00 based on the model used in the NPRM due to cumulative GWh production. [EPA-HQ-OAR-2022-0829-0641, pp. 43-46]

- Cumulative GWh calculation based on production of batteries in the U.S. but it needs to be based on the global production of batteries to establish a baseline. [EPA-HQ-OAR-2022-0829-0641, pp. 43-46]

  - o It is global economics that support the costs of battery production, not the economics of the U.S. alone. [EPA-HQ-OAR-2022-0829-0641, pp. 43-46]

  - o Global battery volume is expected to rise from ~700GWh to 5,300GWh by 2035. 115 [EPA-HQ-OAR-2022-0829-0641, pp. 43-46]

115 https://emobilityplus.com/2023/04/21/global-electric-vehicle-battery-market-to-reach-616-billion-by-2035- report/.

- $75/kWh was selected for 2035; however, the modeling cited above implies a $46/kWh value based on the model parameters. [EPA-HQ-OAR-2022-0829-0641, pp. 43-46]

  - o The cost model cited in the NPRM appears to be voided by several assumptions for cost reduction milestones in section 2.5.2.1.3. [EPA-HQ-OAR-2022-0829-0641, pp. 43-46]

- Manufacturing battery cells operates on the same cost curve as manufacturing standard automotive parts - the cost of the materials in manufacturing battery cells operates on a different cost curve to standard automotive part production and this is not accounted for in the model. [EPA-HQ-OAR-2022-0829-0641, pp. 43-46]

o Resource modeling is not capital-dependent but resource dependent. This curve follows an increasing cost as production levels are increased and not a reduction as cited in the regulatory framework of the NPRM. [EPA-HQ-OAR-2022-0829-0641, pp. 43-46]

• Biasing the model with the initial development phase will not represent the long-term trend and therefore a more appropriate model should be used to represent real-world costs and volume impacts. [EPA-HQ-OAR-2022-0829-0641, pp. 43-46]

Since Argonne has established a 63% critical raw material value in their development of the BatPaC, it is important for the regulation to follow the economics of raw materials rather than capital depreciation and learning models for purposes of accuracy. Perhaps following the economics of oil production would be more representative of modeling the costs of 63% of the batteries in automotive applications. [EPA-HQ-OAR-2022-0829-0641, pp. 43-46]

[See original for graph titled “Figure 1”] [EPA-HQ-OAR-2022-0829-0641, pp. 43-46]

As shown in Figure 1, over the last 40 years the global supply of oil has increased by ~50%.116 During that same period, the price increased by ~200%. [EPA-HQ-OAR-2022-0829-0641, pp. 43-46]

116 EIA Global crude oil production and price sourced in May 2023.

[See original for graph titled “Figure 2”] [EPA-HQ-OAR-2022-0829-0641, pp. 43-46]

As shown in Figure 2, lithium has followed a similar trend to oil – Global production117 is up 400%, and prices are up 600%. [EPA-HQ-OAR-2022-0829-0641, pp. 43-46]

117 USGS Global lithium production and price sourced in May 2023.

[See original for graph titled “Figure 3”] [EPA-HQ-OAR-2022-0829-0641, pp. 43-46]

Nickel also follows a similar trend shown in Figure 3. Rising in price with increased demand and falling with reduced demand over the last 10 years.118 [EPA-HQ-OAR-2022-0829-0641, pp. 43-46]

118 USGS Global nickel production and price sourced in May 2023.

These examples show how real-world resource costs are impacted by demand. Unlike the automotive parts model used in the regulation, price and volume tend to move in the same direction for critical battery raw materials. This is because these raw materials are produced in the lowest-cost locations, to begin with, and then move to higher-cost locations to meet demand over time. We see this with oil resources as well. The lowest cost-to-produce sources are used first and only after those sources are at capacity are the higher cost sources then consumed by the market. We fully expect to see the same trend with all critical raw materials for battery production long term, contrary to the assumptions in the NPRM. [EPA-HQ-OAR-2022-0829-0641, pp. 43-46]

Based on the Argonne value of 63% raw material cost in an average automotive battery, we suggest the agency develop a new costing model to properly account for the 63% resource- based costs and use the current model only for the remaining 37% to account for the capital depreciation and learning on the remaining value of the battery. [EPA-HQ-OAR-2022-0829-0641, pp. 43-46]

Organization: Clean Fuels Development Coalition et al.

B. The proposal rule underestimates future battery costs.

EPA estimates that battery costs will continually decline over the next decade, decreasing from around $12,000 per pack in 2022 to around $7,000 per pack in 2032.13 This projection isn't realistic. For some segments, 2022 battery costs were $153 per kWh, Electric Vehicle Battery Pack Costs in 2022 Are Nearly 90% Lower than in 2008, according to DOE Estimates, Office of Energy Efficiency & Renewable Energy (Jan. 9, 2023), https://www.energy.gov/eere/vehicles/articles/fotw-1272-january-9-2023- electric-vehicle-battery-pack-costs-2022-are-nearly. While there has been a decrease in cost over the last decade, prices have not continued to drop. Instead, cost reduction curves have already begun to flatten out and battery costs rose 7 percent in 2022. [EPA-HQ-OAR-2022-0829-0712, p. 21]

13 Projections assume a 100 kWh battery pack and per kWh prices as described by EPA in the Draft Regulatory Impact Analysis. DRIA 2-53.

Further, many studies project battery costs to rise over the next few years. For example, E Source estimates battery cell prices will surge 22% from 2023 through 2026. Phil LeBeau, EV battery costs could spike 22% by 2026 as raw material short- ages drag on, CNBC (May 18, 2022), https://www.cnbc.com/2022/05/18/ev-battery- costs-set-to-spike-as-raw-material-shortages-drags-on.html. And Benchmark Mineral Intelligence projects that prices could become worse at the end of the decade as an increase in global electric vehicle manufacturing leads to massive lithium short- ages beginning in 2029 and getting increasingly worse as through 2032. Eric Onstad et al., Lithium prices bounce after big plunge, but surpluses loom, Reuters (May 2, 2023), https://www.reuters.com/markets/commodities/lithium-prices-bounce-after- big-plunge-surpluses-loom-2023-04-28/.[EPA-HQ-OAR-2022-0829-0712, pp. 21-22]

An analysis based on the E Source study and the Benchmark Mineral Intelligence Project, suggests that battery prices for a 100 kWh battery will rise from $12,800 per pack in 2022 to a peak of $13,000 per pack in 2027, before stabilizing at $12,000 per pack from 2029 through 2032. See Figure 4. When these additional costs are added to the manufacturing of each of the 15 million electric vehicles needed to comply with the proposed standards, an additional $64 billion in vehicle technology costs are added to EPA's projections. [EPA-HQ-OAR-2022-0829-0712, pp. 21-22]

SEE ORIGINAL COMMENT FOR Figure 4: Projected battery pack costs for 100 kWh battery pack. [EPA-HQ-OAR-2022-0829-0712, pp. 21-22]

Organization: Energy Innovation

III. THE EPA'S FINAL STANDARDS SHOULD ACCOUNT FOR ADDITIONAL FACTORS THAT MAY ACCELERATE ADOPTION OF ZERO-EMISSION TECHNOLOGIES AND IMPACT LEARNING CURVES FOR BEV ECONOMICS.

We appreciate the EPA's attention to vehicle technologies and trends in the proposed rule and draft regulatory impact analysis (DRIA)31 to inform the analysis underpinning the proposed rule. The EPA notes that, “in designing the scope, structure, and stringency of the proposed standards, the Administrator considered previous rulemakings, as well as the increasing availability of vehicle technologies that can be utilized by manufacturers to further reduce emissions.”32 Section 202(a) of the Clean Air Act directs the EPA to regulate emissions from new vehicles or engines that cause or contribute to air pollution that may endanger public health or welfare— and the EPA is authorized and directed under the same statute to consider emerging technologies when determining the level of stringency and feasibility of the standards. As with prior rules, the “EPA is assessing the feasibility of new standards on light of current and anticipated progress by automakers in developing and deploying new technologies.”33 [EPA-HQ-OAR-2022-0829-0561, pp. 12-15]

31 “Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles, Draft Regulatory ImpactAnalysis” (Assessment and Standards Division Office of Transportation and Air Quality U.S. Environmental Protection Agency, April 2023), https://www.epa.gov/system/files/documents/2023-04/420d23003.pdf. [EPA-HQ-OAR-2022-0829-0561, pp. 12-15]

32 U.S. EPA, “Proposed Rules,” May 5, 2023, 29187.

33 U.S. EPA, 29187.

Notably, as the EPA GHG standards have increased in stringency over the past decade, “automakers have relied to a greater degree on a range of electrification technologies…[and] as these technologies have been advancing rapidly in just the past several years, the battery costs have continued to decline….As a result, zero- and near- zero emission technologies are more feasible and cost-effective now than at the time of prior rulemakings.”34 We agree and believe these cost declines will continue for the foreseeable future and exceed projections, due to the effect of battery learning curves, which we discuss further below. [EPA-HQ-OAR-2022-0829-0561, pp. 12-15]

34 U.S. EPA, 29188.

Both of these trends reflect learning curves, which affect the rate of deployment of newer technologies and advances in performance and production. As the market scales up, technologies achieve greater economies of scale, which lowers the cost of production.37 A relevant example of a learning curve is illustrated in Figure 9, which shows the cost to the public to buy Henry Ford’s Model T automobile in the early 1900s—the beginning of the age of the automobile. [EPA-HQ-OAR-2022-0829-0561, pp. 12-15]

37 Hal Harvey and Justin Gillis, The Big FIx: 7 Practical Stesps to Save Our Planet (Simon & Schuster, 2022), 9-35.

[See original attachment for line graph “The Learning Curve of the Model T”] [EPA-HQ-OAR-2022-0829-0561, pp. 12-15]

Figure 9. Learning curve of the Model T, 1909-1925. adjusted for inflation and including all trim lines of the Model T. Source: Harvey, Hal et al., The Big Fix, Simon & Schuster, 2022, 19. [EPA-HQ-OAR-2022-0829-0561, pp. 12-15]

Learning curves affect how quickly BEVs can outcompete ICE vehicles on purchase price, which is a primary factor in market adoption and consumer acceptance. Rapid innovation and falling battery prices have changed the economics of EVs because batteries are the main driver of purchase price differences between EVs and ICE vehicles.38 [EPA-HQ-OAR-2022-0829-0561, pp. 12-15]

38 Chris Busch and Anand Gopal, “Electric Vehicles Will Soon Lead Global Auto Markets, But Too Slow to Hit Climate Goals Without New Policy” (Energy Innovation, November 2022), https://energyinnovation.org/wp-content/uploads/2022/11/Electric-Vehicles-Will-Soon-Lead-Global-Auto-Markets-But-Too-Slow-To-Hit-Climate-Goals-Without-Policy.pdf.

According to a recent analysis from ICCT, “with declining electric vehicle battery and assembly costs, shorter- range BEVs of 150 to 200 miles are projected to reach price parity by 2024-2026, followed by mid-range BEVs with 250 to 300 miles around 2026-2029, and the longest-range BEVs with 350 to 400 miles around 2029-2032.”39 See Figure 10. [EPA-HQ-OAR-2022-0829-0561, pp. 12-15]

39 Peter Slowik et al., “Assessment of Light-Duty Electric Vehicle Costs and Consumer Benefits in the United States in the 2022-2035 Time Frame,” International Council on Clean Transportation, October 2022, https://theicct.org/wp-content/uploads/2022/10/ev-cost-benefits-2035-oct22.pdf, iii.

[See original attachment for table described below] [EPA-HQ-OAR-2022-0829-0561, pp. 12-15]

Figure 10. Summary of year by which battery electric vehicle price parity is reached. Source: Slowik, Peter, et al., Assessment of Light- Duty Electric Vehicle Costs and Consumer Benefits in the United States in the 2022-2035 Time Frame, ICCT, October 2022, ii-iii. [EPA-HQ-OAR-2022-0829-0561, pp. 12-15]

These findings align with the EPA’s finding: “[w]hile the retail price of PEVs is typically higher than for comparable ICE vehicles at this time, the price difference is widely expected to narrow or disappear, particularly for BEVs, as the cost of batteries and other components fall in the coming years.”40 [EPA-HQ-OAR-2022-0829-0561, pp. 12-15]

40 U.S. EPA, “Proposed Rules,” May 5, 2023, 29190.

From our research, we have identified the following factors related to learning curves that may further accelerate future cost declines and improvements to BEV technologies. Based on our assessment, we believe the estimated costs of the proposed rule and Alternative 1 will likely be lower than projected, making compliance more feasible, more cost-effective, and more beneficial to consumers and the economy. We summarize these factors below and urge the EPA’s consideration of them as it develops the final rule. [EPA-HQ-OAR-2022-0829-0561, pp. 12-15]

1. Tendency of battery outlooks to underestimate future learning curves

Historic forecasts of battery prices have largely underestimated the impact of future learning curve effects. Recent, open-source, peer-reviewed research by the Institute for New Economic Thinking (INET) at Oxford University41 shows the persistent underestimation of future innovation for batteries and develops an empirical forecasting approach that performs better.42 [EPA-HQ-OAR-2022-0829-0561, pp. 12-15]

41 “Institute for New Economic Thinking, University of Oxford,” n.d., https://www.inet.ox.ac.uk.

42 Rupert Way et al., “Empirically Grounded Technology Forecasts and the Energy Transition,” Joule 6, no. 9 (September 21, 2022): 2057–82, https://doi.org/10.1016/j.joule.2022.08.009.https://www.cell.com/joule/fulltext/S2542-4351(22)00410-X.

Figure 11 is reproduced from the INET article to help illustrate this point. The figure denotes historical prices for lithium-ion (Li-ion) consumer battery cell prices and Li-ion EV battery packs with black and red data points, respectively, while red line segments trace historical forecasts for the most optimistic scenarios by leading energy-economy modelers such as the International Energy Agency. [EPA-HQ-OAR-2022-0829-0561, pp. 12-15]

The figure's graphing of historical data alongside past forecasts of battery cell and EV battery pack prices reveals the persistent gap between actual and forecasted innovation for batteries. [EPA-HQ-OAR-2022-0829-0561, pp. 12-15]

Even the most optimistic projections for prior forecasts underestimated future learning curves. For each, empirical price reductions trace a steeper trajectory, with cost dropping faster, compared to the forecast's shallower slope. The result is even more compelling considering the comparison to the most optimistic of each battery forecast sampled. [EPA-HQ-OAR-2022-0829-0561, pp. 16-19]

[See original attachment for graph described below] [EPA-HQ-OAR-2022-0829-0561, pp. 16-19]

Figure 11. Empirically grounded technology forecasts and the energy transition, reproduced from Figure 5 from INET. Source: https://www.cell.com/cms/attachment/e50686b6-4cba-47f7-85b6-04ab5411bb7f/gr5.jpg. [EPA-HQ-OAR-2022-0829-0561, pp. 16-19]

2. Battery pack economies of scale

As battery size increases, the added cost of the pack needed to contain battery cells falls, reducing cost ($/kWh), keeping other factors constant. The larger the battery size, the more the costs associated with the packaging and management system can be distributed among more cells. These fixed costs remain largely the same whether the battery is small or large, so increasing the size of the battery allows for a lower cost per cell. A larger battery pack generally allows for more efficient design and packaging of the battery cells. For example, in a larger pack, cells can be arranged more closely together, reducing the amount of wasted space and materials. This again reduces the ratio of battery pack to cell. The ICCT cost analysis shows that larger batteries yield lower costs.43 See Figure 12. Comparing the 2030 cost outlook for a car battery providing 300 miles vs. 150 miles of range, the larger battery costs $68 per kWh vs. $79 per kWh, offering a 14 percent advantage. Pack-level scale economies of scale will be an advantage for battery packs for all vehicles, especially trucks and medium-duty vehicles. [EPA-HQ-OAR-2022-0829-0561, pp. 16-19]

Figure 12. Technical characteristics of electric vehicles for 2022 and 2030. Source: Slowik, et al., Assessment of Light-Duty Electric Vehicle Costs and Consumer Benefits in the United States in the 2022-2035 Time Frame, 10. [EPA-HQ-OAR-2022-0829-0561, pp. 16-19]

3. Faster-than-expected moderation of pandemic-induced supply chain disruption

Key mineral inputs to battery production have dropped in price over the last six months more quickly than had been anticipated. Lithium prices have also fallen, dropping by half from a November 2022 peak.44 The downward trend in cobalt has been even more severe, partly because of the reduction in global cobalt demand due to lithium-ion phosphate batteries' growing market share. In June, the cobalt price had dropped to $14 per pound, down 65 percent from its 2022 peak.45 See Figure 13. [EPA-HQ-OAR-2022-0829-0561, pp. 16-19]

45 Sophie Caronello, "Five Key Charts to Watch in Global Commodities This Week," Bloomberg.Com, June 11, 2023, https://www.bloomberg.com/news/articles/2023-06-11/five-key-charts-to-watch-in-global-commodity-markets-this-week#xj4y7vzkg.

Trends in cobalt and lithium prices are part of a broader trend in moderation of supply-chain pressures on EV batteries. Goldman Sachs Group Inc. is forecasting "softness for battery metals including cobalt, lithium and nickel in the second half of 2023 amid an oversupply."46 [EPA-HQ-OAR-2022-0829-0561, pp. 16-19]

46 "Cobalt Price Has Fallen Nearly 30% This Year," Mining.com, June 12, 2023, https://www.mining.com/cobalt-price-has-fallen-nearly-30-this-year/.

[See original attachment for graph "Global cobalt metal price"]

Figure 13. Global cobalt metal price, 2020-2023. Source: BloombergNEF, available at: https://www.bloomberg.com/news/articles/2023- 06-11/five-key-charts-to-watch-in-global-commodity-markets-this-week. [EPA-HQ-OAR-2022-0829-0561, pp. 16-19]

4. Novel battery chemistries and battery recycling

Novel battery chemistries nearing commercial availability will open new avenues for innovation, and their effects will not be limited to technological change. Novel battery chemistries will also have economic benefits by spreading EV battery demand across a greater array of raw inputs. More diverse mineral input supplies will disperse demand instead of concentrating it, reducing supply-side price pressure. New battery chemistries will also increase competition between battery technologies, reducing producer profit margins and improving consumer economics. [EPA-HQ-OAR-2022-0829-0561, pp. 16-19]

[See original attachment for graph "Changing Chemistries: Demand for cobalt is now less than previously expected as battery chemistries shift"] [EPA-HQ-OAR-2022-0829-0561, pp. 16-19]

Figure 14. Demand for cobalt is now lower than previously expected due to shifting battery chemistries. Source: BloombergNEF, available at: https://about.bnef.com/blog/race-to-net-zero-the-pressures-of-the-battery-boom-in-five-charts/. [EPA-HQ-OAR-2022-0829-0561, pp. 16-19]

In response to supply pressures and other market factors, cobalt-free lithium-ion-phosphate batteries are gaining traction because they can be built at a lower cost than other battery chemistries.47 The result is a dampening effect on cobalt demand. BloombergNEF analysis finds that global demand for cobalt would be 52 percent higher if lithium-ion-phosphate batteries had not experienced this rapid growth.48 [EPA-HQ-OAR-2022-0829-0561, pp. 16-19]

Two new battery chemistries entering commercial use this year in EV battery packs are sodium-ion batteries49 and lithium-sulfur batteries.50 BloombergNEF estimates that sodium-ion uptake, substituting for lithium-based chemistries, could lower lithium demand by 40 percent in 2035.51 See Figure 15. [EPA-HQ-OAR-2022-0829-0561, pp. 16-19]

Figure 15. Impact of sodium-ion battery uptake on lithium demand, 2020-2035. Source: BloombergNEF, available at: https://www.bloomberg.com/news/articles/2023-06-08/ev-sales-are-soaring-and-oil-use-is-about-to-peak-hyperdrive#xj4y7vzkg. [EPA-HQ-OAR-2022-0829-0561, pp. 16-19]

A research team from the University of Michigan is demonstrating the viability of a new battery membrane (made from a network of aramid nanofibers, recycled from Kevlar) that can enable lithium-sulfur batteries to have five times the capacity of lithium-ion batteries, increasing the number of times the battery can be charged and discharged. Sulfur is more abundant than the cobalt, and the aramid fibers of the battery membrane can be recycled from old bulletproof vests. The University of Michigan has patented the membrane and the lead researcher is developing a company to bring it to market.52 [EPA-HQ-OAR-2022-0829-0561, pp. 16-19]

52 McAlpine, “1,000-Cycle Lithium-Sulfur Battery Could Quintuple Electric Vehicle Ranges.”

Finally, battery recycling is on the rise and slated for substantial growth over the coming decades. Numerous factors are fueling the battery-recycling industry, including technological progress, supply-chain stability considerations, decarbonization targets, new IRA incentives for recycled battery materials, and ongoing research & development efforts.53 [EPA-HQ-OAR-2022-0829-0561, pp. 16-19]

53 McKinsey & Company, “Battery Recycling Takes the Driver’s Seat,” Our Insights: Automotive & Assembly, March 13, 2023, https://www.lung.org/research/sota/health-risks.

These and other evolving factors impacting the BEV market are highly likely to result in lower costs to manufacturers and consumers as learning rates improve, faster adoption of zero-emission technologies, and greater emissions reductions over the timeline of the proposed rule.

We recommend the EPA fully consider these factors and other relevant market trends as it develops the final rule. [EPA-HQ-OAR-2022-0829-0561, pp. 16-19]

Organization: Environmental. and Public Health Organizations

C. Battery costs will continue to decline, and EPA should include lithium-iron phosphate batteries in its modeling of battery pack costs.

Developments in battery technology and reductions in battery costs also support the promulgation of strong standards. EPA is correct that battery costs will continue to decline. Improvements in battery chemistries are one reason for that, and EPA should include batteries with lithium-iron phosphate (LFP) chemistry in its modeling. [EPA-HQ-OAR-2022-0829-0759, p. 49]

1. EPA should include lithium-iron phosphate battery chemistries in its BatPaC modeling of battery pack costs.

When modeling the cost of BEV batteries, EPA should consider the use of iron-phosphate cathodes. The use of LFP batteries in current BEV models is growing; these batteries have potential benefits beyond lower material prices, including higher fast-charging rates and greater durability.128 [EPA-HQ-OAR-2022-0829-0759, p. 49]

128 Ford Media Center, Ford Taps Michigan for New LFP Battery Plant; New Battery Chemistry Offers Customers Value, Durability, Fast Charging, Creates 2,500 More New American Jobs (Feb. 13, 2023), at https://media.ford.com/content/fordmedia/fna/us/en/news/2023/02/13/ford-taps-michigan-for-new-lfp-battery-plant-- new-battery-chemis.html (last accessed July 3, 2023).

EPA cites the lower specific energy and energy density of LFP batteries as being less appropriate to the 300-mile range BEVs modeled in its analysis. While there is demand for longer-range BEVs, there is still likely to be a role for BEVs with a range of 200-300 miles; in fact, many current BEV models have a rated range of less than 300 miles. Even if the average range of BEV vehicles is 300 miles, the actual product mix will include vehicles with ranges both above and below that average. And as fast-charging infrastructure with higher-power (>##300 kW) EVSE is deployed, consumers may be more willing to choose a BEV with less than 300 mile range, as mid-trip recharging would require less time. Vehicles with lower range are good candidates for LFP batteries. [EPA-HQ-OAR-2022-0829-0759, p. 49]

For these reasons, EPA should evaluate the potential cost savings if a portion of PEV models use LFP batteries. Using BatPaC version 5,129 switching to LFP from the default of NMC811 reduces battery pack cost 7-10%, depending on battery production volume assumptions and battery capacity. As supported by findings in BloombergNEF's latest Electric Vehicle Outlook, LFP batteries are forecasted to be used in an increasing number of passenger BEVs in the United States, reaching around 30% of new demand in 2032.130 [EPA-HQ-OAR-2022-0829-0759, pp. 49-50]

129 U.S. EPA, Battery Cost Estimation Spreadsheets for US EPA LMDV NPRM, EPA-HQ-OAR-2022-0829-0356_attachment_3, available at https://www.regulations.gov/document/EPA-HQ-OAR-2022-0829-0356.

2. Battery costs will continue to decline.

We concur with EPA's assessment that battery costs will continue to decline. We provide support for EPA's battery cost-per-kWh inputs for its OMEGA modeling and the continued downward price trend of batteries. [EPA-HQ-OAR-2022-0829-0759, p. 50]

In its modeling, EPA used an average battery cost ($/kWh) at the pack-level based on a proprietary analysis by Wood Mackenzie and a report by the Environmental Defense Fund (EDF) and Environmental Resources Management (ERM) compiling battery cost projections from a number of sources.131 The Agency also noted that according to BloombergNEF, global average pack prices were expected to reach $100/kWh by 2026, as the price increase in 2022 due to mineral price volatility will be resolved within a couple of years.132 We believe these costs are an appropriate representation of the market. Our own analysis based on data available to BloombergNEF subscribers in the Electric Vehicle Outlook 2023 yields numbers just slightly below the costs EPA used in its modeling, as shown in the table and figure below, assuming that EPA's costs were shown in 2021$. [EPA-HQ-OAR-2022-0829-0759, p. 50]

131 See DRIA at 2-50.

132 88 Fed. Reg. at 29323

SEE ORIGINAL COMMENT FOR TABLE Pack-Level Cost Comparison (2021$/kWh) [EPA-HQ-OAR-2022-0829-0759, p. 50]

SEE ORIGINAL COMMENT FOR Figure LD Battery Pack-Level Cost Comparison, Cost EPA Used in OMEGA and Alternate Cost Prediction [EPA-HQ-OAR-2022-0829-0759, p. 51]

To develop our estimates, we used battery global cost data (2022$/kWh) for BEVs, global battery demand forecasts, and the most updated learning rate used by BloombergNEF after the 2022 price increase, as well as a 7.02% inflation rate between June 2021 and June 2022 to convert the data back to 2021$/kWh.133 [EPA-HQ-OAR-2022-0829-0759, p. 51]

133 Evelina Stoikou, 2022 Lithium-Ion Battery Price Survey, BloombergNEF (Dec. 6, 2022), at 13-15 & 24-27 (Subscription required).

Lastly, as EPA noted, its analysis does account for access to § 45X Advanced Manufacturing Production tax credits, but there are several other tax credits from the IRA available to battery manufacturers that will reduce costs below what is represented in EPA's analysis, such as the 10% tax credits for electrode active material or critical mineral production. As a result, this is a conservative assumption, which further supports the reasonableness of EPA's battery cost projections. [EPA-HQ-OAR-2022-0829-0759, p. 51]

In sum, EPA's forecast of battery cost per unit of battery power output ($/kWh) aligns with the best available knowledge and prediction of the market at this time. However, EPA's forecast of some of the other factors related to battery technologies, like specific energy, are behind where the market is currently and where it is trending for the future. These inputs can therefore cause the full cost of a passenger BEV and the associated mineral demand to be modeled higher than the most likely real-world scenarios. Therefore, even though the cost per kWh input is appropriate, the cost and minerals needed per BEV are likely overestimated under the EPA's current approach meaning that technological feasibility and benefits are higher than predicted by the EPA. [EPA-HQ-OAR-2022-0829-0759, p. 51]

B. Alternative battery-related modeling inputs increase the feasibility and benefits of PEVs.

EPA's OMEGA modeling likely overestimates the battery cost and material demand per passenger PEV due to conservative technical assumptions made about advancements in lithium-ion batteries that would replace materials, increase specific energy, or allow for the longer use of batteries through refurbishment or reuse. Additionally, the variables discussed below can also cause mineral demand forecasts to be higher than actual future material demand. [EPA-HQ-OAR-2022-0829-0759, p. 142]

1. Technological advancements resulting in decreased mineral demand can also further decrease battery costs.

In addition to the substitution of lithium discussed above, advanced lithium-ion batteries such as solid-state batteries could decrease the amount of lithium required to provide the same kWh and miles traveled. Innovation will increase battery specific energy and energy density, therefore reducing the amount of materials needed per kWh as well as battery cost. [EPA-HQ-OAR-2022-0829-0759, p. 143]

Solid-state battery startups, such as QuantumScape,379 are already partnering with automakers to ensure the technology is suitable for PEVs. Solid Power has partnered with Ford and BMW and has provided BMW with a research and development license to its all-solid-state cell design and manufacturing knowledge, and QuantumScape in December 2022 shipped its first lithium metal battery cells for trial.380 Solid-state batteries have increased specific energy, with QuantumScape reporting their Li-Metal NMC batteries having up to 400 Wh/kg or 1,100 Wh/L depending on the anode. This increase is graphically represented in Figure XVIII.B-1 below, which was produced by QuantumScape. [EPA-HQ-OAR-2022-0829-0759, p. 143]

Sodium-ion batteries are also making their way to the market, providing an alternative to lithium minerals and potentially reducing future lithium demand. CATL (the world's largest PEV battery maker) invested in the technology in 2021,383 and the Chery iCar will be the first EV to use the technology.384 There are already 20 sodium-ion battery factories under construction or planned around the world, demonstrating the uptake of this technology.385[EPA-HQ-OAR-2022-0829-0759, p. 144]

2. Specific energy assumed in the model is lower than expected for LDVs.

"Specific energy" is the amount of energy a battery can store per unit of its weight, and "energy density" is the amount of energy a battery can store per unit of its volume. As shown in Figures XVIII.B-2 and XVIII.B-3 below, both of these metrics have increased dramatically over time for lithium-ion batteries. Improving battery specific energy and energy density increases the amount of energy that can be stored using the same amount of materials. This is important not only for reducing demand for battery minerals but also for improving the range of PEVs. These increases are the result of various factors, including battery chemistry and design improvements. Battery chemistries have different specific energies; nickel- and cobalt-containing chemistries have higher specific energy than LFP. For example, the Tesla Model Y uses an NCA battery with a reported 276-333 Wh/kg, while the Model S and Model X use a battery with slightly less at 250 Wh/kg.386 While lower, this 250 Wh/kg is still a dramatic increase from Sony's commercialization in 1991 when it was 80 Wh/kg.387 [EPA-HQ-OAR-2022-0829-0759, p. 145]

Data Source: BloombergNEF Electric Vehicle Outlook 2022 (subscription required)

a. Specific energy forecasts

U.S. PEV sales are currently dominated by nickel- and cobalt-containing cathode chemistries, representing 100% of sales in 2019.393 The NCA cathode, used by Tesla, represents the most sold PEV batteries in the United States over the last couple of years.394 More recently, Tesla began selling PEVs in the United States that use LFP,395 a trend that is being followed by Ford and Rivian. If reviewed globally, NMC of different ratios (particularly 622 and 811) is the most prevalent chemistry today,396 and LFP is more frequently used globally than in the U.S., with around 40% of global passenger PEV sales expected to contain LFP batteries in 2023.397 While LFP batteries have lower specific energy, and therefore less range than nickel- and cobalt-based chemistries, they are cheaper to manufacture due to the lack of cobalt and nickel, and technological advances are closing the gap between LFP and nickel- and cobalt-based specific energies.398 [EPA-HQ-OAR-2022-0829-0759, p. 147]

397 Id.

398 Id. at 157-158

Although the prevalence of different ratios of nickel- and cobalt-based chemistries (NMC and NCA) vary with time, those chemistries are currently predicted to hold nearly half the global passenger PEV market into the early 2030s, with NMC811 and NMC955 being the most popular chemistries in that category in 2027.399 U.S.-based forecasts similarly assume nickel- and cobalt-based chemistries to be dominant over the next decade, despite the increasing use of LFP.400 [EPA-HQ-OAR-2022-0829-0759, p. 147]

399 Id. at Figure 202

400 Dr. Andy Leach, Lithium-Ion Batteries: State of the Industry 2022, US demand, chemistry mix, and recycling Capacity, BloombergNEF, Sept. 9, 2022. Subscription required.

The OMEGA model uses the NMC811 cathode for a base technology and 180-200 Wh/kg as the base specific energy. There are a few issues with these assumptions: 1) while NMC811 is representative of a technology sold today, NMC611 is currently more common, and NMC955 along with other chemistries like NCA and LFP are expected to be more common than NMC811 in 2027-2032; and 2) the specific energy used in OMEGA does not align with real-world NMC811 specific energy.401 NMC811 has one of the highest specific energies, behind only NCA.402 When paired with a graphite anode, the specific energy of the battery should be at least 250 Wh/kg, as shown in Figure XVIII.B-4 below, compared to the 180-200 Wh/kg used by EPA.403 [EPA-HQ-OAR-2022-0829-0759, p. 147]

403 Marc Wentker, A Bottom-Up Approach to Lithium-Ion Battery Cost Modeling with a Focus on Cathode Active Materials, Energies 12(3):504, at 6, Fig. 2 (2019), available at https://doi.org/10.3390/en12030504

SEE ORIGINAL COMMENT FOR Figure XVIII.B-4: Specific energy of lithium-ion batteries with various cathodes and anodes [EPA-HQ-OAR-2022-0829-0759, p. 148]

Source: Wentker et al., 2019

BloombergNEF's specific energy forecast used linear interpolation to demonstrate that in 2030, the 95% confidence lower limit of specific energy is 210 Wh/kg, with a higher limit of 275 Wh/kg, as shown in Figure XVIII.B-5 below.404 This linear interpretation includes both LFP and NMC, but does not account for the high amount of nickel- and cobalt-containing cathodes used in the U.S. The forecast also does not account for material substitution and large specific energy gains expected from quickly-advancing technology. For example, the use of silicon in the anode can increase specific energy,405 and while it is not yet used widely, startups are progressing this technology and constructing commercial-scale manufacturing facilities.406 [EPA-HQ-OAR-2022-0829-0759, p. 148]

b. An updated specific energy forecast

The relatively low pack-level specific energy described in section 2.5.2.1.1 (Battery sizing) of the DRIA (180-200 Wh/kg) appears to only account for the use of LFP, even though the following section, 2.5.2.1.2 (Base year battery cost estimation), states that vehicles were assumed to contain batteries with the more efficient NMC811 chemistry in the cost analysis. Therefore, EPA's inputs for specific energy are conservative considering that nickel- and cobalt-containing cathodes are used in the vast majority of passenger PEVs sold in the US, and recent advancements, such as the Blade Battery (10 Wh/kg increase), demonstrate specific energy gains faster than historically seen. The EPA forecasts generally align with the lowest limit of specific energy forecasts by BloombergNEF in Figure XVIII.B-5 in the prior section, although it would be more accurate to align with a high forecast scenario considering the share of NMC chemistries in use. [EPA-HQ-OAR-2022-0829-0759, p. 149]

Updating the specific energy forecast would likely lead to lower costs and mineral demand for passenger PEVs, and therefore increased feasibility and cost benefits of PEV technologies compared to EPA's current analytical approach. EPA's assumptions must be revised to reflect what is actually occurring in the market and what the currently predicted trends are for the future. [EPA-HQ-OAR-2022-0829-0759, p. 149]

Table XVIII.B-1 is calculated based on historical energy densities for LFP and cobalt-containing cathodes (NCX) provided by BloombergNEF.408 When specific energy for LFP and cobalt-containing cathodes are individually calculated based on linear interpolation, Table XVIII.B-2 shows the results. If the ratio of 30% LFP and 70% nickel-based is kept, we get the average specific energy in Table XVIII.B-1. [EPA-HQ-OAR-2022-0829-0759, p. 150]

Data Source: BloombergNEF Electric Vehicle Outlook 2023 (subscription required)

Appropriately representing higher specific energies that align with today's technologies and forecasts also has implications for vehicle range, weight, and mineral demand. Batteries with higher specific energies can provide the same amount of power while using fewer minerals, therefore weighing less than batteries with lower specific energies. This means that vehicles with more efficient batteries can travel further with the same amount of energy because the battery significantly impacts the weight, and therefore, the efficiency of PEVs. [EPA-HQ-OAR-2022-0829-0759, p. 151]

Organization: Environmental Defense Fund (EDF) (1of 2)

i. ZEV costs are rapidly declining.

The costs of batteries and ZEVs have declined significantly over the last few years. Recent analyses project that costs will continue to decline, even when IRA investments are not considered. The decline has been dramatically accelerated by the IRA. [EPA-HQ-OAR-2022-0829-0786, pp. 16-17]

3. Rapidly declining ZEV costs are also supported by manufacturers' projections of battery cost declines.

A key driver of BEV costs (and future cost projections) is the projected decline of battery costs. According to a report by ERM for EDF, the cost of battery packs fell dramatically from over $1,000/kilowatt-hour (kWh) in 2010 to approximately $132/kWh in 2021 and analysts and automakers project that battery pack prices will continue to fall overall, reaching $100/kWh between 2023 and 2025 and $61-72/kWh by 2030.51 As early as 2021, companies like Renault and Ford had publicly announced targets of $80/kWh by 2030.52 While ongoing supply chain disruptions caused battery pack prices to rise slightly in 2022, it is expected that the IRA, which provides up to $45/kWh battery cell credit and provides significant incentives for increasing EV manufacturing, will help further lower the cost of battery packs.53 In its Q1 2023 earnings report, General Motors reported that it intends to reduce battery costs down to roughly $87 per kWh by calendar year 2025, a significant decrease from its original projection of $100 per kWh by 2025.54 [EPA-HQ-OAR-2022-0829-0786, pp. 21-23]

51 Electric Vehicle Market Update: Manufacturer Commitments and Public Policy Initiatives Supporting Electric Mobility in the U.S. and Worldwide, ERM for EDF, September 2022, https://www.edf.org/sites/default/files/2023-05/Electric%20Vehicle%20Market%20Update%20April%202023.pdf. (Attachment Q).

52 BNEF, Battery Pack Prices Fall to an Average of $132/kWh, But Rising Commodity Prices Start to Bite, November 30, 2021. https://about.bnef.com/blog/battery-pack-prices-fall-to-an-average-of-132-kwh-but-rising- commodity-prices-start-to-bite/

53 Id.

54 Trey Hawkins, "GM Expects Battery Cells To Cost $87 Per kWh By 2025," GM Authority (May 5, 2023), https://gmauthority.com/blog/2023/05/gm-expects-battery-cells-to-cost-87-per-kwh-by-2025/.

For a 75 kWh battery pack, EPA modeled battery prices as $120/kWh through 2025 falling to $90/kWh by 2029, $75/kWh by 2035, and finally $65/kWh by 2050. EPA's choice is reasonable but conservative. EPA assumed that the per kWh price for battery packs decreases as packs get larger, consistent with modeling by ANL. In Figure 2-26 in the DRIA, EPA plots the average battery pack for vehicles modeled in OMEGA 2 by year. The average battery pack for vehicles throughout the model is roughly 100 kWh. [EPA-HQ-OAR-2022-0829-0786, pp. 21-23]

Plotted below in Figure 4 are EPA's battery pack costs as well as eight projections and DOE's target battery price all made within the last three and a half years. They clearly demonstrate that EPA's battery cost estimates are reasonable, consistent with, and even conservative when compared to manufacturer and expert projections. [EPA-HQ-OAR-2022-0829-0786, pp. 21-23]

https://nap.nationalacademies.org/download/26092 https://www.carexpert.com.au/car-news/volvo-ceo-price-parity-between-electric-and-combustion-vehicles-by-2025

Research into next generation battery chemistries also has the potential to dramatically drive down costs for BEVs. These types of step changes that occur with significant technological breakthroughs are not represented in the battery cost projections discussed above nor are they included in EPA's modeling. Novel technologies such as solid-state batteries and sodium-ion batteries are both promising avenues to reduce battery costs and increase performance. Additionally, many lithium-ion chemistries are being explored that reduce the reliance on rarer metals such as cobalt including lithium nickel manganese oxide, lithium sulfur, nickel iron aluminum oxide, and nickel manganese aluminum oxide.56 [EPA-HQ-OAR-2022-0829-0786, pp. 21-23]

56 V. Nair, S. Stone, G. Rogers, and S. Pillai, "Medium and Heavy-Duty Electrification Costs for MY 2027- 2030," February 2022. Roush for EDF. (Attachment R)

Improvements in the manufacturing of battery cells and packs also have the potential to substantially reduce costs. The dry battery electrode (DBE) process eliminates the need for the wet slurry coating, drying, and solvent recapture steps in conventional battery manufacturing. These steps account for 50% of the energy consumption and 23% of the cost for cell manufacturing. Creating tables electrodes can improve yields, reduce cell costs, reduce internal resistance, reduce battery wear, and improve thermal management, all changes that could increase battery performance and drive down costs. Improvements in battery pack construction are also being investigated. [EPA-HQ-OAR-2022-0829-0786, pp. 21-23]

In their 2022 study Roush only considered conventional NMC and LFP batteries but stated "given the number of technologies that the industry is working on that have the potential to significantly reduce the cost and increase cell and pack energy density, it is likely that the future battery costs will be below those projected in this study [$68/kWh for an NMC battery pack in 2027]".57 [EPA-HQ-OAR-2022-0829-0786, pp. 21-23]

Organization: International Council on Clean Transportation (ICCT)

BATTERY ELECTRIC VEHICLE COST

While ICCT strongly supports the proposed rule, we believe there is evidence available to support lower BEV costs than EPA has modeled. EPA analysis shows clear and significant benefits associated with achieving a reduced combined fleet gram CO2/mile standard and an associated increase in battery electric vehicle penetration. However, the cost of compliance may be overstated due to the use of outdated technology data and information. Electric vehicle and battery technology has been improving rapidly and technology costs have been greatly reduced. Automakers are investing heavily in BEV R&D and manufacturing capacity and are achieving higher production volumes with more advanced technologies at lower costs. We reviewed EPA's analysis on electric vehicle and battery costs and identified a few key parameters within EPA's analysis that we believe could be updated to better reflect the latest evidence and analysis. We make observations below that would reduce the incremental BEV costs and accelerate the timing for cost parity, which further strengthen the case for adopting the proposed rule and would result in relatively greater benefits at lower cost. [EPA-HQ-OAR-2022-0829-0569, pp. 22-26]

New 2022 ICCT research assessed light-duty electric vehicle costs and consumer benefits in the United States in the 2022-2035 time frame and found that without any federal, state, utility, or local incentives, BEV purchase price parity is coming before 2030 for BEVs with up to 300 miles of range across all light-duty car, crossover, SUV, and pickup truck classes.65 Continued technological advancements and increased battery production volumes mean that pack-level battery costs are expected to decline to about $105/kWh by 2025 and $74/kWh by 2030. These developments are critical to achieving electric vehicle initial price parity with conventional vehicles, which the 2022 ICCT analysis finds to occur between 2024 and 2026 for 150- to 200-mile range BEVs, between 2027 and 2029 for 250- to 300-mile range BEVs, and between 2029 and 2033 for 350- to 400-mile range BEVs. These results—along with others discussed below—from ICCT's 2022 EV cost parity study are aligned with those found in similarly recent studies of EV cost parity.66 The cost parity findings are further reinforced by new Energy Innovation and Consumer Reports research showing that in 2023 most new electric vehicles are already cheaper to own than gasoline-powered vehicles in the United States from day one.67 [EPA-HQ-OAR-2022-0829-0569, pp. 22-26]

Electric vehicles save consumers money. https://advocacy.consumerreports.org/research/cr-fact-sheet-electric-vehicles-save-consumers-money/

Total battery pack costs on average in the ICCT analysis are about $3,700 less than in EPA's analysis in 2027 and about $5,200 less than in EPA's analysis in 2032. This is due to several factors, including average BEV pack size (kWh), efficiency (kWh/mile) and pack-level cost ($/kWh). Table 3 summarizes the findings of the underlying technical specifications for 300-mile range BEVs in 2027, 2030, and 2032 in the EPA and ICCT analyses. As shown, on average in the ICCT analysis the pack size is smaller for the same range, the efficiency is higher, and the per-pack costs are lower. As shown in the bottom row, the total pack cost in the ICCT study is about $3,200 to about $4,400 less than EPA in 2027, about $2,800 to $4,100 in 2030, and about $4,200 to $6,000 in 2032. The pack cost per kWh in the EPA analysis increase from 2030 to 2032 along with the phaseout of the 45X battery production tax credit. The pack cost per kWh in the ICCT analysis do not include the 45X tax credit; applying the 45X tax credit to the ICCT battery costs would further reduce BEV costs and the gap between the findings of incremental costs in the ICCT and EPA analyses (Figure 9). [EPA-HQ-OAR-2022-0829-0569, pp. 26-29]

SEE ORIGINAL COMMENT FOR Table 3. Summary of key BEV technical specifications in EPA and ICCT (2022) Note. Numbers in table are rounded [EPA-HQ-OAR-2022-0829-0569, pp. 26-29]

The combination of reduced per kWh costs and smaller pack size for the same range (due to improved efficiency) in the ICCT analysis is the driver for lower costs compared to EPA. The ICCT conducted a thorough battery cost review and applied the best available data and analysis of current and future electric vehicle and battery technical specifications.68 Figure 10 shows the ICCT's 2022 battery cost review, which was based on expert sources, research literature projections, and automaker announcements. Our battery cost review includes the most recent projections by expert sources including the California Air Resources Board (2022), Roush Industries Inc. (see Saxena, Stone, Nair, & Pillai, 2023), Bloomberg New Energy Finance (2020, 2021), UBS (2020) and technical research studies, including Mauler, Lou, Duffner, and Leker (2022), Nykvist, Sprei, and Nilsson (2019), Penisa et al. (2020), Hsieh, Pan, Chiang, and Green (2019), and Berckmans et al. (2017). The automaker announcements shown include Volkswagen for $135 per kilowatt-hour in 2021–2022 (Witter, 2018), Tesla for $55/kWh in 2025 (Tesla, 2020), and Renault and Ford for $80/kWh in 2030 (Automotive News, 2021a, 2021b; Ford, 2021). Not shown due to uncertainties related to timing, General Motors in 2020 announced continued improvements toward below $100/kWh at the cell level, and Volkswagen in 2021 announced developments toward "significantly below" $100/kWh at the pack-level (General Motors, 2020; Volkswagen, 2021).69 [EPA-HQ-OAR-2022-0829-0569, pp. 26-29]

69 Complete referencing is available at https://theicct.org/publication/ev-cost-benefits-2035-oct22/

SEE ORIGINAL COMMENT FOR Figure 10. Electric vehicle battery pack costs from technical studies and automaker statements [EPA-HQ-OAR-2022-0829-0569, pp. 26-29]

Figure 10 also shows the battery pack cost per kWh applied in EPA's OMEGA analysis, illustrated by the brown hashed line. The EPA (2023) cost curve in the figure is based on the volume weighted average pack marked-up cost from EPA Figure 2-27 from the DRIA with the value of the 45X battery production tax credit incentive removed so that it can be directly compared to the ICCT's 2022 battery cost review.70 The EPA (2023) battery cost curve clearly stands out with much higher per-kWh costs than nearly every other study identified in the ICCT battery cost review. On average over the 2023-2035 timeframe, the annual per kWh battery pack costs in the EPA model are about 55% greater than those applied in ICCT (2022). To provide context to these values, industry surveys showed that the volume-weighted average global BEV pack-level prices were approximately $126 per kWh in 2020 and $118 per kWh in 2021.71 EPA is applying about $126 kWh in 2029 and about $115 per kWh in 2030, which is about nine years later than the 2020 and 2021 volume-weighted average global pack prices reported by BNEF. [EPA-HQ-OAR-2022-0829-0569, pp. 26-29]

71 Bloomberg New Energy Finance. (2020). Battery pack prices cited below $100/kWh for the first time in 2020, while market average sits at $137/kWh. Retrieved from https://about.bnef.com/blog/battery-pack-prices-cited-below-100- kwh-for-the-first-time-in-2020-while-market-average-sits-at-137-kwh/ and Bloomberg New Energy Finance. (2021). Battery pack prices fall to an average of $132/kWh, but rising commodity prices start to bite. Retrieved from https://about.bnef.com/blog/battery-pack-prices-fall-to-an-average-of-132-kwh-but-rising-commodity-prices-start-to-bite/

For BEV efficiency, the technical specifications applied in the ICCT study are based on official electric vehicle range and efficiency values from the U.S. Department of Energy and reflect consumer label efficiency.72 The ICCT study applies a charging efficiency factor of 93% for all years. A useable-to-total battery pack size ratio is also applied based on average high-volume MY 2022 electric vehicles such that BEVs can use 92% of the kWh, which increases for new vehicles by less than 1% per year through 2030, based on the best available models from 2022. For context, several BEV models including the BMW i4, Chevrolet Bolt EV, Chevy Bolt EUV, Hyundai Ioniq 5, Nissan Leaf, Polestar 2, and Volvo C40 and XC40 have a useable-to-total battery ratio of 96% or greater in 2022. [EPA-HQ-OAR-2022-0829-0569, pp. 26-29]

Retrieved from https://www.fueleconomy.gov/feg/download.shtml] [EPA-HQ-OAR-2022-0829-0569, pp. 26-29]

72 United States Department of Energy. (2022b). “Download fuel economy data”.

The initial 2022 electric vehicle efficiencies applied in the ICCT study are based directly on existing MY 2022 BEV and PHEV models, accounting for increased electricity-per-mile for longer-range electric vehicles. We apply average technical specifications based on several high-volume MY2022 electric vehicle models within each class. For example, our BEV crossover efficiency is based on the Tesla Model Y, Ford Mach-e, Volkswagen ID 4, Hyundai Kona, Kia Niro, Kia EV6, and Volvo XC40. Electric vehicle efficiency improves annually due to electric component (battery, motor, power electronic) and vehicle-level (mass reduction, aerodynamic, and tire rolling resistance) improvements. The 2030–2035 electric vehicle efficiencies are based on modeling by CARB (2022), accounting for range and adjusting for charging losses.73 Between 2022 and 2030, we apply an average annual improvement that links the high-volume 2022 average electric vehicle model specifications with the 2030 CARB values. By 2030, the efficiencies are somewhat better than those of the “best in class” models from 2022. For example, our representative 350-mile range battery electric car is 0.23 kWh/mile compared to the 358-mile range 2022 Tesla Model 3 at 0.26 kWh/mile. Our representative 350-mile range crossover in 2030 is 0.25 kWh/mile, compared to the 330-mile range 2022 Tesla Model Y at 0.28 kWh/mile. [EPA-HQ-OAR-2022-0829-0569, pp. 26-29]

Very recent BEV-related automaker announcements and developments from automotive suppliers reflect the continued rapid pace of innovation in BEV technologies. For example, Toyota recently announced its 2026 plans to produce battery packs capable of over 600 miles of range at lower cost than its current packs.75 Toyota also plans to produce solid-state battery packs with 20%-50% more range, and bipolar lithium iron phosphate packs at 40% lower cost starting around 2028.76 Beyond reducing costs through battery improvements and vehicle efficiency increases, Toyota plans to reduce vehicle manufacturing costs through improvements in factory operation, giga-casting to reduce parts and complexity, and reduced development times.77 Similarly, Volvo announced its plans to reduce EV costs through cell-to-body battery packaging, integrated motor, inverter, transmission units, and giga-castings.78 Meanwhile, the advent of two-speed transmissions for BEVs from automotive suppliers increases motor efficiency and performance, allowing battery and motor downsizing.79 Another supplier innovation that improves EV efficiency especially for induction motors is Tula’s Dynamic Motor

Drive.80 Still other areas of innovation include higher voltage EV platforms, axial flux motor improvements, and current-source inverters.81 These recent examples go beyond the technology improvements assumed in the 2022 ICCT EV cost study. With these innovations, BEVs become even more cost-effective as a technology option for manufacturers. [EPA-HQ-OAR-2022-0829-0569, pp. 29-31]

Based on the above analysis, we believe that the relative BEV costs may be overstated in the EPA proposal and accompanying OMEGA analysis. If EPA were to update the analysis with the data and evidence regarding BEV cost and technical specifications based on the ICCT cost study, BEV costs would be lower, the costs of compliance would be lower, and the net benefits would be greater. [EPA-HQ-OAR-2022-0829-0569, pp. 29-31]

The above analyses and comparisons were conducted almost entirely relying on OMEGA output files, which can obscure important modeling assumptions. To allow for more complete independent comparisons among the proposal, prior EPA analyses, and third-party studies, ICCT recommends EPA expand its documentation of assumptions and cost breakdowns of underlying technologies or cost components. For example, EPA could provide average or exemplary vehicle and component costs across various body styles or classes over time, similar to tables in prior rulemakings. The general lack of clarity on cost applies to certain combustion technologies, too, which are identified and discussed in the next section. [EPA-HQ-OAR-2022-0829-0569, pp. 29-31]

Organization: Jaguar Land Rover NA, LLC (JLR)

Battery Cost Modeling

JLR would like to highlight to EPA our serious concerns with regards to their battery pack modeling. The overarching assumption that costs "are assumed to decline over time as production volumes grow and manufacturing efficiencies improve" is overly optimistic and the factors considered do not fully account for all of the uncertainties that contribute towards the final cost. JLR's forecast $/kWh cost reduction is considerably lower than EPA's forecasts, [REDACTED]CBI [EPA-HQ-OAR-2022-0829-0744, pp. 10-11]

In response to EPA's request for comment on how they "should consider the issue of global battery production in the context of our application of learning for the final rule analysis", JLR recommends that the modeling should consider in greater detail the increase of global net zero pledges and policies to increase EV uptake and the possible effect on critical mineral supply chains. The International Energy Agency (IEA) noted in their Energy Technology Perspectives 2023 report, "Anticipated supply expansion suggests that production could fall well short of Net Zero Emissions (NZE) Scenario requirements for 2030, with deficits of up to 35% for lithium mining and 60% for nickel sulfate production. If this prediction is correct, despite increased investment announced across multiple continents to expand the supply chains, critical minerals will rise in price. With lead times of up to 10 years for new mines16, we urge EPA to err on the side of caution and amend the learning factor used in the cost reduction calculation to more accurately reflect the potential risks. [EPA-HQ-OAR-2022-0829-0744, pp. 10-11]

16 IEA (2023), Energy Technology Perspectives 2023, IEA, Paris https://www.iea.org/reports/energy-technology-perspectives- 2023, License: CC BY 4.0

JLR requests that EPA acknowledge the risk of further market volatility for critical mineral pricing and take a more conservative approach when modeling battery prices. This will also impact the GHG reductions OEMs can practically achieve, therefore a reduction in stringency is paramount in the early years of the program. [EPA-HQ-OAR-2022-0829-0744, pp. 10-11]

Organization: John Graham

BEV costs assume, implausibly, that shortages of raw materials will be resolved after the mid-2020s. [EPA-HQ-OAR-2022-0829-0585, p. 9]

Finally, the prices of batteries may not fall as rapidly in the future as they have since 2010. There are logistical, regulatory, and political barriers to rapidly expanding the mining and processing of raw materials required to make enough BEVs for motorists in China, Europe, North America, and the rest of the world. [EPA-HQ-OAR-2022-0829-0585, p. 9]

The batteries for HEVs and BEVs are designed differently, and thus the HEV battery costs need to be estimated separately and carefully. It is revealing that the agency devoted much more analysis to the costs of BEV batteries, especially future learning factors, than to the cost of HEV batteries, for which future learning factors are assumed to be extremely small. [EPA-HQ-OAR-2022-0829-0585, p. 10]

5. BEV Costs

EPA defines the costs of the BEV's propulsion system as the sum of battery and "non-battery" costs, where the non-battery costs are driven primarily by the cost of the electric motor. The agency uses differential "learning factors" that cause the predicted costs of BEVs to fall much faster over time than the predicted costs of hybrids. We discuss first the battery costs and then the non-battery costs. [EPA-HQ-OAR-2022-0829-0585, pp. 16-17]

Battery Cost

Baseline battery costs. The DRIA reports a baseline BEV battery cost of $120/kWh for 2022 to 2025, determined using the BatPaC model for a 75 kWh battery pack and 250,000 vehicles produced per year. BatPaC's estimate of $120/kWh in 2022 seems reasonable, assuming that potential issues with battery material supplies are not included in the $120/kWh estimate. [EPA-HQ-OAR-2022-0829-0585, pp. 16-17]

Battery learning factors. Starting in 2026, EPA introduces “learning factors” that slash the cost of producing batteries by 25% by 2029 ($90/kWh), by another 25% by 2035 ($75/kWh), and by yet another 13% by 2050 ($65/kWh). In contrast, HEV costs (which are embedded in “ICE Powertrain Costs and Glider Costs”), decline by only 4% in 2035 and 9% in 2050. [EPA-HQ-OAR-2022-0829-0585, pp. 16-17]

The cumulative learning rates for battery cost are very high and, since no one has a crystal ball, no one knows whether those learning rates will truly apply. Note that the writeup in the DRIA on battery learning just states how it is done – there is no real justification for the learning assumptions. Below we show that the EPA is applying a one-stage learning model to the entire battery supply chain, a simplistic model that has already been shown to be implausible in the peer-reviewed scientific literature. [EPA-HQ-OAR-2022-0829-0585, pp. 16-17]

The agency’s learning model is “one stage” because the agency applies the same learning factors to the mining/processing stage that it applies to the later stages when battery cells are produced and assembled into battery packs. EPA does not disclose that the production-volume model of cost savings that it relies upon was estimated for assembly-like operations, not mining and early- stage processing of mined materials. [EPA-HQ-OAR-2022-0829-0585, pp. 16-17]

In 2019 the MIT Energy Institute produced a report illustrating why treating the entire battery supply chain as one stage leads to erroneous learning factors.21 A simulation was performed where the battery supply chain was broken into two stages – “materials synthesis” (mining and processing) and battery production. Separate learning factors were derived for the two stages. The analysts found that derived learning factors were almost 80% smaller for materials synthesis than for battery production. Moreover, the costs of raw materials and their synthesis place a floor on the amount of cost reduction that can occur for the entire supply chain. The MIT simulation shows that battery costs are “unlikely” to fall below $100/kWh prior to 2030. EPA forecasts them below $80/kWh in 2030 and below $70/kWh in 2032 (DRIA Figure 2-26). [EPA-HQ-OAR-2022-0829-0585, p. 17]

21 MIT Energy Initiative. 2019. Insights into Future Mobility. Cambridge, MA: MIT Energy Initiative, 76-80 http://energy.mit.edu/insightsintofuturemobility; also see Hsieh, I-Yun Lisa, Menghsuan Sam Pan, Yet-Ming Chiang, and William H. Green. 2019. “Learning Only Buys You So Much: Practical Limits on Battery Price Reduction.” Applied Energy 239, (April): 218–224. https://doi.org/10.1016/j.apenergy.2019.01.138.

The folly of EPA’s one-stage model was revealed in 2021 and 2022 when battery prices stopped declining for the first time in a decade. Indeed, EPA acknowledges that battery prices rose 7% in 2022, principally due to an unexpected surge in prices of lithium, nickel, cobalt, and other raw materials used in battery-cell production. Since raw materials account for a much larger share (70%) of battery costs in 2022 than they did in 2015 (40-50%), it is crucial for the agency to analyze the future paths of raw material prices. Decades from now, when recycling of batteries and/or components is widespread, the prices of raw materials may moderate, but for the next two decades, as the battery sector grows explosively and batteries are recycled only 15-25 years after new BEV sales, dependence on mining and processing of raw materials is unavoidable. [EPA-HQ-OAR-2022-0829-0585, p. 17]

The solution to this analytic problem is not to simply suspend learning factors for an arbitrary number of years, as EPA suggests in the NPRM. EPA needs to build a global model of raw material prices, including global demand as well as supply. One of the principal reasons that battery prices are unlikely to drop dramatically between now and 2035 is that global supplies for raw materials will have difficulty keeping up with the explosive growth in demand for batteries from China, Europe, and North America. We examine the raw materials issues in more detail in the next section on The Global Supply and Demand for Raw Materials. [EPA-HQ-OAR-2022-0829-0585, pp. 17-18]

Organization: Mitsubishi Motors North America, Inc. (MMNA)

To determine a realistic maximum volume of EVs the market can support for each of the model years covered by the rule, we believe EPA should consider certain critical factors. Among these factors, we believe EPA must make a thorough and realistic year-by-year assessment of key factors like projected battery costs, projected supply of battery critical-minerals, projected residential and public charging infrastructure availability, projected electrical grid capacity, and consumer acceptance of BEV technology in the broader arena. [EPA-HQ-OAR-2022-0829-0682, p. 2]

EVs currently cost significantly more to produce than equivalent gasoline cars or trucks. The average price of a BEV today is about $9,000 higher than that of a comparable ICE vehicle13. That price difference is driven mostly by the cost of the batteries. Battery cost have come down significantly in the past, but, contrary to EPA's assumption that the price of EV batteries will be substantially lower in coming years, that trend is not likely to continue. Given the anticipated exponential growth in demand for battery critical minerals to meet the proposed GHG standards, combined with the continued limited supply of those materials for the foreseeable future (resulting from the long lead time needed to ramp up mining and processing capacity), costs of these materials and batteries are expected to rise, thereby widening the price gap between ICEs and BEVs. Mitsubishi agrees with Auto Innovators' assertion that the Agency has not adequately addressed projected battery critical minerals availability and associated cost. [EPA-HQ-OAR-2022-0829-0682, pp. 10-11]

13 New-Vehicle Transaction Prices Trend Downward as Incentives Rise, According to Kelley Blue Book - Mar.8, 2023 (kbb.com).

Organization: Paul Bonifas and Tim Considine

Another glaring inconsistency in the EPA's analysis is they assume "the [EV vs ICE] price difference is likely to narrow or become insignificant as the cost of batteries fall…" As economies of scale are deployed, conventional wisdom would anticipate the continued decrease in cost of batteries. However, this may not be the case going forward. BloombergNEF's annual lithium-ion battery price survey shows a "7% increase in average pack prices in 2022 in real terms. This is the first increase in the history of the survey"16. [EPA-HQ-OAR-2022-0829-0551, p. 6]

16 https://about.bnef.com/blog/increase-in-battery-prices-could-affect-ev-progress/

Organization: POET, LLC

Apart from those flawed assumptions about technological feasibility, EPA also makes unfounded assumptions in its analysis regarding costs. EPA first assumes that the cost of batteries for BEVs will drop dramatically in the short term—by about $40 kWh or 33% between 2027 to 2032—and then by a more modest amount—about $14 kWh or 12%—from 2032 to 2050.87 EPA then adds a significant, additional reduction—from about $80 to $90 per kWh from 2027 to 2032 to $40 to $60 per kWh—because of the IRA tax credits.88 This amounts to a total cost reduction of about 50 to 67% in "as few as two to three years" simply because of increased demand and the IRA.89 These large reductions are not justified. First, the battery production capacity that would support these cost reductions has yet to be built. Second, even assuming it is built as EPA predicts, there is no reason to assume that battery manufacturers will pass cost savings from the IRA directly onto customers on a one-to-one basis.90 Additionally, EPA's battery cost assessment appears to ignore the impact of other provisions in the Proposed Rule regarding battery durability and warranty.91 Those requirements will almost certainly impose additional costs that EPA has omitted.92 [EPA-HQ-OAR-2022-0829-0609, pp. 22-23]

87 Id.

89 Id.

90 Id.

91 Id at 6.

92 Id.

OnLocation also finds that additional review by EPA of its battery learning curve (i.e., the extent to which EPA projects battery costs will decline) is warranted, for reasons including that EPA could be substantially understating the total cost of the rule.[434] [EPA-HQ-OAR-2022-0829-0609, pp. 28]

In addition to the technical feasibility of producing BEVs in dramatically greater numbers than at present and relative to the already aggressive forecasts of BEV penetration without the Proposed Rule, the assumed cost of BEVs is of course another key driver in U.S. EPA's BEV penetration forecasts. U.S. EPA's analysis of battery cost is presented in Chapter 2.5 of the DRIA. The agency's basic assumptions regarding the cost of battery production are shown in Figure 2-25 of the DRIA which is reproduced below. As shown, U.S. EPA assumes that the production cost of batteries drops substantially over the period from 2027 through 2032 (~$40 kWh or 33%) but then by only modest additional amounts during the period from 2032 through 2050 (~$14 kWh or 12%). [EPA-HQ-OAR-2022-0829-0609, pp. 57-58]

The next step in the agency's analysis is to lower the $80-90 cost per kWh over the period from MY 2027 to MY 2032 shown in Figure 2-25 to $40-60 per kWh as shown in DRIA Figure 2-27 based on U.S. EPA's assumptions regarding the impact of the tax credits provided by the Inflation Reduction Act (IRA). Overall, U.S. EPA assumes that the current battery production cost of about $120 kWh will fall by 50 to 67% in as few as two to three years because of

[434] *Id*. at 8.

increased demand for batteries and federal tax credits under the IRA. U.S. EPA also assumes similar changes in the marked up prices of batteries as is shown in Figure 2-27. While federal tax credits may lower the ultimate cost of battery production, there is no reason to assume that battery manufacturers will pass these cost savings through by lower battery prices, particularly given the projected worldwide demand for batteries. It is unclear that these credits will continue to be in place over the period from 2027 through 2032 as they could easily be eliminated or modified by future legislation. Therefore, U.S. EPA should perform a sensitivity analysis that shows how dependent the high levels of BEV penetration forecast would be impacted by the elimination of these tax credits. [EPA-HQ-OAR-2022-0829-0609, pp. 57-58]

Overall, given that most of the battery production capacity required to supply the batteries U.S. EPA assumes will be available has yet to be built and that automaker demand for those batteries will be high given the constraints of the Proposed Rule, U.S. EPA's assumptions regarding battery costs are difficult to accept and the much slower decline U.S. EPA assumes post MY 2032 may be much more reasonable to apply over the entire time period and would certainly represent a conservative approach compared to U.S. EPA's highly optimistic approach. [EPA-HQ-OAR-2022-0829-0609, pp. 57-58]

[See original attachment for Figure 2-25. Reference trajectory of future battery pack manufacturing costs for a 75 kWh BEV pack] [EPA-HQ-OAR-2022-0829-0609, pp. 57-58]

Another issue with U.S. EPA's battery cost assessment is that it appears to completely ignore the impact of the cost of the proposed battery durability and warranty provisions of the Proposed Rule. These new regulatory requirements will clearly impose costs on battery manufacturers and automakers which will ultimately be passed on to consumers and should be included in U.S. EPA's analyses. [EPA-HQ-OAR-2022-0829-0609, p. 58]

Organization: Strong Plug-in Hybrid Electric Vehicle (PHEV)

The PHEV battery costs should be based on using BEV batteries as explained in Appendix D in this letter. [EPA-HQ-OAR-2022-0829-0646, p. 8]

PHEV and BEV Costs

Some parties claim that Strong PHEVs cost too much. Our coalition's research community believes there are several methods not yet adopted by many automakers that can reduce the cost of Strong PHEVs. For light-duty PHEVs, our coalition has found that many researchers incorrectly find that PHEVs are high cost compared to BEVs. However, researchers anticipate convergence of the purchase prices of ICEVs and PHEVs in the 2030-2035 timeframe.17 These studies suggest that declining battery costs, along with close integration of electrification subsystems, will play an important role in reducing PHEV costs as adoption increases, and that PHEVs will consequently be manufactured and operated with lower costs than comparable long-range BEVs. Further Argonne National Lab's recent report 18 shows that light-duty PHEVs are less expensive than BEVs for cars, and our experts at Strong PHEV coalition assert that several additional technical modifications can lower the cost of PHEVs that most analyses do not consider. A common mistake we find in reports is not understanding the difference between a strong PHEV and other PHEVs because a strong PHEV can use the same batteries as a BEV which results in significant cost savings. The two charts below show how a light-duty PHEV should use the same batteries as a BEV and not have to use a special low- volume production battery with a different (higher) power to energy ratio. We believe most mid- range and long-range PHEV cars and trucks will need BEV batteries. Also see our critique of the Advanced Clean Car II analysis of PHEV cost.19 Finally, we agree with EPA that BEVs with large battery backs will need stronger chassis which adds costs but note that PHEVs do not need this to the same degree. Thus, EPA's cost analysis for PHEVs should reflect this. [EPA-HQ-OAR-2022-0829-0646, pp. 21-22]

19 Strong PHEV Coalition - Cost Model Inputs 5.2.22.mp4 (sharepoint.com)

Organization: Tesla, Inc.

Consistent with vehicle price reduction, BEV battery prices continue to decline in rapid fashion. As DOE has recently documented, the energy density of lithium-ion batteries Increased by more than eight times between 2008 and 2020, allowing for BEVs to travel the same distance with a smaller battery pack, thus saving space, weight, and manufacturing costs.95 Similarly, DOE has found that BEV battery pack cost dropped 90% since 2008.96 [EPA-HQ-OAR-2022-0829-0792, pp. 14-15]

95 DOE VTO, FOTW #1234, April 18, 2022: Volumetric Energy Density of Lithium-ion Batteries Increased by More than Eight Times Between 2008 and 2020 (Apr. 18, 2022). available at h ttps://www.energy.gov/eere/vehicles/articles/fotw-1234-a pril-18-2022-volumetric-energy-density-lithium-ion-batteries

96 DOE, FOTW #1272, January 9, 2023: Electric Vehicle Battery Pack Costs in 2022 Are Nearly 90% Lower than in 2008, according to DOE Estimates (Jan. 9, 2023) available at h ttps://www.energy.gov/eere/vehicles/articles/fotw-1272-january-9- 2 023-electric-vehicle-battery-pack-costs-2022-are-nearly

Moreover, almost all analysts project profound reductions in battery costs by 2030. For example, UBS reports that leading manufacturers are estimated to reach battery pack costs as low as $67/kWh between 2022 and 2024.97 Recently, others have also projected costs significantly lower than EPA's past projections. BNEF's has estimated that pack prices go below $100/kWh on a volume-weighted average basis by 2024, hit $58/kWh in 2030,98 and could achieve a volume-weighted average price of $45/kWh in 2035.99 The National Academies of Sciences found high-volume battery pack production would be at costs of $65-80/kWh by 2030100 and DNV-GL has predicted costs declining to $80/kWh in 2025.101 The IPCC recently concluded similarly.102 These cost estimates all were projected before the Inflation Reduction Act (IRA) passed Congress. The IRA adds a significant new element to battery cost reduction as Section 45X provides domestically manufactured cells and finished batteries a production tax credit of $45/kWh.103 This new policy has accelerated significant new domestic battery production capacity that will generate further cost reductions.104 Indeed, the 45X production tax credit is predicted to cut one-third to one-half off the total cost of any BEV battery with both cells and pack built in the U.S.105 [EPA-HQ-OAR-2022-0829-0792, pp. 14-15]

In general, Tesla believes the agency's cost assumptions are far too high and are not supported by the record in that they do not fully consider the documented and projected rapid decline in battery cell and pack costs, as well the significant BEV range increases achieved through other efficiencies. From 2017 -2022, the Model 3 powertrain evolved with a 20% lighter drive unit, 25% less rare earth minerals, a 75% smaller powertrain factory, and a 65% cheaper powertrain factory.106 While the agency's proposal suggests that vehicle battery size will grow, Tesla requests the EPA take into account that it has consistently increased range without increasing battery size.107 For example, the Model Y All-Wheel Drive (AWD) achieves 4.0 EPA miles/kWh, which makes it the most efficient electric SUV ever made.108 More profoundly, Tesla is hard at work on battery cell innovations. Tesla has announced and documented a path toward battery cell production that it expects will lower kWh battery costs by over 50%.109 [EPA-HQ-OAR-2022-0829-0792, p. 15]

the agency's assessment should further recognize the technology forcing created by finalization of the proposed regulations by factoring in battery cost reductions that will likely be seen during the MY 2027-32 period as well, including LFP applications110 and sodium ion batteries.111 In some forecasts, LFP is viewed at rapidly growing to capture up to 47% of the EV market by 2026 resulting in dramatically lower battery pack prices.112 Indeed, battery technologies entering the commercialization phase such as silicon anodes, solid state batteries, and sodium-ion batteries are predicted to improve performance and costs and alter current material supply chains.113 The current regulatory impact statement only makes glancing reference to these technologies and the record is deficient in this respect.114 [EPA-HQ-OAR-2022-0829-0792, p. 15]

4. Battery Costs Projections

EPA's assessment of future battery costs is highly optimistic and inconsistent with available sources. The assessment starts with an inaccurate baseline cost for 2022 and then uses an incomplete set of forecasts to develop two trajectories which rely on assumed mid-decade price stabilization of lithium. The assessment appears to ignore the risk for price spikes arising in a tight and geopolitically sensitive market for critical minerals. Please see Appendix A on mineral supply and potential price implications. Lastly, EPA applies tax credits from the IRA 45X provision in a confusing way that could go beyond the intent of the legislation. [EPA-HQ-OAR-2022-0829-0620, p. 18]

4.1. Baseline Assumptions

To arrive at the 2022 baseline for direct manufacturing costs, EPA used ANL's BatPaC 5.0 to develop a sweep of expected costs ($/kWh) for varying battery sizes (gross kWh), at four different production rates as shown in Figure 3. EPA selected a 75kWh battery at 250,000 packs/year to arrive at $120/kWh to represent the baseline. EPA attempts to justify the baseline by comparing it to a Tesla 30-40 GWh capacity “gigafactory”. The assumed production rates are overly optimistic and contrary to our comments above on the lead time and scale up of new battery production facilities. EPA must recognize battery plant sizes and capacities will vary greatly based on a host of factors ranging from site size to workforce availability, to logistical optimization in the vehicle production footprint, to battery mineral/cell/pack supply chains and sources, to capital availability, and so forth. EPA appears to have selected a large capacity facility to represent what it expects will be “typical”. If EPA had data suggesting a 250,000 unit per year battery facility would be “average” then this approach might make sense. As it stands, such a large facility is more likely to be the exception and not the rule, and EPA should expect most battery production to align with the lower capacity curves in Figure 3. Painting the entire industry's manufacturing approaches with a single broad brush likely underestimates costs. [EPA-HQ-OAR-2022-0829-0620, pp. 18-21]

[See original for graph, Figure 3 Proposed Rule Cost Estimates by Battery Size and Production Rates]12 [EPA-HQ-OAR-2022-0829-0620, pp. 18-21]

12 Figure 1 - EPA DRIA Figure 2-20 Plot of Base Year 2022 DMC estimates for different sized BEV battery packs at 4 different production rates.

EPA also seeks to justify the baseline battery cost with a qualitative comparison to the summary of cost projections from EDF/ERM as seen in Figure 17.13 [EPA-HQ-OAR-2022-0829-0620, pp. 18-21]

13 Environmental Defense Fund, Electric Vehicle Market Update (Sep. 2022) at pg. 27. Available at htps://blogs.edf.org/climate411/wp-content/blogs.dir/7/files/2022/09/ERM-EDF-Electric-Vehicle-Market-Report_September2022.pdf.

Toyota's assessment of available sources finds baseline battery costs significantly higher than $120/kWh. We considered three studies by e-Source, Mauler et. al., and BNEF and added them to EPA's DRIA Figure 2-24 (shown in Figure 4). For EPA's battery cost future projections, we added insights from two studies, Mauler et.al. again, and an MITEI study. [EPA-HQ-OAR-2022-0829-0620, pp. 18-21]

[See original for graph, Figure 4 EDF/ERM Batter Cost Survey form Proposal with Added Data] [EPA-HQ-OAR-2022-0829-0620, pp. 18-21]

A 2023 study from e-Source, which specializes in downstream battery supply chain analysis and manufacturing modeling,14 concludes a cost of $158/kWh in 2022 for a 75-kWh NMC811 battery pack produced at US 100-GWh plant at 250,000 packs/year. This is significantly higher than the proposal's stated $120/kWh for 2022 – even at the high production capacity of 250,000 units. [EPA-HQ-OAR-2022-0829-0620, pp. 18-21]

The December 2022 updated annual battery price survey from BNEF observes average lithium- ion battery pack prices of $141 per kilowatt hour in 2021 increasing to $151 in 2022, representing the first increase since 2013 (Figure 5). This agrees with the e-Source study and is consistent with the price volatility in 2022 stemming from skyrocketing raw material prices, record-setting inflation, and geopolitical tensions with Russia. EPA appears to have used the 2022 BNEF data, however the 2022 data point is not included in Figure 4. [EPA-HQ-OAR-2022-0829-0620, pp. 18-21]

14 Proprietary study by e-Source for USA cost per pack of NMC811, 75 kWh packs at 250,000 packs per year assumed

[See original for bar chart, Figure 5 BNEF Battery Pack and Cell Cost Projections] [EPA-HQ-OAR-2022-0829-0620, pp. 18-21]

4.2. Forecasts

The EDF/ERM report referenced in Figure 4 is used to establish a cost trajectory that is anchored by the following data points: $120/kWh baseline for 2022, $110/kWh for 2026 and $90/kWh for 2030. [EPA-HQ-OAR-2022-0829-0620, pp. 21-23]

In Figure 6, direct manufacturer costs for a 75-kWh battery (black line) that decline over time are developed by applying assumed rates of learning to the "reference trajectory". The trajectory for a 100-kWh battery (blue line) was then generated in the OMEGA model. [EPA-HQ-OAR-2022-0829-0620, pp. 21-23]

The steepest reductions occur from 2025 to 2029 due to assumed stabilized lithium prices by the mid-2020s. The price for the 75-kWh battery falls to about $90/kWh in 2030 which implies 25% reduction in cost from 2022 baseline. The 100 kWh battery cost declines from the $115/kWh baseline to about $78/kWh in 2030 resulting in an 32% reduction, and to $61/kWh in 2035, a 21% cost reduction. The resulting costs seem implausible and would be considerably higher if upward pressure on prices cause by tight supply of were appropriately considered. [EPA-HQ-OAR-2022-0829-0620, pp. 21-23]

[See original for graph, Figure 6 OMEGA Battery Pack Costs] [EPA-HQ-OAR-2022-0829-0620, pp. 21-23]

Toyota's referenced sources indicate the cost of batteries is expected to decline in the future, but this decline could be slowed or even reversed if battery raw material prices rise. Technological innovation is expected to lead to significant cost reductions, but there is a significant risk that it may not be able to offset the rising cost of critical minerals. The Mauler et.al. study analyzed several battery forecast studies and found "the methods of technological learning, literature-based projection, bottom-up modeling, and expert elicitation…(and) technological advances... and economies of scale" 15 tend to neglect raw material price volatility. When rising material cost is added to the analysis as a main variable, even the slightest increase threatens to offset those production savings for battery costs. The study found the 2030 battery pack cost for low price case to be $96/kWh, and $130/kWh for the high price case, with a midpoint of $113/kWh. This is in stark contrast to EPA's 2030 battery pack cost projection of $78/kWh in 2030. [EPA-HQ-OAR-2022-0829-0620, pp. 21-23]

15 Id.

Finally, a 2019 study by MIT Energy Initiative (MITEI) finds that "Though battery costs have declined substantially, predictions about future price declines must be approached with caution as they often fail to account for the cost of the raw materials used to make batteries."16 MITEI projects the 2030 price of a Li Ion battery pack will be $124/kWh, despite a decline in costs. This aligns the fluctuating price of Li, Ni, Mn, Co and C found in the Mauler et. al. study, which was done independently and in 2022. [EPA-HQ-OAR-2022-0829-0620, pp. 21-23]

4.4. Conclusions

The battery cost projections in the proposal are not realistic because they do not sufficiently consider the dynamic external variables creating tight supply which increase the risk of supply chain disruptions and volatile raw material prices. Nor does EPA's assessment account for the time it takes to establish and ramp up battery production. The Final Rule must take a broader view of available expert sources and reconsider the applicability cost reductions through IRA. The result should be revised the battery cost projections. [EPA-HQ-OAR-2022-0829-0620, pp. 24-25]

Organization: Valero Energy Corporation

EPA's cost estimates for future battery packs also ignore the customer-readable battery state-of-health monitor proposed by EPA as a new requirement under this rulemaking.209 [EPA-HQ-OAR-2022-0829-0707, pp. 38-40]

209 EPA's Proposed Rule at 29284.

Organization: Zero Emission Transportation Association (ZETA)

The EV battery is one of the most significant factors in the cost of an EV, comprising 20-50% of the total vehicle cost, though this percentage has decreased significantly over time. This decrease is driven by lithium prices, which have significantly dropped over the last year, from $85,000 to $30,000 per tonne from November 2022 to April 2023.51 This trend is driven by a boom in lithium supply from China, Australia, and Chile. The reduction in critical mineral inputs means we will "see more and more electric vehicles selling for $25,000 to $40,000" according to Cox Automotive.52 Overall, the cost of lithium-ion batteries has declined substantially since 2008, down to $153 per kWh, as shown in Figure 2.53 [EPA-HQ-OAR-2022-0829-0638, pp. 12-13]

EPA Summary and Response

Summary:

Several commenters stated the position that EPA's base year battery pack cost per kWh for 2022 was too low. These commenters cited various sources, most prominently the Bloomberg New Energy Finance (BNEF) battery price survey that was published in December 2022, and also Benchmark Minerals and ANL. The Alliance specifically noted that these sources indicated even higher costs for NMC chemistry, which EPA had stated as the chemistry it had assumed. In general, these commenters requested EPA to reconsider its base year battery cost and revise it to be more consistent with these sources. These commenters also frequently indicated that part of the reason that EPA's battery costs were too low, in their view, might be that we assumed average production rates that were too high. For example, the Alliance and Toyota contended that our production rate of 250,000 packs per year was too high for the base year cost case, and recommended that we consider a smaller volume more inclusive of manufacturers who have smaller production rates. Specifically, the Alliance stated that smaller automotive manufacturers may only utilize a portion of a larger plant's total capacity for cells and packs built to their individual specifications. The Alliance also questioned whether "30-40 GWh battery manufacturing plant capacity is common among the largest manufacturers" and stated that this assumption "fails to contemplate the production efficiencies of new battery plants versus those that have been fully operational for years, including variations in battery chemistry." Similarly, Toyota asserted that "such a large facility is more likely to be the exception and not the rule."

In contrast, other commenters indicated that they felt that our base year battery costs were appropriate or too high. Tesla commented that it felt that the agency's cost assumptions "are far too high and are not supported by the record in that they do not fully consider the documented and projected rapid decline in battery cell and pack costs, as well the significant BEV range increases achieved through other efficiencies." Tesla also pointed out that EPA's battery sizes increase over time, and that EPA should consider that Tesla "has consistently increased range without increasing battery size." Similar positions were expressed by ICCT and EDF.

Response:

EPA appreciates the supportive comments from Tesla, ICCT, the Environmental and Public Health Organizations coalition, and EDF, and continues to believe that the battery costs used in the proposal analysis represent one possible outcome for future battery costs. However, in considering the totality of information and data at the present time, including the battery cost analysis conducted by ANL (described in Chapter 2 of the RIA and Section IV.C.2 of the preamble), EPA believes it is appropriate to increase the battery costs in its central case in order to reflect the results of this analysis and better address the uncertainty that continues to exist in the market regarding future mineral prices and other drivers of battery cost.

In the proposal, EPA acknowledged the BNEF survey, which became public very late in our analysis process. We noted that although the nominal cost reported by BNEF for BEV batteries at $138 per kWh was lower than the base year cost in the proposal, there was considerable uncertainty in comparing the battery designs in the proposal to the battery designs represented in the survey, which were not described in detail. We also cited the BNEF report as an example of the fluidity of battery cost projections, and indicated that we would consider this and any new information to update our battery costs for the final rule. We also stated that we would conduct additional analysis of battery costs with Argonne National Laboratory by using a version of BatPaC with specific assumptions for technology improvements over time, and current and forecasted mineral costs. Through this work, and as described in preamble Section IV.C.2 and Chapter 2 of the RIA, our baseline battery costs have increased, and are now in good agreement with the 2022 BNEF price survey. In response to comments relating to ANL and BMI forecasts, we now use battery costs developed by ANL using BMI mineral cost forecasts. Relating to comments that we should be using the higher NMC costs from these sources, in OMEGA we do not specify whether specific vehicles are using NMC or another chemistry, and thus for the purpose of the analysis it is an average cost across all chemistries that may be present in the fleet that is most relevant. Although our battery costs in the proposal were developed using NMC811-G, we now use a weighted average of NMC (varying from 522 to 955) and LFP.

We also note that in light of the most recent 2023 BNEF battery price survey, our new costs are conservative, as the 2023 survey indicates that prices have resumed a downward trend, dropping by 14 percent from 2022 to 2023.

In addition, as described in the proposal, our assumption of 250,000 packs per year was in part due to limitations in how BatPaC has historically modeled pack production volume, in order to capture economies of scale for cell production in cases where a plant manufactures standardized cells at a volume sufficient to supply the annual production volume of more than one pack design. Our updated costs are now based on significantly smaller pack production volumes in the earlier years of the analysis, as described in Table 1 of the ANL study.[435]

Regarding plant size, we continue to assess that many of the operating battery plants and most new plant announcements are in the 30 to 40 GWh range or higher. For example, ANL surveyed U.S. battery manufacturing plants currently in operation and announced for the future and determined that “the majority of the production volume (860 GWh/year) comes from 22 plants with a nameplate capacity between 30-50 GWh/year.”[436] Even if, as the commenter suggests, at the current time smaller plants are also common and that production costs are higher in these plants, the sheer volume represented by the large size of announced plants that will enter production during the time frame of the rule is likely to dominate any calculation of average cost across the industry. If as the commenter suggests, the cost of production is much higher in these plants (that is, enough higher to be significant to the findings of the analysis), this assertion is inconsistent with manufacturers’ decision to construct plants of this size, knowing that they would therefore not be competitive with the majority of future production volume. Given the significance of battery cost to the cost of PEV production, we continue to assess that manufacturers will be motivated to achieve the lowest costs by either constructing large plants or purchasing from suppliers that operate large plants (or alternatively, rationally constructing smaller plants when they anticipate that the size of the plant will not make the production cost

[435] Argonne National Laboratory, “Cost Analysis and Projections for U.S.-Manufactured Automotive Lithium-ion Batteries,” ANL/CSE-24/1, January 2024.
[436] Argonne National Laboratory, “Quantification of Commercially Planned Battery Component Supply in North America through 2035,” ANL-24/14, March 2024.

uncompetitive). Toyota and the Alliance stated the position that EPA's assessment did not account for the time it takes to establish and ramp up battery production, referring specifically to OMEGA and its use of costs derived for a 250,000 pack per year production volume in each year of the analysis. However, the updated analysis for the final rule uses cost correlations developed by the ANL study which determines costs specifically for each year of the analysis with reference to a gradually increasing cell yield and plant production volume that ramp in over time. EPA considers this update also responsive to the Alliance comment that EPA should have accounted for "the production efficiencies of new battery plants versus those that have been fully operational for years, including variations in battery chemistry." With regard to this latter comment, EPA also notes that the commenters did not provide data or evidence as to why or to what degree they believe that production cost is higher in newer plants, or the effect of a plant's prior operating time on production efficiencies. EPA believes that cell yield and production volume are sufficiently representative of any purported such effect that may exist.

Summary:

Several commenters (Alliance, [etc]) stated the position that the learning rates that EPA applied to battery costs after the base year (2023 and beyond) were too high, and resulted in projected battery costs that they felt were unrealistic, or were not in agreement with specific studies that they cited in support of this position. A common theme in these comments was the position that EPA did not appropriately consider factors that might cause battery costs to decline at a much slower than historical rate, or not decline at all. These factors included: increased demand and scarcity of critical minerals, price volatility and geopolitical uncertainty in a time of dynamic global market growth, and factors beyond material costs such as engineering and performance improvements. Also exemplary of some of these comments was JLR's comment that EPA should "acknowledge the risk of further market volatility for critical mineral pricing and take a more conservative approach when modeling battery prices."

Another theme was that EPA should adopt a two-stage learning model in which material cost reductions are assessed separately from technology/process cost reductions. Specifically, the Alliance noted that an MIT report which used such a model concluded that it is unlikely that battery prices will fall below $100 kWh by 2030. The Alliance also stated that EPA should implement a model of the materials synthesis stage to better capture the dynamics of mineral demand and its effect on future prices; similarly, John Graham stated that EPA should "build a global model of raw material prices, including global demand as well as supply."

Some commenters, in particular API, also criticized our use of cumulative GWh of battery production as an input to the battery cost learning equation. The Alliance recommended "that EPA revisit its battery cost analysis and align its 2027-and-later projections with Mauler analysis." The Alliance also expressed the view that "EPA needs to update its modeling to align with current battery costs and future critical mineral costs in its analysis for the final rule."

The Alliance and some other commenters also expressed skepticism that costs would decrease in the future, the Alliance stating that it is "not confident that a net decrease in battery prices will occur; an increase in battery prices is a distinct possibility due to global demand for limited resources." These commenters often pointed out that battery costs had begun to rise in recent years, again citing the BNEF survey and other sources. For example, AFPM stated that "battery costs rose 7 percent in 2022," and that the cost of lithium increased by 738 percent between January 2021 and March 2022. Clean Fuels Development Coalition et al. noted a study by E-

Source that predicted flat battery pack prices through 2032, and a press article that cited projections by BMI that commenter asserts shows "massive lithium shortages" beginning in 2029.

In contrast, Energy Innovation supported the learning rates used in the proposal, and cited a paper to support their position that "historic forecasts of battery prices have largely underestimated the impact of future learning curve effects," and "even the most optimistic projections for prior forecasts underestimated future learning curves."

Response:

As described below, EPA has updated its battery cost modeling to include a year-by-year assessment of future mineral prices, manufacturing volumes, and technology improvements, and the updated costs align well with current battery costs. EPA appreciates the recommendation of the Mauler analysis, which we have considered carefully. We also appreciate the Alliance's specific recommendations for where to set base year and future battery costs based directly on the Mauler paper. However, we disagree that our battery cost analysis should be based on the findings of a single research paper. We also note that our new costs, like the Mauler paper, begin with a year-over-year technology roadmap based on expert expectations, and incorporate analyst forecasts of mineral prices. For the years 2023 through 2035, our new battery costs are based on the aforementioned ANL battery cost study, which predicts battery costs in specific future years resulting from specific technology development pathways, and also incorporates mineral price forecasts published by Benchmark Minerals. Therefore (a) our updated costs now consider the effect of potential mineral scarcity and demand, through the use of forecast mineral prices by a leading analyst firm, and (b) our derivation of the new costs from a specific set of technology improvements means that we no longer rely on a learning rate equation to estimate future costs to 2035. After 2035, because the ANL work did not cover this period, we continue to use a simplified and modest cost reduction rate of 1.5 percent per year. This rate is reasonable in that it results in a battery cost projection for 2055 (the endpoint of our long term analysis) of about $60 per kWh, a figure which is often seen in long-range forecasts in the literature, and often attributed to earlier years than 2055. The figure is also consistent with an analysis performed by Mauler et al. that examined a large number of published battery cost forecasts and established a mean regression out to 2050, which if extended to 2055 would suggest a cost of $63 per kWh.[437] We consider this to be a reasonable if not conservative endpoint, and we also note Energy Innovation's perspective that learning rates have historically been conservative with respect to reality.

The use of mineral price forecasts in the ANL work also obviates the suggestion to adopt a two-stage learning model, since the costs to 2035 are based on specific mineral price forecasts and technology improvements rather than a learning equation. Further, our new central case costs are not in conflict with the MIT report cited by the Alliance in that they do not fall below $100 kWh in 2030.

Regarding the position that EPA should implement a model of the materials synthesis stage including manufacturing, or a global model of raw material prices, we consider our use of mineral price forecasts from a leading analyst firm combined with a technology roadmap over

[437] Mauler et al., "Battery cost forecasting: a review of methods and results with an outlook to 2050," Energy Environ. Sci, v.14, pp. 4712-4739 (2021).

the time frame of the rule to be an effective way of representing the influence of material choice, costs, and global demand over the time frame of the rule.

Regarding comments that battery prices had begun to rise and might not decline in the future, EPA acknowledges that the BNEF 2022 price survey supports that prices had increased between 2021 and 2022. However, it is not clear that battery prices will continue to increase in this manner or fail to continue to decline. The 2022 BNEF survey itself noted that the cause of the reported increase may be due to temporary factors, and that cost reductions are expected to continue in the future. In fact, the 2023 BNEF survey fulfilled this prediction, as it showed that battery prices had dropped by 14 percent since the 2022 survey. EPA also notes that since these comments were submitted, analyst firms indicate that many mineral prices have continued a downward trend and are forecast to continue this trend in the future. For example, ZETA commented that lithium prices have significantly dropped "from $85,000 to $30,000 per tonne from November 2022 to April 2023." Further, the most recent short-range forecast by Wood Mackenzie indicates that mineral prices will moderate and decline over the next several years.[438] While forecasts cannot perfectly predict the future, these developments show that drawing a conclusion regarding future battery costs or mineral prices is subject to uncertainties. EPA's findings on battery and mineral prices recognize these uncertainties, consider the key factors that affect battery and critical mineral prices, and are based upon a thorough evaluation of the technical literature and leading analyst forecasts. Specifically, these most recent forecasts do not support commenters' suggestion that battery prices will continue to rise or fail to decline. With regard to comments that EPA should take a more conservative approach that addresses the risk and uncertainty about mineral prices, EPA considers the updated central case costs to be responsive. With regard to the possibility of higher battery costs than in our updated central analysis, EPA considers the high sensitivity case of 25 percent higher costs to adequately represent these possibilities, especially considering the overall higher costs of the updated central case.

EPA also appreciates comments related to our use of cumulative GWh of battery production in the learning equation for future battery costs. As described in preamble Section IV.C.2, the ANL-derived cost equations for 2023 through 2035 obviate the need for application of a learning factor, and we no longer use cumulative GWh learning to reflect learning by doing.

While we appreciate the Alliance's perspective questioning that a net decrease in battery prices will occur at all over the time frame of the rule, we also note that the most recent analyst outlooks and battery price forecasts continue to anticipate battery and critical mineral cost reductions to varying degrees, even in the knowledge of the possibility of increased mineral demand and price volatility. While the highest cost scenario of the Mauler paper assumes battery costs to stay at a more or less constant level to 2030, that case is arbitrarily based on the most pessimistic of analyst expectations. EPA sees no consensus that costs will behave in this manner. Many other commenters do not see such a likelihood either; for example, Tesla stated that "almost all analysts project profound reductions in battery costs by 2030." Mauler's high cost scenario of perpetually flat or increasing battery cost is clearly inconsistent with prevailing analyst outlooks on mineral or battery prices, and based on the date of the Mauler paper (received November 2021 and published March 2022), appears to be based on earlier outlooks

[438] Wood Mackenzie, "Electric Vehicle & Battery Supply Chain Short-term outlook November 2023", December 1, 2023 (filename: evbsc-short-term-outlook-november-2023_final.pdf). Available to subscribers.

that reflected analyst sentiment that is now out of date and would be considered outlier sentiment today. Similarly, the comment from Clean Fuels Development Coalition et al. that cites a study by E Source projecting "battery cell prices will surge 22% from 2023 through 2026" dates from 2022, and the outlook it describes is not supported by more recent forecasts of mineral prices nor by projections of battery prices such as the 2023 BNEF battery price survey which indicated a 14 percent reduction in battery prices since the time of the E Source study. Further, the commenter's assertion that "massive lithium shortages" will occur after 2029 is based on a chart in a press article that actually projects a market balance and not specifically a "shortage." As EPA explains in Section IV.C.7.i of the preamble, the mere identification of a gap between projected supply and projected demand, particularly in far future years, is not the same as a shortage in which manufacturers would not be able to obtain material; the identification of such a gap is in fact often essential to motivate development of new supply. EPA considers ANL's use of BMI mineral cost forecasts in developing the battery cost correlations that we use in the updated analysis through 2035 to be responsive to these comments.

Summary:

In a related vein, the Alliance stated that EPA omitted consideration of several factors other than materials prices that they contend "are working to keep battery prices high." These included: motivation to increase energy density for greater range; safety, such as minimizing the risk of battery fires; frequent use of DC fast chargers; improved thermal management systems; and adherence to responsible sourcing guidelines, including avoidance of sourcing from lower cost suppliers that are not free trade agreement partners.

Response:

EPA agrees that there are other factors beyond material costs that affect battery manufacturing costs, and that manufacturers regularly pursue improved designs. The costs derived by the ANL study include a capability to fast charge from 15 percent to 95 percent SOC in 26 minutes, and at this time it is not clear that a faster charge rate will necessarily be prevalent in the future. Improving energy density is not the only means to improve range; it can also be achieved by improving energy efficiency of the vehicle, as comments by Lucid and Tesla attest. Safety and improved thermal management are also important, as are responsible sourcing. However, these effects are not readily quantifiable, and the commenter did not provide data or evidence as to how these effects might be quantified. Nor did the commenter persuasively explain or adduce empirical evidence that these technological developments would increase prices, nor by how much, nor that it would reasonably be expected to fully or even significantly offset the cost reductions modeled by EPA. Responsible sourcing is addressed in RTC Section 15 where we discuss topics related to critical minerals.

Summary:

In the context of either base year battery costs or our learning rates, or both, some commenters addressed EPA's consideration of mineral costs. Some commenters supported EPA's assumption that mineral costs would stabilize over the time frame of the rule, while others did not.

Response:

As also noted above, our updated battery cost assessment for 2023-2035 is based on the ANL study that incorporates mineral cost forecasts from BMI, a leading analyst firm, and does not rely on any blanket assumption regarding mineral cost trends over time. We also note that since these comments were submitted, analyst firms indicate that many mineral prices have continued a downward trend, and the most recent mid-range forecast by Wood Mackenzie suggests that mineral prices will moderate or decline over the next several years and through the duration of their forecast (to 2029).[439] While some commenters have cited an outlook for a shortage of lithium beginning to form beyond that time frame, forecasting that far into the future is subject to additional uncertainties, especially in light of the high level of activity in developing new mineral and processing capability at the current time and anticipated high demand continuing into the future, all of which provides a strong environment for investment in these resources. As EPA has pointed out elsewhere, the mere identification of a gap between a future projected supply and a future projected demand does not equate to identification of a future shortage and is in fact one of the signals that spurs development of additional supply. While forecasts cannot perfectly predict the future, these developments do support our outlook that mineral costs will tend to stabilize over time. EPA's evaluation of the evidence, supported by recent analyses from ANL and BMI, is that manufacturers choosing to produce PEVs will not be constrained by the availability of lithium or other critical minerals, including through 2035. See preamble Section IV.C.7 and RTC Chapter 15 for further discussion of the availability of critical minerals.

Summary:

The Alliance stated that the version of BatPaC utilized in the proposal assumes an electrolyte cost that differs from that presented by Argonne National Laboratory in October 2022 and included on the anl.gov website.

Response:

The updated cost analysis was performed by ANL using the latest version of their BatPaC model and cost inputs that they considered appropriate for the purpose of the study.

Summary:

Some commenters including the Alliance questioned the "default labor values currently hard coded into the BatPaC model" as needing reconsideration, given that EPA's assumptions regarding the 45X production tax credit implied that most batteries would be produced in the U.S.

Response:

As described in Preamble Section IV.C.2, our battery costs are now based on twice the default labor cost in BatPaC, which we assess to be similar to prevailing hourly rates and overhead for organized labor in U.S. automotive plants.

Summary:

AFPM commented that "EPA points to the IRA as a mechanism to reduce battery prices, yet this law simply extended the existing battery subsidy and even limited its applicability through domestic sourcing and income requirements. Thus, EPA is relying on an existing program for the proposition that it will lower battery prices in the future." AFPM also stated that "EPA is simultaneously ignoring that the increase in demand for batteries will raise their price."

---

[439] Wood Mackenzie, "Electric Vehicle & Battery Supply Chain Short-term outlook November 2023", December 1, 2023 (filename: evbsc-short-term-outlook-november-2023_final.pdf). Available to subscribers.

Response:

EPA disagrees. While the IRC 30D provisions can be understood as a form of the previous purchase incentive under 30D and is more limited in some ways, we do not apply the 30D incentive as a reduction in battery manufacturing cost. Moreover, the IRA included entirely new credits such as for example the 45X production tax credit which previously was not available to battery manufacturers. With regard to the effect of demand on battery prices, mineral costs are a major part of battery cost and we have included analyst mineral price forecasts, which would include the effect of anticipated demand, in our updated battery costs.

Summary:

Some commenters referred to: the status of battery raw materials as specialty chemicals (AFPM), the potential need for battery replacement (several commenters), and our application of IRA tax credits in OMEGA (several commenters), including comments that it implied negative battery costs.

Response:

EPA appreciates AFPM's observations regarding battery raw materials being considered in the market as specialty chemicals. In referencing the forecasts of respected analyst firms whose forecasts often are widely used by industry actors, for example to negotiate contracts and assess market conditions and outlook, we expect that the commenter's observations on specialty chemical status and volatility of pricing are duly reflected in these forecast products. EPA also appreciates that several commenters on battery cost mentioned the potential need for battery replacement, and/or our application of IRA credits to battery and PEV costs, including the amount of the credits and their accounting in OMEGA as passing to the manufacturer or consumer. We address comments on battery replacement in RTC Section 12.2.5 and on our application of IRA credits in RTC Section 12.4.

Summary:

The Alliance stated that they were unable to examine cell-level costs from our analysis, and recommended that "EPA clearly present its EV sales-weighted $/kWh values in pack-level and cell-level estimates for all model years 2022-2032 to transparently allow comparisons between EPA's projections and the applicable research literature and industry estimates."

Response:

The BatPaC spreadsheets that EPA used to develop cell cost equations for the proposal analysis were included in the public docket and an examination of these files would reveal all of the calculations made by the BatPaC model, including cell costs for the battery configurations that were generated in deriving the equations. That said, EPA disagrees that disclosure of cell costs in addition to pack costs is necessary in order to compare sources. For a given study, the choice of whether to study costs in terms of pack cost or cell cost depends on the context and aims of the study, and as a result, many studies choose only one or the other. The EPA analysis requires cost to be expressed in pack cost, because the unit of interest for costing electrified vehicles is packs, not cells. For this reason, the ANL battery cost equations are expressed in terms of pack cost. Also, the relationship between pack cost and cell cost would vary depending on the size of the battery, making it impractical to maintain a distinction between cell cost and pack cost throughout the analysis.

Summary:

Some commenters stated that the default costs provided in BatPaC for electrode powders and other constituents were not transparent or documented.

Response:

BatPaC is developed by Argonne National Laboratory which develops the default costs based on pricing research and expert views on the costs typically paid for these materials at the present time. These costs are part of the BatPaC product and are clearly visible for inspection and are editable in the model. Our updated battery costs are derived from work by ANL that similarly used BatPaC but provided BatPaC with costs for electrode powders based on mineral price forecasts from Benchmark Minerals Intelligence for each year from 2023 through 2035. As the values used are in fact visible in the model, they are self-evident and can be readily compared with values that the user considers appropriate. The ANL report includes a full accounting of the prices used for precursors, anode active material and cathode active material in the battery cost study.[440]

Summary:

API notes that raw material costs represent 63 percent of battery costs, and recommends following "the economics of raw materials rather than capital depreciation and learning models for purposes of accuracy," further suggesting that "perhaps following the economics of oil production would be more representative of modeling the costs […]", also noting that "over the last 40 years the global supply of oil has increased by ~50% [while] the price increased by ~200%."

Response:

EPA disagrees that the economics of oil production is a proper analogy to the economics of battery minerals. The bulk of oil production is used as fuel and is consumed entirely by its users in proportion to distance traveled over time, while use of battery minerals is fixed for the lifetime of a given vehicle and to a large degree can be recovered for recycling, reducing the amount of new material that must be produced. Although EPA agrees with commenter that mining activities in general seek to first use "the lowest cost-to-produce sources," EPA notes that many factors such as this are well understood in the mining industry, and in the updated analysis our estimates of future battery costs incorporate mineral price forecasts from a leading analyst firm. Such forecasts are based on expert knowledge of the mining industry and consider a wide range of factors that are commonly expected to drive mineral prices in the future. Further, over time, spent batteries will comprise an additional source of minerals through recycling. For more discussion of the difference between energy security and mineral security, see RTC Section 21 (Energy Security) and RTC Section 15 (which includes responses related to mineral security). For more discussion of battery recycling, see RTC Section 15.2.

Summary:

JLR stated that their forecast for battery cost reduction is considerably lower than EPA's forecast for the industry.

[440] Argonne National Laboratory, "Cost Analysis and Projections for U.S.-Manufactured Automotive Lithium-Ion Batteries," Report ANL/CSE-24/1, January 2024 (Appendix A7).

Response:

EPA anticipates that specific automakers may experience differing battery costs over the time frame of the rule, due to differences in factors such as level of previous or planned investment, size of the business operation, or the terms of negotiated supplier agreements and partnerships, among many others. Battery cost inputs to OMEGA are intended to represent an average cost across the industry and are not differentiated by specific manufacturer.

Summary:

With regard to HEV batteries, John Graham stated that HEV battery costs should be given more attention, should be estimated separately from PEV batteries, and that the learning factors EPA used for HEV batteries were too small.

Response:

EPA agrees that HEV battery costs should be estimated separately from PEV battery costs, and did so in the proposal analysis. Our updated battery costs include updated cost equations developed by ANL specifically for HEV batteries and continue to be separate from those used for PEV battery costs. The learning factors implied by the HEV cost equation in the updated analysis result from ANL experts' expectations regarding chemistry, manufacturing and design improvements for these batteries.

Summary:

Mitsubishi Motors recommended that EPA determine a "realistic maximum volume of EVs the market can support for each of the model years covered by the rule," by considering a thorough and realistic year-by-year assessment of projected battery costs and projected supply of battery critical minerals.

Response:

In the proposal and in the current analysis, EPA imposed a constraint on GWh of battery production available to the U.S. automotive market each year for modeling purposes. See also the response to comments on critical minerals and supply chain issues in RTC Section 15.

Summary:

Some commenters stated that the battery durability and warranty requirements would increase battery cost and this should be accounted for.

Response:

See RTC Section 16 where we respond to comments on battery durability and warranty.

Summary:

POET LLC commented that the battery production capacity that would support the cost reductions EPA attributed to the 45X production tax credit has yet to be built.

Response:

For general discussion of supply chain and battery manufacturing capacity, see RTC Section 15. For discussion of our application of the 45X tax credits, see RTC Section 12.4, Modeling of IRA.

Summary:

The Alliance commented that the cost of electricity to manufacture batteries did not account for the potential for electricity rates to become more expensive as renewable generation is added, and cited rates in Germany and California as evidence.

Response:

To the extent that electricity is part of the cost of manufacturing batteries, the BatPaC model accounts for plant utility cost as part of variable overhead. Regarding the idea that renewable generation will increase this cost, EPA disagrees with this assertion. Electricity rates are a result of many factors including national, regional, and state policies and conditions, regional costs of feedstocks, and many other economic and policy factors, all of which must be taken into account when considering the basis for observed electricity rates. The cost of renewable energy capacity is declining faster than other sources and its levelized cost is already highly competitive with or significantly less costly than other sources of new generating capacity,[441] and despite recent increases in commodity costs, renewable energy capacity continues to grow faster than other sources.[442] While integration of renewables with the grid is a consideration that could affect electricity costs at high levels of renewables, EPA does not expect that this rule will specifically drive higher levels of renewables on the grid than utilities are already planning to implement to serve general electricity demand, and as noted previously, the grid is generally expected to be capable of serving near term electricity needs for an increase in PEVs.[443,444]. EPA disagrees that modeling today's rates observed in just one foreign country (Germany) and just one state (California) would be a valid way of identifying the potential future change in electricity costs due to large increases in renewable energy, or to support or quantify such a relationship. In the updated analysis, EPA has carefully analyzed the impact of higher penetrations of PEVs on the electricity grid including the impact on generation and electricity prices. See preamble Section IV.C.2 and RIA Chapter 5. We further respond to comments about the grid in RTC Section 18.

Summary:

The Alliance commented that EPA should "consider costs and specifications that are reasonable for the industry as a whole to inform policy analysis, and not to assume that intellectual property and proprietary production processes that have been the result of billions of dollars of research and development paid by one manufacturer will be readily available to all manufacturers."

Response:

EPA cost inputs to OMEGA are intended to represent reasonable costs for the industry as a whole and are applied in aggregate across the fleet as a whole and not to any specific individual manufacturer. EPA recognizes that different manufacturers may experience different costs resulting from differences in their past research and investments and differences in their

[444] CNBC, "'We could handle it right now' - AEP chief says U.S. power grid can sustain influx of EVs," November 12, 2021. Accessed on December 2, 2021 at https://www.cnbc.com/2021/11/12/we-could-handle-it-right-now-aep-chief-says-us-power-grid-can-sustain-influx-of-evs.html

approach to sourcing components, among other differences. Manufacturers have largely approached the sourcing of batteries through joint ventures or contractual relationships with established cell manufacturers rather than true vertical integration.[445] For example, while Tesla has developed intellectual property relating to pack and cell design and production, their production occurs via a joint venture with Panasonic, and also includes sourcing from other suppliers that are not part of this venture. Other manufacturers are increasingly adopting a similar approach in which new manufacturing plants are constructed as part of a joint venture, by which the OEM may secure a supply of batteries for its products.[446,447,448,449,450] EPA's experience with other technologies has shown that the existence of intellectual property belonging to one manufacturer seldom prevents other manufacturers from developing and benefiting from similarly effective technologies. The battery costs that EPA has used in the compliance analysis are not taken solely from the example of any specific manufacturer but are developed based on an assessment of the industry as a whole. EPA notes that the battery costs used in the updated compliance analysis are in fact higher than projections by BNEF, a widely referenced source on projected battery costs, and are also higher than the costs commonly reported by Tesla, the OEM that currently has the highest rate of battery production.

Summary:

"Environmental and Public Health Organizations" recommended that we consider the cost of lithium iron phosphate batteries as being lower than NMC.

Response:

We have included LFP cost based on a percentage penetration of LFP. See Section IV.C.2 of the Preamble and Chapter 2 of the RIA.

Summary:

Several commenters cite the possibility of new battery chemistries including solid state and sodium ion chemistries in advocating for lower battery cost assumptions. Some of the same commenters also advocate for improved specific energy figures to be used in an updated analysis, higher than the 180 Wh/kg that was used previously.

Response:

In developing battery cost projections for 2023 through 2035, ANL also developed year-by-year pack-level specific energy projections generated by the same BatPaC model that was used

[445] Argonne National Laboratory, "Quantification of Commercially Planned Battery Component Supply in North America through 2035," ANL-24/14, March 2024. (see Figure 14 therein, titled "Modeled lithium-ion cell production capacity in North America from 2018 to 2035 by plant ownership").

to develop the costs, and we are using these values in the analysis. EPA notes that many of the higher specific energy values cited by the commenters are likely to represent cell-level specific energy and not pack-level. Regarding new battery chemistries, EPA agrees that there is potential for these new chemistries to result in even lower battery prices in the future than we project, but due to the nascent stage of development and the lack of high-production examples we are unable to quantitatively assign costs to these technologies. We do agree however that the possibilities offered by these chemistries are widely acknowledged in the industry as a potential route to lower battery costs and we agree that they at least qualitatively support the possibility of battery costs being lower in the long term than currently represented in the analysis. They also represent another factor in considering the possibility that our battery costs estimates are conservative, that is, more likely to overestimate future costs than underestimate them.

Summary:

ICCT cites their own study of BEV vehicle costs and numerous assumptions for specific cost elements that result in these lower vehicle costs. ICCT also states that EPA's battery costs in the proposal are significantly higher than those seen in third party analyses.

Response:

EPA appreciates the ICCT analysis, and also notes that we have made many adjustments to cost inputs that would affect BEV vehicle costs relative to ICE vehicle costs, and updates are reflected in the results of the updated analysis. Despite the alternative costs suggested by ICCT, EPA considers the sources we are using in the updated analysis to be the best possible information, being based on the FEV teardowns as well as recent FEV work estimating costs and cost relationships for the wide variety of component and vehicle types that we must consider in the analysis, and being in a format that is compatible and consistent with the needs of the OMEGA model and transparency of inputs to the public. Regarding the statement that EPA's battery costs in the proposal were much higher than the third party projections cited by ICCT, EPA notes we interpret the third party projections as representing a direct manufacturing cost that is not marked up by an RPE factor of 1.5, while the EPA costs that ICCT cites include this RPE factor. Despite the fact that the BatPaC model does in fact include some cost terms that appear to represent overhead cost, these are assessed in the context of the supplier that produces the battery, and not in the context of the OEM that purchases the battery. In analyses of this type it is customary to develop total costs to the OEM by beginning with a direct manufacturing cost, or a price that an OEM pays a supplier for a part, and marking it up by an RPE factor (in our case, 1.5) that represents specifically the OEM's overhead in specifying the part, integrating it into the design, and managing its role in the product afterward (part inventorying, modifications, etc). Any part, including a simple part like a nut or bolt, or a large part like a battery, incurs this added cost in our analysis, and is customary accounting practice to account for the myriad overhead costs that a large OEM incurs, ranging from ongoing research and development to customer support, advertising, upkeep, recalls, and so on.

Summary:

The Strong PHEV Coalition recommended that we model longer-range PHEVs with BEV batteries.

Response:

The ANL battery cost equations were developed with consideration of higher power-to-energy ratios at the lower end of their kWh capacity range, making those battery sizes applicable to either BEVs or PHEVs. In the updated analysis, only longer-range PHEVs[451] are placed into the fleet, and their battery costs are derived from the same equations as BEVs.

In response to comments relating to IRA incentives being passed on to the consumer, or views relating to a hypothetical withdrawal of IRA incentives, see RTC Section 12.4 where we respond to comments on IRA incentives.

Summary:

Various commenters alluded to the outlook for price parity or cost parity between BEVs and ICE vehicles.

Response:

See our response to cost/price parity issues in RTC Section 12.2.7.

12.2.2 - Battery cost sensitivities

Comments by Organizations

Organization: Alliance for Automotive Innovation

Based on this analysis into the underlying research literature, for the final rule's central analysis, we recommend that EPA increase its reference direct manufacturing battery pack cost per kilowat-hour for 2022 and 2023 to be approximately $153 per kilowat-hour. Further, we recommend that EPA adjust its central case battery projection through 2032 to match the midpoint of the Mauler et al (2022) analysis (i.e., $90/kWh cell-level, approximately equal to $113/kWh at a pack-level in 2030). To better reflect these key inputs, we also recommend that the final rule's low battery case sensitivity analysis go no lower than the "Lowest" value in Mauler et al 2022 (i.e., $77/kWh cell-level, approximately equal to $96/kWh at a pack-level in 2030). This adjustment better matches the U.S.-specific battery characteristics as seen by U.S. automakers and tailored for the U.S. market, better reflects the actual underlying data that EPA references for battery costs, and incorporates research that was not cited in EPA's NPRM and DRIA. [EPA-HQ-OAR-2022-0829-0701, pp. 52-53]

4. Insufficient Sensitivity Analysis of Battery Prices

Auto Innovators appreciates the agency's decision to include a sensitivity analysis of battery prices in the Drati RIA. In addition to the base-case analysis, the agency includes two sensitivity analyses: one where battery prices fall 15% relative to the base case, and the other where battery prices increase 25% relative to the base case. The downward sensitivity case is not very informative because the agency is already showing, under the base-case scenario, that massive

[451] EPA assumed that manufacturers would design PHEVs that would provide enough range to qualify as ZEVs under the ACC II and ACT programs being administered by California and participating Section 177 states. In OMEGA, EPA assumed that light-duty vehicle PHEV batteries would be sized for 40 miles of all-electric range over the US06 cycle, while medium-duty PHEVs would be sized to drive 75 miles over the UDDS while tested at ALVW.

deployment of BEVs has benefits that justify the costs. The more interesting question is how the findings of the DRIA might change if the agency's optimism about future battery prices proves to be incorrect. The Alliance and its members certainly hope that the agency's optimism proves to be warranted, but an objective regulatory impact analysis should seriously consider a pessimistic scenario on battery prices. [EPA-HQ-OAR-2022-0829-0701, pp. 61-62]

What is the basis for the agency's use of a 25% increase in battery prices for a less optimistic position on the future course of battery prices? Little rationale is given except the preamble states that it "bound(s) what EPA considered to be a reasonable envelope for future nominal battery pack cost per kWh, as informed by the full range of forecasts in the literature (see the discussion of battery cost forecasts we considered in Preamble Section IV.C.2 and DRIA Chapter 2.5.2.1.3."112 We have examined with care preamble section IV.C.2; we found no justification for using +25% as the upper sensitivity case on battery prices. We also examined DRIA Chapter 2.5.2.1.3; again, we found no rationale for using +25% as the upper sensitivity case. [EPA-HQ-OAR-2022-0829-0701, pp. 61-62]

112 NPRM at 29335.

Auto Innovators is concerned that the +25% sensitivity case may not be large enough to reveal whether there are sensitivities in the agency's results to a plausible change in a key forecasting assumption. We are concerned for two different reasons. [EPA-HQ-OAR-2022-0829-0701, pp. 62-63]

First, the +25% is applied to an annual series of cost figures that begins in 2022 and extends to 2050. No cost reductions are assumed through 2025 but a 25% decline in battery prices is assumed through 2029. Even if one assumes that EPA starts the series correctly, the +25% upper sensitivity case simply removes the 25% cost reduction that EPA assumed from 2026 to 2029. The same point applies qualitatively to the cost reductions from 2029 to 2050 – they accumulate to such a large magnitude that the +25% sensitivity case does not amount to much of a net change in battery prices. The +25% battery-price sensitivity scenario simply slows the pace of a decline in battery prices from 2022 to 2050 rather than halt the decline or presume an unexpected increase in battery prices over the time horizon of the rulemaking. Auto Innovators is particularly concerned about the years of the applicable CO2 standards (2027-2032) because that happens to be the period when global raw materials are expected to be most out of balance. [EPA-HQ-OAR-2022-0829-0701, pp. 62-63]

Second, it appears that the agency expresses the future battery prices in nominal dollars when they should be expressed in real dollars. When they are expressed in nominal dollars, the purchasing power adjustments for future years diminish their impacts in the sensitivity analysis. [EPA-HQ-OAR-2022-0829-0701, pp. 62-63]

Auto Innovators suggests that the upper sensitivity case on battery prices should represent a more severe, unexpected series: one where the series starts higher than the agency thinks is appropriate and increases slowly yet steadily throughout the time horizon of the rulemaking, at least through 2032. The price growth would represent the reality that China, Europe, and the U.S. will be bidding up the prices of key raw materials over the next decade, before a substantial impact from recycling can occur. Auto manufacturers will also be under increasing pressure to choose higher-cost battery suppliers with excellent ESG profiles and facility locations in North America. It is quite possible that those factors will overwhelm the future economies in battery production and innovations in battery design that appear to be dominating EPA's thinking on this issue. [EPA-HQ-OAR-2022-0829-0701, pp. 62-63]

…

Relatedly, we also recommend that the EPA show a full cost-benefit analysis for each of its sensitivity cases, including for high and low battery cost cases, and also for varying assumptions on IRA tax credit eligibility, phase-out, or elimination. [EPA-HQ-OAR-2022-0829-0701, p. 67]

Organization: American Fuel & Petrochemical Manufacturers

Moreover, although the incremental vehicle manufacturing cost in EPA's High Battery Cost sensitivity is higher (Table 13-140 of the DRIA provides an average increase of $1,547 by 2032 for medium duty vehicles) than the Proposed Rule, EPA does not quantify how much of the increase in incremental cost is due to battery raw material prices. Finally, as part of its ZEV cost assessment EPA relies on data as old as 2017 but does not appear to account for the inflation of cost components in recent years. EPA should make it clear how it is accounting for not just typical inflation to normalize dollars in a similar year, but also the significant changes in supply chains in recent years that have led to significantly higher costs for ZEV parts and materials compared to older data points that EPA references. [EPA-HQ-OAR-2022-0829-0733, pp. 52-53]

Organization: John Graham

The sensitivity analysis of higher battery prices needs to consider scenarios worse than +25% relative to the agency's central cost path, since the central cost path assumes future learning factors that are far larger (cumulatively) than 25%. The sensitivity analysis on battery prices needs to take a more pessimistic view than +25% above the agency's optimistic view.

In a sensitivity analysis, EPA looks at how the results of its modeling might change if battery prices are +25% (or -15%) compared to base case assumptions. However, the +25% is so small compared to the learning factors and the importance of material supply issues that it is too small to reveal any sensitivities that might be there. We suggest that EPA also examine a sensitivity case where battery prices remain at $120/kWh -- or even increase steadily -- until 2035 before falling gradually until 2050. [EPA-HQ-OAR-2022-0829-0585, pp. 17-18]

Organization: POET, LLC

While federal tax credits may lower the ultimate cost of battery production, there is no reason to assume that battery manufacturers will pass these cost savings through by lower battery prices, particularly given the projected worldwide demand for batteries. It is unclear that these credits will continue to be in place over the period from 2027 through 2032 as they could easily be eliminated or modified by future legislation. Therefore, U.S. EPA should perform a sensitivity analysis that shows how dependent the high levels of BEV penetration forecast would be impacted by the elimination of these tax credits. [EPA-HQ-OAR-2022-0829-0609, pp. 57-58]

It should be noted that U.S. EPA purports to perform a "sensitivity analysis" of BEV penetration rates under the Proposed Rule to battery costs, the results of which are presented in Chapter 13 of the DRIA. The results relevant to the proposed standards for the combined light-duty fleet (passenger cars and trucks) are shown in DRIA Tables 13-49, 13-73, 13-102, 13,-103, 13-106, and 13-107. There are two cases considered one labeled “low battery costs” and the other “high battery costs”. Under the low cost case, MY 2032 incremental vehicle costs drop from $1,164 to $490 and BEV penetration increases from 67 to 68%. Under the high cost case, MY” 2032 incremental costs increase from $1,164 to $1,632, and BEV penetration drops from 67% to 65%. Given these results, the apparent conclusion is that differences battery cost relative to those assumed by U.S. EPA for the proposed standards will have virtually no impact on BEV penetration or automakers ability to comply. [EPA-HQ-OAR-2022-0829-0609, p. 58]

However, as discussed above, U.S. EPA’s battery cost estimates range from the current $120 per kWh to as low $40 per kWh following the application of learning effects and federal tax credits. Assuming as U.S. EPA does, that a 100 kWh battery pack size will be common, it follows that the range of battery costs would be on the order of $12,000 to $4,000 with the difference from high to low being $8,000 rather than the $1,142 used by U.S. EPA in the battery cost sensitivity analysis. Clearly, use of a much larger cost differential in the sensitivity analysis will lead to much greater impacts on estimated BEV penetration rates and the potential ability of automakers to comply with the Proposed Rule. [EPA-HQ-OAR-2022-0829-0609, p. 58]

EPA Summary and Response

Summary:

We received several comments regarding the sensitivity bounds for battery costs. General themes were that the selection of 25 percent for the upper bound lacked apparent rationale and/or was insufficiently high. With regard to the upper bound, the Alliance and John Graham suggested that we should consider holding prices steady or increase them, to (in the words of the Alliance) “represent the reality that China, Europe, and the U.S. will be bidding up the prices of key raw materials over the next decade, before a substantial impact from recycling can occur.” The Alliance also commented that the lower bound of 15% was not informative, and recommended that “the final rule’s low battery case sensitivity analysis go no lower than the lowest value in Mauler et al 2022 (i.e., $77/kWh cell-level, approximately equal to $96/kWh at a pack-level in 2030.” Some commenters expressed the position that a fixed percentage sensitivity simply slows the pace of battery price decline and implied that instead it should halt the decline or even increase battery prices. Another commenter stated that EPA “needs to consider scenarios worse than +25% […] since the central cost path assumes future learning factors that are far larger (cumulatively) than 25%.”

Response:

EPA continues to assess that a fixed percentage above and below the central case can be an appropriate way to establish upper and lower bounds for a sensitivity, if the resulting band can be shown to adequately cover a range of reasonably plausible outcomes for future battery costs. For the updated analysis, we examined the appropriateness of this range, particularly in light of the updated, higher central case battery costs. We also examined the Mauler et al. paper and compared the range of scenarios expressed there to the new band of costs that would be defined by 25 percent above and 15 percent below the new central case costs. Please refer to Preamble IV.C.2 for a description of how we justified our sensitivity bands in the updated analysis. It shows that retaining the 25 and 15 percent sensitivities around the new central case costs establishes a band that largely includes the Mauler scenarios, including the highest Mauler scenario, in which costs do not decline at all, out to 2029-2030. Past 2030, we exclude the highest Mauler scenario, as such a scenario of perpetually elevated cost is not consistent with current outlooks for mineral cost or battery cost as EPA previously noted under our responses in Section 12.2.1. Therefore we have generally retained the 25 percent higher and 15 percent lower sensitivities in the updated analysis as it is now largely inclusive of commenters' concerns.

Regarding statements that the high sensitivity should assume constant or rising costs, EPA notes that there is little support for such a scenario among analyst firms. In addition, and as noted in our response to similar comments in section 12.2.1, in the time since these comments were submitted mineral prices have largely continued a downward trend, and the most recent analyst forecasts of mineral prices out to at least 2029 do not support the prospect of battery prices that never decline or actually increase. Regarding the statement that global demand will lead to bidding up of prices, this is to be expected in any market that experiences increased demand, and this outcome also leads to development of new production to serve that demand, and therefore does not necessarily lead to commenter's conclusion that it will prevent prices from falling or cause them to increase.

Regarding John Graham's suggestion that EPA "needs to consider scenarios worse than +25% […] since the central cost path assumes future learning factors that are far larger (cumulatively) than 25%," EPA sees no reason to assume that a percentage of cumulative learning should dictate the bounds of a sensitivity band. Rather, as stated above, the more relevant factor is the ability of the band to capture a range of reasonably plausible outcomes.

<u>Summary:</u>

The Alliance commented that "it appears that the agency expresses the future battery prices in nominal dollars when they should be expressed in real dollars. When they are expressed in nominal dollars, the purchasing power adjustments for future years diminish their impacts in the sensitivity analysis."

<u>Response:</u>

The final analysis is done entirely in 2022 dollars so that costs and benefits can be presented on an equal and consistent basis and in present valuations.

<u>Summary:</u>

The Alliance recommended that we should show a full cost-benefit analysis for each of our sensitivity cases.

<u>Response:</u>

Comments related to sensitivities and their role in the analysis are discussed in section 12.5.4.

EPA notes that, consistent with CAA section 202, in evaluating potential standards we carefully weighed the statutory factors, including the emissions impacts of the standards, and the feasibility of the standards (including cost of compliance in light of available lead time). We monetize benefits of the standards and evaluate other costs in part to enable a comparison of costs and benefits pursuant to E.O. 12866, but we recognize there are benefits that we are currently unable to fully quantify. EPA's practice has been to set standards to achieve improved air quality consistent with CAA section 202, and not to rely on cost-benefit calculations, with their uncertainties and limitations, as identifying the appropriate standards. Nonetheless, our conclusion that the estimated benefits exceed the estimated costs of the final program reinforces our view that the standards are appropriate under section 202(a). More specifically, for this rule our assessment that the rule has positive net monetized benefits, regardless of the magnitude of those positive net benefits, supports our view that the final standards represent an appropriate weighing of the statutory factors and other relevant considerations. Given the very limited role that the benefit-cost analysis for this rule played in decision-making for the standards, EPA deemed a benefit-cost analysis of every sensitivity unnecessary. See RTC 8 for further discussion.

Summary:

POET LLC recommended that we perform a sensitivity analysis that includes elimination of the IRA tax credits, going on to say that "the range of battery costs would be on the order of $12,000 to $4,000 with the difference from high to low being $8,000 rather than the $1,142 used by U.S. EPA in the battery cost sensitivity analysis."

Response:

While we agree with POET's statement that "use of a much larger cost differential in the sensitivity analysis will lead to much greater impacts on estimated BEV penetration rates," we do not agree that this necessarily implies that every such scenario must be analyzed regardless of its reality, relevance, or likelihood. In the case of the suggested scenario, in conducting technical analyses EPA has continued its past practice of considering the effect of laws and regulatory programs that are a matter of law at the time of the rulemaking, rather than presuming finalization of pending rules or laws, or conversely, speculating on potential changes to rules or laws that are in force at the time. At the time of this rulemaking, the assumptions in our analysis are based on the Inflation Reduction Act provisions which are currently in effect and EPA does not see a basis for speculating on potential future changes to the IRA.

12.2.3 – Non-battery costs

Comments by Organizations

Organization: Alliance for Automotive Innovation

H. Electric Motor Cost

EPA assumes a steady decline in the cost of producing electric motors ("non-battery" costs) from now until 2032. This assumption is not consistent with current trends in the industry, as the average price of electric motors for BEVs rose significantly in both 2021 and 2022. The factors that are driving the costs of electric motors are different from the factors that are driving the costs of lithium-ion batteries. [EPA-HQ-OAR-2022-0829-0701, pp. 69-70]

One of the complicated factors that the agency needs to analyze is the current and projected global shortage (2027-2030) of electrical steel. This type of steel is comprised of ultra-thin sheets that transfer electricity into mechanical power. For use in an EV's electric motor, a higher-grade electrical steel is required that entails stamping and stacking steel into precise shapes that may be less than a millimeter thick. The U.S. has very limited production capability for electrical steel and has imposed tariffis on the supplies from South Korea, Japan and China. The cost-reduction factors that the agency is using for electric motors need to be modified, as they ignore the current and likely costs of electric motors. [EPA-HQ-OAR-2022-0829-0701, pp. 69-70]

Sources: [EPA-HQ-OAR-2022-0829-0701, pp. 69-70]

2. Daniel Sims. Electrical Steel Supply and Demand Could Impact EV Prices Later This Decade. Techspot.com. March 28, 2023. [EPA-HQ-OAR-2022-0829-0701, pp. 69-70]

Moreover, the industry has generally moved away from induction motors to permanent magnet synchronous motors, even though they are more costly (50-75%). While the induction motors have no need for rare earth magnets, they are harder to cool at sustained high loads and are inherently less efficient at low speeds. Thus, permanent magnet synchronous motors, due to their efficiency gain, are important for reducing the overall costs of the powertrain. [EPA-HQ-OAR-2022-0829-0701, pp. 70-71]

R&D efforts are looking into new alternatives that can reduce or eliminate the use of rare earths while maintaining the effciency advantages of permanent magnet synchronous motors. Some alternatives require expanded use of liners that depend on the ultra-thin electrical steel, but the cost premium for electrical steel is signiffcant and global shortages are projected in the 2027-2030 timeframe. It is possible that some innovations in motor design will penetrate luxury/premium models prior to 2032, but most of the 2032 light-duty fleet is likely to retain use of rare earth magnets. [EPA-HQ-OAR-2022-0829-0701, pp. 70-71]

Suppliers are also under pressure to design more efficient electric motors. Gallium nitride semiconductors can enable more efficiency. How would larger amounts of gallium be obtained? It is not found by itself in nature but is present in small amounts in bauxite. Thus, it is presently obtained primarily from mining and mineral processing of bauxite ore (as part of aluminum production). For scaling up to the auto-sector quantities, improved methods would be needed to extract and separate the gallium from oxide ore, as only a small percentage of the gallium in ore is now economically recoverable. The amounts of energy and other inputs used in producing gallium nitride also need to be assessed in lifecycle analysis. The United States currently has no capacity to produce gallium nitride. Most is produced in China for use by Asian firms. [EPA-HQ-OAR-2022-0829-0701, pp. 70-71]

The gallium nitride example illustrates that it is too simplistic to assume that the price of electric motors will plummet over the next 20 years. Electric motors are likely to become more expensive to meet the unique needs of EV consumers before they become less expensive in the long run. [EPA-HQ-OAR-2022-0829-0701, pp. 70-71]

Organization: Environmental. and Public Health Organizations

D. EPA should revise its non-battery BEV powertrain costs.

EPA should use the most recent data available to estimate non-battery BEV powertrain costs. The choice of electric motor cost equation used in the OMEGA modeling does not reflect the most recent data and will overestimate the cost of the BEV powertrain, especially in vehicles with higher-power electric motors. In the 2023 draft report "Cost Modeling for BEV Powertrain" by FEV Consulting, Inc., the cost for both induction and permanent magnet electric motors is estimated to have both a fixed cost and a power-dependent variable cost.134 In contrast, the cost assumptions used in OMEGA for motors have no fixed costs and only have a power-dependent variable cost.135 The effect of this choice is that OMEGA will overestimate the motor (and powertrain) costs relative to the most recent FEV Consulting analysis for BEVs as the power of the motors increases. This overestimation of costs will likely create the largest penalty for electric-drive pickups and SUVs, which will require higher-power electric motors in the modeling. Additionally, the FEV Consulting analysis differentiates the cost of gearboxes, wiring harnesses, and coolant circuits for sedans, SUVs, and pickups, which is not reflected in the OMEGA modeling. EPA should revise these costs in its modeling for the final rule, which would more accurately show the feasibility of strong standards. [EPA-HQ-OAR-2022-0829-0759, p. 52]

134 FEV Consulting, Cost Modeling for BEV Powertrain (prepared for U.S. EPA) (Apr. 10, 2023), available at https://www.regulations.gov/document/EPA-HQ-OAR-2022-0829-0384 (as Attachment 1).

135 DRIA at 2-74, Tbl. 2-39.

E. EPA should revisit the teardown study it relied on for the proposed rule.

EPA must also ensure that teardown studies it relies on for its final rulemaking are accurate and defensible. While the use of teardown studies is appropriate to generate combustion vehicle and BEV manufacturing cost estimates, it is important that the comparison vehicles chosen are similar and that any performance differences are quantified. The report "Cost and Technology Evaluation, Conventional & Electrical Powertrain Vehicles, Same Vehicle Class and OEM" by FEV Consulting, Inc. prepared for EPA, presents a detailed comparison between combustion and battery-electric vehicles of similar size made by the same manufacturer.136 While these vehicles have many similarities, there are major performance differences that were not quantified or assigned a cost. The largest variance in performance is in the power, torque, and resulting acceleration performance. The combustion model (VW Tiguan) has a 0-60 mph time of 9.7 seconds, while the more powerful BEV model (VW ID.4) accelerates to 60 mph in 5.4 seconds. If the BEV was designed to have similar performance as the combustion model, there would be downscaling of motor and power electronics, resulting in lower BEV powertrain costs. The teardown analysis should be revised to estimate the cost reductions associated with components that have similar performance as the combustion vehicle model. Similarly, the BEV model chosen has higher towing capacity than the combustion vehicle model, which results in higher costs (e.g., from heavier bumpers). EPA should consider the value of the increased towing performance or adjust the costs of the BEV model to estimate the cost to build a vehicle with the same performance as the combustion vehicle model chosen. [EPA-HQ-OAR-2022-0829-0759, pp. 52-53]

136 FEV Consulting, Cost and Technology Evaluation, Conventional & Electrical Powertrain Vehicles, Same Vehicle Class and OEM (prepared for U.S. EPA) (Feb. 24, 2023), available at https://www.regulations.gov/document/EPA-HQ-OAR-2022-0829-0402 (as Attachment 3).

Organization: International Council on Clean Transportation (ICCT)

EPA’s OMEGA model also includes an analysis of light-duty electric vehicle costs. ICCT examined the BEV cost data from EPA’s OMEGA output files and compared the overall costs and the costs of various battery and vehicle components and technical specifications with those applied in the 2022 ICCT U.S. EV cost study for industry-average 300-mile range BEVs. Specifically, we compared the component-level costs and specifications broadly categorized into powertrain direct, non-powertrain direct, and indirect costs; doing so allowed for the most appropriate and direct comparisons with the findings in the ICCT study. The Figure 8 flowchart below illustrates the BEV cost comparison approach based on EPA data from the OMEGA output file and the ICCT data. [EPA-HQ-OAR-2022-0829-0569, pp. 22-26]

SEE ORIGINAL COMMENT FOR Figure 8. Illustration of methodology for EPA vs. ICCT BEV-300 cost comparison [EPA-HQ-OAR-2022-0829-0569, pp. 22-26]

To calculate EPA's modeled total manufacturing cost – including all indirect costs using the 1.5 retail price equivalent (RPE) factor – the total costs of individual vehicle elements were summed. These individual vehicle elements are electrified driveline, e-machine, battery, driveline (conventional vehicle), engine, glider (non-structure), structure (i.e., chassis/frame). The first five cost elements are powertrain-specific. The last two are non-powertrain. Some vehicles, such as hybrids, have all five powertrain cost elements. All vehicles have both non-powertrain cost elements. [EPA-HQ-OAR-2022-0829-0569, pp. 22-26]

To determine the industry average total costs for each cost component, the individual vehicle model costs were averaged, weighted by model sales. Critically, BEV and ICE platforms are kept separate by only considering costs associated with designated ICE or BEV vehicles, as appropriate. For instance, in calculating the average ICE vehicle battery cost, only ICE vehicle models were considered in the average calculation. Once the average total costs by component are obtained, they are summed into powertrain and non-powertrain (described above), and then summed into full vehicle total costs. Lastly, the direct costs for each cost component and for the full vehicle can be calculated by dividing total costs by 1.5. [EPA-HQ-OAR-2022-0829-0569, pp. 22-26]

While the OMEGA model uses “total manufacturing costs” described above as an input to calculate final vehicle price, for the purpose of comparison with the ICCT 2022 EV cost analysis, these total costs represent the equivalent of “price” as defined and analyzed by ICCT (see the flowchart above). [EPA-HQ-OAR-2022-0829-0569, pp. 22-26]

Figure 9 illustrates the key findings from our comparison of the EPA and ICCT BEV cost analyses. The figure shows the upfront incremental BEV costs for cars, crossovers, SUVs, and pickup trucks relative to their combustion counterparts for a 300-mile range BEV. The top figure shows the incremental BEV costs in 2027 and the bottom figure shows the incremental BEV costs in 2032. The blue bars represent EPA's findings of BEV incremental costs and the orange bars represent the ICCT findings of incremental costs. As shown, ICCT finds that incremental BEV costs are much lower than estimates by EPA by about $2,300 (pickups) to about $5,300 (crossovers) in 2027. As battery and electric vehicle costs fall and technology improves, the incremental costs are reduced. For 2032, the EPA finds that BEVs have incremental costs of about $3,000 to $5,000; during this same timeframe, the ICCT study finds that BEVs will be cheaper to purchase than comparable gasoline vehicles, which is indicated by the negative incremental costs shown in the bottom figure. [EPA-HQ-OAR-2022-0829-0569, pp. 22-26]

SEE ORIGINAL COMMENT FOR Figure 9. Comparison of EPA and ICCT (2022) findings of incremental BEV costs compared to ICEV costs, for 2027 (top) and 2032 (bottom) [EPA-HQ-OAR-2022-0829-0569, pp. 22-26]

The differences in overall incremental cost findings can be explained by comparing the assessments of combustion and electric vehicle costs. For combustion vehicles, on average, the costs in the ICCT analysis are about $500 less than EPA for 2027, and about $1,500 more than EPA for 2032. This shift is for two reasons: 1) the ICCT study applies cost-effective fuel savings technology to combustion vehicle models that improve the new vehicle fleet by about 3.5% per year and increase powertrain direct costs by about 1% per year, and 2) the average combustion vehicle prices in the EPA analysis decline by about $1,400 from 2027 to 2032, along with their reduced efficiency and increase in per-mile emissions. For battery electric vehicles, the average BEV costs in the ICCT analysis are about $5,000 less than EPA for 2027 and about $7,000 than EPA for 2032. The ICCT analysis finds that BEV costs can be reduced faster than the EPA projections. We further assessed BEV costs by powertrain direct, non- powertrain direct, and indirect cost elements (Figure 8). [EPA-HQ-OAR-2022-0829-0569, pp. 22-26]

In addition to the powertrain battery costs, we found that the non-battery powertrain costs in the ICCT analysis are about $600 to $900 less than the EPA modeling in 2027, and that gap declines to about $400 to $600 less than EPA in 2032. In the ICCT analysis, non-battery costs scale with power and are based on several sources. Non-battery powertrain costs are assessed primarily based on a teardown analysis by UBS (2017) and the National Academies of Sciences Engineering and Medicine fuel economy technology assessment (NASEM, 2021).74 Virtually all electric vehicles equipped with AWD do so with additional motors, rather than electronic AWD or another AWD system used on combustion vehicles. By matching electric and combustion vehicle power, combined motor power for electric vehicles with multiple motors is the same as the power for single motor vehicles. With additional motors, costs for high voltage cables and motor cooling increase. It is unclear from literature whether motor costs include driveshaft, which would also increase with the number of motors. According to NASEM, future permanent magnet motor costs are expected to decline due to reduced magnetic material requirements. These future costs scale proportionally with motor power, suggesting that certain cost elements that increase with motor number are not included. Further investigation into the true costs of BEV AWD is beyond the scope of this paper. However, manufacturers may opt for induction motors as a second motor in AWD configurations. Absent permanent magnets, induction motors have the potential to decrease AWD costs further, even below the future permanent magnet motor costs shown in NASEM. [EPA-HQ-OAR-2022-0829-0569, pp. 29-31]

Retrieved from https://neo.ubs.com/shared/d1ZTxnvF2k/ and National Academies of Sciences, Engineering, and Medicine. (2021). Assessment of Technologies for Improving Light-Duty Vehicle Fuel Economy—2025-2035. Washington, DC: The National Academies Press. https://doi.org/10.17226/26092

Table 4 summarizes the findings of the underlying technical specifications for motor power in kilowatts for 300-mile range BEVs and combustion vehicles in 2027, 2030, and 2032 in the EPA and ICCT analyses. As shown, the BEV motor power assumed in the ICCT analysis is significantly less than what is applied by EPA. In the ICCT study, matching electric and combustion vehicle power means that the combined motor power for electric vehicles with multiple motors is the same as the power for single motor vehicles. From the table below, EPA applies BEV motor power that is much greater than comparable combustion vehicles. We compared EPA's assumed motor power on a model-by-model basis for BEVs and their combustion counterparts and found that on average BEV motor power is at least 38% (cars) to 45% (pickups) greater than the assumed motor power of the ICE variants. Because the non-battery powertrain costs in EPA's analysis directly scale with motor power, reducing the assumed BEV motor power (kW) in EPA's analysis to be similar to the motor power applied for combustion vehicles – based on evidence from the ICCT analysis – would reduce the BEV non-battery powertrain costs in EPA's analysis. [EPA-HQ-OAR-2022-0829-0569, pp. 29-31]

SEE ORIGINAL COMMENT FOR Table 4. Summary of fleet average motor power (kW) applied in EPA and ICCT (2022) [EPA-HQ-OAR-2022-0829-0569, pp. 29-31]

Organization: John Graham

Strong Hybrid Cost, Efficiency, and Market Share

Cost

There are two ways in which the hybrid costs in Table 2-36 and Figure 2-21 of the DRIA overstate hybrid costs. First, the proposed rule assumed the use of a 3.5 kW DC-DC converter, while 2021 NAS study assumed just a 1.1 kW converter is needed. Second, and more important, the HEV battery cost is too high. The 2021 NAS study estimated a 1.0 kWh battery plus BMU would cost $880, while the proposed rule cost is calculated to be $934 (without BMU? – unclear from discussion in DRIA). Further, FEV teardown cost analyses indicate that the DRIA cost estimates for HEV batteries are extremely outdated. FEV's teardown studies in 2012/2013 on a 2010 hybrid found HEV battery cost to be 982 Euros for a 1.0 kWh battery pack, similar to the DRIA estimates. However, FEV's teardown study in 2015 on a 2015 hybrid found a much lower cost of 610 Euros for a 1.1 kWh battery.4,5 [EPA-HQ-OAR-2022-0829-0585, p. 10]

4 FEV studies summarized in ICCT's comments to the NHTSA 2024-26 NPRM, Appendix A.2 pages 5-9. FEV, Inc., "2025 Passenger Car and Light Commercial Vehicle Powertrain Technology Analysis," Final Report, Project Number P33597, September 2015. https://theicct.org/sites/default/files/publications/PV-LCV-Powertrain- Tech-Analysis_FEV-ICCT_2015.pdf.

5 Page 2-48 of the DRIA states, "The BatPaC spreadsheet models used to develop the costs for BEVs, HEVs, and PHEVs are available in the Docket (US EPA 2023) and fully describe the BatPaC inputs that were used to generate the cloud of battery pack cost points that are visible in the plots." This is another example of the DRIA burying information in extreme detail and thereby making it inaccessible, thus we were not able to compare the PatPaC model inputs and results for hybrid batteries with the 2015 FEV teardown study.

Getting the HEV cost estimates right is important because they are an input to the OMEGA modeling, which is the source of the projection that HEVs will no longer be cost effective. [EPA-HQ-OAR-2022-0829-0585, p. 10]

Hybrid efficiency estimates in OMEGA are based upon outdated data. Worse, the agency's outdated estimates are assumed to continue through 2032 with no improvements. The bias here is obvious: innovation is assumed to improve BEVs from today through 2032; innovation is virtually ignored for hybrids, even though Toyota has already introduced revised, more powerful and more efficient, hybrid systems for 2023 and there are two more potential redesign cycles by 2032. [EPA-HQ-OAR-2022-0829-0585, p. 11]

Table 2-2 in the DRIA, page 2-18, states that the engine map for dedicated hybrid systems was calculated from a Toyota 2.5L TNGA prototype engine from the 2017 Vienna paper. This dedicated hybrid engine was first introduced in the 2015 Toyota Prius, although in a 1.8L engine. The use of the TNGA prototype engine is an improvement over the hybrid engine map used by NHTSA for the 2024-26 light-duty CAFÉ rule, which was based upon the 2010 Toyota Prius, but it still ignores that there will be three generations of hybrid improvements by 2032 (given the industry's typical schedule for redesigns). [EPA-HQ-OAR-2022-0829-0585, p. 11]

Efficiency improvements averaged about 10% for each previous generation of the Toyota Prius before 2015, in addition to large increases in engine and motor power for each generation.6 Toyota made even larger improvements to the 2015-2022 5th hybrid generation modeled by EPA, with CO2 emissions reduced by 19% on the Camry Hybrid LE relative to the previous generation, by 11% on the Camry Hybrid XLE/SE, and by 19% on the RAV4 Hybrid.7 [EPA-HQ-OAR-2022-0829-0585, p. 11]

6 German, J., Hybrid Vehicles Technology Development and Cost Reduction, ICCT Technical Brief No. 1, July 2015. https://theicct.org/sites/default/files/publications/ICCT_TechBriefNo1_Hybrids_July2015.pdf. Table 2 shows 36 mpg for 1st gen Prius (98-00), 41 mpg for 2nd gen (01-03), 46 for 3rd gen (04-10), and 50 for 4th gen (11-14), along with large increases in engine and motor power for each generation.

7 Summarized in ICCT's comments to NHTSA on the 2024-26 LD CAFÉ proposed rule. For additional information see Joint NGO 2020 Reconsideration Petition, pages 64-68.

Toyota has already brought out the first updated generation of hybrids beyond what was modelled for the proposed rule, starting with the 2023 Prius. The new Prius increased engine size from 1.8L to 2.0L, increased motor power from 71 to 111 hp, and increased combined power from 121 hp to 194 hp – a 60% increase. Acceleration from 0 to 60 as measured by Car and Driver dropped from 10.4 seconds to 7.1 seconds.8 Yet despite the bigger engine and huge performance gains, Toyota also managed to improve efficiency from 54/50/52 (city/highway/combined) for 2022 fwd Prius to 57/56/57 in 2023, or a 10% improvement.9 Part of this is due to improved aerodynamics, but even the city rating improved by 6%. This generational improvement in Prius efficiency is in line with previous efficiency improvements for each generation of the Prius but such innovation is not included in the agency's modeling. [EPA-HQ-OAR-2022-0829-0585, p. 11]

8 https://www.caranddriver.com/reviews/a42221299/2023-toyota-prius-by-the-numbers/.

9 Comparison from fueleconomy.gov calculation, retrieved at: https://www.fueleconomy.gov/feg/Find.do?action=sbs&id=44079&id=46359.

Despite this clear track record of steady HEV efficiency improvements, the proposed rule assumes no hybrid efficiency improvements from 2015 through 2032. From the baseline hybrid engine map for the 2015 Prius there has already been one complete redesign and there is time for two additional hybrid redesigns. The first redesign has already demonstrated major efficiency improvements that are not in the OMEGA model and historical trends show there is every reason to believe that large efficiency improvements will also be achieved in two more redesigns by 2032. The failure of OMEGA to update hybrid efficiency maps after the 2015 Prius means that hybrid efficiency projections in OMEGA will be massively outdated by 2032. [EPA-HQ-OAR-2022-0829-0585, pp. 11-12]

Getting the HEV's efficiency estimates right is important because fuel efficiency is the effectiveness metric in the OMEGA modeling. Incorrect inputs about HEV efficiency help explain why the OMEGA modeling shows BEVs to be more cost effective than HEVs. [EPA-HQ-OAR-2022-0829-0585, pp. 11-12]

Since batteries account for a larger share of BEV costs than non-battery costs, batteries are usually given the most attention by cost analysts. The non-battery components include electric motors, e-axles, inverters, and battery management systems. EPA makes non-battery components even less important by assuming their costs will decline (cumulatively) by 29% in 2030, 45% in 2035, and 54% in 2050. [EPA-HQ-OAR-2022-0829-0585, p. 18]

This assumption is not consistent with recent market trends. The average price of an electric motor for BEVs rose 26% in 2021 and rose slightly again in 2022. The prices of e-axles, inverters, and battery management systems have also been increasing significantly.22 [EPA-HQ-OAR-2022-0829-0585, p. 18]

22 John Irwin. Price Points: As EV Component Costs Rise, Stalling Push for Parity. Automotive News. November 7, 2022, 10-11.

One of the factors boosting the prices of electric motors is the need for a higher grade of thin electrical steel, which has a significant price premium. The ultra-thin sheets of steel transfer electricity into mechanical power. A temporary global shortage of electrical steel exists now but a more severe shortage is forecasted for 2027 to 2030, as most of the production capacity is in Asia, the US has little production capacity, and investments in new capacity are not keeping pace with demand growth.23 [EPA-HQ-OAR-2022-0829-0585, p. 18]

23 Daniel Sims. Electrical Steel Supply and Demand Could Impact EV Prices Later this Decade. Techspot.com. March 28, 2023.

For many years it was also thought that the expensive rare earths (neodymium and dysprosium) used in magnets for electric motors could be avoided through new designs of the electric motor. Those two rare earths account for up to 50-55% of the raw material costs in electric motors. However, induction motors, which have no need for rare earth magnets, are harder to cool at sustained high temperatures and are inherently less efficient at low speeds than permanent magnet synchronous motors. Tesla and BMW recently moved away from induction motors to permanent magnet synchronous motors. Given current trends in the industry, it seems unlikely that major savings in the material costs of electric motors will occur prior to 2035.24 [EPA-HQ-OAR-2022-0829-0585, pp. 18-19]

24 National Research Council. Assessment of Technologies for Improving Light-Duty Vehicle Fleet Fuel Economy, 2025-2035. National Academy Press. Washington, DC. 2021, 83. James Bonnett. The Quest to

Cut the Cost of Electric-Vehicle Motors by Adopting New Material Solutions. Victrix.com. August 28, 2018.

For the final rule, we recommend that, in the base case, EPA moderate the learning factors for non-battery components. In the high BEV cost sensitivity case, we recommend that the non-battery costs be held constant at their 2022 levels through 2032. [EPA-HQ-OAR-2022-0829-0585, pp. 18-19]

In summary, the application of learning factors in the NPRM's cost assessment is biased in favor of BEVs and against hybrids. For the cost comparison of BEVs with hybrid technologies, it is crucial that the agency make sure that the learning factors that apply to batteries and electric motors also apply to those components in hybrids. Any differences in the learning factors between BEVs and hybrids should be itemized and defended explicitly. EPA's current approach to learning factors for hybrids (lumping them with ICEs) is obviously not defensible. [EPA-HQ-OAR-2022-0829-0585, pp. 18-19]

FEV conducted a tear down comparison of ICE and BEV cost for EPA. FEV's draft report in the docket suggests that the heavier weight of the BEV incurs substantial additional costs.25 Suspension costs, including wheels and tires, were $320 higher on the BEV, brake costs $242 higher, steering costs $22 higher, and frame and mounting costs $320 higher, for a total of $895. FEV comments on slides 35-36 suggest that most of these cost increases is due to the higher weight of the BEV. Other parts of the report may also include component costs affected by the higher BEV weight (e.g. instrument panel cross beam on slide 47; possibly body structure and closures on slide 59). [EPA-HQ-OAR-2022-0829-0585, p. 19]

25 Cost and Technology Evaluation, Conventional Powertrain Vehicle Compared to an Electrified Powertrain Vehicle, Same Vehicle Class and OEM. EPA-HQ-OAR-2022-0829-0422, posted to the docket on April 20, 2023. https://www.regulations.gov/search?filter=EPA-HQ-OAR-2022-0829-0422.

Costs associated with the heavier weight of the BEV (due to the battery weight) have previously been ignored. This should be corrected for the final rule. [EPA-HQ-OAR-2022-0829-0585, p. 19]

Organization: POET, LLC

EPA also makes unfounded assumptions regarding the costs of non-battery BEV components.93 EPA assumes that the cost of non-battery components will drop by 42% from 2022 to 2032 and by another 12% between 2032 and 2055. EPA does little to explain those cost reductions, particularly, when BEVs are currently being produced and substantial work has already been performed in optimizing non-battery components.94 [EPA-HQ-OAR-2022-0829-0609, pp. 22-23]

93 Id. at 6-7.

94 See id. at 7.

Although the cost of batteries is the most significant element leading to differences in the cost of BEVs, there are sources of cost some of which U.S. EPA accounts for in the agency's assessment. However, just as with the cost of batteries, U.S. EPA again makes extremely optimistic assumptions regarding how the cost of non-battery BEV components will change over time. These assumptions are presented in Table 2-26 of the DRIA. As shown, U.S. EPA assumes that the cost of non-battery BEV components will drop by 42% from 2022 to 2032 but only by another 12% over the remaining period from 2032 through 2055. These cost reductions are claimed despite the that fact that substantial learning related to the production of BEV componentry has already occurred in the light-duty vehicle sector as evidenced by the current mass production of BEVs and further learning curve benefits would therefore be expected to be much smaller than those assumed by U.S. EPA. It should also be noted that in addition to failing to properly account for the time required for BEV development and component integration for platforms that are replacing existing conventional platforms, U.S. EPA also fails to account for the associated costs. [EPA-HQ-OAR-2022-0829-0609, pp. 58-59]

Organization: Strong Plug-in Hybrid Electric Vehicle (PHEV)

We applaud EPA for commissioning a tear down analysis of BEV costs and request that a similar tear-down analysis be done for a Strong PHEV. Most importantly, In any cost analysis, scenario or tear-down study for PHEVs, special PHEV batteries should not be used, but rather medium and long-range PHEVs should use less expensive BEV batteries and the benefits of PHEVs not needing as strong of chassis as BEVs should be included in the cost. These are the two largest cost savings with mid- to long-range PHEVs compared to BEVs. [EPA-HQ-OAR-2022-0829-0646, p. 8]

Finally, we agree with EPA that BEVs with large battery backs will need stronger chassis which adds costs but note that PHEVs do not need this to the same degree. Thus, EPA's cost analysis for PHEVs should reflect this. [EPA-HQ-OAR-2022-0829-0646, pp. 21-22]

EPA Summary and Response

EPA acknowledges and appreciates all of the comments relating to modeling of non-battery costs in the compliance analysis. Comments in this area related to a number of topics, including: the costs assumed for HEVs and other technologies, the learning rate applied to those costs, and the importance of using teardown data and the latest available data.

In response to comments that EPA should use the most recent data available to estimate non-battery powertrain costs, EPA agrees, and notes that our updated analysis uses updated powertrain costs derived from work performed by FEV that we described in the proposal. Specifically, regarding our use of the updated FEV non-battery costs, which we noted in the proposal, some commenters agreed with using these costs ("Environmental and Public Health Organizations"), while others (AZ State Legislature) objected to our use of these costs, not based on disagreement with the costs themselves but on the grounds that the report was not final at the time of the proposal. EPA disagrees with the latter view, as the proposal clearly described the nature of the FEV work, and our use of the further developed and updated costs is consistent with our longstanding practice of considering relevant data to inform the final rule. Further, a draft of the FEV work was provided in the docket at the time of the proposal and provides a strong indication of the scope of the work and the costs that were emerging from the work at the time, which are similar in scope and magnitude to the costs that were ultimately delivered.

In response to comments that our HEV cost inputs to OMEGA were not accurate and specifically that they were higher than they should be, EPA notes that the HEV costs and non-battery costs used in the updated analysis are based on evidence provided by the FEV work and

EPA believes that they represent the best available data. Even if EPA's estimated costs are too high as commenter suggests, it would not preclude HEVs from entering the market but only affect the analysis' projection of HEVs in the future fleet. Indeed, such an occurrence would lend further support to the feasibility of the standards and the availability of a range of technological pathways for manufacturers to choose for compliance. The presence or absence of relative penetration of any technology as projected in the compliance analysis is in no way binding on the industry and does not dictate what automakers will ultimately choose to use to comply with the standards, as automakers will make these decisions using their own assessment of the relative costs and effectiveness of these technologies according, in part, to the market circumstances they observe at the time. If in future years the commenter happens to be correct that HEV costs will be lower than represented in the compliance analysis, the result would likely be higher penetration of HEVs and likely lower demand for critical minerals and lower compliance costs, compared to EPA's projections, implying that our current analysis is conservative. Commenter has not suggested that this set of events would result in an inability to comply with the standards, but only that a different collection of technologies would be employed to do so. The possibility that manufacturers may ultimately choose to comply with a different set of technologies than were suggested by the compliance analysis at the time of initial rulemaking is well within the scope of expectations regarding any such analysis; in fact, in complying with past rules, manufacturers have often chosen a different set of technologies than we projected in the corresponding compliance analysis. For example, compliance with the 2012 rule was achieved with less penetration of 48-volt mild hybrid systems and dual-clutch transmissions than we had projected.

Regarding comments that a cost term should be included to represent higher chassis cost of BEVs due to higher vehicle weight, EPA did not itemize this cost due to the lack of sufficient data points that would support its characterization as a function of battery mass, and commenter did not provide such data. The FEV teardown provided data for only one BEV, and was unable to characterize how the added cost might be different for vehicles of different configurations or different size battery. We note also that this data informed our decision not to apply an overall cost reduction to a BEV chassis to represent a commonly cited expectation among analysts that a fully optimized, purpose-built BEV platform can realize significant reductions in material cost and assembly cost due to a simpler design with fewer parts.[452,453] Given the possibility of battery weight increasing chassis cost or other factors reducing it, as well as the lack of available data to characterize these effects, EPA found it reasonable to not quantitatively model them. We also note that other aspects of the analysis, in particular our updated battery costs, are likely to be conservative, particularly in light of recent lower forecasts for future mineral costs than were used in deriving the updated battery costs. EPA also considered sensitivities for battery costs. As such, even were battery weight to somewhat increase chassis cost, EPA finds that our analysis would be reasonable. Commenter suggests that not including the added cost places other technologies, such as HEVs, at a disadvantage to being selected as part of the cost minimizing central case compliance path projection. EPA notes, however, that the presence of HEVs or any other technology in the compliance path only represents a projection of what might occur and does not preclude these technologies from having an accordingly higher representation in real

[452] McKinsey & Company, "Making electric vehicles profitable," March 8, 2019. Accessed on March 3, 2024 at https://www.mckinsey.com/industries/automotive-and-assembly/our-insights/making-electric-vehicles-profitable
[453] UBS, "UBS Evidence Lab Electric Car Teardown – Disruption Ahead?," Q-Series report, May 18, 2017.

life if the future costs and other factors vary from the projections in the analysis and make these technologies more attractive to manufacturers as part of their chosen technology mix and compliance strategy.

Regarding comments that EPA assumed cost reduction rates that are too high, EPA notes that applying a learning cost reduction factor to estimate future costs of components is standard practice in the industry and that these learning rates typically flatten out in future years compared to earlier years,[454] as is true of the curve that was used in the analysis. Commenter simultaneously suggests that EPA is "failing to properly account for the time required for BEV development," which suggests that significant development effort is occurring and remains to occur in BEV development, which tends to contradict commenter's earlier statement in support of flattening the learning rates, i.e. that "substantial learning related to the production of BEV componentry has already occurred." Commenter has not provided evidence that would refute the learning rates that EPA used nor has provided alternative rates that are supported by specific evidence relating to the degree of progress that has already occurred or remains to occur.

Regarding comments on performing a teardown of a strong PHEV, EPA notes that this was not within the scope of the FEV teardown study. Further, EPA is unaware of any pair of candidate vehicles that would have been available at the time of the study in both an ICE vehicle and a PHEV version and which also could support the goals of the study. EPA has assessed PHEV non-battery costs using a scaling of the costs provided by FEV in its work supporting the analysis and has no reason to believe that a specific teardown of a PHEV as opposed to the vehicles in the FEV studies would lead to significantly different results.

Regarding comments concerning a potential for increased cost of electrical steel to prevent learning cost reductions in electric machines, EPA notes that the Techspot article[455] cited by commenter is based on a Wall Street Journal article[456] which provides a broader view, emphasizing U.S. investment to increase capacity, choosing as lede for the article the statement that "large U.S. steelmakers are ramping up production […] to capture a fast-growing market." The article also does not describe anticipated supply deficit as a "shortage," only as a gap between projected demand and projected supply, which EPA has already described in other responses as not being proof that an actual shortage will occur, and acting as a signal that motivates investment in new supply. When discussing the global gap, the article also qualifies it with the statement "unless more production capacity for high-grade electrical steel is added," without further suggesting specific barriers that would prevent one from reasonably expecting this increased global capacity to be built. In fact, the article places emphasis on examples of U.S. manufacturers that are making large investments to capture a share of this market. Where the article mentions creating more capacity "will likely take years," this observation is in the context of domestic capacity only (where the steel industry as a whole is relatively inexperienced in its

[455] Sims, D., "Electrical steel supply and demand could impact EV prices later this decade," Techspot.com, March 28, 2023. Accessed on March 3, 2024 at https://www.techspot.com/news/98117-electrical-steel-supply-demand-could-impact-ev-prices.html
[456] Tita, B., "The Paper-Thin Steel Needed to Power Electric Cars Is in Short Supply," Wall Street Journal, March 27, 2023. Accessed on March 3, 2024 at https://www.wsj.com/articles/the-paper-thin-steel-needed-to-power-electric-cars-is-in-short-supply-dbd2a78e

production), and does not go on to suggest that capacity at established global manufacturers would require a similarly long lead time.

EPA also notes an article by S&P Global that provides more context.[457] According to that article, in ICE vehicles "35 to 45 low-power motors are fitted on average per car, with about 20 in the B segment and 80 in the E segment (with some extremes like the Mercedes S-class that has more than 100 motors)." While the article does not quantify the amount of electrical steel these motors need, it does suggest that exposure to increased cost of electrical steel is not unique to PEVs but only resides in a relative increase of the amount needed. S&P also describes the gap more precisely as a "structural imbalance between capacity and […] demand" that "will require significant capital investment in the coming years." Nor does S&P conclude that the gap indicates a shortage will take place, discussing the concept of a shortage with the qualification "without further major investments," and discussing the potential for an impact on OEM electrification plans with the qualification, "if this is not addressed by adding more capacity and investment in new capacity." Nor does S&P indicate any reason to believe that such investments will not occur. According to the Wall Street Journal article, such investment is already occuring in the U.S.; neither article provides reason to believe that similar activity is not or will not be taking place elsewhere in the world to capture the same market gap. In any case, commenters have only alluded to the potential for increased steel cost to impact overall PEV cost and have not described what they think the effect will be. EPA notes that compared to battery cost, electric machine cost is a relatively small portion of PEV manufacturing cost, and the cost of electrical steel only a portion of that, and would likely lie well within the range of the high battery cost sensitivity. No reasonable estimate of a sustained elevation in electrical steel cost would affect PEV cost so dramatically that it would change our conclusion regarding ability to comply with the standards. EPA also notes that our responses under RTC Section 15 relating to investment in critical minerals production and development of the supply chain would also apply to comments relating to the need for increased production capacity for other inputs to PEV production, including electrical steel production.

Regarding one commenter's assertion that the "average price of an electric motor for BEVs rose 26 percent in 2021 and rose slightly again in 2022," the timing and scale of these increases suggests that COVID-19 pandemic supply chain disruptions are likely to have had an influence. Commenter suggests but does not show that this increase indicates similar increases in the future. In fact, the cited Automotive News article[458] indicates that it was "the COVID-19 pandemic, inflation and the war in Ukraine" that led to this increase, and does not suggest that it is evidence of a long term trend. The Automotive News article attributes the 26 percent statistic to Interact Analysis,[459] which in that reference (dated 2022) forecasts an even higher increase of 67 percent in 2022, which incidentally was not borne out by the "slight" 2022 increase indicated by commenter. Interact Analysis also states, "the much higher numbers are mainly because the average power of each motor has been increasing due to the production of more powerful

vehicles and because in 2022 more larger vehicles are electrifying whereas it was mostly smaller commercial vehicles in 2020." In fact, the cited Automotive News article points out that "many of today's EV models have been 'over-engineered' by established automakers." This suggests that increases in cost of motors over time, if they occur, could be addressed by OEMs with design optimization, for example, adjusting vehicle power specifications or reducing the number of motors in models that have multiple motors.

Regarding comments on the use of BEV batteries for PHEVs, see RTC 12.2.1, Battery costs.

12.2.4 - Inclusion of PHEVs

Comments by Organizations

Organization: Alliance for Automotive Innovation

Its assessment is also limited to only battery electric vehicles, ignoring PHEVs as both a technology option and their impact on EV supply chains. [EPA-HQ-OAR-2022-0829-0701, p. 33]

7. Modeling of Plug-In Hybrid Electric Vehicles

In the Proposed Rule, EPA acknowledges that plug-in hybrid electric vehicles "can provide significant reductions in GHG emissions and that some vehicle manufacturers may choose to utilize this technology as part of their technology offering portfolio" and, in particular, that a "PHEV pickup architecture would provide several benefits."210 This is consistent with EPA's analysis in the MY 2023-2026 GHG emissions standards rulemaking, in which the Agency noted that "our updated analysis projects that about 17% of vehicles meeting the MY 2026 final standards will be BEVs or PHEVs," and projected that "BEVs and PHEVs can play a significant role in complying with the final standards."211 [EPA-HQ-OAR-2022-0829-0701, pp. 115-117]

210 NPRM at 29298; see also Drati Regulatory Impact Analysis at 2-75 (same).

211 Revised 2023 and Later Model Year Light-Duty Vehicle Greenhouse Gas Emissions Standards, 86 Fed. Reg. 74434, 74493-94 (Dec. 30, 2021) (emphasis added).

Despite recognizing the importance of PHEVs in meeting GHG emissions standards, EPA has not attempted to model any PHEVs as part of manufacturers' compliance pathways to meet the proposed standards or alternatives under consideration. Auto Innovators believes that this omission of technology that will indisputably be an important part of the transition to a net-zero carbon transportation future is a significant oversight that should be rectified in the final rule. [EPA-HQ-OAR-2022-0829-0701, pp. 115-117]

A number of manufacturers are already building PHEVs or have announced plans to do so. S&P Global Mobility estimates a 5% U.S. market share for PHEVs in 2030.212 Auto Innovators' commitment to reaching 40-50% EV sales by 2030 was inclusive of PHEVs. Likewise, President Biden's Executive Order 14037 Specifically set "a goal that 50% of all new passenger cars and light trucks sold in 2030 be zero-emission vehicles, including battery electric, plug-in hybrid electric, or fuel cell electric vehicles." (Emphasis added.)213 [EPA-HQ-OAR-2022-0829-0701, pp. 115-117]

212 S&P Global Mobility, U.S. light vehicle sales forecast by propulsion system design, January 2023.

213 E.O. 14037 of Aug 5, 2021.

EPA asks for comments on whether PHEVs should be modeled and what type of PHEV technology should be incorporated. Auto Innovators believes EPA should include PHEVs in their modeling and it would be appropriate to model both the typical strong PHEVs (accounting for stronger electrification needed to meet US06 high power cold starts), as well as the range-extending type that EPA is modelling at SwRI. [EPA-HQ-OAR-2022-0829-0701, pp. 115-117]

Moreover, assuming EPA includes PHEVs in the final rule, it should not use PHEV technology as a justification to further increase greenhouse gas stringency. Rather, EPA should treat PHEVs in the context that manufacturers consider them – as a component of EV technology, not as a means to further improve ICE vehicle emissions in addition to rapidly increasing BEV model availability and production. PHEVs offer unique utility, and because some consumers are not ready for a BEV, we do not believe the inclusion of PHEVs should increase the combined ZEV share that EPA has modeled as BEVs in the Proposed Rule. Rather, a PHEV is a preferred EV to a BEV for some vehicle buyers and should be considered as a substitute for a BEV. Additionally, the California ZEV mandate allows for PHEVs, meeting certain criteria, to meet requirements, and treats them as it treats BEVs. At a minimum, EPA could borrow CARB's assumptions regarding PHEV sales and characteristics and apply them for states that follow California's rules only. [EPA-HQ-OAR-2022-0829-0701, pp. 115-117]

PHEVs are well suited to some applications, especially for more capable SUVs and pickup trucks. Specifically, EPA has modeled 60% BEV light-duty pickup trucks in the Proposed Rule, see Figure 34 below. [EPA-HQ-OAR-2022-0829-0701, pp. 115-117]

Figure 34: EPA Omega model output – Pickup BEV share percentage214 [EPA-HQ-OAR-2022-0829-0701, pp. 115-117]

214 OMEGA output abs_share_frac_pickup_BEV divided by abs_share_frac_pickup significant effort to model battery capacity constraints, but it is only a model, which carries uncertainty.

In addition to consumer demand (for utility or as a bridge to full electrification), another reason that EPA should include PHEVs in their modeling is the potential for PHEVs to provide clean electric miles while reducing the amount of battery material needed. EPA has devoted significant effort to model battery capacity constraints, but it is only a model, which carries uncertainty.. [EPA-HQ-OAR-2022-0829-0701, pp. 115-117]

Further, PHEVs can be very useful to sustain the transition to electrification in the case of unforeseen disruptions in the development of battery manufacturing capacity due to constraints in mineral availability, processing, or other supply chain challenges. Using MY 2023 EPA Fuel Economy Guide data, a 300-mile BEV requires a battery of approximately 109kW-hr on average. Accounting for energy efficiency differences, the same battery material could be used to make between four and six PHEVs with 50 miles of all-electric range. Fifty miles exceeds what most Americans drive on most days, enabling significant all-electric driving. Due to battery supply chain concerns, EPA should include PHEVs in their modeling as a substitute for some BEVs so that PHEVs comprise at least 20% of the combined BEV plus PHEV share consistent with California and other ZEV states. [EPA-HQ-OAR-2022-0829-0701, pp. 115-117]

Organization: Betsy Cooper

Together, we write to propose that the EPA reconsider its approach to PHEVs in its recent draft regulations, particularly to incentivize car manufacturers to develop longer range PHEVs. In particular, we recommend you give full off-cycle credits to manufacturers who develop PHEVs with a range of 50 or more miles. EPA's current plan will disincentivize all PHEVs, ignoring the real market benefits to keeping long-range versions of these cars in the market. Intentional or not, the effects of the EPA's current policy will be to push vehicle manufacturers further towards full EVs—before the charging infrastructure is ready to support them. In the meantime, consumers not ready to adopt full EVs – including for the same reasons we are not yet able to do so – will continue to buy gas cars instead. [EPA-HQ-OAR-2022-0829-0654, pp. 1-4]

With more long-range PHEVs on the market, more Americans will be able to drive their full commute on electricity and charge overnight at home (with reduced demand on the grid relatively to fast-charging of full EVs). Moreover, as longer range PHEV cars grow more popular, there will be greater incentives for individuals and communities to invest in improving charging infrastructure, thus reducing the friction facing current consumers. [EPA-HQ-OAR-2022-0829-0654, pp. 1-4]

PHEVs Fill An Important Market Need That Would Otherwise Be Filled By Gas Vehicles

PHEVs remain an important player in the electric vehicle market. PHEVs are excellent introductory electric cars, allowing cautious consumers to try electric driving without fully committing to weaning from gas. Many consumers are not yet ready to fully invest in electric vehicles for valid reasons including range anxiety and a lack of charging capacity in many communities. After driving a PHEV, many will purchase a fully electric car for their next car [Link: https://www.washingtonpost.com/climate-solutions/2023/05/04/plug-in-hybrids-gateway-evs/]—we count ourselves in that category. Without a PHEV option available to them, these consumers will instead purchase all-gas cars—putting more polluting vehicles on the road, not fewer. [EPA-HQ-OAR-2022-0829-0654, p. 2]

PHEVs fill an important gap, providing a transition vehicle that allow consumers to experience the benefits of all-electric driving without some of the risks: [EPA-HQ-OAR-2022-0829-0654, pp. 2-3]

- First, a gas backup can reduce range anxiety, especially in uncertain terrain or cold temperatures. While our family also owns a pure EV, we are not yet ready to commit to being a fully electric household. Not least, our PHEV is our vehicle of choice for any road trip in the snow or mountains, as we do not want to test our full range in a precarious, unpredictable location. [EPA-HQ-OAR-2022-0829-0654, pp. 2-3]

- Second, PHEVs are more family friendly than EVs; as parents (like us) of small children will tell you, charging on a road trip is one thing. Charging on the road with an unhappy toddler – or heaven forbid, one who only sleeps when the car is moving – is quite another. Having the option to keep driving on gas once the electric range runs out is a blessing. [EPA-HQ-OAR-2022-0829-0654, pp. 2-3]

- Third, and relatedly, this is particularly true because charging infrastructure has not yet caught up with EV demand. [EPA-HQ-OAR-2022-0829-0654, pp. 2-3]

- Rural and disadvantaged communities disproportionately lack access to public charging infrastructure [Link: https://www.marketplace.org/shows/marketplace-tech/rural-communities-are-slow-to-adopt-evs-but-a-national-charging-network-depends-on-them/]. So long as charging infrastructure is not as ubiquitous as gas stations are, gas backups remain an important option for long haul driving. [EPA-HQ-OAR-2022-0829-0654, pp. 2-3]

- Moreover, even in areas with well-developed charging infrastructure, such as in California where we live, it can be very difficult to find an available and working charger in a convenient location. Betsy’s current commute has only two chargers within a mile, and both are broken. Aaron’s work sponsors chargers, but even then demand is so high that employees require a complex interoffice notification system to ensure everyone gets a charge by the end of the day. [EPA-HQ-OAR-2022-0829-0654, pp. 2-3]

Short-Range PHEVs Do Not Achieve EPA’s Greenhouse Gas Emissions Goals

While PHEVs fill an important market need, manufacturers’ move to short range PHEVs (those with less than 40 miles of range) has reduced these benefits significantly. Small electric batteries do less to reduce range anxiety. Shorter ranges require more frequent charging, and make it more likely that drivers will need to charge in inconvenient locations away from home. And these annoyances may make it more likely that new PHEVs will rely on gas. [EPA-HQ-OAR-2022-0829-0654, p. 3]

EPA may rightfully wish to disincentivize the use of gas cars for any reason. But doing so by disincentivizing all PHEVs, as the current regulation proposes, is a mistake. The fundamental problem here is not with PHEVs; it is with the small electric range on offer in those vehicles. Longer range PHEVs with smaller gas tanks will reduce reliance on gas, helping to get the first-time electric vehicle consumer more comfortable relying on electric power for their daily needs. [EPA-HQ-OAR-2022-0829-0654, p. 3]

Moreover, by encouraging long-range PHEVs, the EPA may even be able to reduce greenhouse gas emissions more than by supporting traditional EVs alone, at least in our current environment where EV battery materials and manufacturing capacity remain constrained. [Link: https://finance.yahoo.com/news/ford-ceo-on-ev-transition-batteries-are-the-constraint-190948815.html] [EPA-HQ-OAR-2022-0829-0654, p. 3]

- To overcome range anxiety in a pure EV, manufacturers have been adding larger and larger batteries (>##95 kilowatt-hours in some cases [Link: https://ev-database.org/cheatsheet/useable-battery-capacity-electric-car]). Yet given that consumers drive on average 37 miles a day, such a large battery will never be used most of the time. With current battery supply and manufacturing constraints, this is an inefficient use of resources. [EPA-HQ-OAR-2022-0829-0654, p. 3]

- This same 95 kilowatt-hour of batteries could make 5 separate PHEVs with a battery the size of our 53-mile range Chevy Volt. Five vehicles would have electric power and replace gas cars instead of one. [EPA-HQ-OAR-2022-0829-0654, p. 3]

- Moreover, given less embodied emissions in each car from the creation of the battery, these cars each could have lower lifecycle emissions as well (provided sufficient availability of charging). [EPA-HQ-OAR-2022-0829-0654, p. 3]

EPA Should Use Its Regulatory Authority To Incentivize Long-Range PHEVs

The EPA thus should use its regulatory process to encourage PHEV manufacturers to return long-train PHEVs to the market: by providing full off-cycle credits to those who give 50 or more miles of electric range. EPA's current plan will disincentivize all PHEVs, ignoring the real market benefits to keeping long-range versions of these cars in the market. Intentional or not, the effects of the EPA's current policy will be to push vehicle manufacturers further towards full EVs—before the charging infrastructure is ready to support them. In the meantime, consumers not ready to adopt full EVs – including for the same reasons we are not yet able to do so – will continue to buy gas cars instead. [EPA-HQ-OAR-2022-0829-0654, pp. 3-4]

With more long-range PHEVs on the market, more Americans will be able to drive their full commute on electricity and charge overnight at home (with reduced demand on the grid relatively to fast-charging of full EVs). Moreover, as longer range PHEV cars grow more popular, there will be greater incentives for individuals and communities to invest in improving charging infrastructure, thus reducing the friction facing current consumers. [EPA-HQ-OAR-2022-0829-0654, pp. 3-4]

By encouraging both EVs and long-range PHEVs, the EPA will encourage manufacturers to offer more long-range PHEV models, and to make more of them. As demand for the 42-mile RAV4 PHEV shows, consumers crave these long-range PHEV options. There just aren't currently any affordable and available ones to choose from. [EPA-HQ-OAR-2022-0829-0654, pp. 3-4]

We propose a 50+ mile PHEV range requirement for full off-cycle credit. There is already momentum in favor of this standard; California is planning to require 50+ mile range PHEVs by 2035 [Link: https://ww2.arb.ca.gov/news/california-moves-accelerate-100-new-zero-emission-vehicle-sales-2035]. Moreover, even with battery degradation, a PHEV rated for 50+ miles at the point of sale will still cover the average American commute many years later. [EPA-HQ-OAR-2022-0829-0654, p. 4]

The EPA may respond that its scaled utility factor already takes into account miles of range in its calculation. Even if true, by penalizing all PHEVs across the board, the EPA is incentivizing manufacturers to make fewer plug-in hybrid vehicles, period. Especially until charging infrastructure resembles the gas station infrastructure of today, long-range PHEV cars remain an important consumer option. By rewarding manufacturers for making PHEVs with a 50+ mile range, EPA will help bring an important class of climate-friendly vehicles back to market. [EPA-HQ-OAR-2022-0829-0654, p. 4]@

Organization: Environmental. and Public Health Organizations

B. EPA should include PHEVs in its modeling.

While EPA did not include any PHEVs in its modeling for the Proposal, we urge it to do so for the final rule. Modeling PHEVs will both account for manufacturers' plans and help demonstrate the technical and economic feasibility of strong final standards. Although BEVs are likely to continue to be the most common electric vehicle, PHEVs are part of some automakers' stated plans for achieving emissions reductions. PHEVs are currently more commonly used as a powertrain option for larger and less efficient vehicle models, and that trend is likely to continue with future models. Therefore, EPA should include PHEVs as a powertrain option in the final rule, but should focus on pickup trucks and SUVs as the most likely candidates to offer a PHEV variant. [EPA-HQ-OAR-2022-0829-0759, p. 48]

When modeling PHEVs, EPA should examine vehicle parameters that span a range of battery capacities. In particular, EPA should examine vehicles with battery capacity that meets the minimum capacity (7 kWh) requirements for the IRA § 30D credit. PHEVs that are eligible for the full amount of that credit ($7,500) and have the required minimum capacity battery pack are likely to have a lower net cost than conventional vehicles with similar compliance CO2 value. [EPA-HQ-OAR-2022-0829-0759, p. 48]

When considering costs for PHEVs, EPA should assume L1 charging infrastructure for these vehicles with 50-mile or lower electric-only range. The traction battery capacity for these vehicles will likely be in the range of 7-25 kWh, and therefore they can be fully recharged in 4-13 hours using a L1 EVSE connected to a 20-amp, 120V circuit. [EPA-HQ-OAR-2022-0829-0759, p. 49]

Organization: International Council on Clean Transportation (ICCT)

Incorporating PHEVs in the proposal analysis

EPA did not include PHEVs in its OMEGA modeling for this proposal; ICCT recommends EPA include PHEVs in its updated modeling for the final rule, if possible. Since PHEVs are eligible to be used for compliance with the standards, incorporating them into the modeling would more accurately project compliance pathways. If PHEVs are cost effective in some years and segments, including them as an option in the modeling would more accurately reflect the lower compliance costs that could be achieved by PHEVs in those uses compared to modeling that excludes them. [EPA-HQ-OAR-2022-0829-0569, pp. 58-60]

For reference, ICCT previously analyzed the costs of light-duty150 and medium-duty PHEVs.151 For light-duty vehicles, ICCT projected PHEVs to have higher prices and 6-year ownership costs than 300-mile BEVs of all body styles before MY2027. Light-duty PHEVs are also expected to remain costlier than non-plugin vehicles for the foreseeable future. [EPA-HQ-OAR-2022-0829-0569, pp. 58-60]

150 Slowik. P., Isenstadt, A., Pierce, L, Searle, S. (2022). Assessment of light-duty electric vehicle costs and consumer benefits in the United States in the 2022-2035 time frame. International Council on Clean Transportation. https://theicct.org/publication/ev-cost-benefits-2035-oct22/

151 Mulholland, E. (2022). Cost of electric commercial vans and pickup trucks in the United States through 2040. ICCT. International Council on Clean Transportation. https://theicct.org/publication/cost-ev-vans-pickups-us-2040- jan22/

For medium-duty pickups, ICCT projected gasoline PHEVs to reach purchase price parity with 300-mile range BEV pickups around MY2027, but likely to remain costlier than both diesel and gasoline non-plugin pickups. Diesel PHEVs are not expected to reach price parity with either BEVs or non-plugin pickups. For medium-duty vans, gasoline PHEVs are expected to reach price parity with diesel non-plugin vehicles by MY2032, but 300-mi and 150-mile range BEVs are expected to cost less than PHEV vans throughout MY2027-2032. When it comes to 5-year total cost of ownership, medium-duty gasoline PHEV pickups and vans are expected to cost less than diesel non-plugin vehicles before MY2027 (diesel PHEVs are still expected to cost more throughout the timeframe of the proposed rule). [EPA-HQ-OAR-2022-0829-0569, pp. 58-60]

As discussed in the combustion vehicle technology section previously, developments in dedicated hybrid engines suitable for (primarily gasoline) serial/range-extended PHEV applications may simultaneously improve the efficiency of the engine while also reducing its cost. Thus, EPA may consider modeling PHEVs in the largest light-duty segments, as well as both medium-duty pickups and vans. Doing so could lead to reduced overall compliance costs as compared to those currently modeled in the proposal. [EPA-HQ-OAR-2022-0829-0569, pp. 58-60]

ALPHA validations of P2 and PS hybrids were based on PHEVs (DRIA Table 2-6). With PHEV- specific data, response surface equations (RSEs) for PHEVs could be developed and incorporated into OMEGA. Absent full simulation and RSEs for PHEVs, EPA can approximate PHEVs by combining BEV RSE with P2 or PS RSEs (utilizing UF for electric/ICE split). Such a combination would need to be validated against the existing PHEV test data. [EPA-HQ-OAR-2022-0829-0569, pp. 58-60]

Organization: Mazda North American Operations

Mazda strongly requests that EPA take these considerations into account and make necessary adjustments to the proposed rule as it works towards a Final Rule. We feel the Final Rule should have more realistic targets and associated ramp ups, include PHEVs, and adopt CARB's current LEV IV for criteria emissions. [EPA-HQ-OAR-2022-0829-0595, pp. 3-4]

Organization: Minnesota Corn Growers Association (MCGA)

Toyota6 and others7 have argued for a balanced approach to emissions reductions using BEVs and other technologies, saying “perfect should not be the enemy of the good”. The battery size8 for a BEV is about 6 times larger than a PHEV (~75-145kWh vs. ~12-18kWh), and about 60 times larger than a HEV (~1.3-1.9kWh). Given the limited supply of battery materials, a large number of HEVs and PHEVs can clearly achieve substantially better GHG reductions than a small number of BEVs. [EPA-HQ-OAR-2022-0829-0612, pp. 5-6]

6 Gill Pratt, Toyota Motor Corporation’s Chief Scientist, open letter posted on Medium, August 2021; https://medium.com/toyotaresearch/more-straight- talk-about-toyotas-electric-vehicle-strategy-f0aba4be40.

7 Foster, Koszewnik, Wade, and Winer, "Pathways to More Rapidly Reduce Transportation's Climate Change Impact." Issues in Science and Technology, November 17, 2022; https://issues.org/reduce-vehicle-transportation-emissions-foster-koszewnik-wade-winer/.

8 https://insideevs.com/reviews/344001/compare-evs/.

The proposed rulemaking assumes that BEVs will be the dominant technology for future emissions reductions. But relying on a single technology is a risky strategy; many factors could interfere including the supply and/or cost of critical minerals, lack of BEV recharging infrastructure, slow ramp-up of wind and solar power, poor customer acceptance of BEVs in some market segments, etc. EPA estimates that 67% of U.S. vehicles sales will be BEVs in 2032, but most major automakers predict much lower BEV sales, and the world’s largest automaker predicts only 20% in 2030. For comparison, MIT predicts9 that China will achieve only 40% in 2030 despite a head start and extremely strong government interventions. EPA should not base mandatory emissions standards on unrealistic predictions of BEV sales. [EPA-HQ-OAR-2022-0829-0612, pp. 5-6]

9 https://news.mit.edu/2021/chinas-transition-electric-vehicles-0429.

Organization: Mitsubishi Motors North America, Inc. (MMNA)

In addition, based on its considerable experience discussed previously with BEV and PHEV leadership, Mitsubishi provides the following recommendations to supplement the comments of Auto Innovators:

2. Consider the many benefits of PHEVs to consumers and the environment during the expected period of constrained battery critical minerals production capacity, and how PHEVs are the perfect stepping- stone to full BEV acceptance. [EPA-HQ-OAR-2022-0829-0682, p. 2]

Treatment of Plug-in Hybrid Electric Vehicles (PHEVs)

PHEVs offer many benefits and should be an integral part in implementing the proposed Multi-Pollutant Emissions Rule. PHEVs provide environmental benefits and are a viable alternative for vehicle buyers not yet ready or able to own or lease a BEV. PHEVs are a steppingstone to BEV acceptance, teaching consumers the benefits of BEV ownership without the drawbacks – range anxiety, charge anxiety, etc. PHEVs directly address better overall fuel economy, and reduced GHG emissions compared to comparable gasoline-only models, while offering similar utility, comfort, and convenience. [EPA-HQ-OAR-2022-0829-0682, pp. 3-4]

Additionally, PHEVs aid the transition from pure internal-combustion engines to full vehicle electrification, especially during any period when limited battery critical minerals production capacity would not be sufficient to meet the volumes necessary to supply the number of BEVs assumed in EPA's proposal. PHEVs have smaller battery packs that enable clean, electric-only – and, in our case, significant –driving, thereby using less critical minerals than comparable BEVs with bigger battery packs. The All-Electric Range (AER) of today's PHEVs already exceed the average daily commute mileage of most American drivers, and this will only increase in the future. Consumers would also benefit by having less expensive, easier to install, lower amp, home chargers installed to charge their PHEVs, rather than the more expensive, higher amp ones needed to charge larger BEV battery packs. More electrified powertrain options, including PHEVs, support the shift to electrification, reduce the demand for limited critical mineral supply, and enable greater EV access to more consumers. [EPA-HQ-OAR-2022-0829-0682, pp. 3-4]

Mitsubishi supports Auto Innovators' recommendation that EPA include PHEVs in its modeling, as a substitute for some BEVs, so that PHEVs comprise at least 20% of the combined BEV+PHEV share, based on the availability and benefits of PHEVs and concerns with battery critical minerals supply constraints. [EPA-HQ-OAR-2022-0829-0682, pp. 3-4]

Organization: Nissan North America, Inc.

[…] Nissan requests that EPA adjust the proposed GHG standards and targets to account for a blended PEV percentage, taking into consideration emissions reductions from PHEVs and BEVs collectively. EPA has historically considered the emissions benefits of both groups of advanced technology vehicles, acknowledging the importance and need of PHEVs in the consumer shift towards clean vehicles. […][EPA-HQ-OAR-2022-0829-0594, p. 5]

Organization: POET, LLC.

In a violation of the Administrative Procedure Act, the Proposed Rule fails to meaningfully assess PHEV technology, even though it is widely used in vehicles, and has been a key decarbonization strategy by automakers. The Proposed Rule concedes, "EPA's current analysis does not include PHEVs, though we recognize that many manufacturers' product plans include PHEVs" but "EPA plans to incorporate PHEVs into our analysis for the final rule."70 Not only is this failure to assess PHEVs arbitrary and capricious, but EPA seems to misstate the requirements of the Administrative Procedure Act here – analysis like this should be presented in a proposed rule, so that stakeholders can provide comment, not in the "final rule" analysis where the time period for comment has been extinguished. EPA's failure to meaningfully assess PHEV technology deprives stakeholders of the ability to meaningfully comment on this Proposed Rule. It is essential that the final rule provide incentives for PHEV FFVs, and otherwise recognize the contribution of higher-level bioethanol blends like MLEBs and E85 that are used in PHEV FFVs. [EPA-HQ-OAR-2022-0829-0609, pp. 20-21]

70 88 Fed. Reg. at 29329.

Organization: Strong Plug-in Hybrid Electric Vehicle (PHEV)

In order to show additional ways that costs can be reduced and that hard-to-reach markets are served, we respectfully request that EPA develop a scenario in the final rulemaking that reduces the total costs. Specifically, this new scenario should include a modest number of PHEV cars and trucks as that will impact the cost analysis by reducing the cost of charging infrastructure, the amount of critical minerals and by using BEV batteries in strong PHEVs. This scenario could reduce the number of BEVs and FCEVs by a small amount (say 20% collectively) and be instead served by a mix of Strong PHEV cars and trucks and other PHEV cars and trucks. The PHEV battery costs should be based on using BEV batteries as explained in Appendix D in this letter. The use of away-from-home DC fast chargers should be modestly reduced, and the cost of the PHEV including total cost of ownership should be based on work by Argonne national lab for light-duty PHEVs.7 Finally, bidirectional charging using DC off-board chargers should be assumed in our recommended alternative cost analysis for a reasonable percentage of BEVs and PHEVs in order to further reduce the total cost of ownership. [[EPA-HQ-OAR-2022-0829-0646, p. 8]

7 Ibid

Another perspective is dollars spent to achieve GHG reductions. Models such as the new Toyota tool show that PHEVs can be very good at dollars per GHG reduced.20 Finally, total cost of ownership is another perspective. We believe the above Argonne National Laboratory analysis correctly finds that PHEVs are lower cost than BEVs, but, as we point out above and, in the charts below, PHEV costs can be lowered further. In addition, the lower cost for home charging stations compared to BEVs21 and savings compared to using gasoline or diesel further lower the total cost of ownership and make Strong PHEVs very attractive in the near-term and the long-term. [EPA-HQ-OAR-2022-0829-0646, pp. 22-23]

Allowing PHEV cars and trucks to be in the proposed regulation helps low-income drivers

- The flexible nature of Strong PHEV trucks and cars makes them an important solution for low-and moderate-income drivers of used and new PHEV trucks and cars. Many drivers need flexibility in their choice of vehicle because they either change residences often, change jobs often, work two or more jobs or live in areas where charging at night is difficult. This applies to some vocational vehicles that park at home, or commercial businesses that don’t have easy access to charging or that move relatively often. In addition, we understand that low-income drivers in the California Clean Cars for All program preferred light duty PHEVs (e.g., Chevy Volt and BMW i3 REX) over light duty BEVs.22 Some new PHEVs are less expensive than their BEV counterparts.23 Also used PHEV cars and trucks are entering the market more and more and they are attractive to low-and moderate-income owners and renters of cars and trucks. Low-and moderate-income drivers and small businesses often rent their homes or business location or move their residence or business. A PHEV car or truck provides needed flexibility for this hard-to-reach market segment. [EPA-HQ-OAR-2022-0829-0646, pp. 24-25]

22 In the Advanced Clean Cars II final statement of reasons.

23 Ford Escape PHEV and Ford Mach-E are both 5 seat, full-function vehicles, built on the same C2 platform, but Ford’s PHEV has MSRP $8400 less than the BEV for MY 23.

Lower-income drivers have less economic and social capital, and therefore have less margin to be able to bear BEV’s costs associated with inadequate access to charging facilities in many areas, to accommodate unplanned or emergency situations and to pay for and access rented or owned second vehicles for travel to remote areas.24 [EPA-HQ-OAR-2022-0829-0646, pp. 24-25]

[See original for graphic titled "Low-Income (LMI) Customers/Consumer Interest"] [EPA-HQ-OAR-2022-0829-0646, pp. 24-25]

Because of the urgency of the climate and air pollution crises worldwide and the challenges of predicting consumer acceptance, it is important to take an all-hands-on-deck approach and have multiple types of zero-emission car and truck technologies in the final regulation including Strong PHEVs. [EPA-HQ-OAR-2022-0829-0646, p. 25]

• Strong PHEVs offer more options for consumers which means a faster path to zero CO2 worldwide when combined with BEV and FCEV options especially given supply chain, utility grid and charging infrastructure challenges we face today. [EPA-HQ-OAR-2022-0829-0646, p. 25]

• Many areas of the world are relying on EPA's leadership to commercialize new zero carbon solutions to transportation such as Strong PHEVs. [EPA-HQ-OAR-2022-0829-0646, p. 25]

• The longer-term goal should be PHEVs with 100% zero carbon electricity generation for almost all of their electric miles, and advanced biofuels or other ultra-low carbon fuel for the remaining miles. [EPA-HQ-OAR-2022-0829-0646, p. 25]

In addition, we believe that at least some car and truck manufacturers will find a better business case to reach scale and get higher levels of vehicle adoption by producing both PHEVs and BEVs than only producing battery electric vehicles. Such a result is good for truck and car maker competition, for consumers and the planet. [EPA-HQ-OAR-2022-0829-0646, pp. 26-27]

• EPA's actions in this final rule will be heard in many parts of the world. EPA's leadership matters and should be a factor when finalizing how the rule impacts the commercialization of Strong PHEVs. Strong PHEV cars and trucks are an excellent solution for the unique needs of rural areas, mountainous areas and cold weather areas. [EPA-HQ-OAR-2022-0829-0646, pp. 26-27]

• Strong PHEV cars and trucks are potentially a better option for the portion of the US and other countries that cover small and mid-size towns where trip distances (when needed) exceed urban megacity regions. [EPA-HQ-OAR-2022-0829-0646, pp. 26-27]

• Strong PHEVs do well compared to other ZEVs in mountainous areas, cold weather regions and other extreme use cases around the world because they are dual fuel vehicles and technology exists to make the second fuel ultra-low carbon.27 [EPA-HQ-OAR-2022-0829-0646, pp. 26-27]

27 Kambly, K. and Bradley, T.H (2015). Geographical and temporal differences in electric vehicle range due to cabin conditioning energy consumption, Journal of Power Sources 275, 468-475, and Neubauer, J., Wood, E. (2014). Thru-life impacts of driver aggression, climate, cabin thermal management, and battery thermal management on battery electric vehicle utility, Journal of Power Sources 259, 262-275.

- While many trips in these regions are local, both personal and fleet vehicles do take long distance trips, including to remote areas, where charging is lacking or inadequate. Mountainous terrain and very cold weather both significantly reduce the range of battery EVs and/or make charging difficult if not impossible, but PHEVs are not impacted. Even California's recently adopted Advanced Clean Fleet regulation defers compliance for government fleets in 25 of the State's 58 counties that are heavily rural. This is an acknowledgement that the State's rural counties will not have the infrastructure to support zero emission vehicles in the near future. Strong PHEVs are needed in this regulation for cars and trucks that tow or haul for work or recreation. [EPA-HQ-OAR-2022-0829-0646, pp. 26-27]

Due to the large energy requirements of towing, Strong PHEVs are better than other ZEVs. In addition, Strong PHEVs as dual fuel vehicles offer advantages when towing over mountains and rural areas where charging or hydrogen refueling is not common or not feasible from a business case perspective. (Many class 2b and 3 vehicles serve as both work and personal transportation, and this is a relatively large class of vehicles.) Mountain grades are particularly known for reducing the all-electric range of battery EVs, but PHEVs are dramatically less impacted and/or have better access to refueling. [EPA-HQ-OAR-2022-0829-0646, p. 27]

Allowing Strong PHEV cars and trucks to be eligible should result in less need and cost for away-from-home charging stations for individual drivers and commercial fleets. [EPA-HQ-OAR-2022-0829-0646, p. 27]

Allowing Strong PHEV cars and trucks to be eligible will help reach skeptical consumers and other late adopters. [EPA-HQ-OAR-2022-0829-0646, pp. 27-28]

EPA should adopt a provision to discourage low-range PHEVs by requiring them to count as an HEV with no zero emission miles. We suggest a cut-off of 50 km (31 miles). Further we are not suggesting a ban on low-range PHEVs but rather a disincentive to produce them. Low-range PHEVs according to the UC Davis data logger project and the EV Project have greater likelihood of not plugging in and this could increase as PHEVs get older. PHEVs with a long all-electric range offer much greater benefits to consumers and show much higher levels of plugging in. [EPA-HQ-OAR-2022-0829-0646, p. 7]

In a future rule, EPA should require automakers to only produce in the early 2030s PHEVs with 50 miles or greater all-electric range, along with BEVs and fuel cell EVs. Due to the climate catastrophe, even more electrification will be required. However, for all the reasons provided in this letter, we do not believe the approach taken by the European Union to ban PHEVs is appropriate. Further, this current rulemaking by adopting our recommendations above will help lead to a transition in the 2030s to requirements for Strong PHEVs, BEVs and FCEVs. [EPA-HQ-OAR-2022-0829-0646, p. 10]

Allowing PHEV cars and trucks in the regulation provides a better solution especially for commercial vehicles that provide services during major catastrophes and daily emergencies.

- Because Strong PHEV cars and trucks are dual fuel that means they are particularly suited to provide services for society to recover from wildfires, earthquakes, hurricanes, floods, riots, and other catastrophes, as well as provide needed services in more typical daily emergencies (e.g., police, ambulance, fire, power outage recovery). PHEVs for some of their fleet provide the flexibility they need to deal with catastrophes and emergencies as public servants. CARB's Advanced Clean Truck program recognized this by providing exemptions for emergency vehicles, and this emphasizes the need for dual fuel vehicles that can provide the flexibility that some fleets need. [EPA-HQ-OAR-2022-0829-0646, p. 26]

- Because PHEVs and Strong PHEVs are dual fuel vehicles, they provide car and truck owners who also sometimes use their car or truck for personal use or who park their work truck at home with a second fuel to travel in case of emergencies. Further, many PHEVs will come with vehicle-to-load and vehicle-to-building technology that will allow emergency power for their home or a few appliances in their home or small business. [EPA-HQ-OAR-2022-0829-0646, p. 26]

Strong PHEV cars and trucks are an excellent solution for many parts of the world and a long commercialization period is needed to scale up this technology. [EPA-HQ-OAR-2022-0829-0646, p. 26]

Due to the large energy requirements of towing, Strong PHEVs are better than other ZEVs. In addition, Strong PHEVs as dual fuel vehicles offer advantages when towing over mountains and rural areas where charging or hydrogen refueling is not common or not feasible from a business case perspective. (Many class 2b and 3 vehicles serve as both work and personal transportation, and this is a relatively large class of vehicles.) Mountain grades are particularly known for reducing the all-electric range of battery EVs, but PHEVs are dramatically less impacted and/or have better access to refueling. [EPA-HQ-OAR-2022-0829-0646, p. 27]

Organization: Stellantis

Stellantis recommends that EPA should:

GHG Standards

-Include PHEV technology as a critical transition technology to a fully electrified future – without incorrect discounting – particularly in highly capable vehicle segments [EPA-HQ-OAR-2022-0829-0678, p. 24]

-Treat trucks and SUVs fairly by including PHEV technology as an important bridge to a BEV future, and ensure year-over-year required improvements are the same as cars [EPA-HQ-OAR-2022-0829-0678, p. 24]

Organization: Toyota Motor North America, Inc.

6. Role of PHEVs and HEVs

Diversity is the antidote for uncertainty. The Final Rule must be more inclusive of PHEVs and HEVs to hedge compliance and environmental risks in the event the BEV market is slower to develop because of the previously mentioned market uncertainties. Unfortunately, PHEVs are excluded from the compliance modeling used to demonstrate feasibility of the standards; and

HEVs are relegated to a subset of ICEs never exceeding 3 percent combined-fleet penetration when the technology is in 7 percent of all vehicles sold today.19 [EPA-HQ-OAR-2022-0829-0620, pp. 29-30]

19 S&P Global Catalyst for Insight – Data As of April 30, 2023.

The proposal acknowledges “PHEVs can provide significant reductions in GHG emissions and a bridge for consumers that may not be ready to adopt a fully electric vehicle.”20 Toyota is seeking carbon reductions as quickly as possible by providing our customers with a range of low carbon solutions that best fit their incomes, needs, and lifestyles. From that perspective, BEVs, PHVs, and HEVs have a role to play in displacing conventional petroleum vehicles from the road. During the transition to electrification, PHEVs and HEVs offer a broader spectrum of more accessible low carbon options to consumers. [EPA-HQ-OAR-2022-0829-0620, pp. 29-30]

20 88 Fed. Reg. at 29298.

6.1. PHEV Architectures and Applications

This modeling deficiency seems temporary in the case of PHEVs as EPA seeks comment and recommendations on the types of PHEV architectures that should be considered for the analysis supporting the Final Rule. Toyota recommends that modeling for Final Rule include the more capable strong-PHEV designs being introduced to meet US06 high power cold starts as well as the range-extending architecture EPA mentions being studied at Southwest Research Institute. We agree PHEV architectures can provide pickup trucks expanded utility and power in addition to all- electric miles, but believe the technology is viable for the entire spectrum of vehicle classes including sedans, CUVs, SUVs, minivans, and pickup trucks as evidenced by the Prius Prime and RAV 4 Prime. Compliance modeling to support the Final Rule should incorporate the technology into all light-duty vehicle classes. [EPA-HQ-OAR-2022-0829-0620, pp. 29-30]

6.2. Technology Assessments Should Incorporate Critical Mineral Supply and Lifecycle Emissions

The modeling should also include a sensitivity analysis of BEV/PHEV mix on critical mineral usage for any assumed overall PEV penetration. PHEVs can make the most efficient use of the limited battery supply and constrained infrastructure network forecast through the period of the rulemaking. The below example compares different vehicle powertrain emissions for a mid-size SUV using peer-reviewed data from carghg.com. The same amount of lithium in the battery of one 300-mile plus BEV can be used for up to six PHEVs –or more than eighty conventional hybrids. See Figure 10 for the CO2 saved from replacing a mid-sized SUV powered by a conventional gasoline engine with electrified alternatives under a constrained lithium supply. This analysis assumes average US electric grid emissions for BEVs and the electric operation of PHEVs. [EPA-HQ-OAR-2022-0829-0620, pp. 31-32]

[See original for attachment for Figure 10 CO2 Saving from Replacing ICEs Under Constrained Mineral Supply] [EPA-HQ-OAR-2022-0829-0620, pp. 31-32]

PHEVs can rival the emissions performance of BEVs under many real-world operating conditions. PHEVs are not always the best-performing option but can have as good or better lifecycle performance because of lower manufacturing emissions for smaller batteries and lower well-to-tank emissions while still covering a significant fraction of daily trips in electric drive.

Given most average daily trips are under 50 miles, this results in a significant portion of all-electric miles like a BEV. [EPA-HQ-OAR-2022-0829-0620, pp. 31-32]

EPA requests any relevant performance or utility data that may help inform their analyses for the Final Rule. We appreciate the opportunity to share data which will help elevate the role PHEVs in the Final Rule to be an important part of a sustainable transition to electrification. We plan to share such PHEV data outside of the comment period, possibly, including confidential information. For now, we request EPA consider the data we have provided that suggests PHEVs should be considered be an important contributor in whatever assumed PEV sales mix. [EPA-HQ-OAR-2022-0829-0620, p. 32]

The proposal notes "that the inclusion of PHEVs could potentially increase the combined ZEV share projection beyond the BEV penetration levels shown."21 For all the reasons covered to this point in our comments, Toyota strongly believes that PHEVs must be considered a PEV-alternative to BEVs, consistent with President Biden's Executive Order 14037. PHEV buyers seek price, utility, and total driving range that a BEV may not offer. PHEVs must be considered a substitute for BEVs and not ICEs or a way to increase total PEV share beyond 60% in 2030 and 67 percent in 2032. [EPA-HQ-OAR-2022-0829-0620, p. 32]

21 88 Fed. Reg. at 29329.

Organization: Valero Energy Corporation

3. EPA arbitrarily excludes viable LMDV technologies from its compliance modeling.

EPA acknowledges in the Preamble that it "has not specifically modeled the adoption of plug-in hybrid electric vehicle (PHEV) architectures in the analysis for this proposal"16 and asks for comments on whether or how it should model PHEV architectures in the final rule.17 EPA repeats the statement that it "has not specifically modeled the adoption of plug-in hybrid electric vehicle (PHEV) architectures in the analysis for this proposal" five times in the DRIA, without any real explanation for the omission.18 [EPA-HQ-OAR-2022-0829-0707, pp. 3-4]

16 EPA's Multi-Pollutant LMDV Proposal at 29298.

17 EPA's Multi-Pollutant LMDV Proposal at 29298.

18 DRIA at 2-48, 2-74 (twice), 2-75 and 3-19.

This critical omission is wholly at odds with EPA's obligation to consider reasonable alternatives, especially considering the significant role that PHEVs play in light-duty transportation. Between 2011 and 2021, PHEVs accounted for 32% of all new LD ZEV sales in the U.S.19 Looking ahead, IHS Markit projects that PHEVs will comprise 19% of new U.S. ZEV sales over 2022 to 2032.20 [EPA-HQ-OAR-2022-0829-0707, pp. 3-4]

19 IHS Markit "Mobility and Energy Future 2022 light vehicle long-term outlook," September 2022. ZEVs include BEVs, FCEVs, and PHEVs.

20 IHS Markit "Mobility and Energy Future 2022 light vehicle long-term outlook," September 2022.

Moreover, EPA's treatment of PHEVs in its OMEGA modeling is an intentional misrepresentation in EPA's analysis fleets. Starting with the MY 2022 analysis fleet, EPA forces all PHEVs into ICEV fueling and technology classes, ignoring the attributes of the electrical powertrain and arbitrarily excluding the PHEV technology from the modeled compliance scenario.21 For example, OMEGA vehicle ID 18497 (MY 2027 Toyota PHEV, “Midsize:sedan:PHEV:1.0:{'gasoline':1.0}:car:2.0:0.0:2021:2017.0:5.0:PHEV:steel:Toyota:Toyota”), understood to represent the current-day Toyota Prius Prime, is modeled by EPA as having a zero kWh battery, tailpipe GHG emissions of 185 gCO2e/mile, and a vehicle price of $17,079.22 In reality, the 2023 Toyota Prius Prime has a 13.47 kWh battery, 23 tailpipe emissions of 78 gCO2e/mile, 24 and an MSRP of $32,350. 25 [EPA-HQ-OAR-2022-0829-0707, pp. 3-4]

21 EPA LMDV OMEGA GHG Compliance Modeling Runs (Document ID EPA-HQ-OAR-2022-0829-0486), 2023- 03-25-11-46-49-ld-central-compliance-run.zip, “2023_03_25_11_46_49_ld_central_compliance_run_Proposal_vehicle.csv.”

22 EPA LMDV OMEGA GHG Compliance Modeling Runs (Document ID EPA-HQ-OAR-2022-0829-0486), 2023- 03-25-11-46-49-ld-central-compliance-run.zip, “2023_03_25_11_46_49_ld_central_compliance_run_Proposal_vehicle.csv.”

24 See https://www.fueleconomy.gov/feg/Find.do?action=sbs&id=44362, accessed May 2, 2023.

25 See https://pressroom.toyota.com/prime-time-for-more-ev-miles-with-the-all-new-2023-prius-prime/, accessed May 2, 2023.

Given that PHEVs accounted for almost one-third of all LD ZEV sales from 2011 to 2021, failure to account for PHEVs seriously compromises the usefulness of EPA’s modeling exercise. It is unacceptable for EPA to neglect consideration of PHEV in the OMEGA compliance modeling for the proposed rule, and unacceptable that EPA is proposing to model the PHEV architectures in the final rule without adequate opportunity for public review and comment. [EPA-HQ-OAR-2022-0829-0707, pp. 3-4]

Organization: United Steelworkers (USW)

While the proposed rule is “technology neutral”, there is an underlying assumption in it that the shift will be to ZEVs, more specifically BEVs, rather than low- emission vehicles. EPA’s proposal completely writes off plug-in hybrid electric vehicles (PHEVs) and other low-emission technologies through the requirement that BEVs take up over half of the U.S. auto market by 2030. EPA’s proposed rule calls for 37 percent of new light-duty cars and trucks to be BEVs by 2027 and more than 60 percent by 2030. It is important to note that BEV sales were just under 6 percent in 2022.6 Additionally, the proposed rule goes above the Biden Administration’s Executive Order 14037, Strengthening American Leadership in Clean Cars and Trucks, which called for BEVs, PHEVs, and fuel cell electric vehicles to take up 50 percent of U.S. auto market by 2030.7 [EPA-HQ-OAR-2022-0829-0587, pp. 4-5]

Organization: Wisconsin Department of Natural Resources

5. Modeling plug-in hybrid electric vehicles (PHEVs). EPA is requesting comment on if it should model PHEVs in the final rule. Since the emissions from PHEVs can vary substantially (based on how they are operated), to fully assess their impacts in this rulemaking, EPA should update modeling for its final rule to include PHEVs. [EPA-HQ-OAR-2022-0829-0507, p. 3]

EPA Summary and Response

EPA acknowledges and appreciates all of the comments relating to modeling PHEVs in the compliance analysis.

Comments in this area related primarily to the significance of modeling PHEVs in the compliance analysis, and predominantly advocated for their inclusion. Many comments referred to the view that PHEVs have a role to play in compliance with the standards and therefore should be included. Some comments also dealt with the configuration of PHEVs that we should model, with Toyota advocating for "the more capable strong-PHEV designs being introduced to meet US06 high power cold starts as well as the range-extending architecture."

In response, EPA first notes that the exclusion of PHEVs (or any vehicle technology type) in a compliance analysis in no way prevents manufacturers from utilizing the technology in their fleet as an emission reducing technology. EPA's compliance analysis is not prescriptive as to the types of technologies that may be used, but only descriptive of the types of technology that we anticipate manufacturers are most likely to choose to comply with the standards, based on our assessment of the relative cost and effectiveness of various technologies in contributing to compliance with the fleet average standards. Even if PHEVs were left entirely out of the analysis, a manufacturer would remain free to manufacture PHEVs and these vehicles would contribute to the manufacturer's compliance according to the emissions performance that they achieve. If PHEVs were included but the costs assumed for the technology were higher or lower for a specific manufacturer, that manufacturer may see a different value proposition for including that technology than that which was represented in the analysis. In neither case would manufacturers in any way be prevented from using the technology as part of its mix of technologies that contribute toward compliance with the standards.

In response to the totality of comments advocating for inclusion of PHEVs, we have included PHEVs in the updated compliance analysis, and our projections of PEV penetration in the various cases of the analysis now distinguish between BEVs and PHEVs. These PHEVs are modeled as having an extended US06-capable driving range.

In response to comments that modeling PHEVs in the final rule does not provide "adequate opportunity for public review and comment," EPA disagrees. EPA provided notice that we expected to add PHEVs to the final rule analysis, and also provided public notice of the cost estimates that we were likely to use in the case that we did so. The public was therefore given notice to expect PHEVs as a possible addition to the final analysis, and was given notice as to what the primary additional cost inputs to the analysis would likely be. We received very few comments on these costs, and received a large amount of positive comments recommending that we add PHEVs to the analysis.

In response to comments that the exclusion of PHEVs represents "an intentional misrepresentation in EPA's analysis fleets," EPA disagrees. At the time of the proposal, EPA assessed that PHEVs are generally significantly less cost effective than BEVs and would play a very limited role in the cost minimizing compliance pathway that EPA routinely identifies as part of the compliance analysis. In the compliance analysis for the final rule, the cost-minimizing central case bears out this expectation. As we expected, the inclusion of PHEVs in the updated analysis has not materially changed the projection of feasibility of industry's compliance with the standards, but has only provided greater resolution of the specific types and configurations of vehicles that are likely to form what we project to be the cost-minimizing compliance pathway. We note that in addition to the cost-minimizing central case pathway, we also assessed several additional example pathways, which projected various levels of PHEVs as part of the technology mix used to meet the standards. See section IV.E of the preamble for this rule.

In response to comments regarding the configurations of PHEVs we should model, we agree that the longer-range US06 capable configurations are the most relevant to this analysis. Given that blended-architecture PHEVs often have relatively small driving range that results in a relatively low GHG effectiveness due to the nature of the PHEV utility factor relationship, we expect that these vehicles will be less effective at delivering GHG reductions relative to their cost, and also are likely to be somewhat discouraged from entering the market due to their inability to generate ZEV credits in states following the California ACC II program.[460]

In response to the request by Strong PHEV Coalition that we should include scenarios with higher amounts of PHEVs, we note that our sensitivity cases include two scenarios in which BEV penetration is lower than in the central case, both of which indicate a higher level of PHEV penetration.

In response to comments advocating for longer-range PHEVs or that we should incentivize longer-range PHEVs, EPA notes that the PHEVs in our compliance analysis are longer-range PHEVs that have US06 capable electric range. As discussed above, the inclusion of a specific type of technology in the compliance analysis in no way prevents manufacturers from producing different types. Similarly, a specific type of PHEV being represented in the analysis does not incentivize production of that type of PHEV. Longer-range PHEVs are already incentivized to some degree by their treatment under the ZEV program followed by California and the Section 177 states,[461] as well as their more beneficial grams per mile compliance contribution based on the PHEV utility factor.

In response to comments that EPA should apply PHEV technology primarily to pickup trucks and SUVs, EPA agrees that these vehicles are good candidates for the specific attributes of PHEVs, but as these are performance-based standards, the OMEGA model reasonably determines the specific vehicle classes to which each technology is applied based on the relative cost and effectiveness in each potential vehicle application.

In response to comments that EPA should model PHEVs with 7 kWh batteries that meet the minimum requirement for IRA eligibility, we agree that PHEVs with a small battery may have a low battery cost relative the value of the IRC 30D credit. However, these vehicles also have relatively high GHG grams per mile due to the PHEV utility factor assigning a higher value for shorter range PHEVs. EPA has also not seen evidence of a clear trend of manufacturers planning shorter-range PHEVs in order to capture this possible advantage. While it is possible that 7 kWh PHEVs would have a lower net price due to the IRA incentives, it would still depend on the battery qualifying for the FEOC and mineral/component content requirements, and with the battery being much smaller, the 45X production tax credit would have much less of an impact. EPA instead chose to model longer-range PHEVs with US06 capability, in the expectation that

[460] As explained in preamble IV.C, EPA has not at this time approved the waiver that would allow California to follow the ACC II program.
[461] EPA has not at this time approved the waiver that would allow California to follow the ACC II program.

these will be more commonly produced due to their lower GHG grams per mile and their eligibility for ZEV credits in California and Section 177 states.

In response to comments that EPA should assume level 1 charging infrastructure for PHEVs with 50-mile or lower electric-only range, we note that this was not appropriate because as stated above, the PHEVs in the compliance analysis have longer range. For responses to comments on charging infrastructure, see section 17 of the response to comments document. In response to comments regarding the ability of longer-range PHEVs to use BEV batteries, the ANL battery cost equations were developed with consideration of higher power-to-energy ratios at the lower end of their kWh capacity range, making those battery sizes applicable to either BEVs or PHEVs. In the updated analysis, only longer-range PHEVs[462] are placed into the fleet, and their battery costs are derived from the same equations as BEVs.

For response to comments that PHEVs and HEVs are a more efficient use of critical minerals than BEVs, see the responses in section 15 of the response to comments document, Critical minerals and supply chain.

12.2.5 – Battery replacement

Comments by Organizations

Organization: Alliance for Consumers (AFC)

Most notably, while "EPA projects lower maintenance and repair costs for several advanced technologies (e.g., battery electric vehicles)," EPA has failed to properly consider the likelihood, frequency, or expense of repairing or replacing a light-duty or medium-duty vehicle's battery due to wear, accident, or malfunction; a repair or replacement of a battery for an electric vehicle could potentially undo any cost savings projected by EPA in terms of "lower maintenance and repair costs" for "battery electric vehicles." Indeed, as some sources have pointed out: "[t]here will be scenarios in which a new EV battery will cost more than the vehicle's value." Ronald Montoya, Electric Car Battery Replacement Costs, Edmunds.com, May 2, 2023; see also id. ("On one hand, [battery replacement] costs might be cheaper than buying a new EV, but spending $15,000 on a new pack for a car that might be worth $10,000 is a tough sell.").2 EPA has failed to properly consider this aspect of the problem. [EPA-HQ-OAR-2022-0829-0534, p. 4]

2 Available at https://www.edmunds.com/electric-car/articles/electric-car-battery- replacement-costs.html.

[462] EPA assumed that manufacturers would design PHEVs that would provide enough range to qualify as ZEVs under the ACC II and ACT programs being administered by California and participating Section 177 states. In OMEGA, EPA assumed that light-duty vehicle PHEV batteries would be sized for 40 miles of all-electric range over the US06 cycle, while medium-duty PHEVs would be sized to drive 75 miles over the UDDS while tested at ALVW. This assumption is supported by EPA's engagement with manufacturers and our understanding of their product plans. Nonetheless, EPA has not at this time approved the waiver that would allow California to follow the ACC II program, and we are not prejudging the outcome of that separate administrative proceeding.

Organization: American Fuel & Petrochemical Manufacturers

EPA's cost benefit analysis is implicitly built around much longer battery life than is currently achieved, as EPA does not factor in battery replacement costs or the environmental implications of additional battery production, recycling, and disposal. EPA cannot have it both ways – either the batteries are remarkably durable, or the costs of this Proposed Rule are dramatically understated.

Organization: Anonymous

Perhaps the largest omission in EPA's analysis is considering what happens if BEV needs a battery replaced. Battery replacements can cost well into the tens of thousands (https://www.jdpower.com/cars/shopping-guides/how-often-do-tesla-batteries-need-to-be-replaced), and there's some evidence that some BEVs are 'totaled' even with minor damage because it doesn't make sense to repair and replace the battery pack (for example, https://www.caranddriver.com/news/a42709679/tesla-insurance-fixes-expense/). however, this consideration is not included in EPA's analysis of repair and maintenance nor elsewhere in the rule. This unaccounted for cost obscures the true cost of ownership, and if included, could flip the estimated cost per mile of repair and maintenance costs from BEVs being net positive compared to ICE vehicles to net negative. [EPA-HQ-OAR-2022-0829-0565, pp. 1-3]

Organization: Arizona State Legislature

EPA also does not calculate the frequency or likelihood that a light-duty or medium-duty vehicle will need to replace its battery due to wear or accident. Nor does EPA calculate the cost of battery replacement. Battery replacement for a passenger vehicle can cost between $5,000 and $15,000.29 One battery replacement could obviate any cost savings estimated by EPA for that vehicle. [EPA-HQ-OAR-2022-0829-0537, p. 24]

29 Devin Pratt, What Happens to the Old Batteries in Electric Cars, CONSUMER REPORTS, Feb. 23, 2022, available at https://www.consumerreports.org/cars/hybrids-evs/what-happens-to-the-old-batteries-in-electric-cars-a1091429417/.

Organization: Clean Fuels Development Coalition et al.

- Vehicle maintenance and repair costs. EPA underestimates maintenance costs in several ways, not the least of which is by ignoring the massive expense of replacing an electric vehicles battery. For example, a Tesla battery typically costs between $12,000 and $20,000 to replace and is out of warranty after only 8 years. [EPA-HQ-OAR-2022-0829-0712, pp. 5-6]

Organization: Environmental. and Public Health Organizations

3. Design for disassembly holds promise for battery recycling.

The battery design parameters listed in the Proposal, which EPA used to develop battery cost estimates, see 88 Fed. Reg. at 29299, do not include design for disassembly (Dfd), also referred to as design for recycling or design for reuse. Dfd involves factoring end-of-life into the design of the vehicle, meaning that the battery is designed to be taken apart so that cells and modules can be refurbished, reused, or replaced, or so that the battery can be more efficiently and safely disassembled for recycling. This disassembly is typically a difficult, lengthy, and therefore expensive process because Dfd is not included in the design phase.409 [EPA-HQ-OAR-2022-0829-0759, p. 151]

409 CalEPA, Lithium-ion car battery recycling advisory group report (2022), https://calepa.ca.gov/lithium-ion-car-battery-recycling-advisory-group/ (last accessed June 29, 2023).

As reuse and recycling becomes more prevalent and policies begin to require it, we expect that Dfd will also be more common. If Dfd occurs, more reuse, refurbishment and replacement will occur and batteries will have a longer lifespan, therefore reducing the amount of new batteries necessary for electrification.410 The disassembly of a battery from a vehicle and down to the cell level currently represents approximately a third of light-duty vehicle recycling costs in the United States.411 If Dfd occurs, this recycling cost will also decline, therefore leading to more prevalent recycling and greater availability of recycled supply. [EPA-HQ-OAR-2022-0829-0759, p. 151]

Koroma, et al., Life cycle assessment of battery electric vehicles: Implications of future electricity mix and different battery end-of-life management, Sci Total Env. 20;831:154859 (2022), available at https://www.ncbi.nlm.nih.gov/pmc/articles/PMC9171403/ (last accessed June 29, 2023).

411 See Jessica Dunn, et al., Electric vehicle lithium-ion battery recycled content standards for the US – targets, costs, and environmental impacts, Resources, Conservation and Recycling, 185, 106488, 0921-3449 (2022), at 6, Fig. 3, available at https://doi.org/10.1016/j.resconrec.2022.106488

Organization: Fred Reitman

Electric vehicles are unaffordable. New electric vehicles cost about $20,000 more than gasoline-powered vehicles. More than half of Americans are living paycheck to paycheck and cannot afford the higher cost of an electric vehicle (EV). Further, batteries will need to be replaced and the cost of new electric batteries range from $10,000 - $ 15,000. [EPA-HQ-OAR-2022-0829-0432, p. 1]

Organization: John Graham

The BEV model with the longest run of real-world experience, the Nissan Leaf, has experienced troublesome rates of battery degradation within the first half of the Leaf's expected life (Graham, 2021). It is instructive that most battery warranties for BEVs do not extend beyond 8 years or 100,000 miles of vehicle life.26 The NPRM refers to a claim that BEV batteries will last longer than the life of the vehicle but, as noted by NAS in 2021, that claim is based on laboratory tests. Real-world driving conditions are much more diverse (e.g., extreme temperature conditions, extreme uses of batteries and so forth) and may contribute to battery degradation in ways that lab tests do not cover.27 One specific concern with laboratory tests is that they can only simulate cycle life, not battery life, and real-world experience with battery life beyond about 10 years is completely lacking. Since battery replacement costs are so large, they must be addressed in the Final Rule. [EPA-HQ-OAR-2022-0829-0585, p. 20]

26 For data on the Leaf's rate of battery degradation and battery warranty policies, see John D. Graham. The Global Rise of the Modern Plug-In Electric Vehicle: Public Policy, Innovation, and Strategy. Elgar House Publishing, UK, 2021, 44-46.

27 National Academy of Sciences. Improving Light-Duty Vehicle Fuel Economy: 2025 to 2035. National Academies Press. Washington, DC., 2021, 115.

It is worth noting here that the smaller batteries in HEVs do tend to last at least as long as the life of the vehicle. However, that is due to the HEV's battery management system, which restricts the range of the battery charge level, usually between 30% and 70% of a full charge. BEVs require deeper charging cycles to accomplish the driving ranges that customers demand. It is well known that deeper charging cycles contribute to the rate of battery degradation. Unlike HEVs,28 BEVs also need to be designed to recharge as fast as possible, which also increases the rate of battery degradation. [EPA-HQ-OAR-2022-0829-0585, p. 20]

28 John D. Graham. 2021, 154 (see footnote 26 above for full reference).

Organization: Kentucky Office of the Attorney General et al.

But used EVs offer little savings if the buyer has to replace the battery. According to the Department of Energy's National Renewable Energy Laboratory, advanced batteries "wear out eventually," and today's batteries last only 8 to 15 years. Electric Vehicle Benefits and Considerations, U.S. Department of Energy Alternate Fuels Data Center, https://bit.ly/3PcOn9i. Replacing an EV battery costs anywhere from $5,000 to more than $15,000. Electric Car Battery Replacement Costs, Edmunds (May 2, 2023) https://bit.ly/3NutoNS. Such substantial expenses hardly qualify as "reduced repair and maintenance costs." 88 Fed. Reg. at 29,364. [EPA-HQ-OAR-2022-0829-0649, pp. 17-18]

Organization: Paul Bonifas and Tim Considine

Furthermore, batteries are the most expensive part of an EV, representing up to 50% of an EV's price tag40. Though most EV batteries come with a 5- to 10-year warranty, they only kick in if a battery's capacity falls below 70-75%. This means that an ICE vehicle could lose 30% of its mileage range, and still be considered by the warranty as in "good working condition." Any replacement that occurs outside of the warranty is the financial responsibility of the owner. The battery technology in EVs is very similar to that found in everyday smartphones. Anyone who has owned a new smartphone knows that the battery degrades over time, and regardless of how well it is maintained, the battery life will inevitably worsen and eventually die. The same is true for EV batteries. While some studies show that most EVs lose between 5-10% of their battery life in the first five years41, there are many reputable reports of brand- new EVs not living up to their supposed battery life, right off the lot. As an example, MotorTrend tested the F-150 Lighting Platinum EV that has an EPA-rated range of 300-miles on a new battery. When the test was run at an average highway speed of 70 mph – this resulted in a range of 255 miles, 15% less than the EPA rating. MotorTrend warns drivers to "expect driving range to fall with extreme [hot or cold] temperatures, higher speeds, or significant elevation changes. Alternatively, you can extend that range by driving slower, limiting air-conditioning and other accessory usage, and minimizing hard braking"42. [EPA-HQ-OAR-2022-0829-0551, pp. 10-11]

40 https://www.reuters.com/business/autos-transportation/scratched-ev-battery-your-insurer-may-have-junk- whole-car-2023-03-20

42 https://www.motortrend.com/reviews/2022-ford-f-150-lightning-platinum-range-max-charging-test-review/

Organization: POET, LLC

EPA estimates the U.S. will have more than 800 GWh of cell or battery manufacturing capacity by 2025, and 1,000 GWh by 2030, enough to supply from 10 to 13 million BEVs per year.4 This production would roughly be sufficient to meet EPA's compliance requirements. However, EPA did not explicitly consider the battery cost replacement for the current 2 million electric vehicles in the EV sales projections by 2032. Furthermore, the battery lifetime will largely depend on the consumer behavior and how often they charge the battery. Public fast chargers tend to degrade lithium-ion batteries at a quicker rate than slower home charging options. With shorter battery life, a higher battery production rate and critical material supply would be required than otherwise projected over the next 8 to 10 years. [EPA-HQ-OAR-2022-0829-0609, p. 36]

4 DRIA pg. 3-24.

U.S. EPA does not even consider the costs associated with battery replacement outside of warranty later in the life of a BEV or the fact that the overall lifetime of BEVs may be shorter than that of a conventional vehicle which would also impact a cost comparison based on vehicle lifetime that would negatively affect BEVs. U.S. EPA should account for these factors in its analysis of BEV penetration and at a minimum perform sensitivity analyses to determine how they could affect demand for BEVs and automakers ability to comply with the Proposed Rule. [EPA-HQ-OAR-2022-0829-0609, p. 59]

Organization: Steven G. Bradbury

For one thing, EPA ignores the cost of battery replacements for EV owners.34 EV batteries degrade over time with each charge and discharge, and this degradation will be accelerated if the EV gets heavy use, if it is driven through cold winters, or if the owner uses rapid recharging.35 Battery degradation reduces significantly the power and range of the EV and will eventually lead to an unacceptable risk of thermal runaway and fire.36 At a certain point in the life of the EV, depending on the nature of its use, the type of recharging, and the environment where the vehicle is driven, the owner will need to replace the battery (if replacement is even feasible)—just to maintain or restore the utility of the vehicle or for safety reasons. Further, independent of use, if the battery is scratched or suffers other forms of damage in a relatively minor traffic accident, the battery may need to be replaced prematurely (or the vehicle may be considered a total loss).37 [EPA-HQ-OAR-2022-0829-0647, pp. 13-14]

34 Section 3.1 of the EPA's draft regulatory impact analysis (DRIA) for the proposed light- and medium-duty rule, for example, does not include any estimate for the cost of battery replacement.

35 See Jacqueline S. Edge, et al., "Lithium ion battery degradation: what you need to know," Royal Society of Chemistry, March 22, 2021, https://pubs.rsc.org/en/content/articlehtml/2021/cp/d1cp00359c (identifying 5 principal and 13 secondary mechanisms causing degradation of lithium-ion batteries in EVs, and explaining that degradation will be exacerbated by, among other things, usage profile, outside temperature, and the use of fast charging); Niall Kirkaldy, et al., "Lithium-Ion Battery Degradation: Measuring Rapid Loss of Active Silicon in Silicon-Graphite Composite Electrodes," American Chemical Society Applied Energy Materials, November 3, 2022, https://pubs.acs.org/doi/10.1021/acsaem.2c02047 (similar).

36 Significant loss in battery capacity and range over the life of the EV is expected and allowed for even within the parameters of the UN's GTR No. 22 standard for EV battery durability cited by the EPA.

37 See https://www.reuters.com/business/autos-transportation/scratched-ev-battery-your-insurer-may-have-junk-whole-car-2023-03-20/ (full citation in footnote 17 above).

Battery replacement, when available, will undoubtedly be very expensive. For an EV battery pack with a capacity of 100 kWh (the capacity level assumed by the EPA in its models), the replacement battery alone (not including labor, any fee for disposing of the old battery, and any other associated expenses) would cost at least $15,300. That figure is based on the Energy Department's 2022 estimated cost of manufacturing the battery—$153 per kWh of capacity. [EPA-HQ-OAR-2022-0829-0647, p. 14]

Organization: The Heritage Foundation (Kevin Dayaratna and Diana Furchtgott-Roth)

The last detrimental aspect of this arbitrary benchmark is that part of the cost analysis done by EPA included refueling time. With larger batteries come longer recharge times, which again add to the cost. While EPA might argue that the high-speed chargers will make up for that, EPA does not want to address the fact that rapid charge or discharge of a battery accelerates its lifecycle. Every time a consumer inputs or draws large amounts of power from a battery, it damages it more than a slower input or draw, thereby decreasing the timeline for the battery's replacement and moving that expense up sooner in the timeline of EV ownership. [EPA-HQ-OAR-2022-0829-0674, p. 9]

EPA's cost estimate does not include battery replacement.37 With the proposed standards taking effect in 2027, and some of the cost and savings estimates being extrapolated out through 2055, even if Tesla can be the first EV manufacturer to achieve a battery that lasts 20 years, a replacement will be a requirement. Based on the EPA's chosen 100 kWh capacity and the Department of Energy's 2022 estimated cost of manufacturing of $153/kWh, a new battery without labor, disposal fees, and other associated expenses would cost the consumer $15,300. [EPA-HQ-OAR-2022-0829-0674, p. 10]

37 "Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles." EPA, Apr. 2023, www.epa.gov/system/files/documents/2022-12/420d22003.pdf (accessed 5 July 2023).

Table 4-5, which outlines the studies used to justify the proposal, shows that all but one study either came from California or New York. The claimed national study only contained 862 vehicles and therefore poses insignificant statistical relevance. It also shows that the entirety of the country is not represented. While the Census Bureau splits the United States at 80% urban and 20% rural living, New York and California cannot be considered as viable representations of the county's entire population. Due to differences in infrastructure, state-imposed regulations and laws, population density, and other factors, it is likely that differences could be found even between major cities throughout the country. [EPA-HQ-OAR-2022-0829-0674, p. 10]

On page 4-34, when referring to maintenance costs over the 225,000-mile life of a vehicle, EPA does not mention the need for battery replacement.

While EPA does not address this issue directly in any of its cost analysis, they do open the door to scrutiny and show their hypocrisy a bit by mentioning the battery durability standards in 1-4, 1-5, and 1-6. Based on the UN standards, a battery capable of supplying its platform with a range of 300 miles when new would be considered within the standard so long as it could provide 240 miles of range after 5 years or 62,000 miles. Additionally, it would remain within that standard if it could provide 210 miles of range to its associated platform after 8 years or approximately 100,000 miles. It only continues to degrade from there. [EPA-HQ-OAR-2022-0829-0674, p. 10]

In the table below, the initial data is from the UN standard and the rest is calculated from there based on linear degradation of the battery throughout its lifecycle. The reality is that the degradation would be faster than this and fast charging used to compete with ICE vehicle refuel times will only exacerbate the degradation. I have also placed a couple helpful links below that support this claim. [EPA-HQ-OAR-2022-0829-0674, p. 10]

EPA's cost estimate does not include battery replacement.37 With the proposed standards taking effect in 2027, and some of the cost and savings estimates being extrapolated out through 2055, even if Tesla can be the first EV manufacturer to achieve a battery that lasts 20 years, a replacement will be a requirement. Based on the EPA's chosen 100 kWh capacity and the Department of Energy's 2022 estimated cost of manufacturing of $153/kWh, a new battery without labor, disposal fees, and other associated expenses would cost the consumer $15,300. • Full impacts to drivers, including: Costs associated with battery replacements; [EPA-HQ-OAR-2022-0829-0707, pp. 31-33]

c) EPA omits costs of premature battery degradation

Temperature control is important for protecting the functionality of a lithium ion battery. One of the ways battery suppliers and automakers reduce the costs of batteries is to save money on their battery cooling systems. The Nissan Leaf, for example, was designed with a passive air-cooling system, in contrast to Tesla's dual-circuit liquid cooling system.196,197 The cost savings in production were accomplished, but the Leaf battery packs experienced unexpectedly high rates of battery degradation during normal use, especially in the first-generation Nissan Leaf. Even after the 2015 redesign of the Leaf, which improved the air-cooling system, the degradation rate (defined as percent loss of battery capacity in a year) was 18% by the fifth year of use (compared to 24% for the 2014 version of the Leaf). 198 The most recent versions of the Leaf have only 1-3% degradation rates in the first year of use,199 but it is too early to tell how well the improved Leaf batteries will hold up in the middle and later parts of the vehicle's 15-30 year lifespan. [EPA-HQ-OAR-2022-0829-0707, pp. 38-40]

The history of Nissan's warranty policy implicitly acknowledges the battery degradation issue. The original warranty for battery defects in the base Leaf was only 5 years and 60,000 miles.200 The higher-trim version was backed for 8 years and 100,000 miles.201 Consumer complaints about the Leaf's high rate of battery degradation in hot climates compelled Nissan to upgrade the warranty: a replacement battery with superior battery chemistry was pledged if the original battery's capacity fell below 75% within the first five years or 60,000 miles.202 More recently, the 8-year/100,000-mile warranty has been extended to the base version but, again, only if the battery capacity is compromised by more than 25%.203 That means a loss of driving range from 150 miles to 112.5 miles might not be covered under the warranty. [EPA-HQ-OAR-2022-0829-0707, pp. 38-40]

The warranty policy for the Chevrolet Bolt also acknowledges battery degradation issues. Chevrolet states that the Bolt's battery pack should last longer than 15 years.204 However, the Bolt owner's manual cautions that battery degradation could be as large as 40% during the warranty period of 8 years or 100,000 miles.205 A 40% degradation corresponds to a loss of 95 miles out of the Bolt's 238 miles of range.206 The cost of replacing a Bolt battery pack is $16,250 plus $850 for labor.207 That is for the 66 kWh battery back that delivers 250 miles of driving range.208 [EPA-HQ-OAR-2022-0829-0707, pp. 38-40]

EPA's cost analysis ignores the Leaf experience and assumes that all future lithium ion batteries will last longer than the vehicle's lifetime. Thus there are no replacement costs. However, EPA must acknowledge that the Tesla batteries, which form the foundation for EPA's optimistic position on battery degradation, were not designed for an affordable EV. Moreover, the Tesla prediction is based on laboratory predictions where Tesla models were tested. Real-world rates of battery degradation are less well understood because even the first-generation EVs (the Nissan Leaf and early Tesla models) are only beginning to enter their second decade of vehicle life. It is difficult to predict real-world rates of battery degradation based on laboratory testing because of the complexity of real-world operating conditions (mixed operating conditions, various ambient temperatures, different depths of charges, and different voltages). [EPA-HQ-OAR-2022-0829-0707, pp. 38-40]

EPA Summary and Response

In response to comments that we did not consider the cost of replacement of the high-voltage battery in PEVs, EPA disagrees that high-voltage batteries will routinely need to be replaced during the useful life of the vehicle. Based on current experience with vehicles in use in the field, and consultations on this topic that EPA has conducted with experts, stakeholders, and manufacturers, EPA finds no evidence that battery replacements out of warranty will typically be necessary for PEVs during their useful life, and therefore we have no basis for including the cost of battery replacement in the cost of PEV maintenance and repair. Additionally, commenters provided no supporting data to validate their expectation that any specific percentage of PEVs will routinely need a battery replacement during their useful life or that manufacturers widely expect such replacements to be necessary. EPA is not aware of any manufacturer that has publicly indicated that their battery is not designed to last for the useful life of the vehicle.

Commenters put forth several observations that they claim support their view that PEV batteries will need to be replaced and/or that EPA should consider their replacement cost in the analysis, but EPA finds these arguments to lack merit. EPA does not agree with comments that the batteries used in vehicles are similar to those used in smartphones to the degree that one commenter suggests; in contrast, PEV batteries typically employ a robust thermal management system and a battery management system, have a much larger thermal mass that better resists temperature variations, and have a multi-cell design in which individual cells are electrically balanced to maintain working order. Further, EPA does not find the example of the first-generation Nissan Leaf (in production from 2010 to 2017) to be a relevant indicator of the degradation rate of more recent battery designs in other vehicles, which have not shown the same behavior. Moreover, the Leaf had a relatively short driving range on the order of 100 miles, provided by a relatively small battery of about 24 kWh. BEVs modeled in our compliance analysis have batteries averaging about 100 kWh meaning that a given distance driven daily over the life of the vehicle would amount to about one-fourth as many equivalent full discharge cycles as for the Leaf, assuming energy consumption per mile were the same. Even if the energy consumption were higher, the 100 kWh battery would experience far fewer equivalent discharge cycles than the Leaf, leading to less potential for degradation. EPA also notes that ICE vehicles sometimes experience the need for major engine repair, engine replacement, and/or transmission replacement before their useful life is over, and EPA has not attempted to predict these relatively unpredictable events nor has traditionally attempted to quantify their costs in its analyses. We also disagree with the cited example in which an F-150 is said to have battery degradation “right off the lot,” as the cited example does not describe battery degradation but only demonstrates the expected variation in driving range that is understood to result from driving at different speeds or temperatures or similar deviations from the certification test cycles. EPA also disagrees with the contention that the fact we run our analysis out to the year 2055 implies that PEVs in the fleet will have to last to 2055, because our analysis assumes that vehicles that exist in the early years of the analysis fleet gradually leave the fleet as they age. We also disagree with the contention that Tesla batteries are not relevant to establishing the longevity of PEV batteries because they “were not designed for an affordable EV.” Commenter does not provide evidence that the design of the Tesla pack, which commenter suggests has good battery life, is somehow more costly or significantly different than a pack that the same manufacturer would design for a lower priced vehicle; while Tesla has stated an intention to use lower cost lithium-iron-phosphate packs in its lower cost vehicles, this chemistry is not generally regarded as having a shorter life than the nickel-based packs used in its other vehicles.

EPA also disagrees that the example of the Chevy Bolt warranty has evidentiary value in supporting the belief that PEV batteries will need replacement or will regularly decline to less than the 60 percent value cited in the warranty manual; in fact, commenter also notes that “Chevrolet states that the Bolt’s battery pack should last longer than 15 years,” and does not provide evidence or data to show that batteries in this vehicle are showing evidence of having a shorter life or degrading to near 60 percent. We also note that the battery durability and warranty standards established in this rule provide greater assurance and transparency regarding battery performance and the conditions under which a warranty repair or replacement must be honored, which will likely serve to motivate manufacturers to uphold battery longevity in future model years. See Section III.G.2 of the preamble and Section 16 of the response to comments document for expanded discussion of battery durability and warranty.

In response to comments from the Heritage Foundation (Bradbury) that assert a perpetual linear degradation of batteries to as low as 34 percent as suggested by the table commenter provides, EPA disagrees and notes in particular that citations provided by the commenter do not support the calculated figures commenter shows in the table and in fact indicate that battery degradation does not proceed in a perfectly linear manner but commonly assumes different rates at various stages, for example, see Figure 17 of the cited J.S. Edge et al.[463] in which degradation is flat for a long period during middle of life. EPA also notes that generalizations drawn from research papers that concern lithium-ion technology in general or at a cell level often do not apply perfectly to batteries that have been designed for specific applications, including PEV applications. Regarding commenter’s statements on the comparative stringency of the CARB and EPA standards, comparative stringency is difficult to quantify precisely due to the complexity of battery durability, but EPA considers the two standards to be similar in stringency, as the nominal performance criteria are reasonably similar, and where they are not the same, as the commenter has indicated, this is compensated by differences in other specific aspects (see EPA’s response in RTC Section 16, Battery durability and warranty, to comments that EPA should adopt certain specific provisions of the CARB program).

In response to comments that even minor accidents can cause a PEV to be “totaled,” and that EPA should therefore account for this possible cost in its analysis, EPA disagrees. EPA acknowledges that some press reports have suggested that some insurers have chosen not to repair vehicles with relatively minor damage or potential battery damage, but these observations are largely anecdotal and EPA is not aware of any well-documented study that shows that this practice is fundamental to addressing damage to PEVs, nor have commenters provided such data or evidence. EPA also is not aware of data, nor have commenters provided such data, that would quantify the frequency of these practices or the increase in repair costs due to these practices in

[463] Edge, J. S. et al., “Lithium ion battery degradation: what you need to know,” Phys. Chem. Chem. Phys., 2021, 23, 8200.

the current fleet, nor have commenters provided evidence that the practice is likely to continue in a future fleet as familiarity with PEVs increases.

12.2.6 – Other battery/electrification technology

Comments by Organizations

Electric Vehicle Battery and Range Limitations

South Dakota is a large state with significant driving distance between many of our communities. Although several new electrical vehicles indicate they have a 200 mile or greater range (note -it is 224 miles one way from Pierre to Sioux Falls), a recent study shows electric vehicles (EVs) do not consistently achieve EPA's range estimates. In addition, all batteries degrade over time. Reports indicate EV vehicle batteries will degrade between 10 and 40 percent over a 10-year life span. To maintain the battery's life, manufactures recommend batteries are not frequently depleted below 10 percent capacity or charged above 90 percent capacity. This means that an electrical vehicle should be limited to 80 percent of its capacity range to maintain the battery's life. In addition, cold, hot, and windy weather conditions may reduce an EV vehicle's range between 20 to 40 percent and may further impact the reliability of EV. South Dakota is known to have cold and windy winters and hot and windy summers, which, with current EV ranges, batteries conditions, and availability of charging stations, makes widespread use of EVs impractical in South Dakota. [EPA-HQ-OAR-2022-0829-0523, p. 2]

Organization: Valero Energy Corporation

EPA applies a similar approach to FCEVs. For the MY 2021 analysis fleet, EPA correctly identifies base-year vehicles IDs 168, 436, and 438 as FCEV."26 Starting with the MY 2022 analysis fleet, EPA forces all FCEVs into BEV fueling and technology classes, ignoring the attributes of the electrical powertrain and arbitrarily excluding the PHEV technology from the modeled compliance scenario.27 The FCEV technology and costs are distinct from BEVs, and it is not appropriate for EPA to combine FCEV into the BEV cost curve class or assign BEV properties that do not logically apply to FCEV. [EPA-HQ-OAR-2022-0829-0707, p. 5]

Despite the clear history and trends related to BEV recalls, EPA fails to consider the costs of recalls in the cost analysis for the proposed standards. [EPA-HQ-OAR-2022-0829-0707, pp. 40-41]

EPA Summary and Response

EPA acknowledges and appreciates the comment received on other battery or electrification technologies. The comments in this category relate primarily to electrification technologies or costs that were not covered in other sections.

In response to comments advocating for hydrogen fuel cell vehicles, EPA notes that although these vehicles were not explicitly represented in the compliance analysis, they are considered zero-emission vehicles under the program and their inclusion or exclusion from the compliance analysis does not preclude manufacturers from producing this technology as part of their compliance plan. EPA expects that these vehicles will be produced in relatively small volumes during the time frame of the rule due in part to factors such as a relatively high production cost and the availability of other technologies for compliance. EPA's application of BEVs as a replacement technology for redesigned FCEVs in the base year fleet is considered the most similar surrogate technology available in OMEGA, with an equivalent compliance value to FCEVs (0 g/mi). While the costs for FCEVs and BEVs may differ, the small volumes of FCEVs modeled as BEVs should be of minimal impact to the fleet technology costs. Regarding regulating the source of the hydrogen fuel for these vehicles, EPA agrees that hydrogen sources vary in their upstream CO_2 impact but due to the limited expected production of these vehicles during the time frame of the rule we believe that any impacts from hydrogen fueling would have a very small effect on our estimated CO_2 emissions impacts.

In response to comments that we should consider the cost of manufacturers recalling vehicles to repair defects in BEV powertrains, EPA notes that recall and repair costs are commonly encountered with vehicles of all technology types and are typically considered to be part of the cost of research and development, and research and development costs are commonly higher for newer technologies. The use of a multiplication factor applied to direct manufacturing cost of components is the typical way in which such costs are represented in analyses of technology cost, and EPA considers our use of a 1.5 multiplier (RPE factor) to be inclusive of these costs. Commenter has not provided specific data or evidence to support their view that average per vehicle recall costs over time for BEVs should be expected to be fundamentally higher than for ICE vehicles or other technologies, nor that EPA's analysis does not adequately account for these costs by means of the RPE factor.

In response to comments regarding electric vehicles in South Dakota, it is well known that the range of an electric vehicle is affected by cold weather, that range may vary, and that some long trips exceed the range of some electric vehicles. ICE vehicles also do not have unlimited range and the relative importance of range with electric vehicles depends in part on battery size and the availability and speed of charging away from home, which at the current time varies from location to location but is improving. See RTC section 17 for further discussion of charging infrastructure. EPA notes that the standards can be met with a variety of technologies and that the standards do not mandate electric vehicles in South Dakota or any other state. Manufacturers are free to produce vehicles that meet the needs of their customers who are free to choose them. We expect that customers in any state will include those whose needs are best met by an electric vehicle and for those whose needs are best met by another technology such as PHEVs, HEVs, or ICE vehicles, and the standards do not prevent those vehicles from being available.

12.2.7 - PEV vehicle costs and cost/price parity

Comments by Organizations

Organization: Environmental Defense Fund (EDF) (1of 2)

The IRA credits also reduce the time to achieve total cost of ownership (TCO) parity for all classes and segments of light-duty vehicles – or the time it will take consumers to realize net cost savings. In MY 2025, TCO parity is achieved immediately for compact cars, midsize cars, small SUVs, and midsize SUVs, while TCO parity is achieved in 4 years and 2 years for base-segment large SUVs and pickup trucks, respectively. In MY 2030, TCO parity is achieved immediately for all segments and classes. [EPA-HQ-OAR-2022-0829-0786, pp. 17-20]

The net cumulative savings for a BEV with IRA credits compared to a gasoline vehicle is substantial across almost all subclasses and segments in the 2025 timeframe, growing even more significant by 2030 purchase timeframes (see Figure 3). In 2025, the BEV savings over an equivalent gasoline vehicle are sizeable, ranging from more than $11,000 to over $19,000 for compact cars, midsize cars, small SUVs and midsize SUVs, across both base and premium segments. Large SUVs and pickups see fewer savings in 2025, with the premium large SUV still costing more than a comparable gasoline vehicle. However, in the 2030 timeframe, the savings range from more than $14,000 to over $27,000 across all vehicle subclasses and segments, including large SUVs and pickup trucks, with base model pickups seeing the greatest savings. [EPA-HQ-OAR-2022-0829-0786, pp. 17-20]

[See original comment for Figure 3: Cumulative lifetime savings of BEVs over equivalent gasoline vehicles] [EPA-HQ-OAR-2022-0829-0786, pp. 17-20]

Source: Roush, Impact of the Inflation Reduction Act of 2022 on Light-Duty Vehicle Electrification Costs for MYs 2025 and 2030 [EPA-HQ-OAR-2022-0829-0786, pp. 17-20]

Note: The net savings are computed and indicated in the text above the columns [EPA-HQ-OAR-2022-0829-0786, pp. 17-20]

Even without the significant impact of the IRA, BEVs still provide cost savings over the timeframe of EPA's proposal. An earlier Roush report for EDF (which only looked at 2030 purchase timeframe) found that for all BEVs up to a 300-mile range, purchase price parity with a comparable gasoline vehicle is reached by 2030, across all vehicle classes and segments.47 And by 2030, the total cost of ownership for all BEVs up to a 400-mile range were found to be equal to or lower than their gasoline counterparts across all classes and segments. The study found that even without the IRA tax credits, BEVs purchased in 2030 could see an average cumulative net savings of about $15,000 over the lifetime of the vehicle, across all classes and segments. Moreover, as noted in Section 1, above, a new EDF study with WSP demonstrates that consumers are experiencing these savings right now when purchasing BEVs. Over 10 years of owning and operating select, current EVs to comparable gasoline vehicles, the analysis finds that current, higher upfront purchase price and insurance costs for EVs are outweighed by the lower maintenance and fuel costs, with total lifetime savings of up to $18,440.48 [EPA-HQ-OAR-2022-0829-0786, pp. 17-20]

47 Himanshu Saxena, Vishnu Nair, Sajit Pillai, "Electrification Cost Evaluation of Light-Duty Vehicles for MY 2030,"(2023) Roush for EDF, https://www.edf.org/sites/default/files/2023-05/Electrification_Cost_Evaluation_of_LDVs_for_MY2030_Roush.pdf.

48 Electric Vehicle Total Cost of Ownership Analysis, Summary Report, WSP for EDF (July 2023), https://blogs.edf.org/climate411/wp-content/blogs.dir/7/files/WSP-Total-Cost-of-Ownership-Analysis-July-2023.pdf (Attachment G).

The Roush studies support EPA's proposed standards by showing that BEV costs are expected to continue to decline, achieving cost parity with gasoline vehicles over the timeframe of the rulemaking. These findings closely align with EPA's determination that BEVs represent the most cost-effective option for compliance and, in fact, demonstrate that EPA's BEV cost projections are likely conservative. [EPA-HQ-OAR-2022-0829-0786, pp. 17-20]

2. Roush's analyses are consistent with other recent analyses projecting substantial cost declines.

Recent expert analyses corroborate Roush's findings that BEV vehicle costs are declining rapidly and will soon be on par with comparable gasoline vehicle costs. A 2022 paper by ICCT analyzed bottom-up vehicle component-level costs to assess battery electric, plug-in hybrid electric, and conventional vehicle prices across the major classes of the U.S. light-duty vehicle market through 2035.49 Their analysis did not consider the impact of the IRA or other federal or state tax incentives. Even without those benefits, ICCT found declining battery and assembly costs, resulting in shorter-range BEV150s and BEV200s estimated to reach price parity by 2024-2026, with mid-range BEVs seeing parity around 2026-2029 and longer-range BEVs achieving parity around 2029-2032. These findings apply to electric cars, crossovers, sport utility vehicles, and pickup trucks, which cover all light-duty vehicle sales in the United States. Table 3 summarizes the year by which BEVs reach price parity with ICEVs. ICCT's analysis is also consistent with Roush in finding that BEVs provide significant cost savings to consumers before purchase price parity is achieved. ICCT estimates that typical six-year fuel and maintenance cost savings range from $6,600 to $11,000 per vehicle purchased in 2025, with the greatest absolute savings for the pickup and SUV class. [EPA-HQ-OAR-2022-0829-0786, pp. 20-21]

[See original attachment for Table 3: Summary of year by which BEV price parity is reached] [EPA-HQ-OAR-2022-0829-0786, pp. 20-21]

Source: ICCT, Assessment of Light-duty Electric Vehicle Costs and Consumer Benefits in the United States in the 2022-2035 Timeframe [EPA-HQ-OAR-2022-0829-0786, pp. 20-21]

Following their 2022 cost analysis, ICCT conducted a study assessing the future impact of the IRA on electrification rates for light-, medium-, and heavy-duty sales in the U.S. through 2035.50 They estimate, on average over the period 2023-2032, the IRA tax credits will reduce light-duty EV purchase costs by $3,400 to $9,050. ICCT concludes that the IRA will accelerate electrification of both light-duty and heavy-duty sectors. By 2030, the study estimates a range of 48-61% EV share of light-duty vehicles in the U.S., increasing to 56-67% by 2032, which is the last year of the IRA credits. [EPA-HQ-OAR-2022-0829-0786, pp. 20-21]

Organization: Hyundai Motor America

Further, the Agency should reevaluate the assumption that price parity will be achieved by the mid- 2020s. Price parity with ICE is key to the high rates of BEV adoption required under the Proposed Alternative; it is also highly dependent on reducing material costs and costs of battery technology improvements. The recent increase in raw material prices and the unstable nature of battery system material costs in the market are just two examples of the headwinds to price parity. It is exacerbated by the cost impacts resulting from IRA’s battery component, critical minerals, and final assembly requirements even accounting for the benefits of the IRA’s 45X tax credits. This also underscores the need for the EPA to study the true costs of the IRA as described above and its impacts to ICE-BEV price parity attainment. [EPA-HQ-OAR-2022-0829-0599, pp. 6-7]

Organization: International Council on Clean Transportation (ICCT)

ICCT also believes that EPA has overestimated battery electric vehicle (BEV) costs. In in-depth study, we find that incremental BEV costs relative to their combustion vehicle counterparts are much lower than the estimates by EPA by about $2,300 (pickups) to about $5,300 (crossovers) in 2027. For 2032, EPA finds that BEVs have incremental costs of about $3,000 to $5,000; during this same timeframe, the ICCT study finds that BEVs will be cheaper to purchase than comparable gasoline vehicles. This difference is the result of several factors. We find that on average, battery pack costs in the ICCT analysis are about $3,700 less than in EPA’s analysis in 2027 and about $5,200 less than in EPA’s analysis in 2032. We believe EPA has overestimated pack size, BEV energy consumption, and pack-level costs ($/kWh). If EPA were to update their analysis with the data and evidence regarding BEV cost and technical specifications based on the ICCT cost study, BEV costs would be lower, the costs of compliance would be lower, and the net benefits would be greater. [EPA-HQ-OAR-2022-0829-0569, p. 4]

An ICCT and Energy Innovation study assesses the future impact of the IRA on electrification rates for LDV sales in the United States through 2035.4 We analyze the value of the personal and commercial EV tax credits, factoring in the various supply chain, income, and price caps on new EVs, and combine this with new estimates of future light-duty EV cost declines. We find that, on average over the period 2023–2032, the IRA tax credits will reduce EV purchase costs by $3,400 to $9,050 and accelerate the timing for price parity with combustion vehicles. Using methodologies from the Energy Policy Simulator, we project how these changing costs and incentives over time will affect the LDV markets in the United States. [EPA-HQ-OAR-2022-0829-0569, pp. 6-7]

4 Slowik, P., Searle, S., Basma, H., Miller, J. Zhou, Y., Rodriguez, F., Buysse, C., Kelly, S., Minjares, R., Pierce, L. (ICCT) Orvis, R., and Baldwin, S. (Energy Innovation). (2023). Analyzing the impact of the inflation reduction act on electric vehicle uptake in the United States. https://theicct.org/publication/ira-impact-evs-us-jan23/

Figure 1 summarizes the results from the ICCT and Energy Innovation IRA study. It shows the findings of estimated new electric vehicle sales shares for different IRA scenarios depending on how certain provisions are implemented and how the value of incentives is passed on to consumers. The figure shows our modeled projection of how the IRA will accelerate electrification. By providing thousands of dollars in financial incentives, the IRA unlocks widespread consumer benefits. We find rapid projected EV uptake when considering both expected manufacturing cost reductions and the IRA incentives, as well as state policies. By 2030, we find a range of a 48%–61% projected EV sales share, increasing to 56%–67% by 2032, the final year of the IRA tax credits. [EPA-HQ-OAR-2022-0829-0569, pp. 6-7]

EPA Summary and Response

Summary:

EDF commented that, even without the IRA tax credits, BEVs purchased in 2030 could see an average cumulative net savings of about $15,000 over the lifetime of the vehicle, across all classes and segments. EDF also commented on the issue of price parity between BEVs and ICE vehicles. Hyundai Motor America commented that EPA should reevaluate the assumption that price parity will be achieve by the mid-2020s, noting that it is key to the high rates of BEV adoption required under the proposal. ICCT also provided an analysis based on a variety of assumptions that pointed to lower costs for PEVs than in the proposal, and cited outlooks for cost parity or price parity.

Response:

EPA appreciates the comments from EDF and ICCT. EPA agrees that BEVs can provide significant savings to consumers relative to ICE vehicles over the lifetimes of those vehicles. Regarding projections of BEV or PHEV prices lower than those forecast by EPA, we appreciate this input but continue to rely on full vehicle costs that are generated by the cost inputs and other assumptions to OMEGA which we have described in other sections and which EPA believes represent the best available data.

Regarding the issue of cost parity or price parity, including general comments as well as Hyundai's suggestion that EPA reevaluate the issue of cost/price parity between BEVs and ICE vehicles, we have reevaluated most of our technology cost estimates used in our OMEGA modeling. Note that while we do not analyze price parity explicitly as part of our OMEGA modeling analysis, we do discuss the literature on the topic in the preamble for both the proposed and final rules (see Section IV.C.1 of the preamble), and note certain projections that price parity, particularly on a total cost of ownership basis, would begin to occur by the mid- to late-2020s. We discussed these projections as part of our general assessment that interest in, and sales of, BEVs are rapidly increasing in the automotive market. This assessment supports our general view that it is reasonable to account for BEV technologies in assessing the stringency of the standards. Specifically, when doing our technical analysis, we do not believe it is necessary to project or achieve parity between BEV and ICE vehicles, but instead we estimate technology costs and weigh the relative costs and emission reduction potential in assessing the combination of technologies that manufacturers could use to meet the standards.

12.3 - ICE vehicle technologies

Comments by Organizations

Organization: Alliance for Automotive Innovation

6. Modeling of Internal Combustion Engine Vehicles

Some commenters may advocate that EPA maximize CO2 reductions in internal combustion engine vehicles while also driving large increases in EV market share through the adoption of yet more stringent standards than those proposed by EPA. Such comments do not adequately consider the massive human and capital resource requirements of the transition to EVs, and the limited nature of such resources. They also fail to recognize that revenue from relatively more profitable ICEVs is generally being used by legacy automakers to fund investments in EVs. [EPA-HQ-OAR-2022-0829-0701, pp. 111-112]

Other commenters or EPA may downplay concerns associated with the level of EV market share estimated by EPA to meet its proposed standards or the alternatives under consideration, noting that improvements in ICE vehicles could reduce the overall EV market share requirements. Such views again ignore capital and human resource availability, and furthermore fail to consider that such improvements would only have a minimal effect on EV market share given the level of standards under consideration. [EPA-HQ-OAR-2022-0829-0701, pp. 111-112]

We provide the following comments to EPA in support of our position that EPA should assume de minimis improvements in the overall efficiency of the average internal combustion engine vehicle, allowing manufacturers the flexibility to focus investments on the design and production of EVs, and improving ICEVs only where it makes sense to do so. [EPA-HQ-OAR-2022-0829-0701, pp. 111-112]

a) EV vs. ICE Investments

Automakers are focusing investments on electric vehicles. According to the Center for Automotive Research, recent North American investment announcements are overwhelmingly on electric vehicles and batteries (Figure 32).203 [EPA-HQ-OAR-2022-0829-0701, pp. 111-112]

203 Data presented in this figure includes non-plug-in hybrid electric vehicle investments. However, we believe that it is reasonable to assume that almost all of the electric vehicle / battery related investments shown are for plug-in electric vehicles.

Figure 32: Announced Automaker EV/Battery Related Investments, North America, 2009-2023 YTD.204 [EPA-HQ-OAR-2022-0829-0701, pp. 111-112]

204 Center for Automotive Research (Apr. 2023), Book of Deals: Automaker Announced Investment.

b) ICEV Improvement as a Substitute for BEVs

EPA asserts that the standards are performance-based, and therefore improving ICEVs can reduce the overall level of electrification required to meet GHG standards.205 While technically accurate, such actions would only have a small effect on the degree of electrification required by the proposed standards. [EPA-HQ-OAR-2022-0829-0701, pp. 112-114]

205 NPRM at 29342. ("At the same time, we note that the proposed standards are performance-based and do not mandate any specific technology for any manufacturer or any vehicle. Moreover, the overall industry does not necessarily need to reach this level of BEVs in order to comply—the projection in our analysis is one of many possible compliance pathways that manufacturers could choose to take under the performance-based standards. . .")

Although the standards are, in theory, technology-neutral, the level of standard proposed is far beyond the capabilities of non-electrified vehicles. For example, the best-performing (relative to target) MY 2022 or MY 2023 vehicle, a strong hybrid, still exceeds its target by MY 2029 and is almost 40 g/mile worse than its MY 2032 target.206 In Figure 33, we show MY 2022 and MY 2023 207 vehicles relative to their proposed MY 2032 target. The MY 2032 target is shown as neutral (zero). Models with 2-cycle CO2 emissions that exceed the standard are shown as negative (i.e., worse than target) and models with 2-cycle CO2 emissions lower than target are shown as positive (i.e., better than target). Only ZEVs are consistently better than the proposed MY 2032 target. Current PHEVs are both better and worse than the MY 2032 target, depending on the specific model. Strong hybrid electric models are currently about 40 g/mile or more worse than their targets. The best mild- and non-hybrid ICEVs are generally over 100 g/mile worse than the proposed MY 2032 target. [EPA-HQ-OAR-2022-0829-0701, pp. 112-114]

207 Both MY 2022 and 2023 vehicles are used to ensure that the changing availability of some MY 2023 hybrids does not result in missing certain better-performing (relative to GHG standards) models. We acknowledge that there may improvement in certain models between MYs 2022 and 2023, but in general, most models see little or no change between model years, so overall conclusions drawn from such a view are likely still accurate.

Figure 33: MY 2022/2023 Light-Duty Models 2-Cycle CO2 Performance Relative to Proposed MY 2032 Target208 [EPA-HQ-OAR-2022-0829-0701, pp. 112-114]

208 Calculations by Auto Innovators. Data sourced from S&P Global Vehicle Technical Intelligence Platform.

While some ICEVs might be improved, thereby reducing BEV market share requirements to reach the fleet average target, such approaches are unlikely to significantly reduce the BEV market share projected by EPA as necessary to meet the proposed targets. Wells Fargo estimates that BEV market share will need to be 62% to meet the proposed standards, even if automakers "maximize hybrid mix."209 [EPA-HQ-OAR-2022-0829-0701, pp. 112-114]

209 Wells Fargo Equity Research (Jun. 9, 2023), Will Automakers Get Regulated to Unprofitability?

c) ICE Emissions During the Transition to Electric Vehicles

During the transition to electric vehicles, ICE CO2 emissions may not remain completely stable or improve significantly. [EPA-HQ-OAR-2022-0829-0701, pp. 114-115]

Manufacturers are unlikely to remove technologies that they have already sunken investments into. However, an EV model may replace an ICE model that has relatively lower emissions than other ICE models. The overall emissions of the fleet would improve, but the emissions from the remaining ICE portion of the fleet would be higher on average. This is not and should not be considered backsliding. [EPA-HQ-OAR-2022-0829-0701, pp. 114-115]

A similar effect might be observed with industry-average emissions in the remaining portion of the ICE fleet. While all manufacturers are moving toward electric vehicles, they are unlikely to do so at exactly the same rate. If a manufacturer with relatively lower CO2 emission vehicles increases EV market share more quickly than industry on average, the remaining ICE vehicles in the fleet would have higher average emissions. Again, the higher average emissions of the ICE fleet would not be related to removal of technology from the existing ICE vehicles, and should not be considered backsliding. [EPA-HQ-OAR-2022-0829-0701, pp. 114-115]

Organization: American Council for an Energy-Efficient Economy (ACEEE)

Continued improvement in internal combustion engine vehicles is needed

Even under Alternative 1, there would still be over 40 million new ICEVs sold over the life of these standards. These vehicles could be on the road for two decades, contributing significantly to local air pollution, climate change, and costing drivers considerably at the pump. It is critical that the new standards continue improvements on ICEV efficiency while also pushing the market to electrify. Our modelling shows that under EPA's achieved emissions rates, ICEV emission rates would needlessly rise and would be as high as MY 2023 levels. Under the proposed standard, ACEEE estimates that average ICEV emissions could increase by up to 2.9% per year, contributing an extra 805 million metric tons of lifetime CO2 compared to a future where ICEV performance flatlines at model year 2026 levels. This is equivalent to an approximately 11% increase in emissions from the projected savings in the rule of 7,300 million metric tons of CO2 (FR 29198, Table 3). [EPA-HQ-OAR-2022-0829-0642, pp. 3-4]

This calculation assumes BEV penetration reaches what EPA projects under its proposal and includes upstream emissions accounting for all vehicles. However, it also factors in the reduction of credits, which limits the increase in ICEV emissions compared to model year 2026 (when there are significantly more credits available). Removing the effects of the proposed off-cycle and A/C credit changes in both model year 2026 and under the proposed standards means that ICEVs emissions reductions backslide even further, reaching almost 5% annually. [EPA-HQ-OAR-2022-0829-0642, pp. 3-4]

EPA also projects that strong hybrids are completely phased out by MY 2031 in the baseline scenario despite their wide and growing usage today (FR 29329, Table 83). In 2021, hybrids accounted for more than 15% of the fleets of five automakers (collectively responsible for producing 5.5 million vehicles for the US market.) Hybrid vehicles made up 20% of the lineup for 4 out of 5 of those automakers. .9 Hybrid technology is a proven way to considerably reduce the emissions from ICEVs and is a pathway for automakers to meet stronger standards. This is evident in the fact that EPA projects fleetwide strong hybrid penetration to be upwards of 9% in MY 2029 under Alternative 1 compared to only 2% under the proposed standards. Different automakers will choose different compliance pathways and those that already produce a significant number of hybrids could continue to do so, leveraging the investments they've made thus far, to meet the emissions levels in Alternative 1. [EPA-HQ-OAR-2022-0829-0642, pp. 2-3]

9 https://www.epa.gov/automotive-trends

Under EPA's proposed standards, rapid electrification can allow automakers to meet their targets even while letting ICEVs worsen, squandering some of the emissions benefit of electrification and missing an important opportunity for further emissions reductions. This is unacceptable given that mature emissions-reducing technologies, such as hybridization, already exist on the market today and often go underutilized by manufacturers. Our modeled findings are consistent with EPA's own analysis, which projects that ICEV emissions rates will increase over the life of the standard. In fact, EPA compliance modeling indicates that manufacturers will go so far as to remove emissions-reducing technologies from many ICEV models, a completely counterproductive behavior.10 On the other hand, if manufacturers do not move backwards on ICEV efficiency, they will be able to meet the standards with fewer BEVs than EPA projects, also an undesirable outcome. In either case, the conclusion is that the standards should be strengthened to incentivize ICEV improvements more strongly. [EPA-HQ-OAR-2022-0829-0642, pp. 3-4]

10 Based on analysis of EPA's OMEGA model outputs, 2023_03_14_22_42_30_central_3alts_20230314_Proposal_vehicles.csv

Just a 3% annual reduction in the average emissions for ICEVs — compared, for example, to the 4.6% per-year reduction called for under the 2012 standards for MY 2017-202511 — could lead to a further reduction of almost 800 million metric tons of CO2 and ICEVs that are about 30% cleaner compared to EPA's proposal. Much of this reduction could come from the continued adoption of hybrid vehicles in the US market. EPA expects little contribution from strong hybrids in meeting the proposed standard even though hybridization is a proven technology with decades of usage, as discussed above. EPA projects that strong hybrids will be completely phased out under the proposed standards by 2032 (FR 29329, Table 83), despite hybrids accounting for a record 10% of new vehicles offerings in model year 2022.12 We should not be moving backwards on ICEV performance and the penetration of proven efficiency technologies like hybridization over the life of these standards. [EPA-HQ-OAR-2022-0829-0642, pp. 3-4]

11 https://nepis.epa.gov/Exe/ZyPDF.cgi/P100EZ7C.PDF?Dockey=P100EZ7C.PDF

12 https://www.epa.gov/automotive-trends

The standards should take full advantage of the potential for medium-duty ICEV efficiency gains

The expected GHG emissions trajectory of medium-duty ICEVs under the proposal is essentially flat. Backing out ICEV emissions rates from the projected achieved values for all vehicles (FR 29328, Table 26) together with projected BEV adoption rates (FR 29331), one finds that ICE pickup emissions would decline by about 2% per year and ICE vans' emissions would increase by 2% per year under the proposal. ICE MDVs overall would improve at 1% per year. As in the case of light-duty ICEVs, the backsliding of medium-duty ICE van emissions would be unnecessary and counterproductive. These projections may indicate unrealistic assumptions in EPA's compliance modeling; otherwise, the standard should be tightened to prevent this outcome. [EPA-HQ-OAR-2022-0829-0642, p. 10]

ICE pickup emissions rates would decline under the proposed standards at a rate close to the required reduction rate in the Phase 2 heavy-duty rule (2.5% per year for heavy-duty pickups and vans).22 However, if MDV pickups are to reach only 19% EV share in 2032 as EPA projects, much more needs to be done to promote ICE pickup efficiency gains as plans take shape to zero out transportation GHG emissions entirely over the next two decades. EPA acknowledges that hybrids (as well as PHEVs) have high potential for these vehicles (DRIA p.1-20) yet provides no explanation of why substantial adoption is not feasible or desirable. The stringency of the standards should be set to promote adoption of the most efficient ICE technology until any obstacles to electrification can be overcome. [EPA-HQ-OAR-2022-0829-0642, p. 10]

22 Federal Register, Vol. 81, No. 206. October 25, 2016. Table VI-7.

EPA's assessment of the potential for medium-duty ICEV improvements in the proposal is perfunctory at best. The proposal states: "The feasibility of the 2027-2032 GHG standards is based primarily upon an assessment of the potential for a steady increase in MDV electrification, primarily within the van segment" (DRIA p.1-21). For medium-duty ICEV pickup emissions reduction opportunities, the reader is referred to the discussion of efficiency technologies in the 2016 heavy-duty Phase 2 rulemaking (DRIA p.3-12). While stating that "[t]he agency still expects to see additional penetration of many of these technologies" (DRIA p.1-20), EPA provides no account of the extent to which they could cost-effectively reduce medium-duty pickup emissions rates and how this relates to the projected 2% per year improvement project for these vehicles. [EPA-HQ-OAR-2022-0829-0642, p. 10]

Organization: The Aluminum Association

The value of vehicle lightweighting in supporting GHG emissions reductions for internal combustion engine powered vehicles has been well documented by EPA, NHTSA, and others across prior rulemakings6,7,8. As internal combustion engine vehicles will continue to comprise a significant percentage of vehicle sales during the scope of this rulemaking, the Association encourages EPA to continue recognition of this value as applied to ICE vehicles as it considers revisions to the proposed rule toward its finalization. [EPA-HQ-OAR-2022-0829-0704, pp. 6-7]

8 Revised 2023 and Later Model Year Light-Duty Vehicle Greenhouse Gas Emissions Standards, https://www.federalregister.gov/documents/2021/12/30/2021-27854/revised-2023-and-later-model- year-light-duty-vehicle-greenhouse-gas-emissions-standards (Accessed June 23, 2023)

Lightweighting also plays an important role in BEV design considerations as well. In 2022, the Association released groundbreaking research9 wherein it specified three BEV's, analyzed material substitution potentials, assessed the weight, cost, and efficiency impacts of those material substitutions, calculated their effects on vehicle fuel economy and GHG emissions, and developed concluding recommendations. [EPA-HQ-OAR-2022-0829-0704, pp. 6-7]

9 Aluminum Value In Battery Electric Vehicles, https://drivealuminum.org/wp-content/uploads/2022/05/2022-ATG-BEV-Lightweighting-Study_Exec-Summary.pdf (Accessed June 23, 2023)

In particular, this research demonstrates that, despite expected improvements in battery cost and storage density, aluminum lightweighting solutions are expected to remain economically attractive for at least the next decade, and that lightweighting battery electric vehicles with aluminum provides additional economic benefits when the entire sales fleet is considered, creating additional economic benefit and further increasing the economic viability of aluminum lightweighting. [EPA-HQ-OAR-2022-0829-0704, pp. 6-7]

Organization: American Fuel & Petrochemical Manufacturers

Internal combustion engines (ICEs) will continue to play a significant role in the new vehicle fleet in MY 2025–2035 in ICE-only vehicles, as well as in hybrid electric vehicles (HEVs) from mild hybrids to plug-in hybrids but will decrease in number with increasing battery electric vehicle (BEV) and fuel cell electric vehicle penetration. In this period, manufacturers will continue to develop and deploy technologies to further improve the efficiency of conventional powertrains, for ICE-only vehicles and as implemented in HEVs. Developments in the ICE for hybrids will advance toward engines optimized for a limited range of engine operating conditions, with associated efficiency benefits. Major automakers are on differing paths, with some focusing their research and development and advanced technology deployment more squarely on BEVs, and others more focused on advanced HEVs to maximize ICE efficiency.6 [EPA-HQ-OAR-2022-0829-0733, pp. 3-4]

6 Note that the term “zero emissions vehicle” (“ZEVs”), and even near-ZEVs as used by EPA, is a misnomer. ZEVs are not actually zero emission when accounting for the vehicle lifecycle, including GHG and criteria pollutant emissions associated with electricity generation required for charging certain ZEVs and production of the ZEV vehicle and battery. We recognize that in the Proposed Rule, EPA uses “ZEV” to refer only to those vehicles with a specific meaning under California’s EV program, but for ease of review, “ZEVs” is used throughout these comments and encompasses all of the EV technologies, including plug in electric vehicles (“PEVs”) such as plug-in hybrid electric vehicles (“PHEVs”) and battery electric vehicles (“BEVs”).

Organization: American Petroleum Institute (API)

Vehicles powered by internal combustion engines (ICE) offer “outstanding “drivability and reliability” according to the Department of Energy62 and “increasing the effciency of internal combustion engines (ICEs) is one of the most promising and cost-effective approaches to dramatically improving the fuel economy of the on-road vehicle fleet in the near-to mid-term.” Increasing sales of EVs does not necessarily mean they are more reliable. According to this survey data63 “[e]lectric cars are less reliable” than cars powered by petroleum, where software related problems cause reliability issues for consumers. In a Consumer Reports survey,64 data reported by EV owners indicate that EVs, as a category, have “more frequent problems” compared to conventional vehicles. EPA should take into account these factors in their analysis. [EPA-HQ-OAR-2022-0829-0641, p. 19]

63 Hull, R. “Electric cars are LESS reliable than petrols and diesels with nearly a third reporting faults taking longer to fix -and Tesla is rated worst overall, says Which?” March 2022. Daily Mail. https://www.dailymail.co.uk/money/cars/article-10569557/Electric-cars-reliable-petrol-diesel-says-Which.html.

64 Tucker, S. December 2022. “Consumer Reports: EVs Less Reliable Than Gas-Powered Cars.” Kelley Blue Book. https://www.kbb.com/car-news/consumer-reports-evs-less-reliable-than-gas-powered-cars/.

Organization: Arizona Department of Environmental Quality (ADEQ)

While ADEQ is supportive, we are curious as to why this proposed rule is less stringent than similar rules proposed by multiple states. ADEQ recognizes that EPA has adopted some state-implemented electric vehicle program elements; however, ADEQ encourages EPA to consider further strengthening its proposal by continuing to improve upon and incentivize advancements in internal combustion engine technology. By moving the nation towards zero emission vehicle (ZEV) technology and improving upon the existing traditional combustion engine technology, EPA will further reduce criteria pollutants and greenhouse gas emissions from the transportation sector. [EPA-HQ-OAR-2022-0829-0533, pp. 1-2]

Organization: BorgWarner Inc.

Hydrogen combustion engines (H2ICE) are a cost-effective advanced technology that can make a significant positive impact to the environment, and we urge EPA to recognize H2ICE as a technology solution in the Proposal, especially for heavier MD applications. As the IRA and IIJA are providing billions of dollars for the development of a hydrogen economy, EPA should support these efforts with program incentives. [EPA-HQ-OAR-2022-0829-0640, pp. 4-5]

Organization: California Air Resources Board (CARB) (Part 1 of 5)

Given the urgency of the climate crisis, as well as the opportunity to provide real-world cost savings to consumers, CARB recommends that U.S. EPA adopt additional regulatory mechanisms to ensure that all cost-effective technologies that get integrated into conventional vehicle designs will continue to be installed throughout vehicle line-ups and throughout the program lifetime to maintain emission reductions from conventional vehicles and save consumers money. Such a mechanism is especially important in the federal context where there is no ZEV sales requirement and thus a significant fraction of internal combustion engine vehicles are expected to persist in the new vehicle fleet longer than they might in California; those vehicles should not emit more than their counterparts from just a few years prior. In the absence of policies specifically focused on addressing this issue, CARB notes that a tighter fleet average standard could mitigate some of this risk and that manufacturers would have a technically feasible pathway to comply with tighter standards by simply retaining these proven, already deployed cost-effective technologies. [EPA-HQ-OAR-2022-0829-0780, pp. 15-16]

Organization: California Attorney General's Office, et al.

Our States and Cities add three observations to EPA's analysis of costs and lead time. First, EPA's projected costs likely overstate the actual costs attributable to reaching the standards in the allotted lead time, due to conservative assumptions in EPA's no-action case that omit the myriad state and local actions to promote electric vehicle adoption. See supra 18-21; CARB Comment at 16. Second, state and local agencies are implementing ambitious programs to ready power grids and charging infrastructure for the increased adoption of electric vehicles and the associated increase in electricity demand, which further supports EPA's feasibility analysis. Third, although internal-combustion-engine vehicles will make up a smaller portion of the national fleet, it is imperative that EPA's standards continue to encourage the application of feasible, cost-effective emission-reduction technologies to these vehicles, as they still represent a significant source of GHG, criteria, and toxic pollutant emissions. [EPA-HQ-OAR-2022-0829-0746, p. 33]

3. EPA Should Ensure that Internal Combustion Engine Vehicles Continue to Apply Emission-Reduction Technologies

EPA projects that, aside from electric vehicle adoption, auto manufacturers are likely to apply advanced technologies to reduce the GHG and criteria emissions of their internal-combustion-engine vehicles, albeit in lower numbers than is otherwise feasible. 88 Fed. Reg. at 29,330. This highlights an important aspect of the proposed standards: that even as the industry transitions to zero-emission vehicles, internal-combustion-engine vehicles will continue to make up a sizeable portion of new vehicle sales. These new internal-combustion-engine vehicles will continue to drive on the roads and emit GHGs, criteria pollutants, and air toxics for potentially decades, so it is crucial that EPA's standards continue to require improvements from these vehicles' emissions performances. Because of the standards' fleet average structure, a manufacturer's production of zero-emission vehicles may enable it to forego improving or even backslide on internal-combustion-engine vehicles' emissions performance. Indeed, as the California Air Resources Board's comment discusses, the compliance pathway EPA projects for its proposed standards show automakers removing emission-reduction technologies from internal-combustion-engine vehicles while still complying with the proposed standards. CARB Comment at 18-22.

Therefore, even if EPA were to forego encouraging the application of zero-emission technologies, it would still be obligated to tighten these emission standards beyond the proposed standards simply to keep pace with that trend and ensure the continued integrity of its emissions program as to new internal-combustion-engine vehicles. [EPA-HQ-OAR-2022-0829-0746, pp. 35-36]

This dynamic underscores the need for EPA to adopt standards more stringent than those proposed, and to eliminate outdated or redundant compliance flexibilities as proposed and as discussed below. We urge EPA to continue to monitor the industry's ongoing transition to zero-emission vehicles and ensure all of its standards continue to spur necessary and feasible reductions in vehicle pollution of all kinds. [EPA-HQ-OAR-2022-0829-0746, pp. 35-36]

Organization: Center for American Progress (CAP)

c. Improvements for ICE Vehicles–EPA must ensure actual multi-pollutant emissions reductions for ICE vehicles. Under the current proposal and Alternative 1 there is no guarantee that ICE vehicles lower their emissions despite the fact that there is proven technology available to accomplish that goal. Part 3.1.1.1 of EPA's DRIA notes adoption rates of key advanced ICE technology. The technology with the highest rate of adoption across all manufacturers is 7 or more gears, with an adoption rate of 57 percent. This shows that opportunities exist for further emissions reductions from ICE vehicles.25 EPA's final rule should ensure that MY2027 through MY2032 ICE vehicles make increased use of technology that decreases both GHG and criteria pollutant emissions. [EPA-HQ-OAR-2022-0829-0658, pp. 5-6]

25 U.S. Environmental Protection Agency, "Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles Draft Regulatory Impact Analysis," April 2023, available online: https://nepis.epa.gov/Exe/ZyPDF.cgi?Dockey=P10175J2.pdf

Organization: Center for Biological Diversity et al.

EPA's own data shows that multiple technologies exist to make the millions of gas-powered vehicles sold in the next decade much more efficient, from gasoline direct injection and continuously variable transmission to hybrid technologies. The fact that some automakers use some of these technologies some of the time shows EPA that it is possible for automakers to implement more of them consistently. In its final rule, EPA should model widespread adoption of these well-established technologies, and issue even more ambitious standards that hold automakers to the higher standards. At a minimum, this means strengthening the rule to account for annual improvements to the gas-powered light-duty fleet of at least 3.5%, as the International Council on Clean Transportation recommends.6 [EPA-HQ-OAR-2022-0829-0671, p. 2]

6 Slowik, Peter & Miller, Josh, Aligning the U.S. Greenhouse Gas Standard for Cars and Light Trucks With the Paris Climate Agreement, International Council on Clean Transportation (Dec. 19, 2022), https://theicct.org/us-ghg- standard-paris-agreement-dec22/.

These changes would have immediate consequences on the criteria and carbon pollution that continues to poison vulnerable communities and populations. With the climate emergency worsening each day, and public health concerns adding cumulative stress to the lives of vulnerable Americans, there is no time for delay. The rise of EVs is promising but by itself will not guarantee a clean air future at the speed that science and justice require. We urge you to curb pollution from the gas-powered fleet in this critical rulemaking to help ensure a clean and just transportation future for all. [EPA-HQ-OAR-2022-0829-0671, p. 2]

EPA claims that technologies to improve gas-powered cars, pickups, and SUVs have already been widely implemented, and that electrification is therefore the most effective pathway to further emissions reductions.2 The reality is more complicated. Many emissions control technologies are proven and cost-effective, yet manufacturers have dallied to implement them across their fleets. For example, turbocharged engines, which allow for more efficient engine design and operation, have been adopted in 80% of Ford's vehicles, but only in 37% of GM's fleet, 13% of Stellantis', and 3% of Toyota's.3 Cylinder deactivation, which allows for use of only a portion of the engine when less power is needed, has also been adopted unevenly: it exists in 54% of GM's vehicles, but only 22% of Stellantis', 21% of Ford's, and 3% of Volkswagen's.4 Some automakers continue to shrug their shoulders at proven emissions-reducing technologies. [EPA-HQ-OAR-2022-0829-0671, pp. 1-2]

2 Proposed Rule: Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium- Duty Vehicles, 88 Fed. Reg. 29,297 (May 5, 2023).

3 EPA Automotive Trends Report 2022, ES-8, https://www.epa.gov/system/files/documents/2022-12/420s22001.pdf.

4 Id.

EPA's actions make a huge difference in whether these powerful technologies are adopted across-the-board or whether some automakers will remain laggards. As EPA acknowledged for fuel injection technology, "one important driver for adoption was increasingly stringent emissions standards."5 EPA's past rulemakings caused significant overall improvements in the gas-powered fleet. Yet with the proposed rule, if automakers manage to achieve the EV targets, emissions reductions from their gas-powered cars and trucks are allowed to stall. Even worse, there is a risk that automakers will backslide on improvements to their gas-powered fleets, arguing that they need to profit from selling more gas-guzzling trucks and SUVs, while also claiming that the added emissions would be canceled out with increased EVs. That equation is unacceptable, and EPA must foresee and prevent it. [EPA-HQ-OAR-2022-0829-0671, pp. 1-2]

Organization: Consumer Reports (CR)

6. Specific Technical Comments On EPA's Proposal and Modeling

6.1. Internal Combustion Engine Vehicle Backsliding

EPA's modeling accurately considers the high effectiveness of battery EVs at delivering both significant emissions reductions and consumer savings. EPA's modeling finds that EVs are so cost-effective that emissions from the remaining ICE fleet actually increase over the period of the rule by an average of around 4%. This is because EPA's model finds that it would be cost-effective for automakers to remove already developed technology from their ICE vehicles to save money while building more EVs. [EPA-HQ-OAR-2022-0829-0728, pp. 18-20]

However, this modeling result does not seem likely in the real world. Consumer demand for EVs is rapidly increasing, and technology improvements will mean that the remaining gasoline powered vehicles will have to compete with better and better EV offerings.36 In order to continue to find buyers for their remaining gasoline powered vehicles, automakers will need to make them better, not worse. [EPA-HQ-OAR-2022-0829-0728, pp. 18-20]

36 Excess Demand, The Looming EV Shortage, Consumer Reports, March 2023, https://advocacy.consumerreports.org/wp-content/uploads/2023/03/Excess-Demand-The-Looming-EV-Shortage.pdf.

Furthermore, this result ignores consumer demand for cleaner, more efficient gasoline vehicles. Consumer Reports' 2022 fuel economy survey found continued strong consumer demand for more efficient vehicles.37 [EPA-HQ-OAR-2022-0829-0728, pp. 18-20]

37 Fuel Economy: A Nationally Representative Multi Mode Survey, Consumer Reports, November 2022, https://article.images.consumerreports.org/image/upload/v1670867143/prod/content/dam/surveys/Consumer_Reports_Fuel_Economy_National_September_October_2022.pdf.

- 95% of American drivers said fuel economy is at least somewhat important to them when considering what vehicle to purchase or lease, and seven in 10 (70%) say it is very important or extremely important. [EPA-HQ-OAR-2022-0829-0728, pp. 18-20]

- 85% of Americans agreed that automakers should continue to improve fuel economy for all vehicle types. [EPA-HQ-OAR-2022-0829-0728, pp. 18-20]

- 78% of American drivers agreed that they expect each new generation of vehicles available on the market to be more fuel-efficient than the last. [EPA-HQ-OAR-2022-0829-0728, pp. 18-20]

EPA specifically estimates that hybrid vehicles will drop from 4% of the vehicle fleet in 2027 to 0% of the fleet in 2031 and 2032.38 Research from CR has shown that many hybrids on the market today are extremely cost-effective for consumers, delivering a payback on their cost in 3 years or less, with some delivering savings instantly.39 CR's 2022 nationally representative car buying survey of 6,960 US adults found that 32% of consumers planning to purchase or lease a vehicle within a year were considering a hybrid car or truck.40 While consumer demand for EVs is likely to continue to grow rapidly, EVs do not yet work for all consumer lifestyles, and hybrids offer a viable and cost-effective alternative for these consumers to both reduce their emissions and their fuel spending. EPA's modeling that shows that this popular and cost-effective technology will be completely abandoned by the entire market by the end of the decade is at odds with the data on consumer preferences for these vehicles. [EPA-HQ-OAR-2022-0829-0728, pp. 18-20]

38 Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles, Draft Regulatory Impact Analysis, EPA-420-D-23-003, Table 13-68

39 Regardless of Gas Prices, Some Hybrids Pay for Themselves Immediately, Consumer Reports, March 2, 2023, https://www.consumerreports.org/cars/hybrids-evs/hybrids-vehicles-pay-for-themselves-a1092610835/.

40 Fuel Economy: A Nationally Representative Multi Mode Survey, Consumer Reports, November 2022, https://article.images.consumerreports.org/image/upload/v1670867143/prod/content/dam/surveys/Consumer_Reports_Fuel_Economy_National_September_October_2022.pdf.

Finally, over the duration of this proposed rule, EVs will be gaining significant market share. As they do so, ICE vehicles will by necessity be losing market share. Automakers will need to make decisions about which ICE vehicles and powertrains to keep producing and which ones to discontinue. The most logical approach to meeting these standards would be to phase out their oldest and least efficient vehicles and powertrains, while keeping their newest, most advanced, and most efficient powertrains. This process has the potential to result in significant improvements in average vehicle emissions without automakers having to deploy any additional technology. For example, in the 2023 model year, the best selling Ford F150 offers ICE variants that range in emissions from 352 g/mi to 741 g/mi.41 This large range in emissions leaves a lot of room for improving fleet performance by focusing future production on the lowest emitting variants and eliminating the highest emitting variants. A more detailed analysis from the Natural Resource Defense Council found that shifting to the lowest emitting powertrains could result in emissions reductions of between 19 and 65 grams per mile, compared to the current sales weighted average, for the 12 best selling vehicles.42 [EPA-HQ-OAR-2022-0829-0728, pp. 18-20]

41 Fuel Economy of 2023 Ford F150, U.S. Department of Energy, 2023, https://www.fueleconomy.gov/feg/PowerSearch.do?action=noform&path=1&year1=2023&year2=2023&make=Ford&baseModel=F150&srchtyp=ymm&pageno=1&rowLimit=50.

42 Shifting to Cleaner Gas Engines Can Help Reduce Emissions, Natural Resource Defense Council, July 5, 2023, https://www.nrdc.org/bio/kathy-harris/shifting-cleaner-gas-engines-can-help-reduce-emissions

Given the above, CR makes the following general recommendations to improve EPA's modeling:

- EPA's model should not remove technology that automakers have already invested in adding to their existing ICE vehicles. [EPA-HQ-OAR-2022-0829-0728, pp. 18-20]

Organization: David Hallberg

I recognize that the primary thrust of the proposed rule is to propel the electrification of the U.S. light-duty vehicle (LDV) fleet. However, we all know that the "ICE (internal combustion engine) Age" is far from over. EPA itself admits that 100 million or more ICE-powered LDVs will be sold over the coming decade, and the average vehicle's life span is more than 12 years. In the years to come literally trillions of miles will be driven on billions of gallons of gasoline, the typical gallon of which contains on average 20% benzene-based octane enhancing compounds (BTEX), in violation of Congressional mandates. [EPA-HQ-OAR-2022-0829-0548, pp. 1-2]

"Since the U.S. regulation was introduced in 2014, direct injection fuel technology, which improves fuel efficiency, has increased the amount of particulate matter gasoline cars emit, industry experts say. Ultrafine particles are harmful because their microscopic size means they can be drawn deep into human lungs. Even under the most aggressive U.S. scenarios for phasing out ICEs, they will likely be sold into the 2030s."There is a strong argument we should do what we can to make ICE vehicles as clean as possible, whatever the speed of electrification," Molden said." [EPA-HQ-OAR-2022-0829-0548, p. 3]

Organization: District of Columbia Department of Energy and Environment (DOEE)

"Backsliding"

DOEE is concerned that EPA's proposal will allow for increased emission rates from non-zero emission vehicles and internal combustion engine (ICE) vehicles as the share of zero emission vehicles (ZEV) increases. EPA's proposed methodology for determining compliance could allow manufacturers to meet the proposed emission standards while potentially allowing emission rates from ICE vehicles to increase because the increased emissions can be offset by greater shares of ZEVs. The bottom line is that as vehicle emissions become cleaner, no vehicle should have the ability to become more polluting. [EPA-HQ-OAR-2022-0829-0550, p. 5]

Newer ICE vehicle models should be federally mandated to be cleaner than earlier models of that vehicle to prevent any theoretical "backsliding." "Backsliding" is inconsistent with air quality and climate goals necessitating feasible, cost-effective criteria pollutant and GHG reductions. The EPA must include regulatory mechanisms to prevent "backsliding" on non-ZEVs by requiring new models to always be as or more efficient than its predecessor. [EPA-HQ-OAR-2022-0829-0550, p. 5]

Organization: Environmental. and Public Health Organizations

EPA has both an opportunity and an obligation to dramatically reduce emissions of greenhouse gases (GHGs) and other pollutants from light-duty vehicles (LDVs) and medium-duty vehicles (MDVs). The Agency's mandate to protect public health and welfare is made urgent by the ever more dire impacts of climate change, as well as the continuing harms to public health from vehicle criteria pollution. And the opportunity to significantly reduce these impacts is clear. Zero-emission vehicles (ZEVs) are not only feasible and cost-reasonable—they are rapidly penetrating the fleet, with more than 250,000 fully battery electric vehicles sold in the first quarter of 2023 alone, a 44.9% increase over the same period last year.1 In addition, numerous emission control technologies for combustion vehicles are also feasible, cost-reasonable, and already extensively deployed on the fleet, yet still have potential for greater application within the fleet of new combustion vehicles that will continue to be produced. [EPA-HQ-OAR-2022-0829-0759, p. 8]

1 Cox Automotive, Another Record Broken: Q1 Electric Vehicle Sales Surpass 250,000, as EV Market Share in the U.S. Jumps to 7.2% of Total Sales (Apr. 12, 2023), https://www.coxautoinc.com/market-insights/q1-2023-ev-sales/.

- As EV market share increases over the course of the rule, EPA should model a reduction in the number of ICE powertrains that automakers continue to build in such a way that the newest and most advanced options are kept, and the oldest and least advanced are phased out over time. [EPA-HQ-OAR-2022-0829-0728, pp. 18-20]

A. EPA's modeling should more fully incorporate combustion vehicle technologies that reduce greenhouse gas emissions, which would further demonstrate technological feasibility and available compliance pathways.

1. EPA's modeling does not account for the full range of combustion vehicle technology availability and effectiveness.

The technologies EPA assesses to curb GHG emissions from light-duty vehicles are significantly reduced in number and effectiveness compared to the technology assessment supporting the MY 2023-2026 Rule, for which EPA used CCEMS as its modeling tool. In particular, OMEGA2, the modeling tool EPA now employs, omits the following technologies when modeling compliance: advanced 10-speed transmissions, turbocharging with cooled exhaust gas regulation, variable compression ratio engines, and others.120 Moreover, the Agency has adopted many fewer technology packages: in contrast to the 6,500 packages available in the CCEMS modeling for each of the 10 vehicle types, the OMEGA2 modeling is limited to 108 packages for cars and 60 packages for trucks.121 [EPA-HQ-OAR-2022-0829-0759, p. 37]

120 Compare DRIA Table 2-21 with the "Technologies" tab in technologies_NoHCR_LowBEV200_BatteryAdj2023_YearShift.xlsx, a file accompanying the Agency's final modeling supporting the FRIA, as well as Figures 2, 3, and 4 in NHTSA's 2020 CAFE Model Documentation, the documentation included with the agency's CAFE Compliance and Effects Modeling System (CCEMS). NHTSA, CAFE Model Documentation, DOT HS 812 934, EPA-HQ-OAR-2021-0208-0138 (Mar. 2020), at 24-28, Figs 2-4.

121 Here we refer solely to changes in the powertrain. Throughout this section, we do not consider differences in how the road load reduction was modeled, since while that effect was considered discretely in the CCEMS modeling, it was modeled separately and continuously in the OMEGA2 model.

In and of themselves, these changes might not have a significant impact on the modeling if the technologies contained within the packages were sufficiently representative of the relative technical potential for reducing emissions from combustion vehicles. However, there are significant differences between the effectiveness of the packages analyzed by the OMEGA2 and CCEMS models, as well as the maximum improvement they can deliver (Figure VI.A-1).122 Because the OMEGA2 model calculates absolute emissions, effectiveness of the packages is considered relative to the base gasoline package modeled in OMEGA2 for each body type, a direct-injection engine with continuously variable valve timing and five-speed automatic transmission. [EPA-HQ-OAR-2022-0829-0759, p. 37]

122 Owing to differences in the model's architecture, we use representative vehicles from each of the CCEMS classes to obtain the OMEGA2 results using the response surface equations provided. The relevant parameters include the road load coefficients, test weight, and maximum horsepower. Representative vehicles were selected by sales volume, using the classification from the CCEMS model. The identified representative vehicles are: Toyota Corolla, Small Car; Hyundai Elantra, Small Car Perf; Ford Fusion, Med Car; Mercedes C 300, Med Car Perf; Honda CR-V, Small SUV; Ford Escape Titanium, Small SUV Perf; Mercedes GLC 300 4 MATIC, Med SUV; Jeep Grand Cherokee, Med SUV Perf; Toyota Tacoma, Pickup; and Ford F-150 4WD 3.5L EcoBoost, Pickup HT. For the car categories, only unibody packages were defined. For the pickups, only the truck packages were calculated. For SUVs, which can fall into either category, both the car and truck packages were included in the comparison, even if the representative vehicle itself may have been classified as only a light truck.

SEE ORIGINAL COMMENT FOR Figure VI.A-1: Comparison of the effectiveness of packages modeled by EPA to reduce emissions in the Proposal and the MY 2023-2026 Rule [EPA-HQ-OAR-2022-0829-0759, p. 38]

The technology packages modeled in the Proposal using OMEGA2 show a markedly reduced effectiveness compared to the same packages modeled using the CCEMS supporting the MY 2023-2026 rulemaking, as indicated by the increased share of data falling below the X=Y line (black). 74% of the packages modeled in OMEGA2 show a reduced effectiveness. On average, a given OMEGA2 package shows a 3.9 ± 0.3% increase in emissions compared to the prior CCEMS modeling. The most efficient packages show an even greater disparity, with the maximum effectiveness for OMEGA2 showing just a 36% improvement compared to a 53% improvement in CCEMS. [EPA-HQ-OAR-2022-0829-0759, p. 38]

Looking at the relative effectiveness of the modeled packages, it is clear that the CCEMS modeling generally finds a greater level of improvement than the more recent OMEGA2 modeling. Because the benchmark data for the ALPHA modeling supporting OMEGA2 is almost identical to that used to support the previous rulemaking (excepting the Volvo Miller cycle engine, which corresponds most accurately to the prior variable-geometry turbo technology package), and because the changes to the ALPHA model (vis-à-vis the response surface equations) are generally reasonable, as supported by the peer review process, the reason for the disparity in EPA's analysis is unclear. There are some general trends that may be illustrative in assessing the flaws in EPA's more recent modeling. Across all categories of vehicle, the 5-speed automatic transmission package (TRX10) was found to be more efficient than the basic 6-speed automatic (TRX11), which seems implausible and may speak to problems with how the scaling algorithm matches a modeled vehicle's transmission to different engine maps—all the more perplexing since the Agency claims to use the same model as before.123 Similarly, there appears to be little difference in the effectiveness of any of the three hybrid packages, despite significant differences in the underlying engines.124 This is particularly perplexing given that strong hybrids have continued to evolve with each successive generation, and yet, according to EPA's modeling, they appear to be stuck at the efficiency levels of the MY 2019 power-split fleet.125 [EPA-HQ-OAR-2022-0829-0759, pp. 38-39]

123 DRIA at 2-29.

124 Id. at Table 2-2.

125 Id. at Section 2.4.8.6.

In addition to the packages' lack of effectiveness, we question whether these packages cover a sufficiently robust opportunity for reductions from the internal combustion engine. Unfortunately, the answer appears to be that they are also now covering a narrower range than previous modeling (Figure VI.A-2, infra). As expected based on the results discussed above, the shift in the distribution of effectiveness for the current modeling is below that of the CCEMS, but the packages are also overweighted towards less effective packages, in contrast to the symmetric/Gaussian distribution of the CCEMS data. Also of note is the lack of a long tail out to higher effectiveness; as noted previously, while the few hybrid packages available in the CCEMS model can reduce emissions by over 50%, the OMEGA2 packages max out at 36%. This means that about one-third of the assessed maximum potential improvement previously modeled to be available to manufacturers for their combustion vehicle fleets has been eliminated due to unknown factors. [EPA-HQ-OAR-2022-0829-0759, p. 39]

We believe that once these issues have been addressed, it will become apparent that the standards are considerably more feasible than EPA states; that combustion vehicle emissions can be reduced to a much larger degree than EPA assumes; and that even more technologically diverse compliance pathways are available to manufacturers, enabling them to meet the standards at PEV penetration levels lower than EPA projects. [EPA-HQ-OAR-2022-0829-0759, p. 39]

SEE ORIGINAL COMMENT FOR Figure VI.A-2: Available technology packages at different levels of effectiveness [EPA-HQ-OAR-2022-0829-0759, p. 40]

A histogram comparing the share of packages in the current (OMEGA2) and previous (CCEMS) compliance modeling efforts from EPA, grouped by total package effectiveness relative to a GDI engine paired with a 5-speed transmission. It is clear that not only do manufacturers have significantly more package options at, on average, higher effectiveness, but the total absolute range has been condensed as well for the current modeling effort, limiting compliance flexibility for manufacturers in the model that does not reflect the broader range of options available. [EPA-HQ-OAR-2022-0829-0759, p. 40]

VIII. Stronger GHG and Criteria Pollutant Standards for Medium-Duty Vehicles Are Feasible.

We now turn to EPA's proposed emission standards for medium-duty vehicles. Below, we examine the combustion vehicle and zero-emission technologies that can further reduce GHG emissions from the medium-duty fleet, comment on EPA's modeling, address economic considerations, and make suggestions on certain aspects of EPA's regulatory program. We also offer recommendations for the Tier 4 NMOG+NOx standards and PM requirements. As detailed below, strong GHG and criteria pollutant emission standards for MDVs are feasible and cost-reasonable. [EPA-HQ-OAR-2022-0829-0759, p. 64]

A. EPA must strengthen its GHG standards for MDVs.

EPA's proposed GHG standards for MDVs significantly underestimate the potential for feasible emissions reductions from the Class 2b-3 fleet, particularly pickup trucks. EPA has primarily focused on the electrification of MDVs in setting its standards.169 However, not only has it underestimated the share of MDVs that could be electrified, it has underestimated the technologies available to reduce GHG emissions from gasoline- and diesel-fueled vehicles. EPA should adopt more stringent final standards for MDVs that reflect greater application of both the zero-emission powertrain and conventional emission control technologies that are feasible and widely available. [EPA-HQ-OAR-2022-0829-0759, p. 64]

169 DRIA at 1-21: "The feasibility of the 2027-2032 GHG standards is based primarily upon an assessment of the potential for a steady increase in MDV electrification, primarily within the van segment."

1. The combustion vehicle technology pathways show the feasibility of stronger standards.

EPA proposes as its 2027 standard the current (Phase 2) standards for diesel pickups and vans, and then adjusts those standards in the future based on assumptions about the level of electrification within the fleet. In fact, in EPA's modeling, combustion MDVs actually increase average direct tailpipe emissions by 1.5% between 2022 and 2032, with the increase being even larger for the Phase 2 baseline. The modeling thus indicates that no technological improvements to combustion MDVs are needed to comply with even the existing Phase 2 standards through 2027.170 [EPA-HQ-OAR-2022-0829-0759, p. 64]

170 This remains true for the "No IRA" sensitivity, though there is virtually no difference in the assumed production of electric MDVs between the default modeling run and this sensitivity case, indicating the degree to which electrification is expected to take off in the commercial van space due to improved TCO.

Subsequent to finalization of the Phase 2 standards in 2016, a number of technologies have been developed that EPA did not originally consider in establishing those standards; nor were the Phase 2 standards predicated on the full adoption of even those technologies that were identified at the time. As EPA noted in its Phase 3 heavy-duty vehicle proposal: "In developing the Phase 2 CO2 emission standards, we developed technology packages that were premised on technology adoption rates of less than 100%. There may be an opportunity for further improvements and increased adoption through MY 2032 for many of these technologies included in the heavy-duty (HD) GHG Phase 2 technology package used to set the existing MY 2027 standards."171 [EPA-HQ-OAR-2022-0829-0759, p. 65]

171 88 Fed. Reg. at 25960.

By ignoring technologies for Class 2b-3 combustion vehicles that could achieve emissions reductions beyond the Phase 2 standards, EPA is setting its MDV standards below a level of readily achievable technology adoption (and, indeed, many of these technologies are already being deployed). Below, we walk through a number of the technologies that EPA should assume will be deployed by MDV manufacturers in the timeframe of the MDV Proposal. [EPA-HQ-OAR-2022-0829-0759, p. 65]

a. EPA should consider additional compression-ignition (diesel) engine technologies. [EPA-HQ-OAR-2022-0829-0759, p. 65]

Manufacturers of diesel engines for Class 2b-3 pickups and vans will deploy new engines in order to meet the 2027 NOX standards that EPA finalized last year.172 However, the Agency's modeling assumes that diesel vehicles will reduce GHG emissions by less than 1% from 2022 to 2032. This leaves a tremendous amount of technology on the table, not just from what the Agency identified in the Phase 2 rulemaking and assumed would be needed to meet the standards already on the books, but also from additional improvements that have been developed since then. [EPA-HQ-OAR-2022-0829-0759, p. 65]

172 See 88 Fed. Reg. 4296.

Diesel engine efficiency continues to increase, with HHD (Class 8) diesel engines demonstrating up to 55% brake-thermal efficiency (BTE) in response to the second phase of the SuperTruck program. The Navistar and Cummins/Peterbilt teams demonstrated 55% BTE, compared to the 50% target for the first phase, while Daimler, Volvo, and PACCAR all demonstrated over 50% BTE, with a clear pathway towards the 55% target. The PACCAR team's progress is particularly illuminating, as they undertook an additional challenge to meet "ultra low NOX" targets consistent with EPA's recent regulation as part of their overall efficiency effort, indicating that these levels of thermal efficiency are not incompatible with achieving the 2027 NOX standards.173 [EPA-HQ-OAR-2022-0829-0759, pp. 65-66]

173 See Zukouski, Russ, Navistar SuperTruck II: Development and demonstration of a fuel-efficient class 8 tractor & trailer, DOE Annual Merit Review, (Jun. 21-23, 2022) https://www1.eere.energy.gov/vehiclesandfuels/downloads/2022_AMR/ace103_%20Zukouski_2022_o_4-29_1232p m_ML.pdf; Mielke, David, 2022 Annual Merit Review: Cummins/Peterbilt SuperTruck II, DOE Annual Merit Review, (Jun. 21-23, 2022) https://www1.eere.energy.gov/vehiclesandfuels/downloads/2022_AMR/ace102_dickson_2022_o_rev2%20-%20Trai lLife-GCCC%20IN0110%20REVISED.pdf; Bashir, Murad, et al., Daimler: Improving transportation efficiency through integrated vehicle, engine, and powertrain research - SuperTruck 2, DOE Annual Merit Review, (Jun. 21-23, 2022) https://www1.eere.energy.gov/vehiclesandfuels/downloads/2022_AMR/ace100_Villeneuve_2022_o_4-30_1116am_ ML.pdf; Bond, Eric, et al, Volvo SuperTruck 2: Pathway to cost-effective commercialized freight efficiency, DOE Annual Merit Review, (Jun. 23, 2022) https://www1.eere.energy.gov/vehiclesandfuels/downloads/2022_AMR/ace101_bond_2022_o_5-1_129pm_ML.pdf; Meijer, Maarten, Development and demonstration of advanced engine and vehicle technologies for class 8 heavy-duty vehicle ([PACCAR] SuperTruck II), DOE Annual Merit Review (Jun. 21-23, 2022),

https://www1.eere.energy.gov/vehiclesandfuels/downloads/2022_AMR/ace124_Meijer_2022_o_4-29_1056pm_KF. pdf.

Significant improvements in efficiency are not limited to the largest engines and can also be feasibly deployed on Class 2b-3 vehicles. Ford's latest iteration of its 6.7L Power Stroke diesel engine cut GHG emissions by 3.5% over the previous generation when it was introduced in 2020, and 2023 saw an additional 3% improvement due to a revised injection system.174 General Motors released its new 6.6L Duramax diesel engine in 2023 with improved cylinder heads, fuel injection, and other features in a design that is meant to increase both power and efficiency, particularly at higher output.175 These engine improvements are already being deployed today but are not captured in the Agency's OMEGA2 modeling. [EPA-HQ-OAR-2022-0829-0759, p. 66]

174 To assess these improvements, we refer to the combined transient cycle certification results for the MHD Power Stroke family of diesel engines available in the chassis cab/F-650 and F-750 configurations. The engines available in the heavy-duty pickups are not required to certify to isolated engine tests, but are likely to see similar levels of improvement, even with the higher power output, since they also have the same underlying technology.

175 GMC Pressroom, The Ultimate Heavy Duty: GMC Introduces its Most Luxurious, Advanced and Capable Sierra HD Ever (Oct. 6, 2022), https://media.gmc.com/media/us/en/gmc/home.detail.html/content/Pages/news/us/en/2022/oct/1006-sierra.html. It is difficult to compare apples-to-apples between the new and old Duramax engines due to limited certification data and because some of that efficiency improvement was used to reduce tailpipe NOx, since the new diesel-equipped Silverado/Sierra HD 2500 have a reduced NMOG+NOx bin of 200 vs. 250 mg/mile. Additionally, because the standards are set by "work factor," the increase in power used to raise towing capacity by 4000 pounds increases the allowable emissions for the engine, which means that despite an apparent increase in certified CO2 emissions of 2.4%, there could be a net improvement in compliance of up to nearly 5% as the result of up to a 7% increase in the model year 2023 emissions target.

Mild electrification also offers increased emissions reduction capabilities. Eaton demonstrated that it is possible to outperform simultaneously the 2027 NOx standards and the Phase 2 CO2 standards through a number of different aftertreatment and powertrain combinations,176 including those applicable to Class 2b-3 vehicles. A recent research paper by Eaton demonstrates various combinations of control technologies manufacturers can target CO2 and NOx emissions levels over different regulatory cycles to develop a technology package that is suitable for compliance, including packages that can achieve CO2 reductions beyond Phase 2 while meeting EPA's future 2027 NOx standards.177[EPA-HQ-OAR-2022-0829-0759, pp. 66-67]

176 Se-e generally Dorobantu, Mihai, Eaton considerations on MD/HD GHG Phase 3, OIRA-Eaton meeting, (Mar. 23, 2023), https://www.reginfo.gov/public/do/eoDownloadDocument?pubId=&eodoc=true&documentID=215442

177 McCarthy, J., et al. 2023. "Technology levers for meeting 2027 NOX and CO2 regulations." SAE Technical Paper 2023-01-0354. https://doi.org/10.4271/2023-01-0354.

One of the strategies deployed by Eaton is a 48V electric heater, which could be deployed easily with a 48V mild hybrid powertrain, again illustrating the complementary technology packages available to manufacturers to simultaneously meet GHG and NOx standards. The 48V mild hybrid powertrain can power accessories, including those related to emissions control, and can also help reduce engine-out NOx. This was also demonstrated through testing by FEV as a strategy particularly relevant to medium-heavy-duty vehicles that share chassis and power requirements with the Class 2b-3 pickups and vans covered by this proposal.178 Such developments should be incorporated into the Agency's analysis of the level of emissions reductions achievable from diesel-powered Class 2b-3 vehicles. [EPA-HQ-OAR-2022-0829-0759, p. 67]

178 Fnu, D., et al. 2023. "Application of 48V mild-hybrid technology for meeting GHG and low NOX regulation for MHD vehicles." SAE Technical Paper 2023-01-0484. https://doi.org/10.4271/2023-01-0484.

In the Phase 2 rulemaking, EPA excluded cylinder deactivation from medium-duty diesel engines,179 but its own analysis now shows that manufacturers are likely to deploy that technology to meet the heavy-duty NOx standards.180 Similarly, a recent report by Roush identified cylinder deactivation as a likely engine configuration for many Class 2b-3 vehicles.181 The Agency should consider this technology in its OMEGA2 modeling, further increasing the available emissions reductions technologies for diesel-powered vehicles. [EPA-HQ-OAR-2022-0829-0759, p. 67]

179 81 Fed. Reg. at 73754, Table VI-4. Note, however, that the agencies did consider a "right-sizing" of diesel engines, based on a 4-cylinder vs. 6-cylinder engine, and cylinder deactivation could be seen as a control-based attempt to yield the equivalent improvement without altering the maximum output. See NHTSA, Commercial medium- and heavy-duty truck fuel efficiency technology study – Report #2, U.S. Dep. of Transportation, 52–53 (Feb. 2016), https://www.nhtsa.gov/sites/nhtsa.gov/files/812194_commercialmdhdtruckfuelefficiency.pdf.

[hereinafter Saxena et al., Electrification Cost Evaluation].

b. EPA should consider additional spark-ignition (gasoline) engine technologies.

Another significant opportunity for increased improvement to combustion vehicles lies in spark-ignition (SI) engines, for which Phase 2 required no engine improvements beyond the 2016 SI engine standard. While this is somewhat rectified in EPA's move to a fuel-neutral standard for Class 2b-3 pickups and vans—which effectively results in a 5-6% increase in stringency for MDVs—this still does not fully recognize the potential improvement available from gasoline engines. And in fact, in the Agency's modeling, gasoline vehicles see, on average, 5% higher emissions in 2032, compared to 2022.182[EPA-HQ-OAR-2022-0829-0759, p. 67]

182 Because the model preferentially selects vans for electrification, some of this decrease is related to a shift in the vehicles included in the remaining gasoline fleet. However, even when limited to gasoline pickups there is an apparent backsliding in emissions, with an increase of 3%. This is similar to the backsliding that appears in the modeling of light-duty vehicles (see Section VI.A.2).

The weakness in EPA's Phase 2 targets for SI engines and vehicles is apparent in looking at manufacturers' growing bank of compliance credits to-date, particularly for Ford Motor Company, the largest SI engine supplier. Ford has run a credit surplus in every year of the vocational engine program, but this surplus exploded in MY 2020 with the release of its latest 7.3L V8 engine, codenamed "Godzilla."183 Even though the engine platform is relatively low-tech (naturally aspirated, pushrod V8), by utilizing variable cam timing and a variable-displacement oil pump, Ford's engine achieved a significant improvement in efficiency. The engine was also designed with fuel economy at load in mind for applications like towing. A smaller engine built on the same platform replaced the older base engine in 2023, no doubt increasing Ford's overcompliance and increasing the efficiency of even more of the MDV fleet. [EPA-HQ-OAR-2022-0829-0759, p. 68]

183 EPA, Final Phase 1 EPA Heavy-Duty Vehicle and Engine Greenhouse Gas Emissions Compliance Report (Model Years 2014-2020), Appendix B, at 40-42 (Nov. 2022) https://nepis.epa.gov/Exe/ZyPDF.cgi/P1016962.PDF?Dockey=P1016962.pdf.

General Motors is not standing still, either—its fifth-generation small-block V8 platform is getting a next generation update to a 5% improvement over the current generation,184 and the current generation is already a credit generator for GM's heavy-duty vehicles under the Phase 2 program.185 No further details are available about the heir to the current iron-block direct-injection L8T variant found in GM's heavy-duty offerings. [EPA-HQ-OAR-2022-0829-0759, p. 68]

184 Wren, Wesley, This is why GM is launching a new small block V8, Autoweek, (Feb. 3, 2023) https://www.autoweek.com/news/industry-news/a42746723/why-gm-is-launching-a-new-small-block-v8/.

185 EPA, Final Phase 1 EPA Heavy-Duty Vehicle and Engine Greenhouse Gas Emissions Compliance Report (Model Years 2014-2020), Appendix B, at 43.

Note that neither of these new improvements reflect technology adoption that was further anticipated for gasoline engines when the Phase 2 regulations were finalized. EPA assumed that cylinder deactivation (discrete or continuous), downsizing, and mild and strong hybridization would be used to meet those standards,186 yet none have yet been deployed in Class 2b-3 pickups and vans. This further underscores the significant amount of emissions reductions that are still readily achievable for Class 2b-3 vehicles. [EPA-HQ-OAR-2022-0829-0759, p. 68]

186 81 Fed Reg. at 73776, Table VI-13.

Organization: Environmental Defense Fund (EDF) (1of 2)

D. EPA must put in place guardrails that prevent ICEVs from removing greenhouse gas reducing technologies.

EDF reviewed the output from EPA's modeling of manufacturers' compliance with the Proposal using the OMEGA 2 model and found instances where the model removed technology that was either on vehicles in the 2021 baseline fleet or that had been added in subsequent model years. The California Air Resources Board and others have described this technology removal in considerable detail within their comments. We recognize the light-duty GHG program, since its inception, has been performance-based and provided manufacturers flexibility in applying technology to some vehicles and not others. At the same time, the increasing availability of battery electric vehicles provides manufacturers an even greater ability to trade off emissions between vehicles (and potentially significantly increase emissions from some of the remaining combustion engine vehicles in their fleets). While we do not expect manufacturers to take this approach, we are concerned that the compliance model shows technology removal and an outcome along these lines is permitted under the current standards. [EPA-HQ-OAR-2022-0829-0786, pp. 66-67]

Accordingly, we encourage EPA to put in place guardrails to ensure, at the very least, technologies that manufacturers have previously deployed on combustion vehicles are not removed as larger numbers of ZEVs are introduced into the fleet. Notably, EPA's approach to its NMOG + NOx standards is likewise performance based with guardrails. Though those standards are designed somewhat differently around a bin structure, EPA has here proposed to eliminate higher emitting bins in a manner that would ensure, as vehicles become cleaner, manufacturers can no longer offset those gains by certifying vehicles to higher-polluting levels. EPA should consider how it can apply the same concept to its greenhouse gas standards, perhaps through an emissions cap as a function of footprint curve that would retain the flexibility that has been a hallmark of the program but prevent any abuse that might come with increasing deployment of ZEVs. [EPA-HQ-OAR-2022-0829-0786, pp. 66-67]

Organization: Ford Motor Company

Next, each full-line automaker needs to allocate finite resources between EV programs and efforts toward incremental reductions in emissions from ICE vehicles. Insofar as automakers are required to lower emissions from ICE vehicles, the resources invested toward that end will not be available to invest toward EVs. [EPA-HQ-OAR-2022-0829-0605, p. 7]

Organization: International Council on Clean Transportation (ICCT)

There is potential for significant additional GHG savings from ICE vehicles beyond what EPA has modeled for its proposal. Many existing and recently announced ICEV technology improvements have ample room for increased application throughout the ICEV fleet. ICCT has identified several technologies, including advanced mild hybrids and plug-in hybrid EVs (PHEVs) that are commercially available and could significantly and cost-effectively improve ICE vehicle efficiency that EPA has not included in its modeling. We have also identified other technologies for which EPA has overestimated the costs in its modeling, such as Miller cycle engines and mild hybrid technology. If EPA made these changes to its model, we believe the agency would project lower overall compliance costs and lower BEV shares to achieve the same level of GHG reductions compared to its proposal. [EPA-HQ-OAR-2022-0829-0569, p. 4]

ICCT believes there is even greater opportunity to capture technology potential and cost reductions for medium-duty vehicles (MDVs) in EPA's modeling. While ICCT believes EPA underestimated the potential for ICE vehicle improvements for LDVs in its modeling, EPA did not model any ICE vehicle improvement technologies for MDVs. All of the above findings and recommendations about combustion and EV technology potential and cost for LDVs apply to MDVs. In addition, EPA has not included any kind of hybrid technology options in its modeling for MDVs and has omitted other ICE technology options it included for LDVs. All of the LDV technology options we review in these comments can be applied to MDVs and can deliver cost savings in meeting the proposed GHG standards. We strongly recommend EPA add ICE and PHEV technology options and incorporate the latest evidence on declining ICE and BEV technology costs into its modeling for MDVs. We also recommend EPA consider increasing the stringency of the MDV GHG standards since this could be achieved at lower costs when considering the evidence presented here on technology options. [EPA-HQ-OAR-2022-0829-0569, pp. 4-5]

Cylinder deactivation (DEAC)

Application in OMEGA

Based on the response surface equations (RSE) input file (simulated_vehicles_rse_ice_20221021_debug_noP2.csv), there are no technology packages/cost curve classes with DEAC on a turbocharged engine in EPA's OMEGA modeling. While adding DEAC to a turbocharged engine has smaller pumping loss reductions than for naturally aspirated engines, DEAC still has significant pumping loss reductions and has the additional benefit of enabling the engine to operate in a more thermal efficient region of the engine fuel map. As described in the National Academies of Sciences' 2021 report on light-duty vehicle fuel economy (NAS 2021)91, turbocharged engines with DEAC are already in production (NAS 2021, section 4.1.3). EPA could consider adding DEAC option to turbocharged cost curve classes. [EPA-HQ-OAR-2022-0829-0569, pp. 31-34]

91 National Academies of Sciences, Engineering, and Medicine. (2021). Assessment of Technologies for Improving Light-Duty Vehicle Fuel Economy—2025-2035. The National Academies Press. https://doi.org/10.17226/26092

Cooled Exhaust Gas Recirculation (CEGR)

Application in OMEGA

Similar to the application of DEAC, based on the RSE input file, there are no cost curve classes with CEGR on a base turbo engine in EPA's OMEGA modeling (i.e. "TDS" within the input file). As reported in NAS 2021 (section 4.1.3) turbocharged engines with CEGR are already in production. NAS 2021 also provides estimates for the efficiency benefit of including CEGR on a base turbo engine. EPA could consider adding CEGR option to turbocharged cost curve classes. [EPA-HQ-OAR-2022-0829-0569, pp. 31-34]

Atkinson cycle engine (ATK)

Application in OMEGA

EPA appears to have excluded the modeling and application of ATK from pickups and other body-on-frame vehicles (DRIA page 1-10 and RSE input file). However, as detailed in ICCT 2021 comments (pages 14-16), this exclusion could be lifted, allowing all vehicle classes to adopt ATK in the OMEGA model. [EPA-HQ-OAR-2022-0829-0569, pp. 31-34]

To briefly summarize those ICCT 2021 comments, engines in pickup trucks and high-performance vehicles are sized and powered to handle higher peak loads. This means larger engines that operate at lower loads relative to their maximum capacity on the 2-cycle test – and during most real-world driving. This, in turn, means that pickup trucks and high-performance vehicles will spend more time in Atkinson Cycle operation than lower performance vehicles on both the test cycles and in the real world. This includes time spent towing, which represents a very small fraction of light-duty pickup usage.92,93 Altogether, the large majority of pickup trucks spend the vast majority of driving at low loads relative to the engine's capability, where Atkinson Cycle engines are very effective. In other words, ATK is likely a highly cost-effective technology for pickup trucks, which may be the most challenging to electrify, as evidenced by the low BEV share of pickups in the 2027-2031 time frame compared to other body styles in EPA's modeling (Preamble Table 80). Furthermore, the claim that an Atkinson Cycle engine that switches to Otto cycle on demand cannot provide the additional torque reserve is not accurate (a claim previously used to justify blocking ATK on pickups in prior rulemakings, see ICCT 2021 comments). [EPA-HQ-OAR-2022-0829-0569, pp. 31-34]

92 Berk, B. (2019, March 13). You Don't Need a Full-Size Pickup Truck, You Need a Cowboy Costume. Thedrive.com. https://www.thedrive.com/news/26907/you-dont-need-a-full-size-pickup-truck-you-need-a-cowboy-costume

93 Chase, W., Whalen, J., Muller, J. (2023, January 23). Pickup Trucks: from workhorse to joyride. Axios. https://www.axios.com/ford-pickup-trucks-history

Moreover, Atkinson Cycle engines have been used on the Toyota Tacoma pickup V6 engine since 2017, illustrating that Atkinson Cycle engines are cost-effective for use on pickups. [EPA-HQ-OAR-2022-0829-0569, pp. 31-34]

[EPA-HQ-OAR-2022-0829-0569, pp. 31-34]

Effectiveness

Outlined in the table above, MHEV architectures beyond P0 can have substantial CO2-reduction benefits. However, the benefits of more advanced MHEV architectures are expected to exceed those illustrated in the table, through the implementation of higher power systems (20kW- 30kW). Roush 2021 LDV96 describes the additional benefits offered by higher power MHEV systems, including advancements in electric boosting, high energy ignition systems (see section below), accessory electrification, and electrically heated catalysts. Enabling electrically heated catalysts in particular permits further fuel economy optimization through, for example, aggressive stop-start strategies. [EPA-HQ-OAR-2022-0829-0569, pp. 34-37]

98 AVL Webinar on Passenger Car powertrain 4.x – Fuel Consumption, Emissions, and Cost. (2020, June 2). https://www.avl.com/-/passenger-car-powertrain-4.x-fuel-consumption-emissions-and-cost (Slides available at https://www.regulations.gov/comment/EPA-HQ-OAR-2021-0208-0522) (AVL 2020)

Roush 2021 LDV provides specific example applications of high power MHEV systems and the associated fuel efficiency improvements on pickups and SUVs. These examples, which have not previously been considered by either EPA or ICCT, are excerpted below:

Pickup/full-size SUV GHG reduction: As ICCT previously commented, Roush 2021 states "Two powertrain configurations are recommended for study and could support future rulemaking. The first option synergistically combines available technologies (without a major redesign of the underlying engine architecture) to give maximum fuel economy benefit for a relatively low cost, hence high effectiveness. It combines a naturally aspirated DI engine with advanced cylinder deactivation and a 30kW 48V P2 mild hybrid system. The 48V hybrid system is used to actively smooth out crankshaft torque pulsations to enable aggressive cylinder deactivation strategies (advanced deac – like the Tula Skipfire System). Such a system will also enable start-stop, electric creep, regen braking, slow-speed electric driving, and a heated catalyst. Depending on system integration factors Roush estimates a reduction in GHG emissions of 20% or more, compared to a baseline naturally aspirated direct-injection V8." (Roush 2021 LDV page 13).

Additional information can be found at:

- Roush 2021 LDV Section 13.1 page 65 [EPA-HQ-OAR-2022-0829-0569, pp. 37-40]

Compact SUV GHG Reduction: Relatedly, as ICCT previously commented, Roush 2021 states, "A 30kW 48-volt P2 system mated to a low bore-to-stroke ratio Miller cycle engine with electrified boosting, advanced cylinder deactivation, cooled EGR and a heated catalyst can provide a fuel economy benefit close to a full high voltage hybrid powertrain at a much lower cost. The 48V electric motor can supplement the engine torque under low- speed high load conditions, thereby avoiding this knock-prone area of the engine map. Also, the use of an advanced boosting system, combining a turbocharger and a 48V electric supercharger, will reduce engine backpressure (larger turbine) and improve scavenging, reduce combustion residuals, and reduce the propensity for knock. This combination enables the use of a higher compression ratio, thereby increasing engine efficiency. A combination of a high-energy ignition system (high energy spark plug/plasma ignition) and fuel reforming by pilot fuel injection during NVO can be used to increase cEGR tolerance at low loads. The initial part of such a project would include engine and combustion modeling, followed by prototype engine testing. The overall GHG reduction potential will require modeling and optimization of engine design, calibration parameters, and boosting system sizing and control. Roush estimates a reduction in GHG emissions exceeding 30% is possible compared to a level 1 (NHTSA) turbocharged engine." (Roush 2021 LDV page 14). [EPA-HQ-OAR-2022-0829-0569, pp. 37-40]

- Roush 2021 LDV Sections 2.4 and 2.5 pages 26-28 on low bore-to-stroke ratio benefits [EPA-HQ-OAR-2022-0829-0569, pp. 37-40]

- Roush 2021 LDV Section 13.2 page 66 [EPA-HQ-OAR-2022-0829-0569, pp. 37-40]

Strong hybrid (HEV)

Effectiveness

ICCT commends EPA's incorporation of advanced Atkinson and Miller cycle engines. However, the notion of a dedicated hybrid engine (DHE) extends beyond the engine maps used during ALPHA HEV simulation. ICCT recommends EPA consider even further optimized/efficient dedicated hybrid engines, both for HEV applications and for PHEVs. As described in ICCT's 2021 comments and in SAE (2021),101 "EPA should focus on the expanded application of energy management capabilities in full hybrid powertrains to also minimize operation under the low-speed high torque areas of the engine which are prone to knocking by torque augmentation with the electric motor. The instantaneous torque capability of the electric motor can effectively support transient torque demand. This will allow both naturally aspirated and turbocharged engines that are part of a hybrid powertrain to be optimized for a narrow operating range incorporating higher compression ratios and increased EGR dilution (maintaining stoichiometric operation), thereby prioritizing efficiency over peak torque at low engine speeds and transient response." (Roush 2021 LDV page 12) [EPA-HQ-OAR-2022-0829-0569, pp. 37-40]

Negative valve overlap in-cylinder fuel reforming (NVO)

Effectiveness

As ICCT previously commented, Roush states, "In-cylinder fuel reforming by using pilot fuel injection during NVO has shown to significantly improve cooled EGR (cEGR) tolerance, combustion stability, and engine efficiency. Such a system can have wide application in turbocharged and NA engines across different vehicle segments with minimal hardware requirements. Depending on the base engine, Roush estimates an efficiency improvement, and the corresponding reduction in GHG emissions, in the range of 5 to 10% is possible and low cost, therefore correspondingly high effectiveness." (Roush 2021 LDV page 14). [EPA-HQ-OAR-2022-0829-0569, pp. 37-40]

Passive prechamber combustion (PPC)

Effectiveness

As ICCT previously commented, Roush states, “Prechamber combustion systems are one of the most promising technologies for improving the dilution limit of engines, thereby improving system efficiency. It can also enable extremely fast burn rates increasing the knock tolerance of turbocharged engines, allowing higher compression ratios and the associated efficiency improvements. The Maserati Nettuno engine in the 2021 Maserati MC20 will be the first application of a passive prechamber engine in production. However, the primary objective in the MC20 is high performance. It would be very valuable to study the effect of the system on knock tolerance, burn rates, dilution tolerance (EGR and air), and emissions. The effort should focus on quantifying possible efficiency gains in a non-performance application.” (Roush 2021 LDV pages 14-15). In a dedicated hybrid engine developed by Mahle, pre-chamber combustion enabled a CO2 emissions reduction of over 5%.103 [EPA-HQ-OAR-2022-0829-0569, pp. 37-40]

High energy ignition (HEI)

Effectiveness

As ICCT previously commented, Roush states, “High energy volume ignition systems can enable combustion of dilute (cEGR or air diluted) in-cylinder mixtures resulting in a step-change in engine efficiency compared to conventional spark plugs. Such systems can be a drop-in replacement for a spark plug, thereby representing a cost-effective GHG improvement option. Such systems should be evaluated for maximum efficiency potential, in conventional, 48V mild hybrid, and full HV hybrid applications. Roush estimates that systems such as plasma ignition can support good combustion stability with high amounts of cooled EGR, thereby achieving engine efficiency improvements in the range of 5-10% over a baseline turbocharged DI, dual VVT engine. Microwave ignition systems, on the other hand, have the potential to achieve levels consistent with prechamber ignition systems. This would enable lean-burn engines with low engine-out NOx emissions which can achieve brake thermal efficiency which exceeds 45% in light-duty vehicle applications, compared to a level of 36-38% for a baseline turbocharged DI, dual VVT engine.” (Roush 2021 LDV page 15). Additional information can be found at:

-Roush 2021 LDV Section 13.5 page 67

[EPA-HQ-OAR-2022-0829-0569, pp. 37-40]Transmissions

Application in OMEGA

In this proposal, EPA did not consider the application of automatic transmissions with 9 or more gear ratios. This is unrealistic, as nearly 40% of pickups were equipped with such transmissions in 2021, and EPA expects more than a quarter of all vehicles to have such transmissions in MY2022.104 Without including the costs and benefits of transmissions with additional gears, EPA is missing important fuel-savings technology. Consequently, ICCT recommends EPA incorporate in its analysis transmissions with 9 or more gears. [EPA-HQ-OAR-2022-0829-0569, pp. 40-43]

104 EPA. (2022). Automotive Trends Report [detailed automotive trends data]. https://www.epa.gov/automotive- trends/explore-automotive-trends-data

Organization: Kia Corporation

- Kia urges EPA to take further action to improve fuel standards that will lower vehicle fuel consumption and criteria pollutant emissions from legacy and new Internal Combustion Engine (ICE) vehicles. As Kia is significantly increasing resources for developing and transitioning to electrified powertrains, Kia will have fewer resources available to improve ICE. [EPA-HQ-OAR-2022-0829-0555, p. 4]

Organization: Mazda North American Operations

On top of this, the additional criteria emissions requirements placed on internal combustion engine vehicles will also divert limited resources with questionable efficacy. [EPA-HQ-OAR-2022-0829-0595, p. 2]

Organization: MEMA, The Vehicle Suppliers Associated

Technology Neutrality Pairs with Regulatory Certainty

The proposed rule disproportionally favors battery electric propulsion, which in turn discourages any further advancements for internal combustion technology, including carbon-neutral renewable fuels. Emerging innovations and recent technologies offer significant reduction in emissions from ICE vehicles, in both future and current fleets. [EPA-HQ-OAR-2022-0829-0644, pp. 5-6]

Technology-forcing regulations that foster innovation aligned with policy, rather than regulations that mandate a narrowly defined technology path, will lead to a more positive national outcome. [EPA-HQ-OAR-2022-0829-0644, pp. 5-6]

MEMA recognizes that the proposal attempts a performance-based standard, and the agency makes forecasts that estimate a variety of technology combinations in future fleets. By accepting the potential for technologies other than battery electric and hydrogen fuel cell, EPA can make a more immediate, widespread, positive impact on nationwide emissions reductions. Therefore, EPA must incent the development and deployment of advanced technology options to include advanced internal combustion (ICE) technologies, renewable fuels, and post-combustion CO2 capture (known as mobile carbon capture). These incentives will assist in accelerating the necessary infrastructure improvements needed to support advanced technology vehicles. [EPA-HQ-OAR-2022-0829-0644, pp. 5-6]

One of the pathways which deserves to be highlighted is the Hydrogen Internal Combustion Engine (H2ICE). This technology is a promising pathway which for certain applications is preferable to other alternate advanced technologies in the proposed rule. For example, a vehicle towing a trailer requires sustained torque output to tow a heavy load. H2ICE would offer the best solution for this vehicle to achieve the emission targets while fulfilling the customer needs for range and load. BEVs and fuel cell electric vehicles (FCEV) have weight and load limitations that might not allow this vehicle to meet its operational requirements. Indeed, the agency has recognized the benefit of H2ICE in the separate rulemaking for "Greenhouse Gas Emissions Standards for Heavy-Duty Vehicles -Phase 3 [1]. We refer to section II. Proposed CO2 Emission Standards, D. Vehicle Technologies, 1. Technologies to Reduce GHG Emissions from HD Vehicles with ICES, paragraph 5 [2] which states: [EPA-HQ-OAR-2022-0829-0644, pp. 5-6]

1 https://www.regulations.gov/document/EPA-HQ-OAR-2022-0985-1423121

2 11. Proposed CO? Emission Standards, D. Vehicle Technologies, 1. Technologies to Reduce GHG Emissions from HD Vehicles with ICES, paragraph 5

Manufacturers may develop new ICE vehicle technologies through the MY 2032 timeframe. An example of a new technology under development that would reduce GHG emissions from HD vehicles with ICES is hydrogen-fueled internal combustion engines (H2ICE). These engines are currently in the prototype stage of innovation for HD vehicles but have also been demonstrated as technically feasible in the past in the LD fleet. H2ICE is a technology that produces zero hydrocarbon (HC), carbon monoxide (CO), and CO2 engine-out emissions. [EPA-HQ-OAR-2022-0829-0644, pp. 5-6]

Furthermore, a large portion of manufacturing technology and workforce skills needed to manufacture H2ICE equipment may be adapted from currently available gasoline or diesel manufacturing footprints. H2ICE also builds hydrogen demand, which is a nascent market in the U.S. Building that market will help supply the needs of hydrogen fuel cell electric vehicles in due course. The two are complementary to each other's growth and commercialization. MEMA therefore strongly suggests that EPA adopt a consistent pathway for H2ICE for light-duty and medium-duty vehicles just as proposed for heavy-duty vehicles. [EPA-HQ-OAR-2022-0829-0644, pp. 5-6]

MEMA urges:

- EPA to move beyond tailpipe emissions and include emissions from electricity generation in BEV calculations. [EPA-HQ-OAR-2022-0829-0644, p. 7]

- EPA to act decisively to further encourage and incentivize the development and deployment of advanced clean ICE technologies, including renewable fuels, and mobile carbon capture. [EPA-HQ-OAR-2022-0829-0644, p. 7]

- EPA to develop an efficiency metric to comparatively analyze ZEV energy needs and if not incorporated into this rule - report that metric to the public as an initial step. [EPA-HQ-OAR-2022-0829-0644, p. 7]

Organization: Our Children's Trust (OCT)

In short, continuing to promulgate rules that contemplate, facilitate, and allow for continued sales of internal combustion engine ("ICE") vehicles is reckless and nonsensical. Instead, EPA should set the national standard to align with zero ICE vehicle sales by 2030. [EPA-HQ-OAR-2022-0829-0542, p. 1]

Specifically, there is a clear consensus that decarbonizing transportation requires a rapid shift away from fossil fuel vehicles toward Zero Emissions Vehicles ("ZEVs"), including battery-electric vehicles ("BEVs"), plug-in hybrid vehicles running primarily on electricity ("PHEVs"), and hydrogen fuel cell electric vehicles ("FCEVs"). 1 Transitioning from conventional internal combustion engine vehicles to electric vehicles is believed to be one of the most promising pathways for decreasing greenhouse gas ("GHG") emissions from the road transportation sectors and thus should be pursued aggressively. 2 While improving fuel efficiency can help to reduce emissions in the short-term, it cannot achieve the emissions reductions needed to achieve the Administration's net zero emissions target, it contributes to ongoing dangerous levels of GHG emissions, and experts have concluded that the continued use of fossil fuel vehicles is considered "a technological dead end." [EPA-HQ-OAR-2022-0829-0542, p. 1]

In short, continuing to promulgate rules that contemplate, facilitate, and allow for continued sales of internal combustion engine ("ICE") vehicles is reckless and nonsensical. Instead, EPA should set the national standard to align with zero ICE vehicle sales by 2030. There is also no justification, no compelling interest, and no rational basis for not aligning EPA's rule with California and other states that require 100% of light-duty vehicle sales to be ZEVs by 2035. [EPA-HQ-OAR-2022-0829-0542, p. 2]

2 Daniel Sperling et al., 5.2 Accelerating Deep Decarbonization in the U.S. Transportation Sector, in America's Zero Carbon Action Plan 188 (Zero Carbon Consortium, 2020) ("The most compelling strategy for deep GHG emissions reductions . . . is to electrify surface vehicles: to switch vehicles from fossil fuel combustion (e.g., gasoline and diesel) to electric propulsion (e.g., battery, plug-in hybrid, and fuel cell electric vehicles).").

3 Daniel Sperling et al., 5.2 Accelerating Deep Decarbonization in the U.S. Transportation Sector, in America's Zero Carbon Action Plan 198 (Zero Carbon Consortium, 2020).

Organization: Sierra Club et al.

We appreciate the EPA's proposal, which moves our vehicles in the right direction. However, the final emissions standard for light-duty vehicles should: [EPA-HQ-OAR-2022-0829-0668, p. 2]

-Appropriately take advantage of available cost-effective improvements to new fossil-fuel vehicles; [EPA-HQ-OAR-2022-0829-0668, p. 2]

Organization: South Coast Air Quality Management District

2. Ensure manufacturers continue to reduce emissions from conventional engines and vehicle technologies. The proposed rule allows manufactures to include ZEVs and PHEVs in the calculation of fleet average standards. In contrast, ACC II phases out the inclusion of ZEVs and PHEVs in the fleet averages starting with 60% allowed in 2026 to 0% in 2029 and subsequent years. CARB adopted this approach to ensure that conventional engine vehicles would also improve over time on fuel efficiency and emissions control systems. With the increasing stringency of the emissions standards, manufacturers may opt to rely more on the ZEVs sales to comply with the standards while forgoing the allocation of resources and needed development work to lower emissions from conventional engine vehicle technologies. While it is desirable to see increasing market share of ZEVs, it is also important not to overlook the necessary improvements that manufacturers should make on conventional vehicles since these vehicles will be around us for many years to come. Therefore, we recommend U.S. EPA consider including requirements or mechanisms for manufacturers to continue to allocate necessary resources to develop cost-effective technologies for conventional engines and vehicles to maximize emissions reductions, especially in the near term. [EPA-HQ-OAR-2022-0829-0659, pp. 2-3]

Organization: Southern Environmental Law Center (SELC)

EPA must also ensure its modeling accurately captures emissions reductions that can be achieved in internal combustion engine vehicles through existing vehicle efficiency technologies. [EPA-HQ-OAR-2022-0829-0591, p. 8]

Organization: United Steelworkers (USW)

In the proposed rule, the EPA's approach to lowering emissions is termed the technology-neutral way, which envisions using more clean-running gas vehicles, hybrids, fuel cell vehicles, and other innovations to meet more stringent standards. However, in this proposed rule, EPA did not consider improvements to ICE vehicles with off-the-shelf technology. EPA's proposal will outlaw ICE vehicles without considering or encouraging manufacturers to invest in engine and fuel efficiency technologies that would lower emissions. [EPA-HQ-OAR-2022-0829-0587, p. 6]

Engine efficiency and aftertreatment systems can help achieve CO2 reductions, while protecting workers in the ICE vehicle supply chain and oil refinery workers during the transition to low-emission vehicles. Existing and new technologies ranging from engine improvements and hybridization can achieve between 5 and 50 percent GHG reductions. For example, gasoline particulate filters (GPFs) significantly reduce fine particulates black carbon.13 GPFs are required in Europe and Asia in order for vehicles to comply with regulations there. Off-the-shelf technologies that reduce tailpipe emissions from ICE vehicles – such as GPFs – could easily and affordably be applied to light- and medium- duty vehicles sold in the United States, with no additional research and development needed. Automakers should be able to employ a combination of ZEV and ICE improvement technologies to comply with the final rule. [EPA-HQ-OAR-2022-0829-0587, p. 6]

13 DieselNet, (Link: https://dieselnet.com/tech/gasoline_particulate_filters.php) "Gasoline Particulate Filters", Accessed July 5, 2023.

Technology that lowers emissions for ICE vehicles should be elevated in this proposal. EPA could do this by keeping the rule technology neutral and finalizing a more practical timeline for emissions reductions. These technologies protect jobs in the current auto supply chain and ensure that our nation is actively pursuing policy to lower vehicle emissions. Standards must be reassessed with the inclusion of these technologies because the current proposal will eliminate the ICE vehicle all together, and is not an economically or socially viable rule. [EPA-HQ-OAR-2022-0829-0587, p. 6]

EPA Summary and Response

Summary:

Commenters provided a broad number of themes with respect to ICE vehicle technologies. Several commenters noted the significant role ICE powertrains will serve in the LMDV fleet for many years to come. Commenters further noted the opportunity for further ICE-based improvements to reduce emissions while other commenters expressed concern that ICE improvements should not be required in addition to electrification. Other commenters expressed concern regarding the risk of ICE-based vehicles backsliding in emissions.

The Alliance for Automotive Innovation (AAI) noted that, based on current emissions performance, ICE-based vehicles are not able to meet the final standards and levels of electrification would be required to offset the debits generated by ICE vehicles. In contrast, Consumer Reports noted that if vehicle manufacturers replace their oldest and highest emitting ICE vehicles first and retain their newest, most efficient ICE powertrains, significant emissions reductions can be achieved sooner. Consumer Reports went on to recommend reflecting this possible type of fleet turnover in the agency's modeling.

Ford, Kia and Mazda all commented that standards that required additional improvements to ICE powertrains would divert resources away from EV development.

The Aluminum Association and American Fuel & Petrochemicals Manufacturers (AFPM) both noted that ICE powertrains would be part of the LMDV fleet for some time to come. The Aluminum Association noted the benefits of ancillary vehicle technologies, such as lightweighting, while AFPM commented on the benefits of ICE powertrains and drivability.

Commenters recommended that EPA require more improvements from ICE powertrains with the Arizona Department of Environmental Quality (ADEQ) recommending "EPA to consider further strengthening its proposal by continuing to improve upon and incentivize advancements in internal combustion engine technology." Center for Biological Diversity (CBD) noted that "EPA's own data shows that multiple technologies exist to make the millions of gas-powered vehicles sold in the next decade much more efficient, from gasoline direct injection and continuously variable transmission to hybrid technologies" and recommended that EPA adopt more stringent standards further noting that emission reductions would be significant and immediate. Environmental and Public Health Organizations and the Center for American progress echoed the CBD comments. Environmental and Public Health Organizations also commented on the Agencies use of the CCEMS model and commented that CCEMS was more likely to project greater ICE technology improvements. Sierra Club, Southern Environmental Law, United Steel Workers, ICCT and private citizen David Hallberg also recommend that EPA fully consider the potential for ICE improvements, with ICCT noting that EPA had not considered any ICE improvements for MDVs.

Our Childrens Trust (OCT) recommended that EPA "should set the national standard to align with zero ICE vehicle sales by 2030" and that EPA should not align with California's 100% ZEV mandate in 2035. OCT further commented that "continuing to promulgate rules that contemplate, facilitate, and allow for continued sales of internal combustion engine ("ICE") vehicles is reckless and nonsensical."

Consumer Reports commented with a focus on vehicle buyers and commented that "Consumer demand for EVs is rapidly increasing, and technology improvements will mean that the remaining gasoline powered vehicles will have to compete with better and better EV offerings", suggesting that the ICE backsliding, modeled by EPA, would not automatically occur. Consumer Reports also noted the strong demand from consumers for clean vehicles.

The California Air Resources Board (CARB) suggested in their comments "that U.S. EPA adopt additional regulatory mechanisms to ensure that all cost-effective technologies that get integrated into conventional vehicle designs will continue to be installed throughout vehicle line-ups and throughout the program lifetime to maintain emission reductions from conventional vehicles" to prevent backsliding. These comments were also echoed by the California Attorney General's Office which recommended that EPA adopt more stringent standards to prevent backsliding. CBD, District of Columbia Department of Energy and Environment (DOEE), and the Environmental Defense Fund (EDF) similarly commented on the need for EPA to put in place measures to prevent backsliding, with EDF requesting "guardrails" to ensure technology is not removed.

The Motor and Equipment Manufacturers Association commented on hydrogen combustion technology and noted its potential for emission reductions.

South Coast Air Quality Management District (SCAQMD) commented that EPA should "Ensure manufacturers continue to reduce emissions from conventional engines and vehicle technologies." and compared EPA's proposal to CARB's ACC II program.

Response:

EPA appreciates all the comments received regarding ICE vehicle technologies. EPA agrees that ICE technologies will most likely be used in light and medium duty vehicles for years to come and recognizes that further ICE improvements are available to manufacturers and encourages their implementation. EPA's technology projections are based the Agency's assessment of technology application to meet a future set of emission standards in a cost-effective manner. While some technologies may be more cost-effective than others, the decisions as to which technology to adopt to meet future standards are ultimately made by the manufacturers. EPA's modeling in the proposal, being cost minimizing in nature, did project that some manufacturers might remove technology from existing vehicles as their compliance situation develops and significantly more cost-effective technology is brought to market. The modeling may illuminate a possibility of backsliding, but it does not necessarily indicate vehicle manufacturer's intentions. Nevertheless, in our modeling for the final rule, we restricted the model from allowing the backsliding of ICE technology. This modeling approach reflects our expectation that manufacturers are unlikely to backslide on technology in actual practice, as the year over year stringency of the standards will warrant manufacturers to employ a full range of technologies; backsliding on ICE vehicles would only result in additional credit deficits that would need to be made up with more credit-generating vehicles under the fleetwide averaging standards.

EPA has adopted performance-based standards set at a level we have determined to be appropriate to achieve substantial air pollutant emission reduction to protect public health and welfare according to the CAA. Manufacturers are free to adopt any technology strategy, be it via advancements in ICE, hybrids, PHEVs or BEVs, that enables them to comply with the final standards. In this rulemaking EPA is not providing additional credits for specific technologies; that is, we are not providing any advanced technology multipliers for MY 2027 and later years. However, not all technologies emit the same level of GHG emissions and there will be naturally more cost-effective technologies, and it is up to each manufacturer to decide which technologies they ultimately adopt. Performance-based standards account for all emissions reductions and technology benefits that may be implemented by manufacturers. However, given some of the comments received, such as those from Ford, Mazda, Kia and AAI, EPA has reason to believe that vehicle manufacturers are planning to place less emphasis on the design, development, and deployment of ICE-based technologies to focus on the development of electrified vehicles.

EPA has not put in place specific provisions to prevent backsliding or to control which vehicles receive specific technology, as suggested by several commentors including CBD, District of Columbia Department of Energy and Environment (DOEE), CARB, and the Environmental Defense Fund (EDF), although we have made modifications to our fleet analysis modeling to consider the effects of backsliding, as described above. The comment from Consumer Reports regarding manufacturers decisions to replace older, less efficient vehicles first and keep modern, more efficient vehicles longer and that conventional vehicles will need to compete with BEVs seem like reasonable conclusions, although EPA does not reflect these recommendations in our modeling.

EPA did not include hydrogen combustion in assessment of ICE technologies, as recommended by MEMA. Due to the high cost of aftertreatment systems and the availability of other technologies for compliance, we do not at this time anticipate manufacturers to adopt hydrogen combustion technologies at significant rates. We agree that it remains a possible technology pathway that manufacturers are free to choose.

EPA appreciates the supportive comments, such as those from Our Children's Trust, encouraging the agency to adopt more stringent standards more quickly. We respond to comments on the stringency of the standards in RTC 3.3.1.

12.3.1 – ICE costs

Comments by Organizations

Organization: International Council on Clean Transportation (ICCT)

COMBUSTION VEHICLE EFFICIENCY POTENTIAL AND COST- EFFECTIVENESS

While ICCT strongly supports the proposed rule, the cost of compliance may be overstated due to the use of outdated internal combustion engine vehicle (ICEV) technology data and information. ICEV technology has been consistently improving for decades. While automakers are investing heavily in BEV development, the substantial progress that has been—and continues to be—made in ICE technology has yet to saturate the market. That is, many existing and recently announced ICEV technology improvements have ample room for increased application throughout the ICEV fleet. As many ICE vehicles are still to be sold in the MY2027- 2032 timeframe, the proposed rule is an opportunity to maximize their efficiency and minimize their tailpipe emissions, while providing substantial consumer fuel savings. [EPA-HQ-OAR-2022-0829-0569, pp. 31-34]

ICCT commented extensively on recent ICEV technology improvements in its 2018 comments on the SAFE NPRM for 2021-26 cars and light trucks (ICCT 2018 comments)82, its study of LPM and OMEGA modeling of the 2018 Camry (ICCT 2018 Camry)83, its supplemental comments responding to Toyota comments on ICCT's study of LPM and OMEGA modeling of the 2018 Camry (ICCT 2019 comments)84, and its 2021 comments on the Revised 2023 and Later Model Year Light-Duty Vehicle Greenhouse Gas Emissions Standards (ICCT 2021 comments).85 Much of the content of these prior comments are reiterated or summarized in the following subsections, as appropriate and relevant for this proposed rule. Moreover, recent reports demonstrate that further technology improvements are coming that can boost ICE vehicle efficiency levels well beyond that of even the highly-efficient Atkinson cycle engine efficiency levels assumed in this proposal,86,87 as well as show the declining costs of 48-volt mild hybrid systems.88,89 [EPA-HQ-OAR-2022-0829-0569, pp. 31-34]

As documented in the following subsections, the efficiency potential of ICE technology has continued to improve, while costs have remained lower than previously estimated. Thus, if technology costs and benefits were updated with the latest information, it would show that the proposed standards are even more feasible and lower-cost than EPA's analysis indicates. The following subsections discuss various ICE technologies and compare the assumptions about cost and efficiency potential within EPA's OMEGA analysis with independent research by the ICCT and other experts. [EPA-HQ-OAR-2022-0829-0569, pp. 31-34]

Gasoline Direct Injection (GDI)

Cost

Based on the DRIA Table 2-30, GDI direct manufacturing costs in EPA's OMEGA modeling are between $55-$81 per cylinder. ICCT submitted direct injection cost data in our 2018 comments based on a 2016 FEV teardown cost study (FEV 2016)90, which found per-cylinder costs to be about $40 per cylinder. For additional information see:

Miller cycle engine (MIL)

Cost

It is unclear from the DRIA how MIL costs were developed and how OMEGA calculates MIL costs. Nevertheless, based on analysis of output file engine costs, MIL costs appear too high, especially as compared to base turbo costs (TDS). [EPA-HQ-OAR-2022-0829-0569, pp. 34-37]

Table 5 below is an excerpt from the central analysis of the proposed standards (2023_03_14_22_42_30_central_3alts_20230314_Proposal_vehicles.csv). It highlights 9 ICE vehicles which changed from being equipped with MIL to being equipped with TDS only. Note that the change from a more advanced engine (MIL) to a less advanced engine (TDS) is an artefact of the modeling and is unlikely to occur in the real world as such a change may come at the expense of reduced performance, fuel economy, or other consumer-valued function. Comparing solely the engine costs associated with a specific vehicle model (assigned to a base year vehicle ID in the table), the cost of MIL appears to be $600-$2400 more expensive than TDS. As MIL costs very little compared to a turbocharged, downsized engine such as that used in the proposal analysis to represent TDS (2016 Honda 1.5L L15B7) (see NAS 2021), the incremental costs shown in the table suggest the MIL costs are far too high. ICCT 2021 comments, ICCT 2018 comments, and NAS 2021 explain that incremental MIL costs range from $0–$250. [EPA-HQ-OAR-2022-0829-0569, pp. 34-37]

SEE ORIGINAL COMMENT FOR Table 5. Comparison of Miller (MIL) and Turbo-downsized (TDS) engine costs [EPA-HQ-OAR-2022-0829-0569, pp. 34-37]

In prior rulemakings, EPA included the cost of ATK in the cost of MIL which led to unnecessarily high MIL costs. While it is unclear if ATK costs are included in MIL in the current proposal analysis, such an inclusion would contribute to high MIL costs. [EPA-HQ-OAR-2022-0829-0569, pp. 34-37]

For additional information see:

- ICCT 2021 comments page 7

Mild hybrid (MHEV)

Cost [EPA-HQ-OAR-2022-0829-0569, pp. 34-37]

The costs for position 0 (P0) MHEV are determined according to the equations in DRIA Table 2- In Table 6 below, by comparing these MHEV costs to those found by ICCT in 201694 and more recently in 202295, ICCT finds the EPA MHEV costs to be 2x-3x more expensive. Consequently, ICCT recommends EPA reassess and adjust its MHEV costs to better reflect the most recent data, which are summarized below. One possible source of added cost in the proposal is the identical calculation of MHEV and HEV costs (scaled by motor power). This approach may lead to an overestimate of MHEV costs because the 48V electrical systems of MHEVs do not require the same safety and electrical hardware as higher voltage HEVs. ICCT recommends adjusting MHEV cost calculations according to the table below. [EPA-HQ-OAR-2022-0829-0569, pp. 34-37]

94 Isenstadt, A., German, J. (ICCT), Dorobantu, M. (Eaton), Boggs, D. (Ricardo), Watson, T. (JCI). (2016). Downsized, boosted gasoline engines. https://theicct.org/publication/downsized-boosted-gasoline-engines-2/

SEE ORIGINAL COMMENT FOR Table 6. Comparison of EPA and ICCT P0 mild hybrid (MHEV) direct manufacturing costs, ** Alternator removal costs represented by negative cost (cost savings), For further information, see Dornoff, J., German, J., Deo, A. (ICCT), Dimaratos, A. (DITENCO). (2022). Mild-hybrid vehicles: a near term technology trend for CO2 emissions reduction. https://theicct.org/publication/mild-hybrid-emissions-jul22/ and Isenstadt, A., German, J. (ICCT), Dorobantu, M. (Eaton), Boggs, D. (Ricardo), Watson, T. (JCI). (2016). Downsized, boosted gasoline engines. https://theicct.org/publication/downsized-boosted-gasoline-engines-2/ [EPA-HQ-OAR-2022-0829-0569, pp. 34-37]

Beyond P0 MHEV architectures, there are substantial CO2 reduction benefits achievable by implementing P1-P4 architectures, representing placement of the motor/generator in positions of increasing distance from the engine along the driveline. While such systems cost more than P0, they are more cost-effective in that they have lower cost per percent reduction in CO2. Thus, ICCT recommends EPA consider including in its modeling more advanced MHEV architectures beyond P0. Additional discussion on MHEV effectiveness is in the following section. Table 7 below replicates Table 18 in ICCT 2022 MHEV. As shown in the table, P1-P4 MHEV architectures with specifications similar to P0 MHEV can increase cost by at most 53% (P4+P0 for FWD) with P4+P0 for AWD decreasing costs vs P0. At the same time, P2-P4 architectures can more than double P0 effectiveness. Combining the “Total” cost scaling shown in the below table with the ICCT P0 cost in the table above, all architectures have lower cost than the P0 MHEV cost used in the proposal. [EPA-HQ-OAR-2022-0829-0569, pp. 34-37]

SEE ORIGINAL COMMENT FOR Table 7. Mild hybrid architecture cost in 2020 (ICCT 2022 MHEV, Table 18) [EPA-HQ-OAR-2022-0829-0569, pp. 34-37]

For further information, see Dornoff, J., German, J., Deo, A. (ICCT), Dimaratos, A. (DITENCO). (2022). Mild-hybrid vehicles: a near term technology trend for CO2 emissions reduction. https://theicct.org/publication/mild-hybrid-emissions-jul22/ [EPA-HQ-OAR-2022-0829-0569, pp. 34-37]

Cost

EPA's estimated HEV costs also appear to be overestimated. Due to the challenge of disentangling the costs and effects of both electrified and conventional powertrain component changes from one redesign to the next, ICCT examined total powertrain costs from the central analysis output file (2023_03_14_22_42_30_central_3alts_20230314_Proposal_vehicles.csv). Total powertrain costs are calculated as the sum of battery cost, electrified driveline cost, e-machine cost, driveline cost, and engine cost. For redesigns that occur between MY2023-2027, the difference in cost between the HEV powertrain and non-HEV powertrain ranges from approximately $3,400 to over $9,000. For redesigns that occur after MY2027, the HEV powertrain cost difference ranges between approximately $2,700 to over $10,000. Cost changes due to learning notwithstanding, as analyzed in ICCT's 2015 report on hybrids,99 these levels of cost premiums are not plausible. [EPA-HQ-OAR-2022-0829-0569, pp. 37-40]

99 German, J. (2015). Hybrid vehicles: Trends in technology development and cost reduction. International Council on Clean Transportation. https://www.theicct.org/hybrid-vehicles-trends-technology-development-and-cost-reduction

As with MIL costs, it is not clear precisely how HEV engine (MIL, DHE, and DHE2) costs are calculated. Regardless, as HEV engines are modeled as either Atkinson or Miller cycle engines, their costs ought to be very similar to the same types of engines on non-HEV models. As ATK and MIL are fairly inexpensive as compared to a sufficiently advanced engine (NAS 2021), modeled HEV engine costs ought not to be significantly more expensive than their non-HEV counterparts. In fact, due to the capacity of HEV motor to take up low-speed, high torque demand and transient response, HEV engines can be optimized to a narrower operating range than non-HEV engines. This can enable higher compression ratios, increase EGR dilution, and potentially decrease costs. Especially in the case of a serial hybrid or range extended PHEV, the engine is effectively decoupled from the drivetrain, permitting deep optimization, with up to 40% engine cost reduction depending on electrification.100 [EPA-HQ-OAR-2022-0829-0569, pp. 37-40]

100 SAE 2021. (2021). Optimizing hybrids for cost and efficiency. SAE Automotive Engineering. Page 18. https://www.nxtbook.com/smg/sae/21AE04/index.php#/p/18

Lightweighting

Cost

In the proposal, the only lightweighting option is the switch to an aluminum body. This is certainly a viable lightweighting option, but it is not the only one. Manufacturers have many avenues for lightweighting with various degrees of mass reduction and associated cost (NAS 2021 and ICCT 2018 comments). [EPA-HQ-OAR-2022-0829-0569, pp. 40-43]

EPA should consider adjusting its lightweighting options in its analysis to incorporate varying levels of mass reduction at vary levels of cost per unit mass saved. This methodology has been used in prior rulemakings and can fit into EPA's existing mass and cost calculations. Alternatively, EPA can add a single, discrete, intermediate lightweighting option (between the base steel body and lightweighted aluminum body) that mimics the same format as the two existing options. This intermediate option would be composed of primarily ultra-, advanced- and high strength steels (as opposed to conventional or mild steel). Such steels with optimized design can offer mass reductions on the order of 10%-15% (higher for specific parts), at costs comparable to existing steel costs.105 More recent steel developments indicate further mass reductions are possible with both steel and better design optimization, with high strength steel costs similar to mild steel costs up to half the cost of lightweighting with Aluminum.106 [EPA-HQ-OAR-2022-0829-0569, pp. 40-43]

4. Mild Hybrid Efficiency, Cost, and Architecture

The proposed rule did not consider any improvements to mild hybrids. Estimates of mild hybrid effectiveness remain unchanged from the P0 mild hybrid estimate in previous rulemakings. Engine efficiency maps for light-duty non-dedicated hybrid systems in DRIA Table 2-2 all date from 2016 or earlier, with the exception of a turbo Miller cycle engine from 2020, and there are no efficiency improvements for any specific engine through 2032. [EPA-HQ-OAR-2022-0829-0585, pp. 15-16]

Further, EPA implicitly assumed that there would be no improvement in mild hybrid architecture. Only the P0 architecture was considered in the proposed rule.16 However, several recent studies have found that P2, P3, and P4 mild hybrid architectures are much more cost effective than P0 systems.17 They eliminate the losses in the belt, eliminate engine friction and pumping losses during regenerative braking, and enable the use of 20-30 kW electric motors with corresponding higher regenerative braking energy and engine synergies (e.g. launch assist, low-speed electric driving, aggressive fuel cutoff, and torque assist during driver tip-in). Overall, efficiency more than doubles compared with P0 systems at a much smaller incremental cost. Even though these reports were previously submitted to EPA and NHTSA, there was no discussion of mild hybrid architecture and system improvements in the proposed rule. [EPA-HQ-OAR-2022-0829-0585, pp. 15-16]

EPA Summary and Response

Summary:

EPA appreciates the comments from the International Council on Clean Transportation (ICCT) and John Graham regarding ICE costs provided in response to our proposal. ICCT commented that EPA's estimated costs of compliance are too high due to the overestimation of ICE technology costs. ICCT provided several examples and recommendations for changes.

Response:

EPA agrees that the ICE powertrain costs needed updating for the final rulemaking. As we discuss in chapter 2.5.1 of the RIA, for this rulemaking we are now assessing costs on an absolute (rather than incremental) basis. This also has enabled us to update our analysis to include more robust costing of PHEVs which were added to our ALPHA and OMEGA compliance modeling for analysis of the final standards. As discussed in 2.5.2.3 of the RIA, we contracted with FEV to evaluate and update our powertrain costs based on information within their powertrain components and engine database to help inform EPA's scalable cost equations for the engine and electrified powertrain (i.e., mild HEV, strong HEV, PHEV and EV) architectures currently being modeled in ALPHA. As a result, our overall ICE and HEV powertrain costs have decreased which is directionally in agreement with ICCT's comments.

For comments responses related to cost of PM standards and gasoline particulate filters, please refer to section 4.2.3.

Comments by Organizations

Organization: GROWMARK, Inc.

Lack of EV Capability for Farmers

Current electric vehicles do not provide the capabilities that farmers rely on to carry out their operations. According to a study recently released by the American Automobile Association (AAA), the Ford F-150 Lightning saw its range decrease by almost a quarter when loaded close to its maximum payload capacity.4 A gasoline-powered truck, however, would only lose 14 percent of its range with the same amount of weight, and of course it would be quicker and more convenient to refuel.5 [EPA-HQ-OAR-2022-0829-0560, p. 2]

4 American Automobile Association. (2023, June). Effect of payload on driving range of battery electric truck. https://urldefense.com/v3/ https:/u7061146.ct.sendgrid.net/ls/click?upn=4tNED-2FM8iDZJQyQ53jATUZvOEO3mirlEl3vtAic9l7ghAOXNRXkwKaKICrDXA3ZoT75TOvo955EZ6-2FJiQG-2FErJaPZeKHTyfflQJiv4TMR5A-3DMLSQ_wwmARy8TMTevifjaQtiXjzeH-2FSc8WPX2ToRxYAJ5XFXCYIVurVZ- 2F7aCPZDngjq-2BQuMDruqnM8cSNwQPzi5UIwwpztKldVzphs52jy6vxI2xgPnkdzJy3C9ftadJYj76WuUf2T26mkgeQA4pLiS2I3PjMzAEYZZu-2BUbgcPfolgmcVfQ7aEf7LxjMjPw-2B8WF3EQEdXTpy-2BAUfR52wN4rM91gx75Pxivc VYDED1S55BpuarlzGYrR-2Bk3PvHnJeb3rGPLd5dXXuQ8SwSjo-2BWWPLN8Jrn1ZD1e0j05qXvdpcFmg7-2FbUtbDUzAhjkGZGxVpfcOxvWD4YC810LuMOxWhv3kzMP1Xq9BQ4VUljZwYsOjU-2BI-3D;!!A1OrVxnpM0w!A Qdah29wRyKcLjIUYyHo21FIzdyG78ee-sIEhfNe4_m8Dkjdh8iAFlUoJGGzPw1xORQ0wI8g1EedoHHou9l8NRN7$

5 Tucker, S. (2023, June 6). Study: EVs lose range to hauling, more than gas trucks. Kelly Blue Book. https://www.kbb.com/car-news/study-evs-lose-range-to-hauling-more-than-gas-trucks/

Additionally, EVs will have worse results when it comes to towing than ICE vehicles. For example, while an ICE Ford F-150 can tow up to 14,000 pounds, the EV Ford F-150 Lightning has a max towing capacity of two tons less than that.6 Furthermore, testing of towing any considerable weights with the EV truck resulted in dramatic decreases in range, up to a 70 percent decrease in one test.7 [EPA-HQ-OAR-2022-0829-0560, p. 2]

6 Brandt, E. (2022, August 18). Payload and towing capacity on electric vehicles. Kelly Blue Book. https://www.kbb.com/car-news/how-far-can-an-electric-truck-tow/

7 Brandt, 2022.

These figures are simply not acceptable to farmers who rely on their vehicles to do their jobs. Farmers use their trucks to take products to market, bring supplies to their fields, and move livestock. Vehicles that have less capability than current ICE technology will lead to decreased efficiency and increased cost at the farm gate, which will lead to further farm consolidation and threaten our nation's food security. [EPA-HQ-OAR-2022-0829-0560, p. 2]

Organization: Illinois Farm Bureau (IFB)

According to the USEPA, vehicle technology has reduced emissions from common pollutants by roughly 99 percent in both light- and heavy-duty vehicles and buses,1 and CO2 emissions from light-duty internal combustion engine vehicles ("ICEV") have decreased 25 percent since model year 2004.2 All vehicle technologies can continue to reduce emissions effectively and efficiently. According to the U.S. Energy Information Administration ("EIA"), there are about

272 million ICEVs3 on the road today, and EIA projects over 140 million ICEV sales will occur between 2023 and 2032.4 Further, EIA projects there will be about 269 million ICEVs in the fleet in 2050 along with 47 million battery electric and plug-in hybrid electric vehicles. [EPA-HQ-OAR-2022-0829-0532, p. 2]

EPA's proposal to ban most new gasoline and diesel vehicles by 2032 will benefit China at the expense of Americans, our energy security and jobs like mine in U.S. fuel and petrochemical manufacturing. [EPA-HQ-OAR-2022-0829-1707]

Plus stop Ireland from killing 200000 cows. You know it's crap. Cows are not killing the planet. Plus as long as China Keri's doing what they do doesn't matter how much we do. China U.S. the problem for the world and y'all know it. Stop the madness [EPA-HQ-OAR-2022-0829-1707]

The United States is the world's top producer of liquid fuels. American crude oil—not foreign oil—is the number one feedstock for our refineries. [EPA-HQ-OAR-2022-0829-1707]

We do not have the same strength in electric vehicle (EV) batteries and minerals. China owns that market. Even with massive investments, a study from the Dallas Fed suggests the United States is likely to control just 11% of global battery production while China keeps a stranglehold on 70%. This policy would trade U.S. fuel security and influence for dependence on China. [EPA-HQ-OAR-2022-0829-1707]

Consumers will pay for EPA's proposal long before it's implemented. EVs have yet to reach cost parity and sell for about $12,000 more than traditional models according to Kelley Blue Book. Forced EV sales are also inflating the cost of new and used gasoline vehicles. Public financing for the rushed expansion of the electric grid is also going to fall on consumers' and taxpayers' shoulders. [EPA-HQ-OAR-2022-0829-1707]

EPA claims reduced emissions will make up for these costs, but its accounting ignores all but one category of vehicle emissions—just those from a vehicle tailpipe. According to this logic, a Hummer EV, with its nearly 3,000-pound battery, is responsible for ZERO emissions and has less impact on the environment than a Prius. [EPA-HQ-OAR-2022-0829-1707]

In addition to ignoring lifecycle emissions, EPA overlooks the fact that today's fleet—composed almost entirely of consumer-preferred gasoline and diesel vehicles—is the cleanest on record. These improvements can continue—with more carbon capture, clean hydrogen and U.S.

biofuels—providing EPA allows all vehicle technologies to compete. [EPA-HQ-OAR-2022-0829-1707]

Please withdraw the current proposal and replace it with policy that (1) considers the full lifecycle emissions of vehicles, (2) prioritizes consumer choice and (3) commits to upholding to American energy security. [EPA-HQ-OAR-2022-0829-1707]

Organization: Matthew DiPaulo

While OEMs are producing EV vehicles, their entire fleet isn't. The average age of the vehicle car parc is 13 years with an average of 122,000 miles. With OEMs still manufacturing ICE engines, those vehicles will last 15+ years (or more) and will require motor oil. [EPA-HQ-OAR-2022-0829-1514, p. 1]

Organization: Missouri Corn Growers Association (MCGA)

To this point, the rulemaking ignores the fact that the ICE engines can be engineered and further optimized to lower emissions and meet targets. In the 1970s, the U.S. faced a problem with lead tailpipe emissions. To solve the issue, gasoline was reformulated to meet lead-based emission reduction targets. The U.S. didn’t ban or restrict the use of internal combustion engines. Instead, the fuel source was reengineered, allowing auto manufacturers to adjust and optimize powertrain technologies to simultaneously meet emission targets while following and meeting consumer demands. There are low and zero-emission liquid fuel options available today that can accomplish the same thing, including low-carbon ethanol as well as biodiesel. EPA should take the opportunity to focus on solutions that keep ICE engines on the road– because they are on the road in mass today and will be for the foreseeable future. [EPA-HQ-OAR-2022-0829-0578, p. 2]

Suppose EPA is genuinely interested in finding sustainable and workable emissions reduction solutions. Focusing on new fuel technologies that work within existing vehicle powertrains and fueling infrastructure available right now is the smart way forward. To that end, MCGA urges EPA to focus its energy on modernizing the nation’s liquid fuel standards, not cherry-picking winners and losers in the vehicle technology and powertrain sector. [EPA-HQ-OAR-2022-0829-0578, p. 2]

Organization: Reginald Modlin and B. Reid Detchon

The Proposed Rule primarily targets reducing emission of Greenhouse Gas (GHG). In that context, we observe that EPA has missed a substantial opportunity to reduce GHG emissions from vehicles now on the road. In seeking to achieve early wins in the climate challenge, the goal of deploying effective, available, and affordable technology packages should consider improving the fuel used by over 250 million existing vehicles. An analysis of the potential effectiveness of an improved fuel used in Internal Combustion Engine (ICE) powered vehicles now and into the next few decades shows that adoption of an improved fuel could possibly double the CO2 reductions claimed by the Proposed Rule! (See analysis conducted by Steffen Mueller, University of Illinois at Chicago, reported by B. West, “Benefits of Ethanol Blending and Impact on Emissions and Emissions Control,” at SAE Powertrains, Fuels and Lubricants Summit, October, 2021.) This observation alone should cause EPA to give very serious consideration into how an improved fuel can be adopted and deployed. And, an improved fuel would bring along further, substantial, benefits. [EPA-HQ-OAR-2022-0829-0570, pp. 1-2]

Organization: Transfer Flow, Inc

Different technologies are appropriate for different scenarios. [EPA-HQ-OAR-2022-0829-0496, p. 5]

Liquid fuels have a strong heritage of radically improving quality of life, and this history is not going to erase itself overnight. Basing the performance of all liquid fuels on fossil fuels or even gasoline is a limiting perspective that undercuts the potential for a grassroots fuels movement where fuels are created and consumed locally by repurposing the waste created from The United States' rich agricultural resources. [EPA-HQ-OAR-2022-0829-0496, p. 5]

California Senate Bill SB-1383 requires waste management companies to sequester organic materials and keep them out of landfills. Several CalRecycle24 facilities have developed waste-to-energy facilities that convert food and yard waste to carbon-negative biofuels, which are then used to power their garbage trucks and other vehicles. These waste-to-energy projects reduce landfilling and fossil fuel consumption and provide dramatic air quality benefits. They also create good-paying local jobs, often in low-income communities. [EPA-HQ-OAR-2022-0829-0496, p. 5]

24 https://calrecycle.ca.gov/organics/slcp/

Comparing low-NOx renewable natural gas made locally to gasoline is like comparing your current high-speed internet to the old, antiquated dial-up internet. The EPA's bias against internal combustion technologies is a short-sighted assumption and serves to undermine the overall goal of reducing emissions. [EPA-HQ-OAR-2022-0829-0496, p. 5]

EPA Summary and Response

Summary:

EPA received several comments related to ICE powertrains overall, or in relation to potential changes from ICE-based powertrains to EVs. Growmark, Inc. commented that EVs do not have the same functionality as ICE vehicles and may not meet the utility needs of farmers while the Illinois Farm Bureau commented on the historical improvement of ICE-based vehicle efficiency and reductions in emissions. Matthew DiPaulo, a private citizen noted the likely long life of ICE-based vehicles in the fleet. Missouri Corn Growers, Transfer Flow, and Reginald Modlin and B. Reid recommended that EPA focus on alternative fuels that could be used in the existing fleet of vehicles in considering reductions in emissions. EPA also received a number of comments from a mass comment campaign that ranged from calling into question the impact of livestock on climate change to recommending that EPA adopt lifecycle analysis into its standard setting process.

Response:

EPA appreciates all the comments we received related to ICE technologies and fuels. The agency recognizes that no single technology will meet the needs of every consumer which is why the Agency has decided to continue our longstanding practice of adopting performance-based standards instead of a ZEV mandate. Performance-based standards allow vehicle manufacturers the option of building lower emission versions of the vehicles that their consumers and intended applications demand. Under the final standards, we expect that consumers will have more choice of vehicles; though all the technologies we project that manufacturers might use to comply with the standards are available in the market today, over the timeframe of the standards we expect that the technology options will span more vehicle segments and price points.

EPA also appreciates commenters recommendations regarding alternative fuels and the potential emission reductions that could be achieved. Fuel changes are out of scope for this rulemaking, however, the EPA will continue to monitor fuel technology developments for future consideration.

12.4 – Modeling of IRA incentives

Comments by Organizations

Organization: Alliance for Automotive Innovation

EPA underestimates battery costs; unrealistic BEV sales assumptions

The NPRM substantially underestimates the cost of batteries while overestimating the availability of consumer and manufacturing tax credits. For example, the Proposed Rule assumes that in 2029, the combination of cost reductions from installing larger batteries in BEVs and incentives from Inflation Reduction Act (IRA)5 Sections 30D, 45W, and 45X results in consumer incentives and battery production tax credits that substantially exceed the battery cost. If cost reductions and incentives eliminate the entire cost of EV batteries, it is little wonder the EPA model suggests a massive increase in sales of long-range BEVs. However, we do not believe these assumptions are realistic. Moreover, while vehicle cost and affordability are critical to success, they are just one set of factors in the transformation to electric vehicles. [EPA-HQ-OAR-2022-0829-0701, pp. 4-5]

5 H.R.5376 - 117th Congress (2021-2022): Inflation Reduction Act. (2022, August 16). Available at https://www.congress.gov/bill/117th-congress/house-bill/5376/text.

- The Inflation Reduction Act (IRA)21 committed to incentivizing the retail purchase of EVs; however, this incentive comes with criteria that exclude the vast majority of EVs currently for sale in the United States. As of June 2023, due to the North American assembly requirement and the MSRP limitations, less than 20 of the 97 EVs for sale qualify for either half or all of the $7,500 tax credit available to eligible taxpayers. Guidance regarding Foreign Entity of Concern provisions (Section 30D), which go into effect in 2024 (battery components) and 2025 (critical minerals), is still forthcoming from the Treasury Department. These provisions will potentially make qualifying for the tax credit more challenging for eligible consumers in the next 12-18 months. [EPA-HQ-OAR-2022-0829-0701, pp. 26-27]

21 H.R.5376 - 117th Congress (2021-2022): Inflation Reduction Act. (2022, August 16). Available at https://www.congress.gov/bill/117th-congress/house-bill/5376/text.

- The $7,500 retail tax credit under 30D is split in half with eligibility requirements for battery components and critical minerals. The critical minerals portion requires a qualifying percentage (currently 40%) to be extracted or processed in the United States or a country with which the U.S. has a free trade agreement, or recycled in North America. The U.S. does not currently have free trade agreements with many of our allies (e.g., the EU and UK) or mineral-rich nations (e.g., Indonesia for nickel). Similarly, the other half of the 30D tax credit is available for eligible vehicles that contain battery components (currently 50%) that are manufactured or assembled in the United States. [EPA-HQ-OAR-2022-0829-0701, pp. 26-27]

- The IRA also provides an incentive to produce the needed batteries helping to offset their cost; however, this only applies to the United States, ignoring the global supply chain needed to support a 40-50% U.S. EV market. [EPA-HQ-OAR-2022-0829-0701, pp. 26-27]

5. IRA Manufacturing Credits (45X)

a) Application of IRA 45X Credit in EPA Modeling

The Inflation Reduction Act has numerous provisions aimed at increasing domestic manufacturing of clean energy components, including EV batteries, and reducing the cost of EVs through consumer tax credits. [EPA-HQ-OAR-2022-0829-0701, pp. 63-64]

While provisions such as the Advanced Manufacturing Tax Credit (Section 45X) and Advanced Energy Project Credit (Section 48C) will assist in onshoring production of EV batteries and battery components, that will take time. As much as automakers and policymakers would like this transition to happen faster, increasing access to raw materials, expanding manufacturing capacity and broadening domestic supply chains will not happen overnight. [EPA-HQ-OAR-2022-0829-0701, pp. 63-64]

In its modeling, EPA assumes that battery costs will be reduced through the use of the Advanced Manufacturing Tax Credit (Section 45X). The 45X production tax credit provides a credit of $35/kWh for battery cell production and $10/kWh for battery module production. To qualify for the credit, manufacturing must take place in the U.S. While the 45X tax credit will assist in bolstering our nation's competitiveness and economic security, the assumptions made by EPA are overly optimistic. [EPA-HQ-OAR-2022-0829-0701, pp. 63-64]

EPA assumes that 60% of manufacturers will be able to take advantage of the $35/kWh battery cell credit and $10/kWh battery module credit in 2023, ramping up to 100% by 2027.113 The resulting credit is provided in Table 2-49 of the DRIA. [EPA-HQ-OAR-2022-0829-0701, pp. 63-64]

113 DRIA at 2-86.

In order for 100% of manufacturers to claim the credit, all EV battery cells and modules would have to be manufactured in the U.S. As shown in Figure 18, this is an unrealistic assumption. EPA's projections for GWh of battery capacity needed to support its proposal exceed estimates of total U.S. battery cell manufacturing capacity. [EPA-HQ-OAR-2022-0829-0701, pp. 63-64]

Figure 18: Projected battery demand under the EPA proposal114 vs. U.S. battery cell supply115 [EPA-HQ-OAR-2022-0829-0701, pp. 63-64]

114 Calculated by Auto Innovators based on data in OMEGA output file [. . .]vehicles.csv for the proposal central analysis.

115 Benchmark Minerals Intelligence (1Q2023), proprietary model for Auto Innovators. Reflects unweighted U.S. battery cell manufacturing capacity, not weighted for probability.

It does not appear that EPA considered any specific source to support its estimates for future U.S. cell and pack manufacturing capacity relative to its projected battery demand for the proposal. The DRIA simply says, [EPA-HQ-OAR-2022-0829-0701, pp. 64-65]

We estimated that, across the PEV industry as a whole, the capability of manufacturers to take advantage of the $35 cell credit and the $10 module credit would ramp up over time, as new U.S. battery manufacturing facilities come online, allowing manufacturing to increasingly take place in the U.S. We ramped the modeling value of the credit linearly from 60% of total cells and modules in 2023. [EPA-HQ-OAR-2022-0829-0701, pp. 64-65]

. . to 100% utilization in 2027 . . . Although a large percentage of 2023 U.S. BEV battery and cell manufacturing is represented by the production of one OEM, we believe that the many large U.S. battery production facilities that are being actively developed by suppliers and other OEMs (as described in IV.C.6 of the Preamble) will allow benefit of the credit to be accessible to all manufacturers by 2027. We also note that the high value of the credit provides a strong motivation for manufacturers to utilize it.116 [EPA-HQ-OAR-2022-0829-0701, pp. 64-65]

116 DRIA at 2-54.

An assumption of 100% applicability of 45X credits also implies that all imported vehicles will have U.S.-manufactured battery cells and packs. Imported new light-duty vehicles generally arrive fully assembled. In order to have U.S.-manufactured battery cells and packs, those components would either have to be exported (only to later be imported as part of a complete vehicle), or imported vehicles would need to have their battery packs installed upon arrival in the U.S. Such assumptions could only be applied as an exception to the rule. To apply them to every imported vehicle is a clear error that needs correction for the final rule. [EPA-HQ-OAR-2022-0829-0701, pp. 64-65]

In addition, EPA should consider that some manufacturers do not have domestic production facilities and import all of their vehicles. EPA applies its 45X credit adjustment equally to all BEVs, but this would not be a fair or accurate assessment for vehicle importers. [EPA-HQ-OAR-2022-0829-0701, pp. 64-65]

Although U.S. battery cell and pack manufacturing are clearly on an upward trajectory, it is extremely doubtful that 100% of batteries used in vehicles produced for sale in the U.S. will meet IRA 45X requirements. It is going to take time, certainly longer than 2027, to onshore all EV battery manufacturing, and it is unclear whether manufacturers would benefit directly from the $35 kWh credit, or the $10 kWh credit depending on yet to be issued Treasury guidance. [EPA-HQ-OAR-2022-0829-0701, p. 65]

While we are supportive of the 45X production tax credit and view it as a valuable incentive to increase the pace of localizing battery manufacturing, the assumption made by EPA that all battery cell and module manufacturing will be in the U.S. is simply not accurate. This type of industrial transformation will not happen overnight. We recommend that EPA reconsider its assumptions for applicability of IRA 45X in the final rule. The reconsideration should include projected U.S. battery cell and pack manufacturing capacity, domestic versus import vehicles, and impacts on specific manufacturers. [EPA-HQ-OAR-2022-0829-0701, p. 65]

b) Disconnects Between EPA’s 45X Projections and BatPac Inputs

It appears there are likely significant disconnects between EPA's forecasted domestic battery production environment—in which battery supply is assumed to be available for all OEMs to source domestically produced batteries while fully passing along IRA-based tax benefits to their customers—and the agency's acknowledged use of "default" BatPaC values/assumptions in the model. For example, the model defaults to an assumption that all battery manufacturing will be performed "in house." Certainly, for some manufacturers, this is a fair characterization. For others, however, it is unlikely to be the case which, as demonstrated by BatPaC outputs, will result in higher overall battery costs. [EPA-HQ-OAR-2022-0829-0701, pp. 65-66]

c) Impact of 45X and 30D/45W Assumption on Implied Battery Cost

In addition to the IRA 45X credits, EPA also projects the availability of IRA 30D/45W retail and commercial EV purchase incentives. Although we recognize that the 30D/45W incentives are applied to vehicle purchases or leases, this is similar to EPA's approach to the 45X credit, which EPA applies the marked-up battery cost.117 [EPA-HQ-OAR-2022-0829-0701, pp. 65-66]

117 DRIA at 2-54.

Therefore, it is informative to assess the combined impact of EPA's projections of rapidly declining battery costs, 45X, and 30D/45W credits on net battery cost. In Figure 19, we start with EPA's sales-weighted average battery cost in 2029, apply EPA's projected 45X credits, and then apply EPA's projected 30D/45W incentives to calculate a net battery cost. EPA projects that an average 2029 BEV battery of 103 kWh118 will cost $8,190 in 2029. The EPA-projected 45X credit is $45/kWh119 or $4,628 total. EPA's projected 30D/45W credit is $5,250 in 2029.120 The battery is the largest cost driver in an EV and therefore these IRA incentives can be considered as direct offsets to battery cost. After application of 45X and 30D/45W credits the implied net cost of the battery is negative – ($1,688). The estimations that EPA relies upon also presume that Congress makes no changes to the IRA, including the 30D, 45W, or 45X tax provisions that are used to justify the extraordinarily high BEV levels between MYs 2027-2032. [EPA-HQ-OAR-2022-0829-0701, pp. 65-66]

119 DRIA at 2-87 (Table 2-49).

120 DRIA at 2-87 (Table 2-50).

Figure 19: Battery cost walk using EPA projections for average battery cost, 45X credits and 30D/45W credits

Item	Cost	Cost After Credit
2029 average BEV battery (103 kWh)	$8,190	$8,190
EPA-projected 45X credit ($45/kWh)	($4,628)	$3,562
EPA-projected 30D/45W credit	($5,250)	($1,688)

[EPA-HQ-OAR-2022-0829-0701, pp. 65-66]

d) Transparency of EPA's Methodology in Application of 45X Credits

To verify our understanding of EPA's methodology in applying estimated 45X credits, Auto Innovators attempted to recreate results shown in Figure 2-27 based on descriptions of the methodology121 and data from OMEGA input and output files. However, those efforts were unsuccessful. Given the importance of the potential impact of the IRA credits on battery costs in general, the agency's application of these credits must be accurate and fully transparent. We recommend that EPA provide more thorough documentation of the OMEGA input and output files, and descriptions of data used in the final rule. An example calculation for application of the 45X credits based on OMEGA fields could be helpful. [EPA-HQ-OAR-2022-0829-0701, pp. 66-67]

121 DRIA at 2-53 et seq.

e) Economics of 45X Benefits

The DRIA includes a simple analysis of how the tax provisions in the Inflation Reduction Act would affect the cost of producing bateries.122 However, EPA does not take into account that the burden of a tax (or benefit of a credit) does not necessarily accrue to the party that is taxed (or receives the credit).123 If the industry is reasonably competitive, then most of the gains and losses from changes in industrial tax policy may flow through to consumers. If an individual firm does not pass through the benefit (to either an automaker or ultimately a consumer), they are vulnerable to competition from another firm that does pass through the benefit of the credit. The price elasticity of demand for the product also plays a role in the pass-through analysis. Before the final rule, Auto Innovators recommends that the EPA re-evaluate the analysis of the credit provisions of the IRA. [EPA-HQ-OAR-2022-0829-0701, pp. 66-67]

122 DRIA at 2-53 et seq.

123 htps://pressbooks-dev.oer.hawaii.edu/principlesofeconomics/chapter/5-3-elasticity-and-pricing./

I. Consumer Adoption

1. IRA – Consumer Tax Credits

The Inflation Reduction Act has numerous provisions aimed at reducing the cost of EVs through consumer tax credits. It remains to be seen how consumer tax credits, such as the Clean Vehicle Credit (Section 30D) and Credit for Qualified Commercial Clean Vehicles (Section 45W), are implemented. With the passage of the Inflation Reduction Act, the clean vehicle tax credit went from a credit that was widely available to all consumers and all electric vehicles127 to one that includes critical mineral and battery component requirements and that limits eligibility based on location of vehicle assembly, customer income and vehicle manufacturer suggested retail price (MSRP). The previous tax credit provided up to $7,500 depending on battery size. The new tax credit is split in half with battery component requirements accounting for one half and critical minerals requirements the other. The 30D tax credit is now more industrial policy than a simple consumer tax credit. [EPA-HQ-OAR-2022-0829-0701, pp. 71-72]

127 Up to a per manufacturer cap of 200,000 cumulative sales.

As shown in Figure 21 below, the day a tier President Biden signed the Inflation Reduction Act, the portion of all PEV models eligible for 30D dropped from 92% to 35% due to the North American assembly requirement. That percentage further dropped on January 1, 2023, to 24%, when MSRP caps were implemented, and the number of eligible consumers dropped with the implementation of income caps. Battery component and critical mineral provisions then went into effect on April 18, 2023, which dropped the portion of eligible models to just 19%. Of that 19%, only half of the vehicles qualify for the full $7,500. [EPA-HQ-OAR-2022-0829-0701, pp. 71-72]

Figure 21: Percent of Eligible EV Models for the 30D Clean Vehicle Tax Credit

There will also be another hurdle that manufacturers must meet when Foreign Entity of Concern restrictions go into effect in 2024 for battery components and 2025 for critical minerals. We have yet to see any guidance on how these provisions will be rolled out, but it will almost certainly reduce the number of eligible vehicle models. [EPA-HQ-OAR-2022-0829-0701, pp. 71-72]

As of today, there are 97 ZEVs available to purchase in the U.S.128 Only 18 unique models qualify for the Inflation Reduction Act (IRA) 30D tax credit.129 IRS guidance with respect to Foreign Entities of Concern is still outstanding, which JD Power expects will result in more vehicles losing eligibility for the tax credit altogether. [EPA-HQ-OAR-2022-0829-0701, pp. 72-74]

128 htps://www.autosinnovate.org/resources/electric-vehicle-sales-dashboard

129 htps://www.fueleconomy.gov/feg/tax2023.shtml. Accessed on June 29, 2023.

The Inflation Reduction Act also created a new tax credit for qualified commercial clean vehicles (Section 45W). This credit is up to $7,500 and is available for qualified vehicles with a battery capacity of at least 7 kWh and acquired for use or lease by a taxpayer and not for resale. In the instance of vehicles leased to a private retail customer, the captive finance company leasing the vehicle could be the eligible taxpayer and receive the 45W tax credit. The captive finance company may then pass along all, some, or none of the credit onto the customer. [EPA-HQ-OAR-2022-0829-0701, pp. 72-74]

As shown in Table 2-50 of the DRIA (Figure 22), EPA assumes that on average every EV sold will qualify for and receive at least $3,750 of the 30D or 45W tax credit in 2023. Currently, about one-fifth of all available EV models qualify for at least half of the 30D tax credit. EPA expects that the average amount of tax credits to rise by $250 per year, but again, with foreign entity of concern provisions going into effect in 2024 for battery components and 2025 for critical minerals, the amount of available credit is likely to go down, not up. [EPA-HQ-OAR-2022-0829-0701, pp. 72-74]

Additionally, EPA also assumes that 45W will play a significant role in reducing the overall price of EVs. This assumption is flawed for several reasons. First, the percentage of vehicles leased in the U.S. has declined steadily over the past three years. Figure 23 shows the percentage of leased vehicles has dropped from over one-third in January 2020 to less than one-fifth in July 2022.130 While lease rates may rise as a result of the 45W provision, there's no indication they will rise to a level that would result in 80% of BEVs receiving either a 30D or 45W tax credit. [EPA-HQ-OAR-2022-0829-0701, pp. 72-74]

130 https://www.coxautoinc.com/market-insights/leasing-decline-has-short-term-and-long-term-implications/

Second, in the cases where 45W is applied to a leased vehicle to a private customer, the captive finance company leasing the vehicle is the eligible taxpayer to receive the 45W credit. Under existing law, the 45W tax credit does not require that the credit be passed on to the person leasing the vehicle. The captive finance company has discretion to pass along all, some, or none of the credit to the customer. Third, 45W is based on the cost differential between battery and internal combustion engines, and if battery prices decrease as EPA has estimated, the amount available under 45W could quickly phase down. Fourth, while the 30D credit might not be widely available to eligible taxpayers, the 45W credit may or may not be a viable option depending on a host of factors that impact a new vehicle buyer (e.g., credit score, interest rates, etc.). [EPA-HQ-OAR-2022-0829-0701, pp. 72-74]

Figure 22: Assumed IRS 30D and 45W Clean Vehicle Credit in Omega (EPA NPRM Table 2-50) [EPA-HQ-OAR-2022-0829-0701, pp. 72-74]

Figure 23: Retail lease share of retail sales [EPA-HQ-OAR-2022-0829-0701, pp. 72-74]

While there are positive provisions in the Inflation Reduction Act that will help onshore battery and vehicle production, it is going to take time. The assumptions used by EPA regarding the number of vehicles that will qualify for consumer tax credits are overly optimistic and should be reevaluated. [EPA-HQ-OAR-2022-0829-0701, pp. 75-76]

Adding to this uncertainty is the potential for federal legislation that could change the Infrastructure Investment and Jobs Act (IIJA) or the availability of the IRA tax credits. For example, on June 8, 2023, Bill H.R. 3938132 was introduced to "Build it in America", which, if passed and signed into law, would end both the 25E used EV tax credit as well the 45W tax credits. The 30D credit would have the 200,000-vehicle cap per manufacturer reinstated, including previously qualifying vehicles. Additionally, no credit would be allowed under the provision for vehicles which have batteries that contain less than 80% critical minerals extracted or processed in the United States or in any country which the United States has a free trade agreement. The provision would also further restrict the definition of a "free trade agreement." No credit would be allowed under the provision for vehicles in which less than 100% of the value of the battery components contained in the battery were manufactured or assembled in North America. While H.R. 3938 was passed by the House Ways and Means Committee on June 13th by a vote of 24-18, it demonstrates the possibility of Congressional changes that could dramatically and negatively change the entire landscape for EVs - including the assumptions that EPA relied upon for this proposed rulemaking. [EPA-HQ-OAR-2022-0829-0701, pp. 75-76]

Probably the most significant concern is the impact of the 45X production tax credit on the overall estimated cost/price reduction of EVs. As mentioned in Section I.A.2, EPA assumes that every battery cell and every battery module in every EV sold starting in 2027 will be produced in the United States and will therefore receive the benefit of a $45/kWh price reduction. MDVs are larger, heavier vehicles that will likely need larger, higher power batteries. As a result of EPA's assumption, every MDV will receive a significant price reduction scaled to the size of these very large batteries. For example, a 200-kWh battery under EPA's assumed application of the 45X tax credit would receive a $9,000 price reduction. This projected, dramatic reduction in price, as discussed earlier in this comment, is overly optimistic and incorrect, and without doubt positively, increased the EV penetration rate of these vehicles in support of the Proposed Rule. [EPA-HQ-OAR-2022-0829-0701, p. 191]

Organization: American Council for an Energy-Efficient Economy (ACEEE)

The Infrastructure Investment and Jobs Act (IIJA) and the Inflation Reduction Act (IRA) have set aside historic amounts of funding for electric vehicles and will greatly reduce greenhouse gas (GHG) emissions from the transportation sector if that money is invested with climate impacts in mind. EPA's standards must build off of these investments. While we commend EPA for proposing strong standards that help the U.S. achieve President Biden's 2030 goal of 50% zero emission new vehicle sales, these historic investments mean we can go even further.5 Since the IRA was signed into law, $50 billion in investments in EV and battery manufacturing, and supply chain projects have been announced.6 These investments could get the U.S. to over 60% new light-duty EV sales by the early 2030s.7 But more will be needed to adequately address the climate emergency. EPA's MY 2027-2032 standards should fully account for the recent federal activity and build off them to achieve further emissions reductions. [EPA-HQ-OAR-2022-0829-0642, pp. 1-2]

7 https://theicct.org/wp-content/uploads/2023/01/ira-impact-evs-us-jan23.pdf; https://rmi.org/insight/how-inflation-reduction-act-will-affect-ev-adoption-in-the-united-states/

Organization: American Free Enterprise Chamber of Commerce (AmFree) et al.

As for IRA incentives, EPA substantially overestimates the effect that those incentives will have on the upfront purchase price of electric vehicles. See 88 Fed. Reg. at 29,195; Draft RIA at 2-86. Many of the credits EPA models come with stringent restrictions and qualifications that make the benefits una- vailable to most consumers. [EPA-HQ-OAR-2022-0829-0683, pp. 25-27]

For example, EPA relies heavily on the "Clean Vehicle Tax Credit," which offers consumers up to $7,500 for buying a new electric vehicle during the tax- able year. See 26 U.S.C. §§ 30D(a)-(b). The $7,500 is the sum of two credit amounts. Id. § 30D(a). First, purchasers receive $3,750 if certain percentages of the critical minerals in the vehicle's battery are (i) extracted or processed in the United States or a country with which the United States has a free-trade agreement,3 or (ii) derived from materials recycled in North America. Id. § 30D(b)(2). The requisite percentages of minerals that must be extracted, pro- cessed, or recycled in North America or in a nation that is a U.S. free-trade- agreement partner increase year over year, beginning with 40 percent for vehi- cles placed in service during 2023 and reaching 80 percent for vehicles placed in service during or after 2027. Id. § 30D(e)(1)(B). Second, purchasers receive an additional $3,750 if a certain percentage of the battery components are man- ufactured or assembled in North America. Id. § 30D(b)(3). Again, the percent- ages increase year over year, beginning with 50 percent for vehicles placed in service during 2023 and reaching 100 percent for vehicles placed in service dur- ing or after 2029. Id. § 30D(e)(2)(B). In addition, for either of these credit amounts to apply, the purchaser or vehicle must meet additional requirements: [EPA-HQ-OAR-2022-0829-0683, pp. 25-27]

3 The IRS identifies these countries as Australia, Bahrain, Canada, Chile, Colombia, Costa Rica, Dominican Republic, El Salvador, Guatemala, Honduras, Israel, Japan, Jordan, Korea, Mexico, Mo- rocco, Nicaragua, Oman, Panama, Peru, and Singapore. See Treasury Releases Proposed Guidance on New Clean Vehicle Credit to Lower Costs for Consumers, Build U.S. Industrial Base, Strengthen Supply Chains, U.S. Dep't of Treasury (Mar. 31, 2023), https://home.treasury.gov/news/press-re- leases/jy1379.

• Final assembly of the vehicle must occur in North America. Id. § 30D(d)(1)(G). [EPA-HQ-OAR-2022-0829-0683, pp. 25-27]

• The vehicle's retail price cannot exceed certain thresholds ($80,000 for vans, SUVs, and pickups, and $55,000 for all other vehicles). Id. § 30D(f)(11). [EPA-HQ-OAR-2022-0829-0683, pp. 25-27]

• The taxpayer's income cannot exceed certain threshold amounts ($150,000 for taxpayers filing a single return; $225,000 for taxpayers fil- ing as head of household; and $300,000 for taxpayers filing jointly). Id. § 30D(f)(10). [EPA-HQ-OAR-2022-0829-0683, pp. 25-27]

• Finally, whatever percentage of the critical minerals or battery compo- nents that are not sourced from North America or a free-trade partner still cannot come from a "foreign entity of concern"—which is defined by a cross-referenced statute to include (among others) entities that are "owned by, controlled by, or subject to the jurisdiction or direction of" China and Russia. Id. § 30D(d)(7)(A); see 42 U.S.C. § 18741(a)(5)(C); 10 U.S.C. § 4872(d)(2). [EPA-HQ-OAR-2022-0829-0683, pp. 25-27]

That panoply of onerous restrictions will likely limit drastically the number of consumers who will actually benefit from the credit. The critical-minerals sourcing requirements will render many electric-vehicle models ineligible. In April 2023, the IRS concluded that only 22 electric-vehicle models qualify. See Tax Credits for Electric Vehicles: The Latest from the IRS, Bradford Tax Inst. (May 2023), https://tinyurl.com/32akaztz. And the Congressional Research Service reports that, "[o]ver time, as the battery critical minerals and components re- quirements tighten, there are claims that no vehicles would qualify." Molly F. Sherlock, Clean Vehicle Tax Credits in the Inflation Reduction Act of 2022, Cong. Research Serv., at 3 (Aug. 24, 2022) ("Clean Vehicle Tax Credits"). The retail- price threshold will likely further disqualify many purchases of electric vehicles. In September 2022, the average cost of a new electric vehicle was $65,291—far above the $55,000 limit for many passenger vehicles. Renee Valdes, Electric Car FAQ: Your Questions Answered, Kelly Blue Book (Oct. 31, 2022), https://ti- nyurl.com/4zepcvd4. And some consumers who purchase electric-vehicles might have incomes exceeding the statutory thresholds. [EPA-HQ-OAR-2022-0829-0683, pp. 25-27]

Despite these impediments to the Clean Vehicle Tax Credit's uptake, EPA predicts that electric-vehicle purchasers will experience substantial benefits. It states that, "[f]or 2023 [the agency] estimated that an average credit amount (across all PEV purchases) of $3,750 per vehicle could reasonably be expected to be realized" through a combination of this credit and the Qualified Commer- cial Clean Vehicles Credit (which applies for Class 2b or Class 3 vehicles). 88 Fed. Reg. at 29,301. "For later years," the agency assumes that "the attrac- tiveness of the credits to manufacturers and consumers would likely increase eligibility over time" and "ramped the value linearly to $6,000 by 2032." Id. EPA does not explain how it settled upon any of those estimates, offer data to support them, or reconcile them with reports that far less than half of current models qualify today and that none may qualify in the coming years. [EPA-HQ-OAR-2022-0829-0683, pp. 25-27]

In addition, although EPA presents the Clean Vehicle Tax Credit as a new incentive that will accelerate consumer acceptance, it is a successor to a tax credit that has existed for years. And as amended by the IRA, the credit is in most respects more restrictive than its predecessor. Although the prior version of the tax credit was subject to a manufacturer-level cap (that the IRA re- moved)—under which the credit was reduced and ultimately eliminated for a particular manufacturer if it sold a certain number of vehicles—the prior ver- sion was easier for individual electric-vehicle buyers to satisfy. Under the prior version, purchasers were eligible for a base amount of $2,500 with an additional $417 for every kilowatt-hour of capacity above 5 kilowatt-hours, up to $5,000. See Sherlock, Clean Vehicle Tax Credits at 2. There were no restrictions based on the critical minerals or components used in the vehicle's battery; there was no requirement that final assembly occur in North America; and there were no thresholds for income or retail price. Id. [EPA-HQ-OAR-2022-0829-0683, pp. 27-28]

If the pre-existing, easier-to-satisfy version of this tax credit did not result in the widespread adoption of electric vehicles—which, by all accounts, it did not—an amended version with more stringent qualifying requirements is un- likely to do so either. Although the IRA eliminated the manufacturer-level cap on the tax credit's availability, removing one impediment to consumers' ability to receive the tax credit for a particular manufacturer's vehicles, the other changes Congress made to the credit through the IRA could if anything disin- centivize consumers from purchasing electric vehicles by making it more difficult to obtain a tax credit for any electric vehicle. Shortly before the IRA was en- acted, the President and CEO of the Alliance for Automotive Innovation de- scribed the amended credit as a "major setback" to electrification, noting that "Americans who would otherwise receive the credit today (say, the family test driving a car this weekend and on the fence about whether to make the switch to an EV) will no longer be able to take advantage of this financial incentive to purchase an EV." John Bozzella, What if No EVs Qualify for the EV Tax Credit? It Could Happen., All. for Auto. Innovation (Aug. 5, 2022), https://ti- nyurl.com/3fhb6mcu (emphasis added). At a minimum, EPA has not ex- plained how tightening the tax credit's criteria would substantially increase electric-vehicle adoption. [EPA-HQ-OAR-2022-0829-0683, pp. 27-28]

EPA also relies on the "Advanced Manufacturing Production Credit," which (among other things) provides manufacturers with a credit of up to $35 per kilowatt-hour for producing battery cells, 26 U.S.C. § 45X(b)(1)(K), and a credit of up to $10 per kilowatt-hour for producing battery modules, id. § 45X(b)(1)(L). EPA characterizes this tax credit "as a reduction in direct man-ufacturing costs, which in turn is assumed to result in a reduction in purchase price for the consumer." Draft RIA at 2-86. But EPA significantly overstates the likely effect of this credit as well. [EPA-HQ-OAR-2022-0829-0683, pp. 28-29]

Under the Internal Revenue Code, manufacturers do not qualify for these credits unless the battery cells and modules are produced within the United States. 26 U.S.C. § 45X(d)(2). As EPA acknowledges, however, "a large percentage of 2023 U.S. BEV battery and cell manufacturing is represented by the production of one [original-equipment manufacturer]." 88 Fed. Reg. at 29,300 (emphasis added); see also Draft RIA at 2-54. As a result, many batteries do not currently qualify for the tax credit. Cf. Greenhouse Gas Emissions Standards for Heavy-Duty Vehicles—Phase 3, 88 Fed. Reg. 25,926, 25,945 (Apr. 27, 2023) ("there are few manufacturing plants for HD vehicle batteries in the United States, which means that few batteries would qualify for the tax credit now"). [EPA-HQ-OAR-2022-0829-0683, pp. 28-29]

EPA rejoins that the amount of domestically produced battery cells and modules will increase in the coming years and projects that all manufacturers will be eligible for the credit in 2027. See Draft RIA at 2-54. But that assertion depends entirely on EPA's "expect[ation] that the many large U.S. battery pro- duction facilities that are being actively developed by suppliers and other [orig- inal-equipment manufacturers]" will come online in just a few short years and will produce enough battery cells and modules to support the Nation's expected electric-vehicle fleet by the rule's compliance period. 88 Fed. Reg. at 29,300. [EPA-HQ-OAR-2022-0829-0683, pp. 29-30]

That expectation is unwarranted. Some of the battery-manufacturing plants that EPA relies on are still only under consideration. See 88 Fed. Reg. at 29,317 (discussing four plants that companies are "considering" constructing). The plans for one of those plants were reportedly put on hold after executives reached an impasse and decided not to move forward. See Peter Johnson, GM and LG Partnership Falters; Will Another Battery Maker Save the Next US Plant?, Electrek (Jan. 20, 2023), https://tinyurl.com/mvfewj3e. Other planned facili- ties have experienced setbacks in construction and production. For example, LG Chem planned to begin construction on its facilities in the first half of 2023, but construction has been postponed until "about the end of the third quarter." LG Chem to Develop Tennessee Site as Base for Batteries in North America, Pulse (Apr. 20, 2023), https://tinyurl.com/37r49eew. Tesla and Panasonic built a factory in Nevada, but "production ramp-up ran at least a year behind sched- ule" because workers "had to be trained on manufacturing skills they had long lost" and "battery machinery had to be redesigned and adapted." Daniel Zlatev, Tesla Battery Factory Took Panasonic 6 Years to Master Since US Workers Lost Their Manufacturing Skills, Notebook Check (Feb. 27, 2023), https://ti- nyurl.com/3vu8usmd. Thus far, that "facility hasn't grown to the size that the companies originally planned." Fred Lambert, Panasonic Is Planning a Large Bat- tery Cell Factory in the US to Supply Tesla's Demand, Report Says, Electrek (Mar. 3, 2022), https://tinyurl.com/bdz6j9sy. Recent reports indicate that the factory is still only "about 30% complete," Fred Lambert, Panasonic to Add New Battery Production Line at Tesla Gigafactory Nevada, Electrek (June 6, 2023), and although there are plans for expansion, there was "no clear timeline for Tesla to start the construction project" as of October 2022, Fred Lambert, Tesla Is Finally Going to Expand Gigafactory Nevada, Electrek (Oct. 3, 2022), https://tinyurl.com/4de-ump6k. As these examples illustrate, for any number of reasons, the domestic battery-manufacturing sector may not develop at the pace or scale that EPA predicts. EPA's analysis of likely effect of the tax credits for producing batteries, which is predicated on that prediction, is therefore unsound. [EPA-HQ-OAR-2022-0829-0683, pp. 29-30]

Organization: American Fuel & Petrochemical Manufacturers

ii. EV Purchase Price

EPA assumes in MY 2032, there will be a $3500-$6100 price gap between EVs and ICEVs, with ICEVs costing less.234 EPA's purchase price incorrectly assumes that every ZEV will be eligible for the maximum federal purchase incentive.235 EPA asserts the relatively slight increase in the incremental cost of manufacturing a rule-compliant vehicle (Table 13-46 of the DRIA provides an average increase of $1,164 by 2032) is based, in part, on the assumption battery manufacturers are eligible for the IRA's ten percent Production Tax Credit for modules manufactured in the U.S. It is arbitrary and capricious for EPA to ignore the likelihood that battery raw materials will not be mined in the U.S. or available for import from credit-qualifying countries, given Section I.A.1 of these comments illustrates China's dominance in processing critical minerals needed for ZEV batteries and the manufacture of ZEV batteries. Consequently, it is unrealistic for the Agency to assume ZEV purchases will be eligible for the full incentive. [EPA-HQ-OAR-2022-0829-0733, p. 51]

Projecting future battery material and labor costs

The agency assumes that the IRA 45X tax credits will be fully utilized by all OEMs through MY2032 (subject to phase-down in the final years of the program) and applies those reductions to the overall cost of batteries in EPA's OMEGA modeling. This has resulted in profoundly low battery cost estimates, for example, below $40/kWh in 2029.10 The agency does not, however, appear to make any upward adjustments to the core Argonne National Laboratory BatPaC 5.0 material costs to account for exponential growth in critical minerals demand that will occur during this time frame, or to the increased labor cost associated with domestically produced packs. We believe these are significant oversights that likely result in a meaningful underestimation of true vehicle electrification costs. [EPA-HQ-OAR-2022-0829-0652, pp. 7-8]

10 EPA, 2023. Draft RIA, Figure 2-27. Available online at https://nepis.epa.gov/Exe/ZyPDF.cgi?Dockey=P10175J2.pdf

Rather than address those and other concerns head-on, the proposal leans heavily on the Inflation Reduction Act (IRA) and Bipartisan Infrastructure Law (BIL). In particular, the proposal includes generous assumptions about the role that the IRA will play in reducing both battery costs to manufacturers and vehicle prices to consumers. For example, the agency assumes:

- Seamless cascading of incentives through the supply base, retail partners and economy in general [EPA-HQ-OAR-2022-0829-0652, pp. 23-24]

- Domestic production of all batteries in all EVs produced between model years 2027 and 2032 [EPA-HQ-OAR-2022-0829-0652, pp. 23-24]

- Full IRA 45X credit eligibility for all batteries in all model year 2027-2032 vehicles, despite the fact that IRS guidance has not yet been issued and may contain certain restrictions [EPA-HQ-OAR-2022-0829-0652, pp. 23-24]

- Full utilization of domestically produced batteries, even from automakers without domestic battery manufacturing capability [EPA-HQ-OAR-2022-0829-0652, pp. 23-24]

- Consumers' utilization of 80% of IRA 30D credit eligibility ($6000 out of $7500), despite numerous restrictions such as critical minerals sourcing, MRSP caps and household income eligibility restrictions [EPA-HQ-OAR-2022-0829-0652, pp. 23-24]

To be clear, the IRA and BIL are critically important and include policies necessary to support a transition toward greater levels of vehicle electrification. It is important for the agency to understand, however, that these policies are far from set in stone, representing additional degrees of uncertainty when trying to assess the feasibility of future electrification levels. [EPA-HQ-OAR-2022-0829-0652, pp. 23-24]

Threats to the longevity of the IRA and BIL are clearly recognizable. In June 2023, for example, a House tax package proposed to repeal 45W (commercial) and 25E (used) provisions, and to restrict 30D (consumer) incentives by reverting to older manufacturing caps.42 While this specific package is unlikely to be signed into law in the near term, it is a clear sign of opposition by certain policymakers. Surprisingly, the agency does not even appear to acknowledge the possibility that these credits may not exist through 2032, or contemplate the impact that such a change would have on an automaker's ability to comply with the proposed standards. [EPA-HQ-OAR-2022-0829-0652, p. 24]

42 See, for example, H.R.3938, Build it in America Act. https://www.congress.gov/bill/118th-congress/house- bill/3938, and H.R.2811, Limit, Save, Grow Act of 2023. https://www.congress.gov/bill/118th-congress/house- bill/2811

Given the impact that IRA and BIL assumptions play in the agency's resulting standards, it is incumbent upon the agency to also consider the potential for their removal or substantial weakening. To ignore such potential renders the agency's conclusions fatally flawed. [EPA-HQ-OAR-2022-0829-0652, p. 24]

Organization: American Petroleum Institute (API)

iii. Impacts of IRA.

The NPRM cities the Inlaation Reduction Act (IRA – enacted in 2022) as key legislation that will support the domestic supply chain for battery and electric vehicle production, subsidize EV purchases, and incentivize the build-out of charging infrastructure and renewable power production. However, as outlined below, EPA overstates the potential impacts of the IRA. [EPA-HQ-OAR-2022-0829-0641, pp. 23-24]

The EPA makes misleading claims regarding the ability of the IRA's Clean Vehicle Credits to "incentivize the growth and manufacturing capacity of onshore sourcing of critical minerals."78 While critical minerals, from any origin, can be used for manufacturing battery electric vehicles, the IRA establishes restrictive domestic content requirements for tax credit eligibility. In other words, the IRA tax credits are not a subsidy or policy that directly remove "potential barriers to wider adoption of PEVs,"79 but rather potentially only provide tax credits if domestic content requirements are met.80 [EPA-HQ-OAR-2022-0829-0641, pp. 23-24]

78 88 Fed. Reg. 29195 (May 5, 2023).

79 88 Fed. Reg. 29346 (May 5, 2023).

80 Center for Strategic and International Studies. Tax credits are also subject to other requirements – "An Electric Debate: Local Content Requirements and Trade Considerations." October 2022. https://www.csis.org/analysis/electric-debate-local-content-requirements-and-trade-considerations.

According to the National Mining Association:81 demand for minerals is souring and policies in the U.S. are lagging; scaling up the U.S. supply chain requires increased extraction and processing; withdrawing federal leases covering reserves of nickel, cobalt, and copper are described as “self-sabotage”; and “permitting delays have been, and continue to be, one of the most significant risks to meeting domestic mineral production goals.” According to NMA testimony, automakers are “warning with ever greater frequency that the coming battery material shortfall could stop the EV revolution” and a shortage of batteries could arrive as early as 2024. The NMA reports new mining is needed to meet demand, but it takes, on average, 7 to 10 years to secure permits to open or expand a mine. Even as the NMA acknowledges domestically mined minerals are incentivized,82 the NMA indicates the mine permitting process is “unwieldly” and discourages83 investment in domestic mining. [EPA-HQ-OAR-2022-0829-0641, pp. 23-24]

81 “Unleashing American Energy, Lowering Energy Costs, and Strengthening Supply Chains.”, United States House of Representatives Committee on Energy & Commerce, Testimony of Katie Sweeney, Executive Vice President & General Counsel National Mining Association, February 7, 2023.

82 National Mining Association. “The Future of Mining Rests on the Actions of Today.” September 2022. https://nma.org/2022/09/22/future-of-mining/.

83 Legislative Hearing, United States House of Representatives Committee on Natural Resources, Testimony of Rich Nolan, President & CEO, National Mining Association, February 28, 2023. https://nma.org/wp- content/uploads/2023/02/National-Mining-Association-2-28-23-Nolan-Testimony.pdf.

The IRA places income and purchase price limits on tax credit eligibility, along with foreign content restrictions beginning in 2024. Overall, according to the Center for Strategic and International Studies (CSIS)84, it could be “impossible” for a battery electric vehicle to obtain the full value of the tax credit (i.e., $7,500) in the near term. [EPA-HQ-OAR-2022-0829-0641, pp. 23-24]

4. Assumes tax credits are boom for consumers

EPA assumes that the Commercial Clean Vehicle and Clean Vehicle tax credits will lower BEV costs up to $6,000 to consumers and the Advance Manufacturer Battery Production Credits by $45 per kWh. EPA incorrectly assumes that manufacturers will pass on the full credit values to consumers; instead, it is likely that manufacturers will only lower their vehicle prices by a fraction of these credits, and thus increase their profits. This is especially true for the battery credits as they aren’t consumer facing where consumers may not realize that manufacturer are being subsidized. [EPA-HQ-OAR-2022-0829-0565, p. 4]

EPA also incorrectly assumes that the tax credits are free. They use the tax credits to offset the costs of BEVs, but they do not consider the costs to taxpayers to fund the tax credits. This hides the costs of BEVs to the American Population by hundreds of billions. Furthermore, EPA does not address the societal inequities that will be produced by providing tax credits for BEVs. Since BEVs are typically more expensive than basic ICE vehicles and the fact that the tax credits are non-refundable (meaning that you have to carry a tax liability to get the benefits of the tax credit), all taxpayer funds will be going towards funding new BEVs for richer Americans. In this sense, EPA's reduces environmental justice by forcing BEVs. [EPA-HQ-OAR-2022-0829-0565, p. 4]

Finally, EPA's estimates of tax credits overstates their applicability. The Clean Vehicle credit has some restrictions that will limit how many vehicles qualify and how much. EPA should model these restrictions or at the very least make a good faith estimate. For the commercial clean vehicle tax credit, EPA ignores the cost-basis nature of the credit and assumes that everyone will lease a vehicle to get the EV tax credit while ignoring the lost utility of owning a vehicle. [EPA-HQ-OAR-2022-0829-0565, p. 4]

Organization: Arizona State Legislature

V. The proposed rule is arbitrary and capricious because it relies on erroneous assumptions about vehicle costs.

EPA's analysis includes a tax credit from the Inflation Reduction Act to those who purchase or lease a qualifying vehicle. 88 Fed. Reg. 29,301. In EPA's view, the tax credit "will have a strong impact on affordability of these vehicles for a wide range of customers." Id. at 29,195. Indeed, EPA believes the tax credit "effectively mak[es] some [battery electric vehicles] more affordable to buy and operate today than comparable ICE vehicles." Id. at 29,190. These are "significant incentives" in EPA's view. Id. at 29,294. EPA calculated that the average customer could use half of the tax credit and that it would not impact vehicle production costs. Id. at 29,301. [EPA-HQ-OAR-2022-0829-0537, pp. 22-23]

EPA's analysis already has proven inaccurate. Contrary to EPA's assumptions, the price for electric vehicles has not remained static with the passage of the Inflation Reduction Act. Instead, days before passage of the Inflation Reduction Act, "Ford and General Motors announced price increases at similar rates" as the Act's tax credits.17 Inflation and supply-chain issues have caused electric car prices to "surge" and mean fewer buyers can use the Inflation Reduction Act tax credits.18 [EPA-HQ-OAR-2022-0829-0537, pp. 22-23]

17 Ryan King, Inflation Reduction Act promises $7,500 electric vehicle credits after Ford and GM raised prices, WASHINGTON EXAMINER, Aug. 16, 2022, available at https://www.washingtonexaminer.com/news/democrats- extended-credits-evs-ford-gm-prices.

18 Keith Laing, Electric Cars' Surging Prices Mean Fewer Buyers Can Use Tax Credit, BLOOMBERG, Aug. 4, 2022, available at https://www.bloomberg.com/news/articles/2022-08-04/electric-cars-rising-prices-mean-fewer-buyers- eligible-for-senate-tax-credit.

Vehicles also have been eliminated from receiving the full tax credit. Ford and Chrysler parent Stellantis reported in April that "most of its electric and plug-in electric hybrid models will see tax credits halved to $3,750 on April 18 after new U.S. Treasury rules take effect."19 In fact, just 11 electric cars from four automakers qualify for the full tax credit.20 And this limited availability comes before any changes made in response to Senator Joe Manchin, the critical vote to passing the Inflation Reduction Act, who threatened to repeal the bill or sue the Treasury Department because the tax credit standards are too liberal.21 [EPA-HQ-OAR-2022-0829-0537, pp. 22-23]

19 David Shepardson and Nathan Gomes, Ford, Stellantis says new rules will cut EV tax credits for most models, REUTERS, Apr. 5, 2023, available at https://www.reuters.com/business/autos-transportation/ford-confirms-all-three- evs-plug-in-hybrids-eligible-ira-subsidies-2023-04-05/.

20 Lawrence Ulrich, Electric Vehicle Tax Credit Rules Create ‘Chaos for Consumers,” The New York Times, Apr. 20, 2023, available at https://www.nytimes.com/2023/04/20/business/electric-vehicle-tax-credits-consumers.html.

21 Ramsey Touchberry, Sen. Manchin threatens to repeal his own climate law if Biden continues to ‘liberalize’ it, WASHINGTON TIMES, Apr. 25, 2023, available at https://www.washingtontimes.com/news/2023/apr/25/sen-joe- manchin-threatens-repeal-his-own-climate-l/; David Shepardson, Manchin threatens to sue US Treasury over EV tax credit rules, REUTERS, Mar. 30, 2023, available at https://www.reuters.com/world/us/democratic-sen-manchin- threatens-legal-action-over-treasury-ev-battery-guidance-2023-03-29/.

EPA also does not grapple with the economic reality that the Inflation Reduction Act’s “net impact is likely to be negative on electric vehicle sales in the immediate future.”22 Other economic analysis concluded the strings attached to the Inflation Reduction Act tax credits “are likely to make [electric vehicles] even more expensive.”23 [EPA-HQ-OAR-2022-0829-0537, pp. 22-23]

22 Anderson Economic Group, “An estimated 3/4 of recent EV purchases would no longer qualify for tax credits under the proposed ‘Inflation Reduction Act’,” Aug. 9, 2022, available at https://www.andersoneconomicgroup.com/at- least-four-ira-provisions-will-negatively-affect-sales-of-electric-vehicles/.

23 Tori Smith, “Proposed Tax Credits Would Make Electric Vehicles More Expensive,” AMERICAN ACTION FORUM, Aug. 4, 2022, available at https://www.americanactionforum.org/insight/proposed-tax-credits-would-make-electric- vehicles-more-expensive/.

This all significantly affects EPA’s analysis. Vehicles that EPA’s analysis includes as eligible for the credit are now ineligible due to price increases or Treasury Department regulations. The resulting higher prices for electric vehicles, and reduced amount and availability of subsidies, will affect consumer demand. EPA’s conclusions that there is no cost difference between gas-powered and electric-powered vehicles, and that there will be a corresponding increase in purchaser demand, are thus erroneous. [EPA-HQ-OAR-2022-0829-0537, pp. 22-23]

EPA’s failure to include accurate estimates for vehicle costs and the resulting impact on customer demand is arbitrary and capricious. [EPA-HQ-OAR-2022-0829-0537, pp. 22-23]

Organization: BlueGreen Alliance (BGA)

At the same time, EPA must consider that the manufacturing investments from the Inflation Reduction Act and Bipartisan Infrastructure Law will take time to achieve their full production capacity. EPA should coordinate with DOE, the U.S. Department of Transportation (DOT), and the U.S. Department of Commerce (DOC) to ensure that the manufacturing investments from the Inflation Reduction Act and Bipartisan Infrastructure Law will be fully leveraged to support regulatory compliance. Programs like the Battery Manufacturing and Recycling Grants (DOE), the Battery Material Processing Grants (DOE), the Domestic Manufacturing Conversion Grants (DOE), the 48C Advanced Manufacturing Tax Credit (DOE/DOC), the Advanced Technology Vehicle Manufacturing Loan Program (DOE), the National Electric Vehicle Infrastructure (NEVI) Program (DOT), and the Charging and Fueling Infrastructure Grant Program (DOT) all provide unprecedented federal resources that manufacturers and fleet owners can leverage to support both supply and demand for low- and zero-emission light- and medium-duty vehicles. However, these programs take time to bear fruit—whether that means a complete public, affordable, and interoperable EV charging network, or a robust domestic supply chain for vehicles eligible for the battery component and critical mineral requirements of the 30D Clean Vehicle Tax Credit. [EPA-HQ-OAR-2022-0829-0667, pp. 8-9]

It is essential to workers and communities that these programs be carefully designed and implemented, with robust stakeholder engagement. This helps ensure that they adhere to Justice40 requirements and new Build America, Buy America provisions that are critical to ensuring that federal programs support domestic manufacturing investments that are fully supported by their communities. [EPA-HQ-OAR-2022-0829-0667, pp. 8-9]

With that, EPA must account for the time it takes to convert federal awards and allocations into actual domestic production capacity and critical on-the-ground infrastructure. EPA should coordinate with DOT and DOE to fully assess the availability of charging and fueling infrastructure for electric vehicles, and related grants and loans. [EPA-HQ-OAR-2022-0829-0667, pp. 8-9]

Organization: California Air Resources Board (CARB) (Part 1 of 5)

Critical Minerals

CARB appreciates the consideration U.S. EPA has given to understanding critical minerals availability, production, and costs and the impacts that the Inflation Reduction Act (IRA) will have on these factors. The IRA Production Tax Credit provides a key mechanism for helping to significantly reduce production costs of vehicle traction batteries in the near term which will help to lower prices for consumers of ZEVs. Additionally, the Production Tax Credit is one policy tool that will help accelerate domestic processing and production of critical minerals and batteries, which can support more reliable supply chains for increasing volumes of ZEVs in the years to come. [EPA-HQ-OAR-2022-0829-0780, pp. 49-50]

Despite those very important production tax credits being put in place, there is still uncertainty estimating future technology costs. CARB supports U.S. EPA's decision not to include the 10 percent tax credits for critical minerals production and active cathode materials production. That decision represents a more conservative cost position which bolsters U.S. EPA's future battery cost projections and imparts even more confidence in its future modeled ZEV volumes as the least costly means of meeting the emission standards. [EPA-HQ-OAR-2022-0829-0780, pp. 49-50]

Organization: California Attorney General's Office, et al.

Recent congressional actions demonstrate the federal commitment to substantial electrification of the transportation sector. In 2021, Congress passed the Bipartisan Infrastructure Law, which allocates $7.5 billion to building out a national network of electric vehicle chargers, $7 billion to ensure domestic manufacturers have the critical minerals and other components necessary to make electric vehicle batteries, and $10 billion for clean transit and school buses.110 In 2022, Congress passed the CHIPS and Science Act, which invests $52.7 billion in America's manufacturing capacity for the semiconductors used in electric vehicles and chargers.111 Later in 2022, Congress passed the Inflation Reduction Act, which provides $7,500 to buyers of new electric vehicles and $4,000 to purchasers of pre-owned electric vehicles.112 Additionally, the Inflation Reduction Act provides billions of dollars to support vehicle manufacturers' expansion of their domestic production of clean vehicles,113 and billions to support battery production in the United States and mining and processing of critical minerals needed for battery cells and electric motors.114 The Inflation Reduction Act also allocates billions to upgrade the nation's power grid in order to help address the new surge in grid demand from electric vehicles.115 [EPA-HQ-OAR-2022-0829-0746, pp. 18-19]

Organization: Center for American Progress (CAP)

As recognized by EPA, the historic investments contained in the Infrastructure Investment and Jobs Act (IIJA) and Inflation Reduction Act (IRA) have significant implications for the American light and medium duty fleet, accelerating an existing market shift towards electric vehicles. While EPA's proposal takes these changes into account, CAP asserts that the baseline trend toward electrification is even stronger than EPA's assumptions and that the proposed standards can be significantly more ambitious. [EPA-HQ-OAR-2022-0829-0658, pp. 2-3]

EPA appropriately recognizes that the IRA will have substantial effects on the costs of electric vehicles and batteries, acknowledging several of the important provisions including up to $7,500 towards the purchase of new electric vehicles, $35 per kWh for the production of battery cells, and $10 per kWh for the production of battery modules. However, there are several additional incentives included in the IRA that EPA should also consider. [EPA-HQ-OAR-2022-0829-0658, pp. 2-3]

First, EPA should account for the 10 percent electrode active materials component of the 45X credit. Not accounting for this component of the credit significantly underestimates its value. Electrode active materials include cathode and anode materials. Cathode material costs range from approximately 22 to 51 percent of the total cost of a battery cell.11Anode and electrolyte costs comprise another 19 percent.12 Analysis by the Environmental Defense Fund (EDF) and Deloitte finds that this component of the 45X could amount to an additional credit of $30 per kWh.13 This is a significant increase and EPA should account for this component of the 45X credit in its final rule. [EPA-HQ-OAR-2022-0829-0658, pp. 2-3]

Second, EPA should account for the 10 percent critical mineral production cost component of the credit. This portion of the credit will likely be claimed by firms engaged in critical mineral production and not battery manufacturers, however, the related cost savings may be passed on to manufacturers. Analysis by EDF and Deloitte finds that this component of the credit could amount to over $20 per kWh for lithium-ion batteries.14 This portion of the 45X credit is also notable because it will not phase out as the other components of the credit do between 2030 and 2032. EPA should account for the full impact of the 45X on critical mineral input costs in the final rule. [EPA-HQ-OAR-2022-0829-0658, pp. 2-3]

14 Ibid.

Third, EPA should also consider the effects of other IRA provisions, including the modified 48C Qualifying Advanced Energy Project Credit and multiple DOE loan and grant programs that have already been influential in establishing battery production capacity. Through the IRA and IIJA, the DOE may make up to $8.95 billion in grants to support EV, battery, and critical mineral production as well as battery and critical mineral recycling.15 The IRA also authorizes an additional $3 billion for DOE’s Advanced Technology Vehicle Manufacturing (ATVM) loan program and removes the program's $25 billion cap on total lending.16 While the 48C credit and these grant and loan programs are discretionary in nature, thus making outcomes for individual companies difficult to predict, EPA should consider accounting for their effects, at least in a conservative manner. [EPA-HQ-OAR-2022-0829-0658, pp. 3-4]

16 U.S. Department of Energy, Loan Programs Office, “Inflation Reduction Act of 2022,” available online: https://www.energy.gov/lpo/inflation-reduction-act-2022

Accounting for the full range of incentives is critical to accurately predicting industry and technological trends. Analysis by EDF and WSP Global finds that 42 percent of all EV investment announcements in the United States, by amount invested, have occurred between the passage of the IRA and March 10, 2023.17 Following current trends and announcements, the U.S. is expected to be able to produce approximately 4.3 million EVs per year by 2026 which equates to 33 percent of all U.S. new vehicle sales in 2022.18 [EPA-HQ-OAR-2022-0829-0658, pp. 3-4]

Organization: Clean Fuels Development Coalition et al.

D. The proposed rule overestimates the availability of Clean Vehicle Tax Credits.

The proposal also relies on the tax credits to offset the cost of new electric vehicles. The IRA modified the electric vehicle tax credit in Section 30D of the tax code, expanding that up-to-$7,500 credit to all "clean" vehicles while placing strict sourcing requirements on the materials and components within clean vehicle batteries to promote domestic manufacturing and energy security, while stabilizing supply chains for the same. To that end, the IRA established threshold "applicable percentages" of domestically sourced critical minerals and components that must be met to qualify for the credit. 136 Stat. 1956. This "applicable percentage" ramps up over time, increasing from "40 percent" when the vehicle is placed in service "after the date on which the proposed guidance … is issued … and before January 1, 2024," to "50 percent" in 2024, "60 percent" in 2025, "70 percent" in 2026, and "80 percent" after December 31, 2026. Id. Similarly, the "applicable percentage" for battery components increases from "50 percent" "before January 1, 2024," to "60 percent" in 2024 and 2025, "70 percent" in 2026, "80 percent" in 2027, "90 percent" in 2028, and "100 percent" after December 31, 2028. Id. at 1957. Finally, whatever percentage of the critical minerals or battery components that are not sourced from North America or a free-trade partner still cannot come from a "foreign entity of concern"—which is defined by a cross-referenced statute to include (among others) entities that are "owned, controlled by, or subject to the jurisdiction or direction of" China and Russia. See 136 Stat. 1957; 42 U.S.C. § 18741(a)(5)(C); 10 U.S.C. § 4872(d)(2). [EPA-HQ-OAR-2022-0829-0712, p. 23]

Despite these restrictions, EPA estimates that a steadily increasing share of vehicles will qualify for the credit. The proposal states that, "[f]or 2023, [the agency] estimated that an average credit amount (across all PEV purchases) of $3,750 per vehicle could reasonably be expected to be realized" through a combination of this credit and the Qualified Commercial Clean Vehicles Credit (which applies for Class 2b or Class 3 vehicles). 88 Fed. Reg. 29,301. "For later years," the agency assumes that "the attractiveness of the credits to manufacturers and consumers would likely increase eligibility over time" and "ramped the value linearly to $6,000 by 2032." Id. [EPA-HQ-OAR-2022-0829-0712, pp. 23-24]

This is unreasonable. The proposal does not explain how it reached these estimates or offer any data to support them. The proposal makes no mention of the what fraction of minerals are mined domestically and glosses over the fact that China is a key supplier of some 85% of the global stock of critical minerals (including rare earths, copper, cobalt, etc.), Robert Bryce, The Electric Vehicle Push Empowers China, Wall St. J. (Dec. 23, 2021), and that almost no vehicles will be able to qualify for this credit in the near future. [EPA-HQ-OAR-2022-0829-0712, pp. 23-24]

Indeed, as of April 17, 2023, only 22 of the 68 available electric vehicle models qualify for the light duty tax credit, and some of those only qualify for half of the tax credit because they only meet the critical mineral or battery components standards.14 See Tax Credits for Electric Vehicles: The Latest from the IRS, Bradford Tax Inst. (May 2023), A more reasonable assumption is that roughly the same share of electric vehicles will qualify—and for the same fractional share of the credits—throughout the compliance period as currently qualify, as domestic manufacturing and sourcing improves in step with the increasingly stringent standards. See Figure 5. When the reduced availability of Clean Vehicle Credits is added to the manufacturing of each of the 15 million electric vehicles needed to comply with the proposed standards, an additional $55 billion in vehicle technology costs are added to EPA's projections. [EPA-HQ-OAR-2022-0829-0712, p. 24]

14 Only three battery electric vehicle models qualify for the under-$55,000-MSRP credit: the Chevrolet Bolt, Chevrolet Bolt EUV, and Tesla Model 3.

SEE ORIGINAL COMMENT FOR Figure 5: Projected availability of Clean Vehicle Credits. [EPA-HQ-OAR-2022-0829-0712, p. 24]

Organization: Electric Drive Transportation Association (EDTA)

The speed of the transition to e-mobility will also be materially impacted by the coherence of the policy landscape. For instance, consistent and rapid market growth means expanding consumer interest and confidence, which will require accessible incentives for vehicles and infrastructure. However, material elements of the IRA's incentives are awaiting final interpretation. Federal investment in innovation, as well as infrastructure deployment, also needs to be consistent and coherent to support a rapid transition to e-mobility. [EPA-HQ-OAR-2022-0829-0589, p. 2]

Organization: Energy Innovation

We agree with the EPA that the passage of the BIL and IRA represent significant "support for investment in expanding the manufacture, sale, and use of zero-emission vehicles by addressing elements critical to the advancement of clean transportation and clean electricity generation in ways that will facilitate and accelerate the development, production and adoption of zero-emission technology during the time frame of the rule."20 Our modeling supports these findings. [EPA-HQ-OAR-2022-0829-0561, p. 8]

20 U.S. EPA, 29195.

In a January 2023 study by the International Council on Clean Transportation (ICCT) and Energy Innovation, Analyzing the Impact of the Inflation Reduction Act on Electric Vehicle Uptake in the U.S. (ICCT-EI Study), we examined the IRA's impact on the sale of new EVs in the LDV and HDV sectors in the U.S. through 2035. We used a customized Excel model based on Energy Innovation's U.S. EPS, using updated data on vehicle costs, battery pack estimates, efficiencies, charging behavior, future fuel prices, and state adoption of Advanced Clean Cars II (ACC II)[vi] rules and Advanced Clean Truck (ACT)21 rules. We have attached the full study with our comments.[vii] [EPA-HQ-OAR-2022-0829-0561, p. 8] vi California’s ACC II rule requires that by 2035, all new passenger cars, trucks, and SUVs sold in California must be zero-emission vehicles, from MY 2026 through MY 2035. It relies on currently available advanced vehicle technologies, including battery-electric, hydrogen fuel cell electric, and plug-in hybrid electric vehicles, to meet air quality and climate change emissions standards. See https://ww2.arb.ca.gov/our-work/programs/advanced-clean-cars-program/advanced-clean-cars-ii for more information.

21 “Advanced Clean Trucks,” California Air Resources Board, accessed June 28, 2023, https://ww2.arb.ca.gov/ourwork/programs/advanced-clean-trucks.

vii The EPA included the ICCT-EI study on the regulations.gov website as part of the supporting and related material for the docket, but the content was marked as restricted due to copyright reasons. We believe this was an error. The study is not restricted and is publicly available at https://theicct.org/publication/ira-impact-evs-us-jan23/. The report is also included as an attachment to these comments.

We evaluated three IRA scenarios: Low, Moderate, and High, with different assumptions for each scenario to reflect how certain provisions of the IRA (the Personal Tax Credits for Clean Passenger Vehicles (30D), the Commercial Vehicle Tax Credits (45W), and the Advanced Manufacturing Production Tax Credit (45X)) are implemented and the value of incentives passed on to consumers. We compared these scenarios to a Baseline without the IRA and with just California adopting ACC II and ACT. For LDVs, we modeled different scenarios to reflect the impact of California-only adoption of ACC II and increased state adoption of ACC II. Our results do not evaluate the impact of federal GHG standards for model years 2027 and beyond. [EPA-HQ-OAR-2022-0829-0561, p. 8]

As shown in Figure 4, we found that the IRA will accelerate electrification in both the light-duty and heavy-duty sectors. For light-duty, we find a range of 48 to 61 percent EV sales[viii] share by 2030, increasing to 56 to 67 percent by 2032. [EPA-HQ-OAR-2022-0829-0561, pp. 9-11]

viii: In our study, we use the term “EV” for new light-duty BEVs and plug-in hybrid vehicles. Used EVs are not included in the analysis.

[See original attachment for line graph “Light-duty vehicles”] [EPA-HQ-OAR-2022-0829-0561, pp. 9-11]

Figure 4. Baseline, Low, Moderate, and High projections of EV sales share for LDVs, considering ACC II adoption in only California versus increased states, 2023-2035. Source: Slowik, Peter, et al., Analyzing the Impact of the Inflation Reduction Act on Electric Vehicle Uptake in the United States (ICCT-EI Study) (ICCT and Energy Innovation, January 2023), available at: https://theicct.org/wp- content/uploads/2023/01/ira-impact-evs-us-jan23.pdf. [EPA-HQ-OAR-2022-0829-0561, pp. 9-11]

Given that the proposed rule applies to vehicles that will be manufactured starting in 2027, we expect more vehicles to qualify for the full 30D incentive, and we also anticipate more supply chain operations will be in place to serve increased demand for EVs that meet the new IRA incentive requirements. As of June 2023, private investment commitments for new EV and battery facilities in the U.S. have already reached nearly $150 Billion.22 These new investments will create jobs, economic development, and support a stronger domestic supply chain for BEVs for decades to come. [EPA-HQ-OAR-2022-0829-0561, pp. 9-11]

22 The White House, “Investing in America,” President Joe Biden Investing in America, n.d., https://www.whitehouse.gov/invest/.

Similarly, BloombergNEF updated forecast to its account for the IRA’s positive impact on the EV market. Its September 2022 outlook shows an increase in sales shares of EVs from 43 percent of new sales pre-IRA to 52 percent of new sales in 2030 post-IRA.23 See Figure 5. [EPA-HQ-OAR-2022-0829-0561, pp. 9-11]

23 Ira Boudway, “More Than Half of US Car Sales Will Be Electric by 2030,” Bloomberg.com, September 20, 2022, https://www.bloomberg.com/news/articles/2022-09-20/more-than-half-of-us-car-sales-will-be-electric-by-2030.9

[See original attachment for line graph “Smashing the Pedal”] [EPA-HQ-OAR-2022-0829-0561, pp. 9-11]

Figure 5. Share of U.S. passenger vehicle sales, pre- and post-IRA. Source: BloombergNEF via Ira Boudway, “More Than Half of US Car Sales Will Be Electric by 2030” (Bloomberg, September 2022), available at: https://www.bloomberg.com/news/articles/2022-09- 20/more-than-half-of-us-car-sales-will-be-electric-by-2030. [EPA-HQ-OAR-2022-0829-0561, pp. 9-11]

As shown in Figure 6, taken from the ICCT-EI Study, we expect BEVs to make up the majority of new sales, whereas plug-in hybrid vehicles (PHEVs) constitute a small percentage of vehicles in all scenarios. [EPA-HQ-OAR-2022-0829-0561, pp. 9-11]

[See original attachment for table described below] [EPA-HQ-OAR-2022-0829-0561, pp. 9-11]

Organization: Environmental. and Public Health Organizations

D. Congressional support will increase ZEV deployment and cost-competitiveness.

In addition to highlighting the investments from the BIL (explored in further detail later in these comments), EPA rightly points to the historic funding from the IRA as building on and supporting EPA’s efforts to regulate tailpipe emissions from vehicles:

Congress passed the Bipartisan Infrastructure Law (BIL) in 2021, and the Inflation Reduction Act (IRA) in 2022, which together provide further support for a government-wide approach to reducing emissions by providing significant funding and support for air pollution and GHG reductions across the economy, including specifically, for the component technology and infrastructure for the manufacture, sales, and use of electric vehicles.262 [EPA-HQ-OAR-2022-0829-0759, p. 103]

262 88 Fed. Reg. at 29187.

Together, these legislative measures represent significant congressional support for accelerating the deployment of and market for ZEV technologies. First, the BIL and IRA provide an unprecedented level of investment (over $430 billion) in ZEV infrastructure, technology, and supply chains, through a variety of key tax provisions, manufacturing investments, grants, rebates, loans, and other investment mechanisms.263 BIL and IRA programs will, among other things, provide both direct grants and tax credits to lower acquisition costs of vehicles and increase the range of cost-effective applications,264 help entities conduct planning for fleet electrification,265 enable deployment of charging and hydrogen fueling infrastructure,266 and facilitate advances in technology that can lower future vehicle costs. These programs also invest in vehicle and battery manufacturing and recycling, driving cost reductions and increasing domestic supply. EPA should accordingly ensure that these important laws are reflected in its estimate of baseline LD ZEV market penetration. [EPA-HQ-OAR-2022-0829-0759, p. 104]

263 U.S. DOE Office of Policy, The IRA Drives Significant Emission Reductions and Positions America to Reach Our Climate Goals, DOE/OP-0018 (August 2022), https://www.energy.gov/sites/default/files/2022-08/8.18%20InflationReductionAct_Factsheet_Final.pdf.

264 See, e.g., 42 U.S.C. § 7432 (appropriating $1 billion to EPA to create a program that awards grants and rebates for the costs of replacing existing class 6 and 7 HDVs with ZEVs, purchasing, installing, operating, and maintaining infrastructure needed for ZEVs, associated workforce development and training, and planning and technical activities needed to support the deployment of ZEV); 26 U.S.C. § 45W (providing up to $40,000 in tax credits to assist with vehicle replacements and reduce the effective cost of commercial ZEVs).

265 See, e.g., 42 U.S.C. § 7432.

266 See, e.g., 26 U.S.C. § 30C (providing tax credits to qualified alternative fuel vehicle property); 42 U.S.C. § 16161a (providing $8 billion to DOE to fund regional hydrogen hubs across the country); 23 U.S.C. § 151 (appropriating $2.5 billion to support the build-out of clean charging and fueling infrastructure projects along designated alternative fuel corridors of the National Highway System).

These federal incentives are a key market enabler and will help drivers (and commercial L/MD fleets) adopt advanced clean transportation technologies (like ZEVs) that lower operating costs and reduce emissions. Manufacturers also stand to reap significant benefits, as several key tax credits are expected to add up to provide robust support of ZEV production. Passing those savings on to consumers could drive down the cost of new ZEVs and spur sales.267 For example, Tesla alone could qualify for $1 billion in tax credits this year, while its Giga Nevada plant could gain up to $17.5 billion in credits for its projected annual production rate of 500 gigawatt hours.268 Ford and General Motors also stated that they could reap significant benefits as a result of IRA investments. Ford expects $7 billion in tax credits over the next three years and GM could gain $300 million in 2023.269 [EPA-HQ-OAR-2022-0829-0759, p. 104]

267 Tom Taylor & Noah Gabriel, The EV Transition: Key Market and Supply Chain Enablers, Atlas Public Policy (Nov. 2022), https://atlaspolicy.com/wp-content/uploads/2022/12/2022-EV-Transition-Key-Market-and-Supply-Chain-Enablers.pdf.

268 Joann Muller, Biden’s EV Surprise, Axios (Feb. 1, 2023) https://www.axios.com/2023/02/01/electric-car-ev-tax-incentives-biden.

269 Muller, Biden’s EV Surprise.

Second, the congressional investments from the IRA and BIL further the public health goals of the Clean Air Act and of this rulemaking: the reduction of harmful pollution from light- and medium-duty vehicles. A preliminary assessment conducted by the U.S. Department of Energy (DOE) found that the IRA, in combination with other enacted policies and past actions, will help drive 2030 economy-wide GHG emissions down to 40% below 2005 levels and move the United States towards its overall 2030 target of achieving a 50 to 52% reduction in GHG emissions below 2005 levels.270 DOE also noted that the impacts of these congressional investments can be further amplified and accelerated when paired with ambitious and consistent executive branch, state, local, and private sector actions to reduce transportation sector emissions and to make large-scale investments in PEV manufacturing and battery supply chains.271 These investments are key factors driving industry developments in ZEVs and reducing manufacturing costs, in turn helping make compliance (with the stringency levels in Alternative 1) through enhanced ZEV deployment even more feasible and cost-effective for manufacturers. [EPA-HQ-OAR-2022-0829-0759, pp. 104-105]

270 U.S. DOE Office of Policy, The IRA Drives Significant Emission Reductions.

271 U.S. DOE Office of Policy, The IRA Drives Significant Emission Reductions.

Third, congressional funding will prompt and support private sector investment. An analysis by Atlas Public Policy explains that the combination of a strong regulatory environment (like EPA's vehicle standards help provide) along with congressional investments has and will continue to encourage substantial private sector investment in ZEVs, and finds that the U.S. is on track to reach $210 billion in economic commitments by automakers and battery manufacturers by 2030.272 Clear regulatory signals – like EPA's vehicle emissions regulations – can create further confidence in the private sector to accelerate and expand investments and help ensure companies follow through on their ZEV commitments. In the Proposal, EPA highlights several IRA clean vehicles provisions that will help bolster ZEV deployment, drive down costs, and facilitate compliance with strong standards. These include the clean vehicles tax credit (§ 30D), the previously owned clean vehicle tax credit (§ 25E), the commercial clean vehicle tax credit (§ 45W), and the advanced manufacturing production credit (§ 45X). The § 45X credit is anticipated to be the most lucrative program for automakers, offering a tax credit of $35 per kilowatt-hour for each domestically made battery cell, which could slice manufacturer production costs by a third. [EPA-HQ-OAR-2022-0829-0759, p. 105]

272 Gabriel, $210 Billion of Annouced Investments.

Fourth, a number of other congressional investments can be leveraged to address timelines for deploying ZEVs, human capital issues, potential supply chain constraints, consumer demand, and workforce development issues. For example, the IRA provided $500 million for the enhanced use of the Defense Production Act (DPA) – which President Biden recently invoked to support critical minerals production – on top of the funds made available for the DPA through the normal appropriations process.273 This provision will support domestic mineral supply chains for large-capacity batteries, including those used in PEVs, and is intended to help increase productivity, workforce safety, and sustainability in the various steps of the critical minerals lifecycle. [EPA-HQ-OAR-2022-0829-0759, pp. 105-106]

273 The White House, Building a Clean Energy Economy: A Guidebook to the Inflation Reduction Act's Investments in Clean Energy and Climate Action. (2023). https://www.whitehouse.gov/wp-content/uploads/2022/12/Inflation-Reduction-Act-Guidebook.pdf

Additionally, the CHIPS and Science Act will strengthen American manufacturing, supply chains, and national security, and will invest in research and development, science and technology, and the workforce of the future to position the U.S. as a leader in clean transportation.274 This law is further complemented by other congressional investments like the IRA's Advanced Energy Project Credit (§ 48C), which provides a $10 billion investment to expand clean manufacturing and recycling (including critical minerals refining, processing and recycling) and to address technology supply chain gaps. Manufacturers and other private parties are more likely to fully leverage these and other congressional investments if strong regulatory signals are in place, as would be the case under any policy scenarios that are at least as stringent as Alternative 1. This too helps bolster EPA's conclusion of feasibility for the standards outlined in Alternative 1 and in EPA's main Proposal. [EPA-HQ-OAR-2022-0829-0759, p. 106]

274 The White House. "CHIPS and Science Act Will Lower Costs, Create Jobs, Strengthen Supply Chains, and Counter China." press release, August 9, 2021. https://www.whitehouse.gov/briefing-room/statements-releases/2022/08/09/fact-sheet-chips-and-science-act-will-lo wer-costs-create-jobs-strengthen-supply-chains-and-counter-china/.

Lastly, EPA's Proposal references a number of studies that look at the effect congressional investments (especially the IRA) have on ZEV penetration levels. These studies include reports from ICCT, BloombergNEF,275 IHS Markit,276 and others that suggest that even before the IRA, the U.S. was on track to reach as much as 50% new ZEV sales by 2030 due to a range of preexisting policies and market forces. When adjusted for the effects of the IRA, ZEV penetration levels are expected to increase to as much as 61% of sales in 2030, increasing to as much as 67% of new sales by 2032, per ICCT's analysis.277 These studies further support the feasibility of a final rule at least as stringent as Alternative 1. i. ZEV costs are rapidly declining.

The costs of batteries and ZEVs have declined significantly over the last few years. Recent analyses project that costs will continue to decline, even when IRA investments are not considered. The decline has been dramatically accelerated by the IRA. [EPA-HQ-OAR-2022-0829-0786, pp. 16-17]

The IRA provides $369 billion in investments to help achieve a 40 percent nation-wide reduction of carbon emissions by 2030.36 The IRA significantly reduces the upfront cost of ZEVs by offering consumers $7,500 in tax credits for new light-duty EVs and $4,000 for used EVs.37 In addition, the IRA provides $3 billion to the Department of Energy's Advanced Technology Vehicle Manufacturing Loan Program for loans to manufacture clean vehicles and their components in the United States, $2 billion to the Department of Energy for Domestic Manufacturing Conversion Grants, which will fund manufacturers' retooling of production lines for clean vehicles, and $40 billion in loan authority supported by $3.6 billion in credit subsidy for innovative clean energy technologies, including critical minerals processing, manufacturing, and recycling, all of which will drive down the costs of batteries and EV manufacturing.38,39 In addition, the IRA will distribute $500 million to accelerate domestic manufacturing of clean energy technologies and components,40 $2 billion for auto manufacturing facility conversion,41 and $3 billion in loans to build out the domestic clean vehicle manufacturing network,42 all of which will drive down the costs of batteries and EV manufacturing. EDF and WSP found that over $120 billion in private EV supply ecosystem investments and 143,000 new jobs have been announced in the last eight years and nearly $50 billion of that, representing 42 percent of all announced EV investments, has occurred since the passage of the IRA.43 [EPA-HQ-OAR-2022-0829-0786, pp. 16-17]

1. Independent analyses commissioned by EDF show rapidly declining ZEV costs.

A May 2023 study by Roush for EDF assessed and quantified, where possible,44 the key impacts of the IRA on the cost of electrifying MY 2025 and 2030 light-duty vehicles, using costs from a previous Roush study45 as a baseline. Both studies analyzed six subclasses of light-duty vehicles—compact cars, midsize cars, small SUVs, midsize SUVs, large SUVs, and pickup trucks—under two segments: base (non-performance) and premium (performance). With the exception of large SUVs and pickups, BEV200s were assumed to be a viable alternative to base model gasoline vehicles and BEV300s a comparable substitute for premium model gasoline vehicles. For large SUVs and pickups, the analysis assumes BEV300s as an alternative to base gasoline model, and BEV400s as a comparable substitute for premium gasoline models. [EPA-HQ-OAR-2022-0829-0786, pp. 17-20]

44 Roush for EDF, Saxena, S. Pillai, “Impact of the Inflation Reduction Act of 2022 on Light-Duty Vehicle Electrification Costs for MYs 2025 and 2030” (2023) https://www.edf.org/sites/default/files/2023-05/Impact_IRA_LDV_Electrification_Costs_for_MYs_2025_and_2030_Roush.pdf (Attachment N).

45 Himanshu Saxena, Vishnu Nair, Sajit Pillai, “Electrification Cost Evaluation of Light-Duty Vehicles for MY 2030,”(2023) Roush for EDF, https://www.edf.org/sites/default/files/2023-05/Electrification_Cost_Evaluation_of_LDVs_for_MY2030_Roush.pdf (Attachment O).

Roush’s May 2023 study concluded that IRA vehicle and charger credits enable the purchase price of BEVs to be equal to or less than an equivalent gasoline vehicle in both MYs 2025 and 2030 for compact cars, midsize cars, small SUVs, and midsize SUVs, in both base and premium segments.46 As shown in Table 2, which applies IRA vehicle tax credits, purchasers of some subclasses will see savings of more than $7,000 over an equivalent gasoline vehicle in 2025. With the IRA credits, large SUVs and pickup trucks will achieve purchase price parity by MY 2030. The analysis shows that these credits will help lower the purchase prices of BEVs faced by consumers. [EPA-HQ-OAR-2022-0829-0786, pp. 17-20]

46 Roush, Saxena, S. Pillai, “Impact of the Inflation Reduction Act of 2022 on Light-Duty Vehicle Electrification Costs for MYs 2025 and 2030” (2023) https://www.edf.org/sites/default/files/2023-05/Impact_IRA_LDV_Electrification_Costs_for_MYs_2025_and_2030_Roush.pdf

[See original attachment for Table 2: Upfront savings of BEV over gasoline vehicle in 2025 and 2030 purchase timeframes] [EPA-HQ-OAR-2022-0829-0786, pp. 17-20]

Source: Roush, Impact of the Inflation Reduction Act of 2022 on Light-Duty Vehicle Electrification Costs for MYs 2025 and 2030 [EPA-HQ-OAR-2022-0829-0786, pp. 17-20]

Note: Positive numbers represent BEV upfront savings compared to combustion vehicles and negative numbers represent an upfront increase in price [EPA-HQ-OAR-2022-0829-0786, pp. 17-20]

The IRA will also result in an estimated 30 percent reduction in charger-unit costs for all consumers. The consumer will save $300 on a $1,000 Level 2, 11.5 kW charger and the affordability and savings associated with the purchase price and charger unit price improve significantly over time. [EPA-HQ-OAR-2022-0829-0786, pp. 17-20]

Organization: Greg Dotson

It is already apparent that Congress’ effort to encourage electric vehicles through incentives in the IRA has been successful. According to one analysis, the automobile industry has invested more than $120 billion in electric vehicle manufacturing in the U.S.123 Moreover, Congress has increased these incentives even while preserving and ratifying EPA’s Clean Air Act authority to require further reductions in greenhouse gas emissions from mobile sources.124 [EPA-HQ-OAR-2022-0829-0685, p. 20]

123 Environmental Defense Fund, Report Finds Investments in U.S. Electric Vehicle Manufacturing Reach $120 Billion, Create 143,000 New Jobs, Mar. 14, 2023, https://www.edf.org/media/report-finds-investments-us-electric- vehicle-manufacturing-reach-120-billion-create-143000 (finding that more than 40 percent of these investments were announced in the six months after passage of the IRA).

124 For a discussion of how Congress ratified the Clean Air Act’s regulatory structure for mobile source greenhouse gas reductions in the Inflation Reduction Act, see Dotson, Greg and Maghamfar, Dustin, The Clean Air Act Amendments of 2022: Clean Air, Climate Change, and the Inflation Reduction Act (January

1, 2023). Environmental Law Reporter, Vol. 53, No. 10017, 2023, Available at SSRN: https://ssrn.com/abstract=4338903.

Organization: Hyundai Motor America

The NPRM's No Action Case is Overly Optimistic.

We encourage EPA to revisit the proposed No Action case. As a baseline-setting scenario, it fundamentally impacts the alternatives under the agency's consideration for a proposed rule. In this case, the No Action case's assumptions create a rosier picture than reality. The NPRM assumes 54 percent BEV penetration in MY 2032, adjusted upward from 39 percent based on the sensitivity analysis that accounts for impact of state adoption of California's Advanced Clean Cars II Zero Emission Vehicle regulation ("ACC II ZEV Regulation"). The NPRM also lauds the Inflation Reduction Act's ("IRA") consumer tax incentive ("30D tax credit") and assumes the 30D tax credit will generate unprecedented consumer EV acceptance thereby enabling the Proposed Alternative's BEV penetration requirements. Data suggests consumers are more likely to purchase EVs with the availability of tax incentives.5 A majority of Consumer Reports 2022 survey respondents indicated that the most impactful EV tax incentive is a rebate applied at point of sale followed by 45% of respondents identifying tax credits such as the 30D tax credit. Id. [EPA-HQ-OAR-2022-0829-0599, p. 3]

5 "Battery Electric Vehicles and Low Carbon Fuel: A Nationally Representative Multi-Mode Survey," Consumer Reports, Page 7, April 2022.

Yet, predictable headwinds caused by federal and state policies are insufficiently contemplated by the No Action case. Before the enactment of the IRA, 72 BEVs and PHEVs were eligible for the predecessor 30D tax credit of $7,500 compared to five models that were ineligible.6 As of March 2023, there are 76,7 plug-in electric vehicles ("PEV") and FCEV,8 light-duty models offered for sale in the U.S. market. The IRS guidance on the IRA's battery component and critical mineral sourcing requirements effective on April 18, 2023,9 qualified just 17 of these vehicle models for the 30D tax credit's full amount of $7,500.10 It is uncertain when more vehicle models will become fully eligible, particularly as industry awaits key IRS guidance on the IRA's Foreign Entities of Concern ("FEOC") provisions. FEOC guidance has the potential to eliminate all vehicles from 30D tax credit eligibility in the short and medium term, which could chill EV sales leading up to and during the first few years of the Proposed Rule's timeframe as automakers shift their supply chains to non- FEOC controlled suppliers and shift EV manufacturing operations to North America. [EPA-HQ-OAR-2022-0829-0599, p. 3]

The IRA Significantly Reduces Availability of the 30D Tax Credit and May Inhibit EV Purchases during the Proposed Alternative's Term. [EPA-HQ-OAR-2022-0829-0599, pp. 5-6]

The NPRM's cost assumptions include the benefits purportedly conferred by 30D tax credit and the IRA's Credit for Qualified Commercial Clean Vehicles ("45W tax credit").15 The NPRM indicates that an estimated average 30D tax credit of $3,750 can be claimed by the purchaser in 2023.16 However, as stated above and more fully explained here, less than one quarter of current EVs are currently eligible for at least $3,750 under the 30D tax credit. The 30D tax credit is constrained by the IRA's strict requirements on final assembly in North America and battery and critical mineral sourcing requirements. For example, effective April 18, 2023,17 the battery must contain a minimum of 40 percent (doubling to 80 percent or more by 2027) critical minerals extracted or processed in the U.S. or in a country of which the U.S. has a free trade agreement ("FTA"), or from materials recycled in North America. Similar battery manufacturing requirements are also in place: at least 50 percent (doubling by 2029) of components must be manufactured or assembled in North America and must not come from a FEOC. Further complicating the matter is the fact that while sourcing from a FEOC is prohibited, industry still awaits guidance on this term. Once released, the scope of the FEOC guidance could curtail even partial access to the 30D tax credit for an unknown period of time. Although the 45W tax credit may provide a boost, the market demand for EV leases dropped significantly from 26 to 12.5 percent in CY 2022.18 Generally, leases do not account for a majority of transactions and therefore, due to the unprecedented nature of the 45W tax credit, it is difficult to forecast whether EV lease rates will jump significantly to offset the unavailability of the 30D tax credit. [EPA-HQ-OAR-2022-0829-0599, pp. 5-6]

17 88 Fed. Reg. 23370 (April 17, 2023). IRS Critical Mineral and Battery Component Guidance.

18 Zabritski, M. Auto Finance Year-In-Review Electric Vehicles & Affordability, January 2023. Online slide presentation available at http://www.experian.com/content/dam/marketing/na/automotive/pr-folder/experian-automotive-2022-yir-evs-affordability.pdf.

We request that EPA conduct additional analysis to more accurately capture cost impacts resulting from the IRA's critical minerals requirements and the likely unavailability of full tax credits for the near term. For example, Benchmark Mineral Intelligence has determined a one (1) TWh shortfall in domestic supply by 2032.19 Assuming a 30-40 GWh battery capacity for one plant,20 25 to 30 battery plants will need to be constructed in order to supply the level of critical minerals needed to meet the estimated BEV penetration rates required by the Proposed Alternative. In addition, it takes between 5 to 15 years to build one new mining operation.21 China is the only region which will have excess manufacturing to fill the gap.22 [EPA-HQ-OAR-2022-0829-0599, p. 6]

19 Benchmark Mineral Intelligence, Report for: Alliance for Automotive Innovation U.S. Electric Vehicle Feasibility Study. page 1.

20 EPA NPRM, Draft Regulatory Impact Analysis Report, Figure 2-20, page 2-46.

21 Benchmark Mineral Intelligence, Report for: Alliance for Automotive Innovation U.S. Electric Vehicle Feasibility Study. page 45.

22 Benchmark Mineral Intelligence, Report for: Alliance for Automotive Innovation U.S. Electric Vehicle Feasibility Study. page 4.

This will leave many consumers unable to receive the full tax credit, or with little choice on what vehicles they can purchase in order to take advantage of it. In addition, high demand for critical mineral and battery components are expected to spike EV production costs, impacting affordability likely through the IRA's statutory life. Again, the uncertainty of the FEOC provision is not yet priced into the vehicle cost. The IRA's statutory language strongly suggests industry must move all battery component and critical mineral contracts away from their current primary country of origin – primarily China, which is expressly listed as a FEOC – to non-FEOC controlled suppliers without the same capabilities. It will take time to robustly develop these operations outside of FEOCs. IRA costs to both consumers and automakers, including the near and long term cost of uncertainty, are significant and we urge the EPA to better understand and assess them. Hyundai supports a confidential EPA survey through AFAI to aggregate industry data that would help accurately assess this impact. [EPA-HQ-OAR-2022-0829-0599, p. 6]

Organization: International Council on Clean Transportation (ICCT)

The Inflation Reduction Act (IRA) of 2022 will accelerate electric vehicle sales in the United States across all vehicle types. The $370 billion allocated to climate and clean energy investments dramatically expands tax credits and incentives to deploy more clean vehicles, including commercial vehicles, while supporting a domestic EV supply chain and charging infrastructure buildout. IRA transportation sector provisions will accelerate the shift to zero-emission vehicles by combining consumer and manufacturing policies. Consumer tax credits for new and used EVs and tax credits for commercial EVs, along with individual and commercial charging infrastructure tax credits, will increase sales. Domestic supply chain incentives and investments will boost EV manufacturing and battery production. Critical mineral mining and refining incentives will bolster industrial development. [EPA-HQ-OAR-2022-0829-0569, pp. 6-7]

Organization: International Union, United Automobile, Aerospace and Agricultural Implement Workers of America (UAW)

Short of including safeguards in the proposed standards to support the domestic auto manufacturing base, the EPA expects minimal incentive for manufacturers to shift to foreign production as a result of the rule.13 However, in its analysis, we are concerned the EPA overvalues the incentives available to domestic manufacturers to produce vehicles and components domestically.14 The new 30D Clean Vehicle Credit for the purchase of light-duty EVs includes domestic assembly and domestic content requirements, however they are not stringent enough to prevent the credit from applying to vehicles produced by automakers who have shifted production to Mexico and Canada. And the 45W Commercial Clean Vehicle "lease loophole" provides up to $7,500 for light-duty BEVs and PHEVs without any domestic or regional sourcing requirements on final assembly, battery component, or critical mineral content. The industry has already seen a significant increase in BEV leasing, as automakers shift sales strategies to take advantage of the loophole.15 Thus, federal incentives may serve as a potential inducement for the further offshoring of manufacturing job or may merely dissuade original equipment manufacturers (OEMs) from onshoring more of these jobs. Since November 2022, the import of goods generally, and of automotive vehicles and parts in particular, has increased as more goods arrive from Mexico and Canada.16 For this reason, these federal investments should not prima facie be expected to support the domestic build-out of the EV supply chain. Targeted safeguards are necessary to ensure the proposed standards support the domestic production of vehicles and components, instead of encouraging a shift to foreign production. We encourage the EPA to implement standards that strengthen the domestic auto manufacturing supply chain and require the EV transition to provide the same level of investment and quality jobs as the current ICE footprint. [EPA-HQ-OAR-2022-0829-0614, pp. 6-7]

13 See id. at 29313 (”It is also our assessment that widespread automotive electrification in the U.S. will not lead to a critical long-term dependence on foreign imports of minerals or components”).

14 See id. at 29187 (”Congress passed the Bipartisan Infrastructure Law (BIL) in 2021, and the Inflation Reduction Act (IRA) in 2022, which together provide further support for a government-wide approach to reducing emissions by providing significant funding and support for air pollution and GHG reductions across the economy, including specifically, for the component technology and infrastructure for the manufacture, sales, and use of electric vehicles”).

Organization: Jaguar Land Rover NA, LLC (JLR)

Inflation Reduction Act (IRA) Clean Vehicle Tax Credits

Prior to the publication of the IRA last year, our vehicles qualified for the 30D Clean Vehicle Credit. The changing incentive landscape has adversely affected Jaguar Land Rover, with our manufacturing facilities located outside the US, we are now ineligible for the amended 30D credit. Due to the positioning of our vehicles and our customer demographics as a premium luxury vehicle manufacturer, the income and MSRP pre-requisites for the 30D credit also exclude us from claiming. We are fortunately eligible to claim the 45W Commercial Clean Vehicle Credit and we are pursuing this opportunity to potentially benefit our customers. [EPA-HQ-OAR-2022-0829-0744, pp. 9-10]

JLR challenges the assumption made by EPA that: “While the restrictions imposed by the IRA on the 30D credit (income, MSRP, critical mineral content, and manufacturing content) limit the vehicles which are eligible for the full $7,500 incentive under 30D, we believe that manufacturers will work to increase the number of vehicles that qualify over time due to the high marketing value of the credit.” Despite the work that manufacturers carry out, factors relating to the critical mineral and battery component requirements are largely out of their control. For example, currently 65% of battery cells and almost 80% of cathodes are manufactured in China.15 Until the US develops a robust battery manufacturing industry, it cannot be guaranteed that a high percentage of the fleet will be able to claim. [EPA-HQ-OAR-2022-0829-0744, pp. 9-10]

15 IEA (2023), Global EV Outlook 2023, IEA, Paris Trends in batteries - https://www.iea.org/reports/global-ev-outlook- 2023/trends-in-batteries License: CC BY 4.0

We suggest that EPA incorporate the following into the final rule analysis and the monitoring reports mentioned previously to ensure that the portion of BEV sales eligible for credit under 30D in OMEGA is appropriate.

- Industry fleet GWh of cell and battery capacity eligible
- Industry fleet battery minerals extraction eligible
- Number of IRS eligible vehicles [EPA-HQ-OAR-2022-0829-0744, pp. 9-10]

JLR requests that EPA amends the central case compliance model to reflect a more accurate and realistic credit utilization of the IRA credits. [EPA-HQ-OAR-2022-0829-0744, pp. 9-10]

We disagree with the assumptions made by EPA referencing the 45X Advanced Manufacturing Production Tax Credit. In the Draft Regulatory Impact Analysis (DRIA), EPA stated, "Although a large percentage of 2023 U.S. BEV battery and cell manufacturing is represented by the production of one OEM, we believe that the many large U.S. battery production facilities that are being actively developed by suppliers and other OEMs… will allow benefit of the credit to be accessible to all manufacturers by 2027." This statement is highly unlikely, in JLR's case, our vehicles and batteries are produced outside of the US therefore we are ineligible for the credit. [EPA-HQ-OAR-2022-0829-0744, pp. 10-11]

Market Comparison

Current and forecast electrification trends show that the US is behind other markets such as the EU, China and Canada. Despite great advancements recently with policies such as the Bipartisan Infrastructure Law and the Inflation Reduction Act, the effects of these policies will take time to realize. The Global EV Outlook 2023 from the IEA expects the US to reach the government target of 50% ZEV in 2030.6 Based on this forecast, it would seem that EPA's proposal is too optimistic and leaves no room for error. [EPA-HQ-OAR-2022-0829-0744, p. 5]

6 IEA (2023), Global EV Outlook 2023, IEA, Paris, Prospects for electric vehicle deployment - https://www.iea.org/reports/global- ev-outlook-2023/prospects-for-electric-vehicle-deployment License: CC BY 4.0

Organization: John Graham

A major bias introduced into the cost of future BEVs is the vehicle tax credits from the Inflation Reduction Act (IRA). Inclusion of the vehicle incentives would be appropriate if the incentives continued indefinitely, but they end after 2032. Thus, while the vehicle tax credits will certainly influence manufacturer decisions in the early stages of the standards, manufacturers will anticipate the end of the program in 2032 and will make decisions on how to comply in 2032 (and beyond) that do not include the IRA vehicle tax credits. HEVs may look like a better long-run investment. The Final Rule should reflect this consideration and address in 2032 the reality of complying without the IRA vehicle tax credits. [EPA-HQ-OAR-2022-0829-0585, p. 22]

Organization: Kia Corporation

EPA's Analysis of Supporting Government Policies is Extremely Optimistic

EPA over-estimates the utility of the Infrastructure Investment and Jobs Act (IIJA) and Inflation Reduction Act (IRA) that have started but are nowhere near complete. And we certainly cannot tell yet if these programs will be successful. Kia is also hopeful that the IIJA and IRA clean vehicle tax credit can help expedite the sales of EVs, but EPA justifies its proposal with overly optimistic forecasts about these programs. [EPA-HQ-OAR-2022-0829-0555, p. 6]

As an example, EPA forecasts that the average IRA clean vehicle credit amount (30D) will be $6000 across all EV purchases by 2032.11 Currently, there are 91 ZEVs available to purchase but only ten vehicles qualified for the tax credits in February 2023. The Internal Revenue Service (IRS) proposed rules released in March 2023 further decreased the vehicles eligible and will continue to decrease the vehicles eligible, at least in the short-term. [EPA-HQ-OAR-2022-0829-0555, p. 6]

11 88 Fed. Reg. 29,201.

There are several actions that will greatly reduce the number of eligible vehicles. Each year, larger percentages of critical minerals and battery components are required to be sourced outside China. The Foreign Entities of Concern (FEOC) definition and requirements will start in 2024, which will greatly impact the eligibility of vehicles over the lifetime of the program, yet has not been defined. The FEOC is a blind spot for how automakers need to invest and source their materials. Outside of 30D, 45W is forecast to supplement incentives to consumers for vehicles ineligible for 30D. Currently, leases do not account for a majority of vehicle transactions. [EPA-HQ-OAR-2022-0829-0555, pp. 6-7]

Therefore, it is unlikely the 45W leasing tax credit will fully offset the unavailability of the 30D tax credit, as assumed in the proposal. [EPA-HQ-OAR-2022-0829-0555, pp. 6-7]

Importantly, we do not yet know the ability or impact (cost or otherwise) of sourcing EV batteries outside of China and in North America and Free Trade Agreement (FTA) countries. Given the limited supply of critical minerals in FTA countries, the future growth of EVs will be reliant on IRA ineligible sources. This will stunt the growth of the EV market. EPA's optimistic assumptions on the IRA skews the predicted cost of EVs in the future, and, consequently, results in underestimating the future price disparity between EVs and ICEs.12 This will have significant consequences to the vehicle industry and our investments. [EPA-HQ-OAR-2022-0829-0555, pp. 6-7]

12 Benchmark Mineral Intelligence, U.S. Electric Vehicle Feasibility Study, Report for Alliance for Automotive Innovation (Quarter 1, 2023).

Organization: Lisa Allee

[*From Hearing Testimony, May 9, 2023*] And lastly money, you talk about incentives to car companies, please consider getting incentives directly to consumers so that consumers can afford to buy electrical and hydrogen fuel cell vehicles because if you give the money to the car companies, doesn't necessarily pass onto the consumers, you give the money to the consumers, they buy the cars, the car companies make money, we all win. [From Hearing Testimony, EPA-HQ-OAR-2022-0829-5115, Day 1]

Organization: Mayor Becky Daggett, City of Flagstaff, Arizona et al.

Throughout the rulemaking process, EPA should also recognize and consider investments from the recently enacted Infrastructure Investment and Jobs Act (IIJA) and Inflation Reduction Act (IRA). [EPA-HQ-OAR-2022-0829-0732, pp. 1-2]

Together, these two laws are expected to reduce adoption costs for ZEVs by providing at least $245 billion in federal funds—through tax credits, loans, and grants—to support ZEV charging infrastructure, manufacturing, and purchasing. Long-term regulatory certainty will push domestic manufacturers to take full advantage of these investments. [EPA-HQ-OAR-2022-0829-0732, pp. 1-2]

The final standards should:

- Ensure the LDV and HDV standards support greater zero-emission vehicle adoption by considering market growth expected from IRA and IIJA investments (which will surpass existing commitments outlined in Executive Order 14037);

Organization: Mazda North American Operations

We also can't ignore the requirements of the recently passed Inflation Reduction Act (IRA)'s EV incentives. The requirements for consumers to access the full $7500 incentive are complicated and confusing, and they are driving further changes to EV supply chains and manufacturer product plans. In the short term the changes to section 30D have reduced the number of eligible vehicles by 70% including eliminating Mazda's current EVs. While the long-term effects are not yet fully known, the IRA EV incentives will impact consumer demand in some ways, and this will impact EPA's aggressive EV goals. [EPA-HQ-OAR-2022-0829-0595, p. 2]

Organization: National Automobile Dealers Association (NADA)

4. EPA’s Modeling Values the IRA’s EV Tax Credits Inconsistently.

EPA’s approach for estimating electrification technology costs for its technical feasibility analysis does not assume that all consumers will receive the full $7,500 value of the IRA’s EV tax credits, opting instead to combine portions of the Section 30D and Section 45W tax credits in its modeling.46 The initial value of the credit used in the modeling starts at $3,750 in MY 2027 and increases annually until reaching $6,000 in MY 2032.47 But when elsewhere discussing the TCO savings and expenses for a MY 2032 vehicle, EPA assumes a maximum value of $7,500 when comparing the net purchase price of an EV with that of an ICE vehicle.48 [EPA-HQ-OAR-2022-0829-0656, p. 10]

46 88 Fed. Reg. at 29301; EPA DRIA. p. 2-87.

47 88 Fed. Reg. at 29301; DRIA. p. 2-87, Table 2-50.

48 DRIA. p. 4-20, Table 4-7.

This approach is inconsistent. If EPA’s own technical feasibility modeling assumes a credit value of only $6,000, the agency should use this same value in its TCO analysis, even if doing so would result in more favorable average purchase price for an ICE powered vehicle versus a comparable EV. For example, assuming application of a $7,500 credit, an EV CUV/SUV may have a net purchase price $400 lower than its ICE counterpart, but assuming application of a $6,000 credit, the ICE CUV/SUV would be $1,100 less expensive than its EV counterpart. [EPA-HQ-OAR-2022-0829-0656, p. 10]

EPA’s assumption that the IRA’s clean vehicle credits will have an increasing impact on vehicle affordability over time is questionable. First, to qualify for the Section 30D credit, future battery electric (BEV) and plug-in hybrid (PHEV) vehicles will need to satisfy ever more stringent critical mineral and battery component requirements. Second, vehicle MSRPs are likely to increase over time, making an increasing percentage of vehicles ineligible for Section 30D credits. Today, only a relatively few EV make/models qualify for the full $7,500 tax credit, and most OEMs are expected to be challenged through 2032 to establish supply chains for necessary battery componentry independent of China and other foreign entities of concern.49 NADA urges EPA to revisit its assumptions regarding the extent to which the IRA's tax credits will have a significant positive impact on the affordability of BEVs and PHEVs.50 [EPA-HQ-OAR-2022-0829-0656, p. 10]

49 See Get Connected EV Quarterly Report 2023 Q1.pdf (autosinnovate.org), pp. 12-15; Transforming Personal Mobility | AAI (autosinnovate.org).

50 NADA agrees with AAI's suggestions in its comments that EPA should incorporate an adjustment mechanism into its modeling assumptions to account for EV market uncertainties regarding the various federal tax incentives, battery cost improvements, and infrastructure development.

Organization: North American Subaru, Inc.

Federal and state consumer incentive programs aim to help bridge the price gap. The 2022 Inflation Reduction Act created a consumer purchase incentive program for new EVs (30D Clean Vehicle Credit Program), but the program's strict eligibility conditions disqualified most EVs on the market and many consumers are unable to use it on the vehicle of their choice. As Auto Innovators has previously noted, seventy percent of previously eligible vehicles became ineligible the day the Inflation Reduction Act was signed into law 5• As additional conditions were implemented in January 2023 and again in April 2023 fewer vehicles qualify for the consumer incentive. The Proposed Rule notes the importance of consumer incentives, but unfortunately the 2022 IRA creates a consumer incentive program where few vehicles qualify. limited access to the critical minerals that are needed for EV batteries like lithium, cobalt, and nickel, pose enormous challenges to automakers' transition to electrification. Significantly more extraction and processing capabilities are needed to support increased battery demand by automakers. Critical mineral availability and the impact on battery and vehicle costs should be considered by regulators. [EPA-HQ-OAR-2022-0829-0576, p. 3]

5 Alliance for Automotive Innovation blog "EV Tax Credit: Is This is Good as it Gets?" March 31, 2023.

Organization: Northeast States for Coordinated Air Use Management (NESCAUM) and the Ozone Transport Commission (OTC)

D. Deployment of Federal Funding

The recently enacted Bipartisan Infrastructure Law (BIL) and the Inflation Reduction Act (IRA) provide billions of dollars of funding to advance transportation electrification including substantial funding for state governments. Combined with state and federal financial incentives for ZEVs and charging and fueling infrastructure, and other market-enabling policies, the LDV and MDV market segments are primed for rapid and widespread electrification. [EPA-HQ-OAR-2022-0829-0584, p. 7]

The NESCAUM and OTC states are already beginning to deploy the $5 billion made available through the National Electric Vehicle Infrastructure program to accelerate installation of public charging and other alternative fueling infrastructure, and the $5 billion Clean School

Bus grant program for zero-emission school buses and technology. Additional funding will be available soon through the $7.25 billion Low or No Emission and Grants for Buses and Bus Facilities programs, the $2.5 billion Charging and Fueling Infrastructure program, the $1 billion Clean Heavy-Duty Vehicle program, and many other new and existing federal programs for which activities that support transportation electrification are eligible. All of the NESCAUM and OTC states recently submitted applications for the $5 billion Climate Pollution Reduction Grant Planning and Implementation programs, which require states to develop and implement priority and comprehensive climate action plans to reduce economy-wide GHG emissions. [EPA-HQ-OAR-2022-0829-0584, p. 7]

Organization: Paul Bonifas and Tim Considine

The EPA argues that because of the maximum federal purchase incentive tax rebate of $7,500, this would reduce the price paid by consumers. However, tax rebates are not magic wands. The money must originate from somewhere: the US economy, aka taxpayers. The tax rebate does not increase nor decrease the “net benefit” to the US economy. Moreover, there are income limits to the EV tax rebate, and the current EV owner demographic would not qualify for any tax rebate when purchasing a new EV. [EPA-HQ-OAR-2022-0829-0551, p. 6]

Organization: Plug In America

These regulations are essential to keeping our climate commitments. They are fortified by billions of dollars of federal funding authorized through the 2021 Infrastructure Investment and Jobs Act and the 2022 Inflation Reduction Act. Federal funding has catalyzed private investment in this market. Vehicle and battery manufacturers are expected to invest $210 billion in the U.S. by 2030, nearly a quarter of global financial commitments toward the EV transition and more than any other country in the world.2 [EPA-HQ-OAR-2022-0829-0625, p. 1]

2 https://www.atlasevhub.com/data_story/210-billion-of-announced-investments-in-electric-vehicle-manufacturing-headed-for-the-u-s/.

Organization: POET, LLC

EPA then adds a significant, additional reduction—from about $80 to $90 per kWh from 2027 to 2032 to $40 to $60 per kWh—because of the IRA tax credits.88 This amounts to a total cost reduction of about 50 to 67% in “as few as two to three years” simply because of increased demand and the IRA.89 These large reductions are not justified. First, the battery production capacity that would support these cost reductions has yet to be built. Second, even assuming it is built as EPA predicts, there is no reason to assume that battery manufacturers will pass cost savings from the IRA directly onto customers on a one-to-one basis.90 [EPA-HQ-OAR-2022-0829-0609, pp. 22-23]

88 Id.

89 Id.

90 Id.

Finally, EPA assumes that the significant federal tax incentives supporting batteries and reducing the purchase price of BEVs for consumers will continue throughout the term of the

Proposed Rule, when those incentives could be eliminated or modified by future legislation.100 [EPA-HQ-OAR-2022-0829-0609, p. 24]

100 Id.at 7.

Beyond the assumptions of dramatic reductions in the cost of batteries and other BEV componentry over the period from 2022 through 2032, U.S. EPA also assumes that federal tax incentives will be available that dramatically lower the purchase price of BEVs. In some instances, U.S. EPA assumes that purchase incentives of $7,500 per BEV apply (see DRIA Table 4-7 for example) but in U.S. EPA's analysis of BEV penetration, somewhat lower values are used which range from $4,750 in MY 2027 to $6,000 in MY 2032 as shown in DRIA Table 2-50. Purchase incentives are assumed to end with MY 2033. The main concern with U.S. EPA's treatment of purchase incentives is the assumption that they will continue to be in place over the period from 2027 through 2032 as they could easily be eliminated or modified by future legislation. This assumption should clearly be subjected to a sensitivity analysis as the elimination of purchase incentives would be expected to dramatically lower BEV penetration rates during the MY 2027 to 2032 period while U.S. EPA's assumptions regarding dramatic reductions in BEV battery and component costs are occurring. [EPA-HQ-OAR-2022-0829-0609, p. 59]

Organization: Sierra Club et al.

The EPA should ensure that the final standard reflects the investments from the Infrastructure Investment and Jobs Act and Inflation Reduction Act. Together, these two laws are expected to reduce ZEV adoption costs by providing at least $245 billion in federal funds—through tax credits, loans, and grants—to support ZEV infrastructure, manufacturing, purchasing, and charging.2 Long-term regulatory certainty, through strong federal clean car standards, will encourage domestic manufacturers to take full advantage of federal investments and spur ZEV innovations that can reduce pollution and save families money. [EPA-HQ-OAR-2022-0829-0668, pp. 1-2]

2 Noah Gabriel, $210 Billion of Announced Investments in Electric Vehicle Manufacturing Headed for the U.S., EV Hub (Jan. 12, 2023), https://www.atlasevhub.com/data_story/210-billion-of-announced-investments-in-electric-vehicle-manufacturing-headed-for-the-u-s/.

Organization: Specialty Equipment Market Association (SEMA)

The Inflation Reduction Act of 2022 further expanded these investments by offering $7,500 tax incentives to American consumers to purchase electric vehicles. While initial estimates from the CBO determined the cost of the program at $30.6 billion over the next 10 years, the University of Pennsylvania now estimates the EV tax incentive's total cost has increased by over 1,000 percent to $393 billion over 10 years.3 [EPA-HQ-OAR-2022-0829-0596, p. 3]

3 University of Pennsylvania: Budgetary Cost of Climate and energy provisions in the Inflation Reduction Act (Link: https://budgetmodel.wharton.upenn.edu/estimates/2023/4/27/update-cost-climate-and-energy-inflation-reduction-act).

Organization: Stellantis

- The Inflation Reduction Act (IRA) committed significant funds to incentivize the purchase of EVs [EPA-HQ-OAR-2022-0829-0678, pp. 3-4]

– however these incentives come with criteria that exclude many EV models today, and pending guidance from the IRS likely could exclude more in the future. [EPA-HQ-OAR-2022-0829-0678, pp. 3-4]

- The IRA also provides an incentive to produce the needed batteries helping to offset their cost – however this only applies to the U.S., ignoring the global supply chain needed to support a 40- 50% U.S. EV market. [EPA-HQ-OAR-2022-0829-0678, pp. 3-4]

Another example of overly optimistic assumptions is how EPA overestimated the impact of the federal incentives introduced by the IRA. EPA's modelling assumes all batteries in all EVs will be built in the U.S. getting the maximum $45/kWh credit offered by the 45X battery production tax credit for 2027- 2029MY. This results in an assumed price reduction of $4,500 for a vehicle with a 100kWh battery and scales up to ever larger price reductions with larger batteries. As shown in Figure 4 below, EPA combined the IRA 30D (retail) and 45W (lease/commercial) incentives assuming on average vehicles receive $3,750 to $6,000 of price reduction. Applying both the 45X IRA production and 30D/45W purchase incentives assumes average BEV price reductions of >##$9K starting in 2027MY, having a significant influence on EPA's forecasted market demand and affordability for EVs. EPA justifies its assumption citing most batteries are U.S. manufactured today (even though data is heavily skewed by one OEM) and that the lucrative credit will drive OEMs to invest in U.S. production. Stellantis supports Auto Innovators' comments recommending that EPA take a less optimistic approach in applying IRA incentives incorporating a more realistic price influence on future EV market projections. [EPA-HQ-OAR-2022-0829-0678, pp. 5-6]

SEE ORIGINAL COMMENT FOR Table 2-49: IRA Battery Production Tax Credits in OMEGA and Estimated BEV Price Reduction Assumed due to IRA Incentives. Figure 4 - IRA incentives assumed in the EPA NPRM [EPA-HQ-OAR-2022-0829-0678, pp. 5-6]

Organization: Steven G. Bradbury

EPA is confident that generous federal subsidies for EV purchases will help con- sumers overcome their reluctance, but that confidence is questionable at best. EPA's cal- culations assume that the current subsidies promised in the Inflation Reduction Act will apply to all EV purchases in the U.S., which they do not and never will, and that these subsidies will remain available going forward, which will not be the case if a future Con- gress changes course and repeals these costly subsidies. [EPA-HQ-OAR-2022-0829-0647, p. 12]

Organization: The Heritage Foundation (Kevin Dayaratna and Diana Furchtgott-Roth)

The Environmental Protection Agency claims that costs of battery cell and pack manufacturing will continue to decline due to the learning curve, shared costs across larger volumes, and government subsidies. However, the introduction of government subsidies artificially reduces the cost of manufacturing and provides an unrealistic perspective of the actual costs should the government stop subsidizing battery manufacturing. [EPA-HQ-OAR-2022-0829-0674, p. 8]

Organization: Toyota Motor North America, Inc.

4.3. Application of IRA

Projected battery costs are further reduced in EPA's analysis by applying the IRA 45X cell and module tax credits. To do this, the direct manufacturing costs above are scaled up to their retail price equivalent (RPE) from which the IRA tax benefits are subtracted resulting the lower cost curve in Figure 7. [EPA-HQ-OAR-2022-0829-0620, pp. 24-25]

[See original for graph Figure 7 IRA 45X Cost Reductions] [EPA-HQ-OAR-2022-0829-0620, pp. 24-25]

It is unclear as to how the IRA tax credits are applied to arrive at the lower curve. The RPE curve seems to be missing from Figure 7making it impossible to visualize the actual cost reductions due to the IRA tax credits. Toyota recommends the Final Rule clearly describe and illustrate each step of the process and provide an accounting of the cumulative IRA tax credits applicable each year, as well as the marked-up (RPE) costs prior to the IRA tax credits being applied for comparison. Toyota believes EPA must reconsider how the IRA benefits are being applied to achieve battery cost savings for the proposed standards. The resulting battery costs seem implausible as total battery costs after the tax credit can be negative. [EPA-HQ-OAR-2022-0829-0620, pp. 24-25]

EPA assumes that starting in 27MY virtually every battery produced on the path to hitting the 67% BEV target in 32MY will be produced in the U.S. and earning the 45X credit. This is unrealistic and not supported by the U.S. Department of Energy or any other projections. EPA's own analysis of this scenario would put the cost of the 45X credit related to the proposed rule at around $160 billion between 2027 and 2032 - nearly six times the total CBO score of $30.6B. [EPA-HQ-OAR-2022-0829-0620, pp. 24-25]

Further, EPA assumes that starting in 27MY, every BEV sold in the US will receive part of the combined 30D+45W Clean Vehicle Credits, up to a maximum of $6,000 per BEV in 32MY. EPA's own analysis of this scenario would put the total cost of the 30D+45W Clean Vehicle Credits related to the proposed rule at around $270 billion between 2027 and 2032 – nearly twenty-five times the total CBO score of $11 billion ($7.5 billion for 30D and $3.5 billion for 45W). [EPA-HQ-OAR-2022-0829-0620, pp. 24-25]

6 Conclusion

A deeper analysis of global and IRA-compliant critical material supply and demand is needed to support the final rule. The proposal's high-level assessment results in overly optimistic observations that "critical battery mineral supply is likely to be adequate to meet anticipated demand, in some cases by a significant margin".19 The proposal lacks the evidence to support this finding. Demand for critical minerals today is now higher than the years referenced in the proposal due to new policy and OEM targets. Future demand growth for PEVs is unclear given the uncertain geo-political considerations and supply chain operations beyond the control manufacturers and EPA. It is highly plausible the tight supply-demand for lithium and graphite will lead to volatile prices and the proposal fails to consider how this could suppress demand and annual EV market share. The Final Rule must encompass a significantly deeper analysis based on a boarder array of sources for assessing global supply-demand by country of origin to support the use of IRA tax credits. [EPA-HQ-OAR-2022-0829-0620, pp. 65-66]

19 Id.

Organization: United Steelworkers (USW)

EPA relies heavily on the potential critical role and incentives from the manufacturing investments from the Inflation Reduction Act (IRA) and the Infrastructure Investment and Jobs Act (IIJA) for its proposed emissions standards. Programs related to the auto manufacturing sector include the Battery Manufacturing and Recycling Grants, the Battery Material Processing Grants, the Domestic Manufacturing Conversion Grants, the 48C Advanced Manufacturing Tax Credit, the Advanced Technology Vehicle Manufacturing Loan Program, the National Electric Vehicle Infrastructure Program, and the Charging and Fueling Infrastructure Grant Program. [EPA-HQ-OAR-2022-0829-0587, p. 4]

While the proposed rule is not wrong that the investments made by IRA and IIJA should spur investments in new technologies to lower emissions of vehicles, it does fail to consider the timeline and effectiveness of program implementation. Undoubtably, these manufacturing investments will take time to achieve their full production capacity. [EPA-HQ-OAR-2022-0829-0587, p. 4]

Organization: Valero Energy Corporation

6. EPA's application of price modifications is inconsistent with the Inflation Reduction Act ("IRA") and IRS's proposed implementation of 26 U.S.C. §30D and §45W. [EPA-HQ-OAR-2022-0829-0707, p. 9]

In Section 2.6.8 of the DRIA, EPA describes its methodology for incorporating IRA tax incentives into OMEGA modeling,37 and those price modifications are reflected in the OMEGA input file.38 However, EPA misapplies the §30D and §45W tax credits in the following ways: [EPA-HQ-OAR-2022-0829-0707, p. 9]

37 DRIA at 2-86 and 2-87.

38 EPA LMDV OMEGA GHG Compliance Modeling Runs (Document ID EPA-HQ-OAR-2022-0829-0486), 2023- 03-25-11-46-49-ld-central-compliance-run.zip, "vehicle_price_modifications_20230314b.csv."

• As of April 18, 2023, only 14 light-duty vehicles in the MY 2023 fleet are eligible for any credit amount under 30D.39 Nonetheless, EPA applies a price modification to every BEV in the MY 2023 to MY 2032 analysis fleets, without any consideration of: [EPA-HQ-OAR-2022-0829-0707, p. 9]

39 https://www.politico.com/news/2023/04/17/ev-treasury-department-regulation-00092123 and https://fueleconomy.gov/feg/tax2023.shtml, accessed 4/28/2023.

o Cost of the vehicle – the §30D tax credit is only available for pick-up trucks, vans and SUVs with an MSRP ≤ $80,000 and other qualified vehicles with an MSRP ≤ $55,000. The BEV to which EPA applies the price modification have OMEGA-projected prices ranging from $24,633 to $360,545;40 [EPA-HQ-OAR-2022-0829-0707, p. 9]

40 EPA LMDV OMEGA GHG Compliance Modeling Runs (Document ID EPA-HQ-OAR-2022-0829-0486), 2023- 03-25-11-46-49-ld-central-compliance-run.zip, Column AB of "2023_03_25_11_46_49_ld_central_compliance_run_Proposal_vehicles/csv."

- Location of final assembly – from August 17, 2022, the §30D tax credit is only available for vehicles whose final assembly occurs in North America; [EPA-HQ-OAR-2022-0829-0707, p. 9]
- o Battery components – Starting in 2023, an increasing percentage of battery components must be manufactured or assembled in North America; [EPA-HQ-OAR-2022-0829-0707, p. 9]
- o Battery critical minerals – Starting in 2023, an increasing percentage of battery critical minerals must be extracted, processed or recycled in eligible locations; and [EPA-HQ-OAR-2022-0829-0707, p. 9]
- o Purchaser income – the §30D tax credit is only available for taxpayers with adjusted gross income less than thresholds. [EPA-HQ-OAR-2022-0829-0707, p. 9]

• EPA does not apply a price modification to even a single PHEV in the MY 2023 to MY 2032 analysis fleets. Eligible vehicles under 26 U.S.C. 30D include plug-in electric vehicles with a battery capacity ≥ 7 kWh and capable of being recharged by external source of electricity,41 so certainly PHEVs are eligible. And in fact, of the 14 models currently eligible for 30D tax credits, six are PHEVs. [EPA-HQ-OAR-2022-0829-0707, p. 9]

41 PHEVs available in the US have a mean battery size of 14.9 kWh, https://evstatistics.com/2022/04/bev-batteries- average-83-kwh-versus-15-kwh-for-phevs/ (accessed 4/27/2023)

Organization: World Resources Institute (WRI)

Locking in cleaner vehicle standards, and potentially extending them through 2035 as requested by auto manufacturers, will create market stability and will give manufacturers, investors, and consumers greater confidence in the direction of the vehicle market. [EPA-HQ-OAR-2022-0829-0544, pp. 1-3]

Based on the current and growing uptake of electric vehicles, paired with public and private investments in charging, purchasing, and manufacturing from the Inflation Reduction Act and the Infrastructure Investment and Jobs Act, these standards would be achievable under the model years proposed. Public investments from recent legislation include but are not limited to: [EPA-HQ-OAR-2022-0829-0544, pp. 1-3]

• National Electric Vehicle Infrastructure Program [Link: https://www.fhwa.dot.gov/environment/nevi/]

• Electric Vehicle Tax Credit [Link: https://www.irs.gov/credits-deductions/credits-for-new-clean-vehicles-purchased-in-2023-or-after]

• Commercial Clean Vehicle Credit (45W) [Link: https://www.irs.gov/credits-deductions/commercial-clean-vehicle-credit]

- Used Clean Vehicle Credit [Link: https://www.irs.gov/credits-deductions/used-clean-vehicle-credit]

- Advanced Manufacturing Production Credit (45X) [Link: https://www.irs.gov/instructions/i7207] [EPA-HQ-OAR-2022-0829-0544, pp. 1-3]

Thus, we urge EPA to strengthen and finalize the strongest rule possible as

1. Complementary policies provide incentives for vehicle manufacturers and consumers in the transition; and

2. Strong private investments are rapidly expanding supply chains and manufacturing, helping to accelerate the transition to cleaner, electric vehicles. [EPA-HQ-OAR-2022-0829-0544, pp. 1-3]

Complementary policies provide incentives

By leveraging the billions of dollars in new federal investments in electric vehicle charging in the Infrastructure Investment and Jobs Act and the hundreds of millions of dollars of clean transportation incentives in the Inflation Reduction Act these standards have the potential to be the floor not the ceiling for transportation emissions reductions. [EPA-HQ-OAR-2022-0829-0544, pp. 1-3]

These policies provide unprecedented levels of public support for electric vehicles specifically including at least $83 billion of loans, grants, and tax credits that could support the production of low or zero-emission vehicles, batteries, or chargers according to a recent analysis [Link: https://www.atlasevhub.com/data_story/210-billion-of-announced-investments-in-electric-vehicle-manufacturing-headed-for-the-u-s/#_ftn4] by Atlas Public Policy. [EPA-HQ-OAR-2022-0829-0544, pp. 1-3]

Complemented by existing state policies like the Advanced Clean Trucks and Advanced Clean Fleets rules, which require manufacturers to begin selling an increasing percentage of zero- emission vehicles starting in 2024, EPA's proposed rules can help to accelerate the transition to zero-emission transportation while improving public health and reducing climate pollution. [EPA-HQ-OAR-2022-0829-0544, pp. 1-3]

Private investments are rapidly expanding supply chains and manufacturing

Since the passage of the Inflation Reduction Act less than one year ago, companies have announced tens of billions of dollars in renewable energy, battery, and electric vehicle projects across the country. From the announcement that Our Next Energy [Link: https://www.michiganbusiness.org/press-releases/2022/10/whitmer-announces-2000-jobs-investment-of-$1.6-billion-michigan-based-our-next-energy-builds-battery-manufacturing-campus-wayne-county/] has invested $1.6 billion in their first battery manufacturing campus in Wayne County, Michigan to the news that Hyundai Motor Group and SK On [Link: https://fortune.com/2022/12/08/hyundai-new-5-billion-electric-battery-plant-georgia-atlanta-biden-inflation-reduction-act/] are jointly investing $4-$5 billion to build electric battery plants outside of Atlanta, Georgia to BMW's [Link: https://apnews.com/article/technology-north-america-spartanburg-south-carolina-climate-and-environment-96753f092b29e0d384903591b5221f13] recent announcement of their $1.7 billion investment near Spartanburg, South Carolina in their shift to EV manufacturing there is ample evidence that recent policies are helping to drive substantial private investments. [EPA-HQ-OAR-2022-0829-0544, pp. 1-3]

These investments are leading to rapidly developing supply chains, domestic battery production capacity, and increased manufacturing which will lead to further reductions in the cost and increases in the availability of zero-emission vehicles. This market growth will continue to increase with additional supportive policies and regulations, such as these proposed rules. [EPA-HQ-OAR-2022-0829-0544, pp. 1-3]

EPA Summary and Response

EPA acknowledges and appreciates all of the comments relating to IRA provisions and their modeling in the compliance analysis. Comments on this topic included a number of distinct themes that we individually identify and respond to in this section. Our responses to these themes collectively respond to all of the individual comments on these topics. Some comments touch on topics that are responded to in other sections of the RTC, and we cite these other sections at the end of this section.

In general, comments in this area were related either to the potential for IRA provisions to promote feasibility and adoption of PEV technology, or to our representation of specific IRA provisions as inputs to the compliance analysis.

Comments relating to the potential of IRA provisions frequently cited the intent of the Act to support industry development, and cited supportive information relating to recent examples of how this is occurring robustly and as expected. For example, comments from ACEEE, CARB, CAP, Energy Innovation, "Environmental and Public Health Organizations", EDF, ICCT, NESCAUM, Plugin America, and others strongly supported the position that the IRA and other governmental programs are already and would continue to have a strong and positive influence on development of the supply chain and promoting feasibility of PEV technology. Other comments related to the importance of EPA reflecting the potential impact of the IRA in its compliance analysis (both in the No Action case and the action cases), and setting the stringency of the standards accordingly. For example, this view was advanced by ACEEE, CAP, the Sierra Club, and others, including comments that the full potential of the IRA provisions should be utilized by actively taking full advantage of its provisions. Other commenters were more skeptical of the impact of the IRA provisions. For example, the Alliance and Stellantis suggested that the IRA would not be enough, and others (such as Honda, Kia, API, and NADA) generally expressed the view that the provisions were unlikely to have the impact EPA had assumed in its analysis (for example, that the 30D Clean Vehicle Credit is more restrictive than its predecessor and may be severely restricted in applicability, or that the IRA would take longer than expected to influence the domestic supply chain). Others stated their view that, because the IRA provisions could potentially be modified or repealed by a future Congress, EPA should have either not included the IRA provisions in its analysis or should conduct a sensitivity to account for this possibility. Others suggested that the limited lifetime of the IRA provisions means that EPA should have accounted for the effect of their discontinuation after 2032, and specifically that their inclusion at all biased the analysis toward PEVs and discouraged HEVs and other ICE technology from playing as significant a role in the modeled compliance fleet.

Comments relating to our representation of specific IRA provisions in the compliance analysis primarily consisted of comments about our numeric OMEGA inputs for average values of credits under 30D (Clean Vehicle Credit), 45W (Commercial Clean Vehicle Credit), and 45X (Production Tax Credit). Some commenters agreed with our numeric values and in some cases suggested that our values may be conservative. In particular, some commenters urged EPA to include the 45X provision that provides 10 percent credit for manufacturing cost of domestic electrode active materials and critical minerals. Other commenters stated the view that our assumptions for any or all of the credit programs were too optimistic, for example, that they did not account for various limitations on eligibility, or did not fully explain the basis for the values that were used, or did not address the ability of U.S. battery manufacturing facilities currently planned or under construction to ramp up quickly enough.

EPA acknowledges the comments relating to the current and potential effects of the IRA provisions, the need for actions and timely progress on the part of other parts of the government, and the effectiveness of such actions. EPA agrees with commenters who argued that the PEV-related incentives and other programs under the IRA have strong potential to advance development of the PEV supply chain and PEV feasibility, not only at the manufacturing level but also at the infrastructure level, and are already demonstrating this effect through industry's increased emphasis on building a domestic supply chain, manufacturing battery cells in the U.S., securing IRA-compliant mineral and component inputs, and stimulating private investment. EPA also acknowledges comments relating to the need for action and timely progress across the government, and/or the likely effectiveness of these efforts, such as the programs under the Bipartisan Infrastructure Law, the CHIPS Act, and various funding and assistance mechanisms administered by agencies across the government. The bulk of our responses to these topics are in RTC 15. EPA also acknowledges the views of adverse commenters who cite uncertainty or skepticism with respect to the rate at which IRA provisions and other governmental efforts will grow the domestic supply chain, the effect of specific requirements of specific tax credits or incentives, and similar concerns. EPA addresses these comments in turn in the paragraphs below.

In response to commenters who stated that our OMEGA inputs for the average composite value of 30D and 45W credits across the fleet were too optimistic, or more specifically that the domestic supply chain, including critical mineral mining and processing and electrode active material manufacturing, will not grow fast enough to allow the assumed levels of 30D credits, EPA disagrees. EPA acknowledges that eligibility for 30D specifically was reduced for many manufacturers in 2023 with the activation of critical mineral and battery component sourcing requirements, and this reduction in the number of eligible vehicle models was understood across the industry at the time of the proposal. EPA disagrees with commenters who assert that this means that 30D will be a disincentive to PEV sales, or that it means that few or no vehicles will be eligible in the future. It is clear that the supply chain is growing in response to market forces and incentives, and manufacturers are actively pursuing compliance with the IRA incentives, meaning that some percentage of vehicles will in fact qualify in the future and the primary uncertainty is to what degree. To reexamine the validity of our assumptions for 30D and 45W, we requested the Department of Energy to perform an independent assessment[464] of the likely average yearly value per vehicle of combined 30D and 45W, taking into account the various eligibility constraints, trends in leasing, and rate of growth in U.S. battery manufacturing

[464] Department of Energy, "Estimating Federal Tax Incentives for Heavy Duty Electric Vehicle Infrastructure and for Acquiring Electric Vehicles Weighing Less Than 14,000 Pounds," Memorandum, March 11, 2024.

facilities including an accounting for gradual ramp-up over time. This work resulted in a set of year-by-year fleet-average credit values for the combined effect of 30D and 45W that are described in preamble Section IV.C.2. These updates estimates from DOE represent a more complete and independent assessment of the issue and EPA believes it to be the best publicly available accounting of the potential value of the credits given their specific requirements. We note that the DOE figures are very close to the figures used in the proposal. As described in more detail in Preamble IV.C.2, in our updated compliance analysis we adopt the DOE figures for 30D/45W but reduce them to conservatively account for uncertainties. See Preamble IV.C.2 for a full discussion.

Some commenters also expressed the view that the proposal did not adequately explain the basis for the combined 30D and 45W values that were used in the proposal. In response, we refer to the DOE analysis which provides specific information on the basis of the estimates used in the updated compliance analysis.

In response to comments that the IRA's mineral and battery component sourcing requirements have already reduced the number of PEVs that qualify for one or both halves of the 30D credit, or that the IRA sourcing requirements will severely limit the percentage of PEVs that qualify for 30D in the future, EPA agrees that not all PEVs qualify for 30D today and that it is likely that some portion of PEVs will not qualify in the future. However, EPA disagrees with the implication that our values for combined 30D and 45W are therefore too optimistic. First, we note that we have modeled 30D and 45W in combination, either of which potentially provide for up to $7,500 in credit toward a vehicle transaction, albeit in different forms. The 45W credit is applicable to commercial vehicles, which includes vehicles that are purchased for the purpose of leasing, whether to businesses or to consumers, and it is not subject to the sourcing requirements of 30D. Also, the independent DOE analysis largely corroborates the figures that were used in the proposal. Some commenters cited current or past lease rates across the vehicle market or within their own operations, and used this to question whether lease rates would be sufficient in the future to combine with 30D as described. EPA disagrees that past history or recent trends in lease rates has a bearing on future rates given 45W; the data for current or past leasing rates would not reflect the influence of 45W on PEV transactions and thus has limited if any value in predicting future rates. We also note that there is evidence that vehicle leasing has or is likely to increase in response to this provision; for example, JLR indicated that it is considering leasing in response to this provision, and the DOE analysis also observes an increase in leasing rates. Although some commenters appeared to question the appropriateness of IRS guidance clarifying that the leased vehicles may qualify for 45W, The Department of Treasury and the IRS have explained that the guidance simply follows the statutory text of the IRA and longstanding tax rules regarding leasing. Regarding comments expressing the view that 45W consumer eligibility will depend in part on the cost differential from ICE vehicles, MSRP is considered in the DOE study. Regarding comments that some consumers may not qualify for a lease due to credit score or interest rates, these factors influence ability to purchase a vehicle as well and are not limited to leasing.

In response to comments that the IRA provisions will take time to have their full effect, EPA agrees that development of the supply chain will not occur overnight, but also notes that robust progress is being made. EPA also notes, as stated in comments from "Environmental and Public Health Organizations" among others, that these programs as well as the standards themselves provide clear regulatory and market signals that are likely to accelerate this progress. For more discussion of comments related to the supply chain, critical minerals, and the impact of the IRA, BIL, and other measures toward this end, see RTC 15.1.

In response to comments that our assumptions for the value of combined 30D and 45W were not documented, or that specific requirements such as for example the MSRP limitations on 30D were not quantified, please see Preamble IV.C.2 where we describe the DOE study that independently estimated yearly values for combined 30D and 45W,[465] and largely confirmed the estimates used in the proposal. The DOE analysis provides a rigorous accounting of most of the various restrictions on the credits in developing its estimates, and EPA believes that the study provides a strong estimate of 30D/45W. However, some commenters additionally noted limitations on 30D that DOE did not explicitly consider, including: that inflation could affect vehicle eligibility under the MSRP limit, or that over time buyers might increasingly fail to qualify under the income limit which also is not adjusted for inflation, or that some buyers would not have enough tax liability to claim the full credit, and various other uncertainties about the other limitations on 30D. While EPA continues to believe that the DOE estimates are reasonable and likely to be an accurate representation, in the interest of addressing these comments and as described immediately below and in more detail in Preamble IV.C.2, in our updated compliance analysis we adopt the DOE figures for 30D/45W but reduce them to conservatively account for these uncertainties. For example, DOE considered the MSRP limit, but did not project increases in vehicle prices due to inflation, and was unable to include the effect of income limits because of lack of citable data on customer incomes. See Preamble IV.C.2 for a full discussion.

EPA notes that JLR's comment that "65% of battery cells and almost 80% of cathodes are manufactured in China" is not relevant to commenter's points on 30D eligibility, as this appears to refer to global production, the majority of which is not sold into the U.S. market.

In response to comments that significant uncertainty remains regarding Treasury guidance on the application of the IRA credits (for example, the definition of foreign entities of concern (FEOC)), EPA notes that the Treasury Department has issued much of this guidance in the time since the proposal was issued, and EPA has considered this guidance, which was largely as had been expected across the industry and by EPA at the time of the proposal. The DOE analysis of 30D/45W was conducted with consideration of aspects of Treasury guidance that were under development at the time and subsequently proposed for rulemaking by Treasury.

In response to comments expressing the view that domestic battery manufacturing capacity will not grow fast enough to allow the assumed levels of 45X in our analysis, or that the value of the 45X production tax credits we assumed are not justified by projections of future U.S. manufacturing capacity, EPA disagrees. The proposal cited work by Argonne National Laboratory and other organizations on which we based our expectation that planned and announced U.S. cell manufacturing capacity would grow at a rate greater than expected domestic battery demand under the central case of the analysis. Comments received on our modeling of the 45X cell and module credit led us to further investigate our inputs for the phase-in schedule and average amount realized. Our updated analysis includes updated figures from ANL that include an allowance for ramp-up time based on ANL's assessment of typical plant construction and growth rates in the industry. Further, our updated compliance analysis projects less battery

[465] Department of Energy, "Estimating Federal Tax Incentives for Heavy Duty Electric Vehicle Infrastructure and for Acquiring Electric Vehicles Weighing Less Than 14,000 Pounds,", March 11, 2024.

demand than in the central case of the proposal, and we have included sensitivity cases and other examples of pathways that project less demand. With projected U.S. manufacturing capacity exceeding projected demand in every compliance scenario we have analyzed, PEV manufacturers and cell suppliers are well positioned to take significant advantage of the 45X credit throughout the time frame of the rule.

In response to comments that EPA did not sufficiently document our conclusion that 45X could be accommodated by projected U.S. battery manufacturing, EPA disagrees. EPA clearly based its conclusion on the ANL projection of North American battery manufacturing capacity plans presented in the proposal. In the final compliance analysis, we updated these projections with a new study by ANL that explicitly takes into account newly announced plans as well as the time necessary to build and bring the plants to capacity.

In response to comments that smaller manufacturers may never move battery manufacturing capacity to the U.S. and thus never realize 45X credits, EPA disagrees that this need be the case in all situations or that significant value of the credit cannot be realized by other means. In the case that a manufacturer has not constructed U.S. battery manufacturing capacity for its own use, we note that many vehicle manufacturers today procure cells and/or modules from suppliers that do manufacture in the U.S., making it possible for the 45X credit to be passed along in the price of the product. The ANL report also identifies production capacity associated with suppliers that have not identified offtake agreements that could be used as a U.S. manufacturing source. We expect that cell and module suppliers will compete on price by reflecting the advantage of the 45X credit in their pricing to these and other manufacturers.

In response to comments that EPA's accounting for 30D/45W and 45X together causes battery costs to be unrealistically low or negative, EPA disagrees. Specifically, EPA disagrees with the characterization by some commenters that the sum of 30D, 45W, and 45X credits imply that battery costs will be negative. The 30D/45W credit does not impact the modeled battery net manufacturing cost (only 45X does) but is realized within our modeling on the consumer side in making the overall cost of the vehicle more attractive to the buyer relative other technologies. EPA therefore has not assumed that the manufacturing cost of batteries will be negative or zero. EPA also disagrees with comments alleging that vehicle costs are inaccurate as a result of our IRA modeling or other OMEGA inputs. As described in the Preamble, RIA, and this RTC, the large set of OMEGA inputs that result in our estimates of vehicle cost are based on many data sources, studies, and analyses that EPA considers to be the best available.

In response to comments that there is no guarantee that 30D, 45W, or 45X tax credits will be passed on to the consumer, but instead could be taken as profit by the manufacturer or otherwise lost to the consumer, EPA agrees that there is no guarantee but notes that the motivation to compete in the market on pricing is likely to encourage manufacturers to pass the savings along. To the degree that manufacturers will choose to produce PEVs as part of their means to comply with the standards, they are likely to be incentivized to compete with one another on a pricing basis. If a manufacturer were to arbitrarily capture a large portion of the credit as additional profit at the expense of selling the vehicles as part of its compliant fleet, this would conflict with the manufacturer's ability to sell the vehicles, which manufacturers are motivated to do as one of the lowest cost pathways to meeting the standards. Some commenters have suggested that some manufacturers appear to have raised MSRP for PEVs in response to the availability of the 30D credit. EPA notes that the commenter's cited reason for such events is speculative, as manufacturers consider a host of factors in setting MSRP for specific vehicle types or models. The cited example occurred during a time of low vehicle inventory and higher vehicle prices across the industry, and evidence that the price change was a direct result of availability of 30D is only speculative and circumstantial, as EPA is not aware of any manufacturer having announced such a policy. In addition, DOE validated its 30D/45W estimate for 2023 against actual 2023 market transaction data from J.D. Power illustrating that OEMs are indeed passing on the value of the credits by reducing the cost of both purchases and leased BEVs and PHEVs.[466] At any rate, in a more mature and competitive PEV sales environment in which manufacturers are relying on sales of PEVs to comply with increasingly stringent standards, failure to pass on the credit is unlikely to be beneficial to the manufacturer as it would affect their ability to comply. In this final rule analysis, EPA continues to apply the full estimated average value of the 30D/45W credit toward the purchase price seen by the consumer, and to apply the full estimated average value of the 45X cell and module credit to the cost seen by the manufacturer. The 30D/45W credit amount is modeled in OMEGA as a direct reduction to the consumer purchase costs,[467] and therefore has an influence on the shares of BEVs demanded by consumers within the model. The purchase incentive is assumed to be realized entirely by the consumer and does not impact the vehicle production costs for the producer. For more discussion and the values used within OMEGA, please see RIA Chapter 2.6.8.

In response to comments from the Alliance that the BatPaC default setting for in-house production is somehow in conflict with the assumption that batteries will benefit from 45X cell and module credits, EPA disagrees. Whether a battery is made entirely in-house by an OEM from cells and modules manufactured in-house, or is purchased from a supplier, 45X cell and module credits are earned by the applicable manufacturing entity and can be transferred or passed along in the purchase price, given a competitive industry as discussed elsewhere. The ANL battery pricing study on which our updated costs are based considers the OEM to be the consumer that purchases the pack from the supplier, rather than an in-house operation.

Regarding the Alliance's assertion that the value of the 45X credit for MDVs would be unrealistically large due to the size of the battery, EPA does not see a basis for commenter's concern, as it is well understood that the amount of the 45X cell and module credit scales with the energy capacity of the battery in kWh. EPA sees no reasoning that would suggest that large batteries for large vehicles are somehow limited in the amount of credit they can realize simply because they are too large.

Regarding AmFree's comment suggesting that a statement from the proposal, "a large percentage of 2023 U.S. BEV battery and cell manufacturing is represented by the production of one [original-equipment manufacturer]," implies that the rest do not qualify for 45X, EPA disagrees. Batteries manufactured in the U.S. qualify for 45X regardless of which OEM makes them. Further, AmFree wrongly cites the Heavy Duty rule, which specifically deals with batteries manufactured for the heavy-duty market, which are in lower volumes than the light-

[466] Department of Energy, "Estimating Federal Tax Incentives for Heavy Duty Electric Vehicle Infrastructure and for Acquiring Electric Vehicles Weighing Less Than 14,000 Pounds," March 11, 2024.

[467] As described in Chapter 4.1 of the RIA, the modeling of consumer demand for ICE and BEV vehicles considers purchase and ownership costs as components of a "consumer generalized cost" for the ICE and BEV options. The purchase cost reflects the vehicle purchase price and any assumed purchase incentives under 30D or 45W.

duty market and are subject to other factors specific to HD vehicles, as support for the incorrect implication that many light-duty batteries are not eligible.

Regarding AmFree's citation of examples that in their view indicate a hesitance on the part of industry to proceed with announced battery manufacturing development plans, and that therefore EPA's assessment of future U.S. battery manufacturing capacity is "unsound," EPA disagrees. DOE has assessed future battery manufacturing plants in the U.S. and North America and based on the latest data, including ramp-up time estimates, continues to conclude that capacity is on track. EPA is aware that in the second half of 2023, some commentators began reporting on specific changes in previously announced investment plans by some automakers; see the discussion in Preamble I.A.2 and IV.C.7.i. As we explain there, EPA does not consider such recent news stories to be indicative of any general trend that would change our assessment of the outlook for investment in PEV technology, including domestic battery manufacturing capacity.

In response to comments that IRA credits could be repealed by a new Congress and therefore EPA should consider that possibility in its analysis, EPA disagrees. EPA has traditionally and consistently considered only the effect of final enacted laws and regulations in its feasibility analyses, and does not consider speculation about possible actions of Congress, the executive branch, states, or other entities in assessing the impact or outcome of its rulemakings. The range of possible future actions by any lawmaking, policymaking, or rulemaking entity would by definition encompass almost every possible outcome, including those with either positive or negative implications for the assessment, rendering the selection of any individual outcome merely speculative and potentially contradictory to the objectiveness of the assessment. EPA also notes that any regulatory action is subject to potential modification by a future Administrator subject to the public notice and comment process, just as other laws or regulations are subject to potential change. In response to the view that the limited time frame during which the IRA incentives will be available (2023 to 2032) means that they should not be considered in the analysis, EPA disagrees. The credits are available during this time frame and are very significant, and there is no reasonable basis for their arbitrary exclusion when it is clear that the credits are already being claimed and are already impacting the market as intended by Congress.

In response to comments that we should include the 10 percent provisions of 45X, EPA continues to believe that this aspect of the credit program is relatively small in comparison to others, and its exclusion makes the analysis conservative. To investigate the potential value of these credits across the new PEV fleet as a whole, we consulted with the Department of Energy and Argonne National Laboratory to characterize the potential value of the 10 percent provisions of 45X on a dollar per kWh basis. ANL determined that the maximum value of the credits would change over time, as critical minerals become a larger share of battery manufacturing cost due to efficiencies in other material and manufacturing costs. The maximum value for the electrode active materials (EAM) credit, or both the EAM credit and the critical minerals (CM) credit, would range from $5.60 to $10.70 per kWh in 2026 and decline to $3.50 to $7.60 per kWh in 2030, depending on chemistry. The decline is a result of ANL's projection that the amount (and hence manufacturing cost) of critical mineral content will decline over time. While these tax credits will be significant to manufacturers that produce EAM and CM in the U.S., their effect on average battery manufacturing cost across the fleet depends on the degree to which the average battery uses U.S.-produced EAM and CM. Because qualifying domestic production of CM and EAM is unlikely to supply all U.S. PEV battery production (as described in Preamble IV.C.7.i), the average value of the credit on a per kWh basis across the fleet will be less than the figures above. Because of the uncertainty in predicting the use of qualifying EAM and CM across the industry at this time, we have chosen to not include an estimate of the 10 percent credits in this analysis. Because some manufacturers will likely be in a position to qualify for some portion of the credit, this represents a conservative assumption, and thus is directionally consistent with addressing comments that our assumptions for other IRA credits were optimistic.

In response to comments that we should consider in our analysis the full range of IRA incentives extending beyond 45X and 30D/45W, EPA acknowledges that other parts of the IRA, for example the 30C charger credit, the 25E used vehicle credit, the 48C energy project credit and other programs, are likely to have a tangible impact. However, the impacts of these provisions vary in their ability to be estimated and quantified in the scope of our compliance analysis and so we have limited our analysis to the largest incentives that are relatively easy to model. EPA considers the exclusion of these other aspects of the IRA as making our analysis conservative.

EPA appreciates comments from Center for American Progress (CAP) advocating for inclusion of the 45X 10 percent provisions, but EPA disagrees regarding the cited size of the credit. CAP states that the EAM portion of the credit can amount to $30 per kWh and the CM portion to $20 per kWh. However, the credit is equal to 10 percent of manufacturing cost of EAM and CM; if for example 10 percent of EAM cost amounts to the cited credit of $30 per kWh, it implies that total EAM cost alone for a battery is $300 per kWh, which clearly cannot be correct for batteries whose total manufacturing cost is on the order of $100 per kWh.

In response to comments expressing the view that imported PEVs are unlikely to be able to benefit from the 45X cell and module credit in accounting for their battery cost, EPA agrees that imported vehicles are likely to continue to comprise some portion of the future PEV market, and that imported PEVs currently have limited options to utilize batteries whose cost benefits from 45X. In IV.C.2 of the preamble, we discussed some ways in which imported vehicles may be able to realize a similar benefit, including using batteries or cells exported from the U.S. or by benefiting from similarly sized subsidies in their home countries, and EPA still believes that this is likely to be the case for some foreign manufacturers. Ultimately we decided, for the purpose of this analysis at this time, to conservatively reduce the 45X credit amount for several reasons including the uncertainty surrounding imports, as described in section IV.C.2 of the preamble.

In response to the recommendation by the Alliance that we should consider 45X "impacts on specific manufacturers," the Alliance was unclear about the nature of these impacts, and EPA assumes that this is a reference to nearby text referring to domestic manufacturers that import some of their vehicles. As such, this comment is addressed above. In the case that the Alliance was referring to other reasons that it believes specific manufacturers may not be able to access the benefit of the credit, EPA also notes that other conservative aspects of our analysis would tend to offset the effect on our fleetwide 45X amounts, if in fact such an issue exists. For example, we have conservatively chosen not to account for potential savings from the 45X 10 percent credits for electrode active materials and critical minerals. Similarly, regarding comments generally suggesting that some U.S. vehicle manufacturers may nonetheless not have access to 45X, presumably due to internal business decisions to import batteries and/or the decision not to manufacture batteries in the U.S., we note that manufacturers are free to make their business decisions as they see fit and consider it reasonable to assume that such decisions are rational and lead to a lower cost for the manufacturer. We also note again, as previously noted, that manufacturers have the option to purchase cells, packs, or modules from suppliers that manufacture in the U.S. that can claim the credit.

EPA disagrees with API's assertion that the IRA tax credits cannot help to address "potential barriers to wider adoption of PEVs." Although 30D does not apply to every PEV depending on eligibility requirements, those that are eligible certainly benefit, and the IRA includes other tax credits that do not carry such restrictions.

Regarding the view expressed by UAW that the applicability of the 45W Commercial Clean Vehicle Credit to vehicles offered for lease may prevent 30D from encouraging domestic manufacture of vehicles, EPA disagrees and notes that 30D is likely to remain a powerful incentive for several reasons. This is in part because in order to benefit from 45W, customers must choose to lease rather than purchase, and a lease model may not fit all customers' preferences. Also, the amount available under 45W depends on the price difference between a PEV and a comparable ICE vehicle, which is widely expected to diminish or disappear for many vehicles over time while 30D will not, and over time manufacturers should increasingly be able meet the 30D sourcing requirements. Further, manufacturers have continued to demonstrate that 30D remains highly influential in manufacturer siting decisions; for example, as discussed in section I.A.3 of the preamble, while Hyundai has increased the leasing of vehicles to consumers it has simultaneously also continued plans to site battery and vehicle manufacturing in the U.S.[468] Regarding UAW's suggestion that 30D and/or 45W may promote moving assembly to Canada or Mexico or dissuade onshoring of jobs, EPA does not see reason to believe that 30D would specifically or additionally promote such an outcome, as the 30D incentive applies equally to vehicles assembled in the U.S. and the 45X battery manufacturing tax credits apply specifically to U.S. manufacture. To the degree that the design and interpretation of IRA tax incentives are determined by Congress and the Treasury Department, EPA does not have authority over how the IRA incentives are implemented but has accounted for their likely effect as written and based on our observation of the market.

Comments related to CBO projections of the cost of the IRA incentives compared to other estimates are out of scope, as the accuracy or inaccuracy of CBO estimates does not in any way bear on the availability of IRA incentives.

Regarding the comment advocating for a point of sale option for 30D, EPA notes that the point of sale option has become available to registered dealer entities as of 2024. EPA also notes, in response to comments that accessing 30D may be complicated or confusing, that the point of sale option makes access easier.

In response to the comment from Valero that EPA did not apply IRA incentives to "a single PHEV," EPA notes that there were no PHEVs in the proposal's compliance analysis, as was clearly noted in the proposal. The updated compliance analysis includes PHEVs and these vehicles receive the IRA credits appropriate to PHEVs.

In response to general comments citing various uncertainties with regard to future development of the supply chain, critical minerals, and similar concerns, see also our responses to comments on such uncertainties in RTC 15.1.

---

[468] Korea Economic Daily, "Hyundai Motor to boost EV leasing in US for tax credits from 2023," December 30, 2022. Accessed on February 14, 2024 at https://www.kedglobal.com/electric-vehicles/newsView/ked202212300014

In response to comments that EPA should improve documentation of 45X assumptions in OMEGA, EPA believes that docketing of OMEGA files and the provided level of documentation is sufficient. Stakeholders have in the past contacted EPA staff for assistance with OMEGA files and are encouraged to do so if desired.

For our response to comments that the total cost of ownership (TCO) example in the proposal (DRIA p. 4-20 Table 4-7) assumed a different 30D credit amount from the amounts used in the OMEGA analysis, see RTC 13.5. Comments that relate the IRA to projections of vehicle cost, cost parity or price parity are discussed in RTC 12.2.7. Comments related to the interaction between IRA assumptions and estimation of battery costs, or the effect of critical mineral cost or availability on same, are addressed in RTC 12.2.1. For response to comments related to 30D being a less effective successor to the previous 30D program, see our response to AFPM on a similar topic in 12.2.1 where we discuss battery costs. Comments related to the PEV penetrations in the No Action case are discussed in RTC 12.5.6, Modeling of the No Action case. Comments related to monitoring development of the supply chain or similar developments in order to modify stringency of the standards are addressed in RTC 3.4. Comments suggesting that tax credits have a societal cost are addressed where we discuss transfers in RTC 8.1.

It is important to note that when estimating the emission reductions of gasoline particulate filter (GPFs), EPA used percent reductions obtained from testing new GPFs on test vehicles. New GPFs would be expected to have high efficiencies. For consistency with MOVES modeling of criteria pollutants, EPA should consider lifetime average filter efficiency, not just efficiency on new vehicles in estimates of related emission benefits. [EPA-HQ-OAR-2022-0829-0701, p. 152]

Organization: Clean Fuels Development Coalition (CDFC)

EPA's judgement is misdirected by OTAQ's MOVES Model. As explained further in the "Supporting Documentation and End Notes" section, OTAQ's now repudiated MOVES Model underwent a highly questionable "development process" facilitated by BP and Chevron refinery experts. OTAQ emails obtained via FOIA requests reveal a shocking degree of collaboration/collusion between OTAQ experts and Coordinating Research Council (CRC) scientists funded by the petroleum industry. Their "cooperation" went so far as OTAQ agreeing to delete fuel samples that produced emissions results that "appeared too positive" when more ethanol was added. Rather than adhering to market practices in full display at the time—e.g., splash-blending additional ethanol on top of market gasoline, thus reducing BTEX content by dilution—OTAQ/CRC experts developed an incomprehensible "match-blending" scheme that resulted in more BTEX being added to fuel samples at the same time as more ethanol. Naturally, the resulting emissions were worse, but they were attributed to ethanol rather than the BTEX. [EPA-HQ-OAR-2022-0829-0630, pp. 5-6]

EPA's testing methods (and relative outcomes) for ethanol-gasoline blends seemed to undergo a fundamental shift beginning with the Tier 3 NPRM. In 2012, during development of the Tier 3 Rule when EPA was initially requesting comment on encouraging E30 higher octane blends, OTAQ published test results that compared E10 to E0 fuel sample. In this Tier 3 Fuels Impact Study [Link: https://nepis.epa.gov/Exe/ZyPDF.cgi?Dockey=P100TLC7.pdf], E10 had a 0.3% efficiency gain over E0 gasoline and the E10 fuel had 1.3% less carbon per unit of energy due to lower aromatic content. Thus, EPA's own data shows a 1.6% CO_2 reduction mostly due to E10's lower aromatic content (22 vol. % vs. 30 vol. % in the E0 test fuel). These results are consistent with the 2015 Ford/Leone E30 chart in the endnotes, see p. 13. [EPA-HQ-OAR-2022-0829-0630, pp. 5-6]

However, seven years later, in its 2019 E15 RVP Rule (ultimately rejected by the courts), EPA's MOVES Model concluded that compared to E10, E15 blends increased NMOG by 2.2%, NOx by 2.5%, and PM by 4.1%. Recently, buried deep in OTAQ/CRC footnotes, we found one clue: It turns out that CRC admitted in the fine print of one of their subsequently released studies that ethanol's alleged propensity to increase PM and NOx emissions was observed ONLY WHEN ETHANOL WAS MIXED IN A HIGH- AROMATIC FUEL BLEND. Of course, the burning question is why would EPA encourage the blending of ethanol into fuel samples that contain elevated levels of aromatics, especially when Congress has directed it to promote technologies that REDUCE aromatics to the "greatest degree achievable"? [EPA-HQ-OAR-2022-0829-0630, pp. 5-6]

CRC clarified (after prodding) that "the two-phase vaporization is NOT seen in fuel blend with lower aromatic content". In other words, if EPA had complied with Congressional directives to REDUCE aromatics content to the greatest degree achievable there would not be a MOVES PM controversy.2" [EPA-HQ-OAR-2022-0829-0630, pp. 5-6]

2 For further explanation of CRC's rationale, see Endnotes, p. 13.

This connection between aromatics and higher PM emissions was indirectly validated by EPA in the NPRM at p. 590, "Estimated Emissions and Air Quality Impacts", where EPA begins to acknowledge that changes in fuel composition (e.g., aromatics controls) "may also impact secondary pollutants formed in the atmosphere". EPA goes on to note that "Mobile sources are an important contributor to secondary aerosols formed from…organic precursors [aromatics]", and that "Changes in aromatic content may also affect NOx emissions". (P. 592) [EPA-HQ-OAR-2022-0829-0630, pp. 5-6]

Clearly, the CRC refinery experts knew about the linkage between aromatics and increased PM emissions very well, which explains why they insisted on adding more aromatics to fuel samples whenever they added more ethanol. [EPA-HQ-OAR-2022-0829-0630, pp. 5-6]

Organization: David Hallberg

I respectfully urge that you and your experts pay careful attention to the CFDC et al. NPRM comments—[link here-- https://cleanfuelsdc.org/wp-content/uploads/2023/06/EPA-CommentsOnMulti-pollutantRule-July23.pdf.] Of particular importance is the discussion in the end notes which quotes OTAQ's 2015 UFP Workshop report's admission that its controversial MOVES Model is defective because it utterly fails to predict the highly potent UFP/SOA-bound PAHs. They also explain how OTAQ's collusion with oil experts at the Coordinating Research Council (confirmed by FOIA-secured internal correspondence) manipulated fuel samples in a way that deliberately pinned the additional PM emissions caused by higher BTEX content on ethanol. [Experts were amazed at such a counterintuitive finding: EPA's 2013 Tier 3 Rule confirmed that ethanol does not produce either SOA or PAH.] [EPA-HQ-OAR-2022-0829-0548, p. 3]

Administrator Regan, eight years ago OTAQ formally admitted that its defective MOVES Model requires replacement. It is unconscionable that EPA continue to rely on MOVES as the basis for highly consequential rulemakings as it did with the MY2023 LDV GHG Final Rule. [EPA-HQ-OAR-2022-0829-0548, p. 3]

Clearly, EPA is acting unlawfully in its use of the MOVES Model as well as its recent RFS "set" rule, because they both contravene the Congressional directive to displace maximum achievable amounts of BTEX with ethanol's "clean octane". [EPA-HQ-OAR-2022-0829-0548, p. 7]

Organization: Environmental. and Public Health Organizations

A. Policy Scenarios

ERM investigated five different policy scenarios: EPA's no action "baseline" ("EPA No Action"); EPA's preferred approach ("EPA Main Proposal"); our recommended approach, which reflects greater increases in stringency after model year 2030 ("Alternative 1+"); EPA's strongest option ("EPA Alternative 1"); and EPA's weakest option ("EPA Alternative 3"). [EPA-HQ-OAR-2022-0829-0759, p. 27]

B. Modeling Background

EPA's updated MOVES model (MOVES3.R3105) was utilized to model electric vehicle (EV) adoption rates (sales and in-use), vehicle miles traveled (VMT), and pollutant emissions by vehicle type. Cost assumptions (battery costs, incremental vehicle costs, charging equipment costs, etc.) and vehicle classification/identification information and sales shares were incorporated into both ERM's BCA framework and its modification and application of MOVES3.R3 data outputs. ERM's BCA framework was applied to compare and evaluate the impacts across several policy scenarios as compared to the EPA No Action case. [EPA-HQ-OAR-2022-0829-0759, p. 27]

105 Although MOVES3.R1 was used for L/MD rulemaking, MOVES3.R3 reflects an updated version of MOVES3.R1 but maintains relevant L/MDV data and assumptions.

SEE ORIGINAL COMMENT FOR PIE CHART - Figure V.B-1: National Light- and Medium-Duty Vehicle Fleet106 [EPA-HQ-OAR-2022-0829-0759, p. 28]

106 ERM, Impacts Report at 6.

This pie chart is based on EPA's modified version of MOVES. EPA projects that the majority of vehicles subject to the rule will be SUVs and light trucks (~160 million), followed by passenger cars (i.e., sedans), which are projected to number just over 100 million vehicles. The remainder is made up of Class 2b (chassis-certified only) and Class 3 medium-duty vehicles, projected to number around 14 million vehicles nationwide; note that "incomplete" class 2b/3 vehicles covered by the proposed Phase 3 heavy-duty rulemaking were not included in this analysis. [EPA-HQ-OAR-2022-0829-0759, p. 28]

Organization: International Council on Clean Transportation (ICCT)

In evaluating the health benefits of the proposed rule, it is critical to consider the evidence of increases in PM from recent model year vehicles. The health benefits assessment included in EPA's proposal uses emission factors from Motor Vehicle Emission Simulator (MOVES), which likely underestimates PM emissions from recent model year vehicles. Figure 15 shows a comparison between EPA MOVES emission factors and remote sensing UV smoke averages by model year, shown as a percent change from each sources respective model year 2005 averages.140 From model years 2006–2015, year-to-year changes, shown in the slopes of the lines, are relatively consistent between EPA MOVES and remote sensing data. However, from model year 2015 on, the trends diverge. For light-duty passenger trucks, the EPA MOVES PM emission factors sharply decline while the remote sensing data show an increase in UV smoke averages.141 Though less significant, a similar trend is observed for passenger cars, with the

EPA MOVES PM emission factor continuing to decline after 2015 and remote sensing UV smoke averages showing a slight increase. These findings suggest that the modeled air quality and health benefits of the proposed rule may be underestimated when considering the large benefits of replacing 2015–2020 model year vehicles with future vehicles meeting the proposed PM emission limits. [EPA-HQ-OAR-2022-0829-0569, pp. 53-54]

140 EPA MOVES emission factors are converted from fuel-specific to distance-specific emission factors for this comparison. This is done using real-world fuel economy data from EPA Automotive Trends report, the same source used to convert the remote sensing emissions from fuel-specific to distance-specific.

141 Light-duty passenger truck emission trends from EPA MOVES are compared to light-duty truck (LDT) emission trends from remote sensing data. Similarly, passenger car emission trends from EPA MOVES are compared to light-duty vehicle (LDV) emission trends from remote sensing data.

SEE ORIGINAL COMMENT FOR Figure 15. Percent change in distance-specific PM emission factor from EPA MOVES and remote sensing (RS) UV smoke measurements from Colorado (CO) and Virginia (VA) sources by model year, compared to model year 2005. [EPA-HQ-OAR-2022-0829-0569, pp. 53-54]

Organization: Reginald Modlin and B. Reid Detchon

2. EPA’s modeling – Part 2

a. EPA's Motor Vehicle Emission Simulator (MOVES) is a modeling system that estimates emissions for mobile sources at the national, county, and project level for criteria air pollutants, greenhouse gases, and air toxics. Its use is required for the development of State Implementation Plans to reduce air pollution in areas that do not meet National Ambient Air Quality Standards. [EPA-HQ-OAR-2022-0829-0570, p. 29]

i. In 2014 EPA updated the MOVES model to incorporate new emissions factors for ethanol blends. These changes were based on a laboratory analysis that used “match blending” to simulate the performance of various fuel formulas. This approach was fundamentally flawed, as a published paper by industry engineers observed: [EPA-HQ-OAR-2022-0829-0570, p. 29]

1. Aromatics were added (above the 25% legal limit for reformulated gasoline) to match certain parameters of fuels that had less ethanol. The resulting degradation of emissions was primarily caused by the added aromatics but was incorrectly blamed on the ethanol. [EPA-HQ-OAR-2022-0829-0570, p. 29]

148 James E. Anderson et al., "Issues with T50 and T90 as Match Criteria for Ethanol-Gasoline Blends," SAE International Journal of Fuels and Lubricants (2014): 7(3): pp. 1027-40: https://saemobilus.sae.org/content/2014-01-9080/ (accessed Feb. 24, 2021).

2. This mistake causes the MOVES model to predict incorrectly elevated emissions factors for ethanol blends. For example, smog-forming nitrogen oxides (NOx) have been shown in the real world to decrease as the percentage of ethanol increases, but the MOVES model predicts higher NOx emissions for ethanol blends. [EPA-HQ-OAR-2022-0829-0570, p. 29]

149 Ioannis Gravalos et al., "Performance and Emission Characteristics of Spark Ignition Engine Fuelled with Ethanol and Methanol Gasoline Blended Fuels," chapter 7, Alternative Fuel, Maximino Manzanera (ed.) (2011): p. 170: https://www.researchgate.net/publication/221914443_Performance_and_Emission_Characteristics_of_Spar

k_Ignition_Engine_Fuelled_with_Ethanol_and_Methanol_Gasoline_Blended_Fuels (accessed Feb. 24, 2021).

3. In fact, EPA's Phase I testing results showed that NOx and PM "have significant decreases in emissions as ethanol levels increase from E0 to E10" – and EPA then "decided to drop the Phase 1 test fuels … from the Phase 3 fuel matrix." [EPA-HQ-OAR-2022-0829-0570, p. 30]

150 Adam R.F. Gustafson, Boyden Gray & Associates, "EPA Emails Show the Agency Relied on the Oil Industry to Design Anti-Ethanol Fuel Effects Study," memo to Urban Air Initiative, Nov. 4, 2016: pp. 15, 17: http://cleanfuelsdc.org/wp-content/uploads/2019/04/BGA-FOIA-EPA-EPact-Emails-Nov-4-2016.pdf (accessed Sept. 14, 2021)

4. At a meeting in June 2015 with the Energy Future Coalition, EPA Administrator Gina McCarthy erroneously asserted that her hands were tied on mid-level ethanol blends because they would increase NOx – a comment probably based on the flawed tests and the MOVES model. [EPA-HQ-OAR-2022-0829-0570, p. 30]

151 Reid Detchon, Energy Future Coalition, personal recollection.

ii. Emissions tests by the U.S. Department of Energy have confirmed that "even though ethanol is more catalytically reactive than other gasoline components, ethanol will likely neither help nor hinder compliance with NOx, non-methane organic gases (NMOG), and CO regulations in realistic fuel blends." [EPA-HQ-OAR-2022-0829-0570, p. 30]

152 Daniel Gaspar, Pacific Northwest National Laboratory, "Top Ten Blendstocks For Turbocharged Gasoline Engines: Bioblendstocks With Potential to Deliver the Highest Engine Efficiency." PNNL-28713 (2019): p. 34: https://www.osti.gov/servlets/purl/1567705 (accessed June 22, 2021).

iii. Despite repeated calls to fix this clear error, EPA has not done so. [EPA-HQ-OAR-2022-0829-0570, p. 30]

Organization: Wisconsin Department of Natural Resources

8. Incorporation of standards into the Motor Vehicle Emission Simulator (MOVES). EPA should ensure these standards, when finalized, are incorporated into the MOVES emissions model as soon as possible so that they can be reflected in the regulatory modeling associated with state implementation plans and transportation conformity. EPA should also consider if additional MOVES guidance is necessary to address situations in which an individual state's future on-road electric vehicle penetration ends up differing substantially from those on which these standards are based. [EPA-HQ-OAR-2022-0829-0507, p. 3]

EPA Summary and Response

Summary:

One commenter states that EPA should consider lifetime average exhaust particulate filter efficiency (not just efficiency on new vehicles) in estimates of related emission benefits.

Other commenters state that the MOVES model incorrectly predicts increases in particulates and other emissions for mid-level ethanol blends compared to E10 gasoline. They also suggest this situation has contributed to avoidance of regulatory actions that should have imposed limits on the aromatic content (referred to as BTEX) in market gasoline, which in turn could have reduced emissions of a range of toxic pollutants including compounds known to form secondary organic aerosols. Some commenters attribute these problems with MOVES to an emissions study (known as EPAct) using test fuels that didn't represent real-world gasoline formulations. A commenter asserts that this issue has been brought to EPA's attention in the past, but EPA has not made corrections to the MOVES model.

One commenter states that EPA's MOVES model underestimates exhaust particulate matter emissions from recent light duty vehicles.

Another commenter asks if EPA should consider changes to EPA guidance on using MOVES.

Response:

We thank the commenters for their review of the proposed program. With regard to the comment on lifetime particulate filter efficiency, while we do not yet have data on the effectiveness of future gasoline particulate filters over the full life of in-use vehicles, we do know that filtration efficiency increases rapidly in the first ~1,500 miles and then increases slowly after that. At the same time, gasoline engines typically produce more particulate matter as they age, and there will be some GPF removal, tampering and damage with age. Considering all these factors, the net PM is likely fairly stable after the first 1,500 miles, which implies an increasing percent filter effectiveness. The modeling done in the regulatory analysis applied a constant percent filter effectiveness to all MOVES ages, and thus may have underestimated the GPF benefits for older vehicles.

We have responded to the comments related to the EPAct study and its application in MOVES in multiple documents over the past several years. Regarding the central issue of the design and conduct of the EPAct study, it was not intended to only assess the effects of incremental increases in ethanol but changes in multiple fuel parameters separately or together so that it could be applied to a wide range of gasoline formulations found in the market. The multivariate parametric treatment design used in the EPAct fuel matrix reflects a standard practice across a wide range of scientific disciplines. Additional responses to specific comments on the EPAct study are covered at length in Section 3 of a document entitled "*Agency Response to Request for Correction of Information Petition #17001 Concerning the EPAct/V2/E-89 Fuel Effects Study and the Motor Vehicle Emissions Simulator (MOVES2014)*" available via the EPA website and in this rulemaking docket.[469]

Regarding the comments about BTEX, imposing limits on BTEX in gasoline would force refiners to reformulate their gasoline to use other high-octane components, one of which may be additional ethanol. Understanding the impact of such reformulations on overall air quality would necessarily include changes in a broad range of vehicle emissions (including refueling and evaporative processes), as well as changes in petroleum refining and increases in ethanol production and agricultural intensity. These things may reduce the overall air quality benefits significantly. We are not aware of any analyses integrating all these pieces at this time, and such work is beyond the scope of this final rule. The CAA imposes a significantly different regulatory regime for regulating fuels under 211(c), and EPA solicited comment on potential changes to fuels regulations but did not propose changes.

---

[469] Available at https://www.epa.gov/sites/default/files/2018-09/documents/ethanol-related_request_for_correction_combined_aug_31_2018.pdf

We understand that new data on fuel properties and their effects on emissions are being generated continuously, and through a process of ongoing and deliberate review, we update the MOVES model when the weight of evidence warrants. As described in Section IX of the proposal, as part of a separate, potential future action, we are considering a potential limit on heavy aromatics in market gasoline, which could reduce particulate emissions and other pollutant precursors in many areas of the country.

With regards to concerns that MOVES may underestimate exhaust particulate emissions from recent light duty vehicles, the ICCT analysis seems to have been done with an earlier version of MOVES. The MOVES3.R1 version used to support the NPRM was revised from MOVES3 to better account for the phase-in of vehicles with gasoline direct injection engines. For more information see NPRM Docket Memo " Updates to MOVES for the Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles," FROM: Megan Beardsley, Environmental Scientist, Assessment and Standards Division, Office of Transportation and Air Quality, TO: Docket Number EPA-HQ-OAR-2022-0829, DATE: February 10, 2023, and Section 4 of Exhaust Emission Rates for Light-Duty Onroad Vehicles in MOVES4 (pdf) (8.5 MB, August 2023, EPA-420-R-23-028). Also, it is not clear how the ICCT analysis accounts for vehicle age. The cited ICCT report says that the data summarized in the figure was collected over the calendar years from 2015 to 2021, implying that the data points for older model years represent average values across a range of MOVES age bins. Presumably, the MOVES emissions shown in the figure are for a single calendar year and thus incorporate deterioration factors that increase with age (and decline with model year). That means the graph shared in the comment is not comparing like quantities. Nevertheless, if additional analysis confirms the commenter's claim that MOVES has underestimated the emissions from light-duty vehicles, this would further support the need for more stringent PM controls as finalized in this rule.

With regards to MOVES guidance, the MOVES4 Technical Guidance: Using MOVES to Prepare Emission Inventories for State Implementation Plans and Transportation Conformity included in the docket for this rulemaking provides guidance on how to forecast future on-road electric vehicle fractions. If needed, we will update this guidance for future MOVES versions.

12.5.2 – [Reserved]

12.5.3 – Compliance modeling pathways

Comments by Organizations

Organization: Alliance for Automotive Innovation

A de facto battery electric vehicle mandate

Our concerns cover both the GHG requirements and the criteria emission requirements. Taken together, the proposed GHG and criteria pollutant standards are so stringent as to set a de facto BEV mandate. [EPA-HQ-OAR-2022-0829-0701, p. 3]

Auto Innovators is concerned that the proposed standards leave little or no room for error to address foreseen and unforeseen challenges and overestimates the potential for the EV market to develop as rapidly as EPA assumes – effectively 10x greater BEV market share than in 2022. In the past, multiple technologies were available for manufacturers to pick from or to fall back on if a chosen technology encountered technical or market issues. For example, for a short time, some manufacturers applied dual clutch transmission technology and then moved on to advanced planetary gear automatic transmissions due to customer acceptance issues. Some engine stop-start systems also encountered challenges, slowing their anticipated roll-out. [EPA-HQ-OAR-2022-0829-0701, p. 89]

In the case of emissions standards largely premised on zero-emission vehicles, such as EPA's proposed rule, there is no such fallback. By 2032, under the proposed standards, only EVs are likely to meet their individual footprint-based targets. [EPA-HQ-OAR-2022-0829-0701, p. 89]

Organization: American Fuel & Petrochemical Manufacturers

Despite EPA's assertions that the standards are technology-neutral, the reality is the proposed tailpipe-only approach is a de facto ban on ICEVs. AFPM does not oppose electric vehicles comprising an increasing share of the transportation mix, but we oppose regulations that are framed to ultimately ban ICEVs. EPA should establish standards, based on the full lifecycle of each vehicle class, that are achievable by each powertrain technology. ICEVs will continue to have a place in a diverse transportation future. This approach was summarized well in a 2021 report from the National Academies of Science [EPA-HQ-OAR-2022-0829-0733, p. 3]

In addition, by factoring in ZEV performance into standards broadly applicable to both ZEV and non-ZEV, utilizing averaging, EPA is ignoring the technological feasibility of emissions-related systems and simply requiring the production of fewer ICEVs. This approach also ignores the fact that major automakers are on differing technological paths, as noted by the National Academies of Sciences, "with some focusing their research and development and advanced technology deployment more squarely on ZEVs, and others more focused on advanced HEVs to maximize ICE efficiency."88 During the last two years, 17,000 research articles were published that focus on improving ICEVs or lowering their carbon footprint with liquid fuel technologies, such as lower carbon fuel production technologies, the substitution of lower carbon feedstocks and lower carbon fuels, and by optimizing fuel properties like octane.89 Instead of focusing on advances to ICEV technologies when setting the standards, the Proposed Rule relies on ZEVs as the only relevant advanced technology, which is arbitrary and capricious given that many ICEV technologies, unlike mass adoption of ZEVs, "permit the development and application of the requisite technology" within the time necessary to comply with the forthcoming standards.90 [EPA-HQ-OAR-2022-0829-0733, pp. 22-23]

88 National Academies of Sciences, Engineering, and Medicine. 2021. Assessment of Technologies for Improving Light-Duty Vehicle Fuel Economy—2025-2035. Washington, DC: The National Academies Press. p. 369. https://doi.org/10.17226/26092.

89 Fuels Institute. Literature Review Summary: Future Capabilities of Combustion Engines and Liquid Fuels. Nov. 2022.

90 42 U.S.C.(a).

Organization: American Honda Motor Co., Inc.

Unlike with previous automotive emissions regulations, in which an OEM had numerous compliance technology pathways and could strategically invest in a package of technologies that best suited its customers' needs, this proposal sets stringencies at such a level where there is just one way to comply: significant levels of electrification. Yet should the market not pan out within the agency's ambitious timeline – even for reasons entirely beyond an automaker's control, such as a slower-than-expected rollout of public charging infrastructure that has a chilling effect on consumer interest in EVs – there is no safety net, no alternate package of technologies to which an OEM can pivot and maintain compliance. Regulated parties will simply fall short, facing a profoundly disruptive and costly set of noncompliance obligations. [EPA-HQ-OAR-2022-0829-0652, p. 5]

In fairness, it is reasonable for the agency to consider announced industry targets as evidence of automakers' meaningful shift toward an electric portfolio. Similarly, however, it is equally reasonable to expect that the agency also consider automakers' stated concerns – the availability and pricing of critical minerals, the availability of sufficient domestic battery production capacity, the availability and reliability of public charging infrastructure and today's comparatively modest consumer uptake of EVs that falls well short of the agency's high expectations for only a few years down the line. In our view, the agency has not adequately addressed the above noted concerns, or properly accounted for them in its standard-setting process. [EPA-HQ-OAR-2022-0829-0652, p. 22]

Organization: American Petroleum Institute (API)

iii. Non-electrification solutions.

EPA's analysis is flawed in that it failed to account for non-electrification solutions. [EPA-HQ-OAR-2022-0829-0641, pp. 9-10]

1. Technology neutrality – all solutions should be allowed to compete.

In the preamble to the proposed rule, EPA states that "[t]he proposed standards are performance based and do not mandate any specific technology for any manufacturer or any vehicle type" and "[e]ach manufacturer is free to choose its own set of technologies with which it will demonstrate compliance…".20 We disagree, as the stringency of the proposed standards – and even the technology mixes suggested by EPA in the proposal – essentially forces manufacturers to solely focus development efforts on BEVs. [EPA-HQ-OAR-2022-0829-0641, pp. 9-10]

20 88 Fed. Reg. 29329 (May 5, 2023).

Although EPA asserts that the proposed rule standards do not mandate any specific technology, EPA demonstrates compliance with its proposed standards by modeling new light-duty BEV sales that increase from 36% in 2027 to 67% in 2032. That means, within 5 years, the ratio of new BEV sales to total sales will increase from one third to two thirds of new car sales. For the MDV category, EPA21 modelled compliance with average new sales reaching 46% in 2032, up from 17% in 2027. EPA modeling relies heavily on the electrification of vans, which reaches 98% by 2032. These compliance projections are much higher than sales of battery electric MDVs in 2020 of less than 1 percent.22 [EPA-HQ-OAR-2022-0829-0641, pp. 9-10]

21 88 Fed. Reg. 29331 (May 5, 2023).

22 Table 3-1. "Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles - Draft Regulatory Impact Analysis", EPA-420-D-23-003. April 2023.

API strongly believes in an all-of-the-above strategy to reducing emissions, and we recommend that EPA adjust the standards to allow all solutions the ability to compete. Further, doing so would provide more time for other technologies to be proven with less risk to vehicle original equipment manufacturers (OEMs) and the public if electrification expansion of LMDVs does not pan out in the proposal's implementation timeframe. [EPA-HQ-OAR-2022-0829-0641, pp. 9-10]

To that end, various studies have highlighted the importance of allowing all technologies to be utilized to reduce emissions faster, more effectively, and at a lower cost.23,24 By limiting the scope to tailpipe emissions, the proposal is inherently not technology neutral. Setting strict tailpipe-only standards results in a limited, prescribed solution set. [EPA-HQ-OAR-2022-0829-0641, pp. 9-10]

e. API Supports Consumer Choice for Vehicles.

API 53 supports the concept that different vehicle technologies that reduce greenhouse gas emissions should be allowed to compete equally for consumer and market acceptance and growth. However, API has concerns with regards to the EPA's approach and its effect on consumer choice. [EPA-HQ-OAR-2022-0829-0641, pp. 18-19]

53 https://www.api.org/news-policy-and-issues/blog/2021/05/18/us-consumers-need-balance-choice-in-transportation-policy.

The stringency of the proposed standard is essentially forcing electrification of the transportation sector and is not in alignment with most Americans that, according to a Pew Center survey,54 favor "using a mix of energy sources to meet the country's needs" and a majority of survey respondents oppose phasing out gasoline powered vehicles by 2035. Concerns with charging availability55 could be relieved with vehicle technologies (e.g., PHEVs56) where the length of an average daily trip is approximately 30 miles.57 [EPA-HQ-OAR-2022-0829-0641, pp. 18-19]

56 EPA is proposing a fleet utility factor (FUF) curve that will increase CO2 compliance values for PHEVs. 88 Fed. Reg. 292557 (May 5, 2023).

57 2019 Bureau of Transportation data indicates 49% of 2019 national trips by distance were less 25 miles.

Organization: BlueGreen Alliance (BGA)

And while automakers will certainly need to produce and sell zero-emission vehicles to meet the standards laid out in EPA's range of proposals, the standards are ultimately performance-based, which means that manufacturers can leverage a range of pollution-reducing technologies to help bring their fleets into compliance with both the GHG emissions standards and the local pollutant emissions standards within the proposals. These technologies include plug-in hybrids, waste heat recovery systems, aerodynamics, lightweighting, and gas particulate filters (GPFs). [EPA-HQ-OAR-2022-0829-0667, pp. 4-5]

The range of EPA's proposals effectively advances research, development and deployment of zero-emission technologies like those in battery electric and fuel cell vehicles, while also pushing other pollution reducing technologies. The tech-forcing and tech-agnostic nature of EPA's proposals means that the standards have the potential to create and protect domestic manufacturing jobs in a diverse range of facilities, from those producing battery components for plug-in hybrids to those making gas particulate filters for pickup trucks (see Figure 3). A standard that advances the deployment of zero emission and tailpipe pollution-reducing technologies provides manufacturers with ample flexibility as they determine how they will meet the requirements, while also maximizing the standards' potential to create and protect jobs in the domestic automotive supply chain. [EPA-HQ-OAR-2022-0829-0667, pp. 4-5]

Organization: BorgWarner Inc.

BorgWarner supports performance-based regulations and opposes technology mandates.

We advise regulators to develop standards that are technology neutral and performance-based to encourage innovation.5 All technology pathways with practical applications should be included as potential solutions to assist the U.S. in achieving its environmental goals. Regulations based on the end goals of a clean environment, minimizing CO2 emissions, and preserving resources should not give preferential treatment to a specific technology. Public policies should let innovation and market dynamics determine the most effective solutions. [EPA-HQ-OAR-2022-0829-0640, p. 6]

5 See BorgWarner Comments EPA-HQ-OAR-2019-0055; FRL-7165-03-OAR.

HEV, PHEV, BEVs, FCEVs, and H2ICE all have strengths depending on the use case, and regulators must enable every technology solution to reduce GHG emissions as fast as possible. EPA has demonstrated an enthusiasm for BEV and FCEV technologies, and we urge EPA to include pathways for all technologies in its clean transportation strategy. [EPA-HQ-OAR-2022-0829-0640, p. 6]

Organization: California Air Resources Board (CARB) (Part 1 of 5)

While the proposal is technology-neutral, U.S. EPA's modeling shows that ZEVs will in many cases be the most likely pathway to comply with the standards. Indeed, ZEVs can simultaneously reduce greenhouse gas (GHG), toxic air contaminant, and criteria air pollutant emissions while saving consumers money. Consumers have more choices than ever, and ZEVs are increasingly capable of functioning equivalently to their conventional gasoline- and diesel-fueled counterparts. U.S. EPA has also rightly recognized the availability of improved technologies to control emissions from conventional internal combustion engine vehicles, and the proposed standards will help maintain emission benefits from these vehicles that will remain on the road. [EPA-HQ-OAR-2022-0829-0780, pp. 7-8]

Organization: Competitive Enterprise Institute

The MY 2023-2026 standards are estimated to increase EV market penetration "from about 7 percent market share in MY 2023 (including both fully electric vehicles (EVs) and plug-in hybrid vehicles (PHEVs)) up to about 17 percent in MY 2026."10 The EPA acknowledges that the standards coerce increased EV sales, as that is the only way automakers can comply: "Compliance with the final standards will necessitate greater implementation and pace of technology penetration through MY 2026 using existing GHG reduction technologies, including further deployment of BEV and PHEV technologies." 11 [EPA-HQ-OAR-2022-0829-0611, p. 4]

11 86 FR 74493 (emphasis added). See also 86 FR 74484 ("This is a greater penetration of BEVs and PHEVs than projected in the proposed rule, and is driven by several factors, including the increased stringency of our final standards….") and 86 FR 74485 ("Our updated analysis projects that the final rule can be met with a fleet that achieves a gradually increasing market share of EVs and PHEVs….")

Organization: Consumer Reports (CR)

2.1. Automakers Have Multiple Options for Compliance

EPA's proposal for MY27+ Light- and Medium-Duty vehicle GHG standards are strong, achievable, technology-neutral performance standards. EPA's analysis found that electric vehicles (EVs) are likely to be the most cost-effective compliance pathway for automakers to meet these standards, but they are not the only option. EPA estimated that an EV-only compliance pathway would require 67% of vehicles sold to be EVs by 2032. However, automakers can also use a mix of improvements in internal combustion engine (ICE) fuel efficiency, conventional hybrids, plug-in hybrids (PHEV), and even hydrogen fuel cell electric vehicles (FCEV) to comply with these standards. CR's modeling presented in Section 6.2 shows that automakers can utilize a wide range of options to comply with these rules. Most automakers will be able to comply with these rules while only selling between 50-60% battery electric vehicles (BEVs) by using a mix of widely available and cost effective technologies. Automakers that invest heavily in conventional and plug-in hybrids will be able to comply while selling as few as 40% BEVs in 2032. [EPA-HQ-OAR-2022-0829-0728, pp. 7-8]

6.2. Modeling of Compliance Pathways

EPA's compliance modeling estimates the single most cost-effective compliance pathway for the vehicle fleet under the proposed regulation. However, it is not the only possible compliance pathway automakers can take. Different automakers are likely to take wildly different compliance pathways, with some automakers going all in on EVs, while other automakers may hedge their bets with more hybrids and PHEVs. [EPA-HQ-OAR-2022-0829-0728, pp. 20-21]

CR modeled a range of reasonable alternative compliance pathways that automakers might consider. The modeling considers different levels of continued ICE improvement and deployment of PHEVs as a percentage of all plug-in vehicles.43 The results of this analysis for model year 2032 are shown in Table 6.1. They show that a wide range of compliance pathways are available to automakers that can reduce the required BEV sales market share for model year 2032 to between 50-60% with varying levels of ICE improvement and PHEV deployment. There is even a feasible compliance option which would allow compliance with only 40% BEVs with heavy investment in hybrid and PHEV technology. [EPA-HQ-OAR-2022-0829-0728, pp. 20-21]

43 ICE improvements of 1% (low), 3.5% (medium) and 5% (high) are modeled. PHEV market share was modeled as a percentage of all plug-in vehicles with values of 0%, 10%, 20% and 40% modeled.

[See original comment for Table 6.1 - Modeling of Compliance Alternatives for EPA's Proposed Standards for MY2032] [EPA-HQ-OAR-2022-0829-0728, pp. 20-21]

A few scenarios were also modeled for EPA's Alternative 1. These results are shown in Table 6.2. They find that with only a small improvement in ICE vehicles (1% per year reduction in emissions), automakers can comply with these stronger standards with a minimal increase in BEV market share from 67% to 68% compared to EPA's modeling of the proposed standards. Further reductions in BEV market share are also possible with further investment in ICE improvement and PHEV deployment. [EPA-HQ-OAR-2022-0829-0728, pp. 20-21]

[See original comment for Table 6.2 - Modeling of Compliance Alternatives for EPA's Alternative 1 for MY 2032] [EPA-HQ-OAR-2022-0829-0728, pp. 20-21]

Overall these results show that automakers have many potential reasonable compliance pathways to comply with either EPA's proposed standards or the stronger Alternative 1. [EPA-HQ-OAR-2022-0829-0728, pp. 20-21]

Organization: Energy Innovation

Ultimately, though, increased adoption of BEVs is the most expedient and effective way to eliminate harmful tailpipe pollutants. We encourage the EPA to push the auto industry to reduce all emissions more rapidly through the adoption of BEVs. [EPA-HQ-OAR-2022-0829-0561, p. 7]

Organization: Environmental Defense Fund (EDF) (1of 2)

Because EPA's OMEGA 2 model is designed to show only the most cost-effective compliance pathways, it does not capture the full range of possible pathways automakers may choose to take based on the numerous factors that influence product lines. To demonstrate that the standards can be met with a range of technologies (including increased deployment of PHEVs), EDF contracted with Roush to project the relative cost of PHEVs and BEVs in the 2024-2035 timeframe.27 EDF then used Roush's cost projections for PHEVs in conjunction with EPA's costs for BEVs and ICEVs to conduct an analysis of compliance costs under possible scenarios in which PHEV and ICEV sales represent a greater proportional share of manufacturers' sales than EPA modeled while still meeting the GHG emissions targets set in EPA's proposal. [EPA-HQ-OAR-2022-0829-0786, pp. 12-13]

27 Vishnu Nair, Himanshu Saxena, Sajit Pillai, Alternative Powertrain Pathways for Light-Duty and Class 3 Vehicles for MYs 2024, 2027, and 2035 to Meet Future CO2 Emission Targets, Roush for EDF (June 2023). (Attachment L)

EDF evaluated 3 alternative pathways towards compliance with EPA's proposed standards:

- Pathway 1 (ICEV Pathway): assumes the greatest possible GHG control from ICEVs using EPA's OMEGA 2 model; assumes no PHEV technologies [EPA-HQ-OAR-2022-0829-0786, pp. 12-13]

- Pathway 2: sets PHEV and BEV sales to roughly equivalent levels leaving ICEV emissions at the level projected in EPA's compliance simulation of its proposed standards [EPA-HQ-OAR-2022-0829-0786, pp. 12-13]

- Pathway 3: increases PHEV sales further than Pathway 2 by maximizing ICEV emission controls as in Pathway 1 [EPA-HQ-OAR-2022-0829-0786, pp. 12-13]

Because Pathway 1 does not assume PHEV deployment, EDF was able to model it using EPA's OMEGA 2 model directly. EDF constrained battery availability in the model to limit BEV sales so that the model would apply more ICEV control technology than EPA modeled.28 By running OMEGA 2 multiple times with various battery capacity caps, we found that limiting annual battery capacity to 954 GWh produced the lowest ICEV emissions while still enabling compliance with the proposed standards. ICEV emissions averaged 205 g/mi and represented 40% of new vehicle sales, with BEVs accounting for the remaining 60 percent. These ICEV emissions were 18% lower than in EPA's simulation, while ICEV sales were 7% higher. [EPA-HQ-OAR-2022-0829-0786, pp. 12-13]

28 The ICEV pathway required both ICEV control and increased BEV sales. Since increased BEV sales are generally more cost effective than reducing ICEV emissions, the only way to force OMEGA 2 to apply more ICEV control was to limit BEV sales. This was done by reducing the total battery capacity available to manufacturers per model year, which is input to the model on line 67 of the batch file.

Recent work performed by the ICCT is consistent with these findings and indicates that even greater levels of ICEV greenhouse gas control could offset BEV sales.29 The ICCT projected that manufacturers could reduce MY 2022 emissions by 25-37% in the 2030-2035 timeframe.30 This is 2-18% more than the potential reduction we found using OMEGA 2 above. This greater degree of ICEV emissions reduction would reduce the number of BEVs required to meet the proposed 2032 GHG standards to as low as 50%, significantly lower than the 60% level EDF modeled above. Moreover, neither EDF's nor ICCTs ICEV analysis separately accounts for the role of PHEVs could play.31 [EPA-HQ-OAR-2022-0829-0786, pp. 12-13]

29 Slowik, Peter, Aaron Isenstadt, Logan Pierce, Stephanie Searle, White Paper, "Assessment of Light-Duty Electric Vehicle Costs and Consumer Benefits in the United States in the 2022–2035 Time Frame," The International Counsel on Clean Technologies (2022), https://theicct.org/wp-content/uploads/2022/10/ev-cost-benefits-2035- oct22.pdf (Attachment M).

30 Id.

31 Some manufacturers, including Toyota, have indicated that they will rely more heavily on PHEVs for emissions reductions. Peter Johnson, Toyota's New CEO Adjusts EV Plans but Sticks to a Hybrid Approach, electrek (Apr. 7, 2023), https://electrek.co/2023/04/07/toyotas-new-ceo-adjusts-ev-plans-but-sticks-to-a-hybrid-approach/. Adjusts EV Plans but Sticks to a Hybrid Approach

For Pathways 2 and 3, we evaluated the role PHEVs could play either in isolation (Pathway 2) or in combination with ICEVs (Pathway 3) in allowing manufacturers to meet the standards and, as a consequence, sell fewer BEVs. EPA discusses PHEV technology in its proposal and includes several aspects of PHEV technology in the OMEGA 2 input files. However, the model does not appear to allow the selection of PHEV technology as a compliance pathway. Thus, EDF used estimates of the emissions and cost of PHEVs to adjust OMEGA 2 projections outside of the model. We assumed PHEVs would have an onroad all-electric range of 50 miles, as this is the effective minimum onroad range allowable for a PHEV to qualify as a ZEV under California's Advanced Clean Cars II program. While this is the type of PHEV EDF chose to use in its modeling, vehicle manufacturers would be free under EPA regulations to choose the best mix of PHEV ranges which still met the GHG standards. [EPA-HQ-OAR-2022-0829-0786, pp. 12-13]

Using EPA's proposed formula for calculating a vehicle model's utility factor (UF)—the split of a PHEV's driving between gasoline and electricity—the UF for a PHEV50 is about 0.67. This means that 67% of a PHEV50's mileage is performed using electricity and 33% of its mileage uses gasoline. In terms of CO2 emissions, a PHEV50 can be considered equivalent to two-thirds of a BEV and one-third of a strong hybrid ICEV. EDF further assumed that the GHG performance of a PHEV50 while operating on gasoline would be 205 g/mi, the same level as described in the ICEV control-focused run above.32 [EPA-HQ-OAR-2022-0829-0786, pp. 13-15]

32 Since PHEVs are required to meet the same criteria pollutant emission standards as ICEVs when operating on gasoline, substituting PHEVs for BEVs at equivalent fleetwide GHG levels has no impact on criteria pollutant emissions.

PHEVs cost more than BEVs due to requiring both electric and gasoline powertrains. Because the OMEGA 2 output did not project costs for complete PHEVs, we used the incremental cost difference between Roush's BEV and PHEV50 costs and applied that difference to EPA's BEV costs to derive projected PHEV costs.33 On a sales-weighted basis, considering the difference in electrification costs across vehicle segments and the types of vehicles that OMEGA2 is projecting to become electrified, we found that the average incremental PHEV50 cost, absent IRA vehicle tax credits, was $6,700 in MY 2032 relative to a BEV.34 Following EPA's methodology for applying the IRA vehicle tax credits, we included the credit for the additional number of BEV plus PHEV sales in each pathway, as EPA had already accounted for the tax credits available for BEVs projected in their analysis. [EPA-HQ-OAR-2022-0829-0786, pp. 13-15]

33 Roush's BEV costs are lower than EPA's, so we took this approach in lieu of substituting Roush's costs for both BEVs and PHEV50s.

34 Based on interpolation between costs in MY 2027 and MY 2035.

As the Table shows, manufacturers choosing to comply with increased application of ICEV control technology (per OMEGA 2) (Pathway 1) could reduce the need for BEV sales by 7% in 2032. Average vehicle costs increase to $800 after IRA credits which is more than offset by vehicle savings principally in the form of less fuel usage. Likewise, cumulative net benefits still exceed one trillion dollars. [EPA-HQ-OAR-2022-0829-0786, p. 15]

Manufacturers choosing to comply by adding PHEVs (either on their own or in combination with ICEV improvements) (Pathway 2 or 3) could further reduce BEV sales in 2032 to be anywhere from 31-38% and remain compliant with the standards. These are well below EPA's projected level of 67% in the least cost BEV-only pathway. Per vehicle costs increase to $1,850-$2,900, though still well below operation savings. Cumulative net benefits decrease significantly, but remain above zero due to the relatively high vehicle operation savings. [EPA-HQ-OAR-2022-0829-0786, p. 15]

In summary, EDF's modeling, plus ICCT's projections of manufacturers' capability in reducing CO2 emissions from ICEVs, provides three viable examples of compliance pathways automakers could choose to take—one reliant on ICEVs, one on PHEV controls and the third on both—all of which demonstrate the flexibility afforded manufacturers to cost-effectively reduce emissions using a mix of technologies with lesser reliance on BEV sales than is shown in EPA's modeling. Of course, these are illustrative compliance pathways, and manufacturers could choose to rely on a combination of ICEV improvements and PHEV sales in a manner that would provide yet further cost-effective options to meet EPA's standards. [EPA-HQ-OAR-2022-0829-0786, p. 15]

Organization: Environmental. and Public Health Organizations

5. Automakers can feasibly and inexpensively improve combustion vehicle emissions simply by shifting sales to the cleanest trims of popular models.

Yet another pathway that automakers could use to comply with stronger standards lies in shifting their sales to the cleanest trims of their popular combustion vehicle models. In 2022, 8.6 million sales – more than half of all new automotive sales – were from just twelve combustion vehicle nameplates. These top-selling vehicles were sold by five automakers: Ford, General Motors, Honda, Stellantis, Toyota. Within each nameplate, the automakers provided different powertrain options (such as engine size, transmission gearing, hybridization and other characteristics), and each had their own emissions performance – some better than others. These vehicle options are all in production, and selling more of any one powertrain could lead to reductions in sales volumes of the same nameplate with a different powertrain. These changes in volumes within a nameplate are a regular feature of the automobile market. [EPA-HQ-OAR-2022-0829-0759, p. 47]

An automaker could improve the emissions performance of its vehicles simply by shifting sales within a nameplate to versions with cleaner powertrains. This shift could achieve emissions reductions without an investment in new emissions technologies or large-scale capital expenditures for factory retooling. Similar emissions improvements could also be achieved due to a consolidation or reduction in powertrain options as ZEVs replace sales of these combustion vehicle nameplates. [EPA-HQ-OAR-2022-0829-0759, p. 47]

We estimated the emissions savings that could be achieved by shifting production in a nameplate from the mix of powertrains sold in 2022 to the cleanest powertrain currently available in that nameplate. Table VI.A-5 shows the top-selling twelve nameplates analyzed and the emissions reductions that could be achieved. [EPA-HQ-OAR-2022-0829-0759, p. 47]

SEE ORIGINAL COMMENT FOR Table VI.A-5: Emissions Reductions in Top-Selling Nameplates by Focusing Sales on Cleaner Powertrains127 [EPA-HQ-OAR-2022-0829-0759, p. 48]

127 This analysis relies on sales estimates of each powertrain version within each nameplate and total sales per manufacturer provided by Baum & Associates. Emissions rates per nameplate version were accessed from www.fueleconomy.gov.

The high-volume nameplates analyzed comprise between 25% to 51% of each automaker's total sales in 2022. Adjusting sales within these nameplates toward the versions with the cleanest powertrains would provide significant emissions reductions. [EPA-HQ-OAR-2022-0829-0759, pp. 47-48]

Organization: Exxon Mobil Corporation

EPA's Proposal establishes standards for emissions reductions that can be achieved only through a rapid transformation of the transportation sector and through limited technology pathways. Specifically, the proposed standards could require as many as two-thirds of all new light-duty vehicle purchases to be battery electric vehicles (BEVs) by 2032. ExxonMobil believes BEVs will play an important role in reducing transportation sector emissions. Indeed, we produce plastics that can help reduce vehicle weight and increase fuel efficiency, butyl rubber that improves air retention in tires and can improve BEV range by up to 7 percent,6 and our Mobil EV™ suite of electric vehicle fluids and products help enable further, longer, and safer performance for electric cars, vans, and trucks.7 We believe, however, that EPA should encourage a diversity of technology pathways that allow for consumers to choose between vehicle types. Standards that encourage a combination of BEVs, plug-in hybrids, full hybrids, and efficient internal combustion engine vehicles, that could operate with bio and renewable fuels, are a better way to reduce GHG emissions and manage dependence on foreign critical minerals. Such a technology-neutral policy approach would foster innovation and competition across all technologies and could ultimately help encourage more effective and lower cost solutions for consumers and businesses. [EPA-HQ-OAR-2022-0829-0632, p. 2]

Organization: Growth Energy

Second, the proposed rule's stringency makes the impact of EPA's failure to consider both the upstream carbon sinks of biofuels and the upstream carbon emissions of EVs much greater. To date, EPA's tailpipe rules have incentivized EVs at the expense of other technologies, but they have done so in a manner that left room for other vehicles and fuels to play an important part in meeting the country's transportation needs. Today, EPA is putting all of its eggs in the EV basket. The only compliance scenario EPA discusses in the proposal would require more than two-thirds of all new vehicles to be EVs by 2032 (and, if it continues on its current trajectory, the percentage will presumably climb from there). That dramatic shift to EVs is fundamentally different than in prior rules. It disincentivizes biofuel use, even where biofuels could help reduce GHG emissions and be more suited to certain applications, like providing a low-carbon option in areas without sufficient charging infrastructure or with a carbon-intensive electric grid. [EPA-HQ-OAR-2022-0829-0580, p. 14]

Organization: Illinois Corn Growers Association

In the current rulemaking, there is only one technology that could achieve the standards in the current rulemaking: electric vehicles. EPA estimates that it will be necessary for automakers to electrify over half of the light and medium duty vehicles they produce and sell by the 2032 model year. This is less than nine years from now. [EPA-HQ-OAR-2022-0829-0756, p. 1]

Moreover, successful electrification of the transportation sector involves sweeping changes in other sectors, such as power generation, energy distribution and the extraction of rare materials essential to making everything from bateries to computer chips. There is no guarantee these changes will be in place by 2032. [EPA-HQ-OAR-2022-0829-0756, p. 1]

The standards being proposed in the current rulemaking are at least as difficult to achieve as those promulgated by the U.S. Environmental Protection Agency (EPA) for criteria pollutants for the 1975 model year. Meeting those standards required the adoption of catalytic converters, unleaded gasoline detuned engines and ultimately on-board computer control. [EPA-HQ-OAR-2022-0829-0756, p. 2]

Today, EPA is proposing even more stringent standards for criteria pollutants and Carbon Dioxide (CO2), the most significant of the greenhouse gases that are altering the global climate. It is estimated that the rise in CO2 levels since the 1950’s has largely been the result of the burning of fossil fuels such as gasoline. [EPA-HQ-OAR-2022-0829-0756, p. 2]

[See original attachment for table titled “Table 1. Fuel Consumption Impact Due to Proposed Standards”] [EPA-HQ-OAR-2022-0829-0756, p. 2]

Table 1 is reproduced from EPA’s Draft Regulatory Impact Analysis for the proposed Multi-Pollutant Emissions Standards.1 According to this table, EPA expects the consumption of liquid fuel in the U.S. (primarily gasoline, diesel and biofuels) to drop by 50% and electrical use to increase by 110% as a result of these rules. Clearly this will result in sweeping changes to the transportation system even greater than the emission standards enacted in the 1970’s. [EPA-HQ-OAR-2022-0829-0756, p. 2]

1 “Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles Draft Regulatory Impact Analysis,” EPA-420-D-23-003 April 2023

In justifying the technological feasibility of the standards, the Technical Support Document3 supporting the rulemaking listed 34 technologies automakers could potentially use to comply with the standards. [EPA-HQ-OAR-2022-0829-0756, pp. 4-5]

3 “Draft Joint Technical Support Document: Proposed Rulemaking for 2017-2025 Light-Duty Vehicle Greenhouse Gas Emission Standards and Corporate Average Fuel Economy Standards Office of Transportation and Air Quality, U.S. Environmental Protection Agency and National Highway Trafic Safety Administration, U.S. Department of Transportation EPA- 420-D-11-901,November 2011

By contrast, in support of the proposed Multi-Pollutant Emissions Standards, EPA listed only 9 potential technologies that they believe could be employed to meet the proposed standards. As shown on Table 2, page 5, the twelve automakers with the most U.S. sales have already significantly adopted these technologies on the vehicles they are producing today. [EPA-HQ-OAR-2022-0829-0756, pp. 4-5]

For instance:

-9 of the 12 automakers have employed at least one of the technologies on 70% or more of their products sold in the U.S. [EPA-HQ-OAR-2022-0829-0756, pp. 4-5]

-5 of the 12 automakers have employed at least three of the technologies on at least 70% of their products sold in the U.S. [EPA-HQ-OAR-2022-0829-0756, pp. 4-5]

-One manufacturer has employed three of these technologies on over 90% of their products sold in the U.S. [EPA-HQ-OAR-2022-0829-0756, pp. 4-5]

It appears that automakers have already widely utilized those technologies that work best with their company's vehicles and powertrains while meeting the needs of their customers. Technologies that have not found favor with multiple manufacturers are likely to have been found to be ineffective, overly expensive or failure prone. [EPA-HQ-OAR-2022-0829-0756, pp. 4-5]

Organization: International Council on Clean Transportation (ICCT)

Potential technology penetration impacts of improved ICE technology adoption

With the above recommended adjustments to ICE technology costs and effectiveness, potential implementation of such technology on the MY2027-2032 ICEV fleet can result in significant reduction in tailpipe CO2 emissions from ICE vehicles. In its study of updated light-duty vehicle costs,107 ICCT assumed updated ICE technology adoption as described above would continue to provide ICEV improvement equivalent to 3.5% per year through at least 2032. Fuel savings with that level of improvement more than offset incremental technology cost. Starting from a 2022 fuel economy value of 27 mpg (328 g/mi), the overall real-world efficiency of the combustion light-duty vehicle fleet was 32 mpg (275 g/mi) in 2027 and 36 mpg (247 g/mi) in 2030 and 39 mpg (230 g/mi) in 2032. In total, over MY2027-2032, the net reduction in ICE tailpipe emissions is 16.4%. Applying that same annual improvement to the industry average car and truck ICE fleets as modeled for this proposed rule results in a total 16% reduction in ICE tailpipe emissions, reducing the reliance on BEVs as a compliance pathway. Specifically, we find that improvements in ICE efficiencies would reduce the projected BEV shares from 60% in 2030 to about 54%, and from 67% in 2032 to about 59%. In other words, the same GHG levels as proposed can be reached through improved ICE and fewer BEVs. [EPA-HQ-OAR-2022-0829-0569, pp. 40-43]

107 Slowik. P., Isenstadt, A., Pierce, L, Searle, S. (2022). Assessment of light-duty electric vehicle costs and consumer benefits in the United States in the 2022-2035 time frame. International Council on Clean Transportation. https://theicct.org/publication/ev-cost-benefits-2035-oct22/

Table 8 summarizes these and additional results under several ICE improvement pathways. The ICE fleet, as modeled in the proposal, shows a net increase in 2-cycle tailpipe emissions in MY2032 versus MY2027. The share of advanced ICE technology, especially mild and strong hybridization, changes little or even decreases within the ICE fleet. Updating the OMEGA model to reflect the full technology options and lower costs we detail above would lead to higher tailpipe GHG reductions from ICE vehicles and, consequently, lower shares of BEVs needed for any particular GHG standards scenario. As just one example, considering the low share of hybrids in the ICE fleet as modeled, there is considerable room for powertrain electrification. With the MHEV and HEV developments discussed above, deeper application of hybridization could yield total ICE improvements of 15%-30%, easily matching 3.5%/year or even 5%/year. The MY2032 ICE vehicles in these scenarios would emit 16%-22% lower CO2 emissions than the ICE vehicles modeled in the proposal. The resulting estimated BEV shares in 2032 could be

12%-20% lower than proposed. The availability of hybrid and other ICE technologies explored above further strengthens the case that automakers have a variety of technological pathways to pursue to meet the proposed standards and realize substantial ICE improvements. The potential impact on the future fleet composition in Table 8 is illustrative of this variety of pathways automakers can choose to meet the proposed targets. Incorporation of the above ICE technology changes into OMEGA and subsequent modeling runs are needed for precise estimates of projected impacts of the above-listed technology updates. [EPA-HQ-OAR-2022-0829-0569, pp. 40-43]

Organization: John Graham

we turn to our critique of EPA's NPRM, whose signature forecast is that the BEV share of new passenger vehicle demand will rise from 8% in early 2023 to 67% in model year 2032. During the same period, the share of HEVs in the new vehicle market will decline from about 10% to virtually zero. The penetration of MHEVs and PHEVs in 2032 will be so small that EPA does not even bother to quantify and report them. EPA would have the reader believe that the proposal is technologically neutral, and the dominance of BEVs in 2032 reflects the simple fact that BEVs are the most cost-effective propulsion technology. We respectfully disagree, as we explain below. [EPA-HQ-OAR-2022-0829-0585, p. 10]

Overall. The real-world marketplace is obviously receptive to HEV offerings. Is it plausible that manufacturers would add HEV systems to their models for just one generation, and then drop them before 2032 or even by 2027? This is what EPA's modeling finds. We believe the more likely explanation is that the inputs to -- and assumptions in -- EPA's OMEGA modeling are not accurate, in part due to outdated inputs for HEVs [EPA-HQ-OAR-2022-0829-0585, p. 15]

Organization: Letter Campaign, Ethanol Producers (7)

[The following letter was submitted by seven commenters; it is reproduced only once: Commonwealth Agri-Energy, LLC (EPA-HQ-OAR-2022-0829-0739). The other commenters are: Highwater Ethanol, LLC (EPA-HQ-OAR-2022-0829-0552), Heartland Corn Products (EPA-HQ-OAR-2022-0829-0622), Absolute Energy, LLC (EPA-HQ-OAR-2022-0829-0716), Trenton Agri Products LLC (EPA-HQ-OAR-2022-0829-0755), Western New York Energy LLC (EPA-HQ-OAR-2022-0829-0753), Southwest Iowa Renewable Energy LLC (EPA-HQ-OAR-2022-0829-0582)]

Commonwealth Agri-Energy, LLC appreciates the Biden administration's goals of increasing vehicle efficiency and reducing carbon emissions. That's why two years ago, we committed to achieving a net-zero carbon footprint for our ethanol plant by 2050 or sooner.1 [EPA-HQ-OAR-2022-0829-0739, p. 1]

1 Letter from RFA Member Companies to President Joe Biden. July 27, 2021. See more at https://ethanolrfa.org/pledge.

However, we firmly oppose regulatory approaches that arbitrarily favor certain technologies over others, which regrettably seems to be the case with this proposed rule. EPA's proposal would effectively force automakers to produce more battery electric vehicles and discourage them from pursuing other technologies that could achieve the same, or even better, environmental performance at a lower cost to American consumers. [EPA-HQ-OAR-2022-0829-0739, p. 1]

If our nation is to reach its goal of net-zero GHG emissions by mid-century, we will need cleaner, more efficient cars AND cleaner, more efficient fuels. To that end, we will need honest accounting using a full lifecycle approach that does not ignore upstream emissions. [EPA-HQ-OAR-2022-0829-0739, p. 2]

Protect Affordable Vehicles

The Biden Administration and climate change alarmists are moving swiftly to get rid of gas-fueled carsessentially through abolition. [EPA-HQ-OAR-2022-0829-1714]

The latest proposed rule from Biden's politiczed EPAs effectivly mandate that electric vehicles make up the majority of vehicles sold in America. [EPA-HQ-OAR-2022-0829-1714]

Because the limit would be so severe, it would force carmakers to ensure that two-thirds of the vehicles they sold were all-electric by 2032, or automakers will be forced to pay fines. Automakers buy credits or pay fines if they cannot meet the Corporate Average Fuel Equivalent (CAFE) requirements. [EPA-HQ-OAR-2022-0829-1714]

Stellantis, then known as Fiat Chrysler, paid $152.3 million in total CAFE fines for 2016 and 2017 and faces additional civil penalties. In 2022, NHTSA more than doubled CAFE penalties. [EPA-HQ-OAR-2022-0829-1714]

Essentially, the proposed regulations are depriving the American public of vehicle choice that most fits their lifestyle and could easily affect economic growth in this country by stifling transportation. This is especially true when only one-third of Americans would consider purchasing an electric vehicle. [EPA-HQ-OAR-2022-0829-1714]

Organization: Minnesota Biofuels Association

As proposed, the rule notably deviates from the traditional technology-neutral approach that EPA has historically taken when setting greenhouse gas emissions standards for motor vehicles. The rule effectively compels automakers to produce battery electric vehicles to the detriment of similar technologies that can achieve the same or better environmental performance. [EPA-HQ-OAR-2022-0829-0672, pp. 1-2]

Organization: Missouri Corn Growers Association (MCGA)

Proposed standards are not "technology neutral."

EPA claims the standards are "technology neutral," implying no favoritism toward a specific fuel or engine type. However, a straightforward reading of the rule paints a different story. Once implemented, the rule will play out as a federal directive to auto manufacturers to produce battery electric vehicles (BEVs). Auto manufacturers will face an impossible federal compliance and legal quagmire if they cannot substantially increase EV sales. To comply with the standards, the proposed rule estimates BEVs will comprise 67% of new passenger vehicle sales by 2032 and 46% of medium-duty vehicle sales. Given the low BEV adoption rates today, rates heavily weighted towards urban areas, these numbers are astonishing. [EPA-HQ-OAR-2022-0829-0578, pp. 1-2]

The proposed standards effectively box automakers into a BEV-only corner, forcing them to produce BEVs at an increasingly rapid rate. The rule gives no consideration or opportunity for other liquid fuel technologies to meet emissions goals. The proposed emissions standards would effectively ban gasoline and diesel-powered vehicles by incentivizing, if not dictating, auto manufacturers build BEVs. In doing so, the federal government has picked winners and losers in the energy/technology sector. If implemented, EPA is unilaterally stripping the freedom of choice away from American consumers and declaring ICE powertrains are on the losing side. [EPA-HQ-OAR-2022-0829-0578, pp. 1-2]

Organization: Renewable Fuels Association (RFA)

II. The Proposed Rule Uses Inappropriate GHG Accounting Gimmicks to Create a De Facto Mandate for Battery Electric Vehicles

For light-duty vehicles, EPA is proposing an industry-wide average GHG emissions target of 82 grams CO2/mile (g/mile) in model year (MY) 2032. This represents a drastic 56% reduction from the MY 2026 target of 186 g/mile and a 63% reduction from the MY 2022 target of 224 g/mile. Notably, the estimated industrywide average GHG emissions rate has exceeded the annual standard each year since 2016, requiring automakers to use banked credits and other adjustments to comply.4 [EPA-HQ-OAR-2022-0829-0602, pp. 4-5]

4 Congressional Budget Office. “Emissions of Carbon Dioxide in the Transportation Sector.” December 2022. https://www.cbo.gov/publication/58861.

For the purposes of calculating fleet-average GHG emissions, EPA is proposing to allow auto manufacturers to use a compliance value of 0 g/mile for BEVs, fuel cell electric vehicles (FCEVs), and the electric-only portion of operation for plug-in hybrid EVs (PHEVs). As EPA acknowledges, a compliance value of 0 g/mile for EVs ignores the upstream emissions associated with battery production and electricity generation (i.e., the “fuel” for EVs). [EPA-HQ-OAR-2022-0829-0602, pp. 4-5]

Given the stringency of the proposed standards (and the inability of most internal combustion engine (ICE) vehicles to meet them), EPA expects auto manufacturers will be strongly compelled to substantially increase EV production in order to benefit from the 0 g/mile assumption when calculating fleet-wide average emissions. According to EPA’s own analysis, it is highly unlikely that automakers will be able to meet EPA’s proposed emissions standards for 2027-2032 without dramatically increasing the production of EVs and reducing the production of ICE vehicles. The proposal’s forced push toward EVs would be exacerbated by EPA’s proposal to eliminate the “multiplier incentive” that allows automakers to count one BEV as more than one “zero emissions vehicle” in compliance calculations. In this way, EPA is essentially forcing auto manufacturers to increase production of EVs, and in turn forcing the entire transportation supply chain to undergo a massive shift toward electrification. [EPA-HQ-OAR-2022-0829-0602, pp. 4-5]

While significantly increasing the production of EVs may help automakers comply with the proposed future emissions standards, such a transition certainly does not guarantee that real-world GHG emissions associated with the full transportation supply chain will be meaningfully reduced. In fact, depending on the sources of electricity used to power EVs and the practices used for extraction and refining of critical battery minerals, EPA's proposal to force increased EV production could fall far short of accomplishing the administration's climate objectives. Thus, EPA's tailpipe emissions standards could perversely incentivize the production and sale of more expensive vehicles that, in reality, have little practical impact on reducing overall emissions. [EPA-HQ-OAR-2022-0829-0602, pp. 4-5]

Organization: Specialty Equipment Market Association (SEMA)

Technology Neutral Alternatives

The proposal intends to lower carbon emissions in a way that essentially forces BEVs to become the only option for automakers to produce. Given the subsidies in place for BEV purchases and production, BEVs are the de facto choice to achieve the rulemaking's climate goals, as other options, such as hydrogen, new synthetic fuels, and multiple renewables, do not enjoy a level playing field of subsidies. SEMA believes government should not pick winners and losers regarding automotive technology. Unfortunately, the EPA has chosen to place their thumb squarely on the scale for electric vehicles. The agency should help the market drive technology solutions like Cummins' 15- liter fuel-agnostic engine platform, capable of running on hydrogen, natural gas, or diesel.7 Further, the EPA must recognize that the U.S. has trillions of dollars' worth of infrastructure already in place for ICE vehicles. The newest ICE vehicle technology can be considered carbon competitive with EVs when all of the vehicle life cycle costs are analyzed, including the ICE infrastructure already in-place and paid for versus EV subsidies to install non-existent EV infrastructure and coax consumers to abandon cost-efficient ICE vehicles. [EPA-HQ-OAR-2022-0829-0596, p. 4]

EPA Needs to Address EV Market Uncertainty & GHG Stringency Concerns [EPA-HQ-OAR-2022-0829-0678, pp. 13-14]

As discussed above, EPA has erred by assuming an overly optimistic market adoption of a single EV technology justified by policies that represent partial solutions. The GHG targets justified by these assumptions exceed what industry and the Biden administration jointly agreed to and likely exceed what reasonably can be achieved in a 50-state market. Targets are front-loaded and biased against the most popular trucks and SUVs that customers demand today. [EPA-HQ-OAR-2022-0829-0678, pp. 13-14]

Organization: Steven G. Bradbury

Congress has not delegated to EPA the power to force the conversion to electric vehicles. [EPA-HQ-OAR-2022-0829-0647, p. 6]

EPA is very candid about the goal of its proposed rules: The Agency is trying to use tailpipe emissions limits on carbon dioxide and criteria pollutants as a tool to coerce the automotive industry to build far more electric vehicles (EVs) than market demand would currently support. [EPA-HQ-OAR-2022-0829-0647, p. 6]

Right now, EVs account for less than 6 percent of new light-duty vehicle sales in the United States and an even lower percentage of medium- and heavy-duty commercial truck sales. Following the script laid down by President Biden in an executive order,12 the EPA is aiming to force those percentages way up—to 60 percent of light-duty vehicle sales by 2030 and 67 percent by 2032. [EPA-HQ-OAR-2022-0829-0647, p. 6]

Organization: Toyota Motor North America, Inc.

5.2. Limited Compliance Paths

EPA suggests that manufacturers have the flexibility to pursue alternative paths that require less BEVs than assumed in the preferred alternative. In practice, standards based on 60 to 70 percent of the fleet performing at zero grams per mile severely constrain the ability of non-ZEV technologies to displace the assumed BEV penetration and still comply with the combined fleet target of 102 g/mi standard in 2030 model year and 82 g/mi in 2032 model year. Based on data from the OMEGA model for the 2027 model year, the projected combined-fleet performance for conventional ICE and strong hybrid vehicles, on average, cannot attain the proposed combined-fleet standards for that model year (Table 2). The performance gap of these technologies relative to the standards widens with each following model year. This does not mean every ICE vehicle and hybrid will no longer comply with its footprint target in 2027 model year but increasingly these vehicles will need to be offset with larger and larger shares of BEVs and PHEVs for compliance with the fleet standards. [EPA-HQ-OAR-2022-0829-0620, pp. 27-29]

[Table 2: 2027 Model Year Combined Fleet Performance Relative to the 2027 Model Year Standard

Standard (g/mi): 152

CO2 (g/mi) Performance HEV: 192

CO2 (g/mi) Performance ICE: 240

Comply: No] [EPA-HQ-OAR-2022-0829-0620, pp. 27-29]

In Figure 9, the performance of every 2022 model year vehicle is compared to its respective footprint target proposed for the 2030 model year. Vehicles are distinguished by powertrain technology type with strong and mild hybrids lumped together. BEVs are the only technology for which every vehicle can meet the proposed 2030 standard. This further illustrates that 2030 standards are essentially a BEV mandate. [EPA-HQ-OAR-2022-0829-0620, pp. 27-29]

[See original for graph, Figure 9 U.S. Combined Fleet 2022 MY Performance Relative to 2030 Footprint Targets] [EPA-HQ-OAR-2022-0829-0620, pp. 27-29]

This poses significant risks to consumers, automakers, and the environment. Should the BEV market not mature at the rate EPA expects due to any of the myriad factors already described, consumers may be unable to find suitable non-BEVs that meet their needs as automakers would likely have cut back investment in these products. The result could be that consumers hold on to older, higher-emitting vehicles longer. Such a scenario is not beneficial for consumers or the environment. If automakers can somehow "backfill" weak BEV demand with other vehicles and technologies, they could face compliance challenges. The simple technology market share analysis using combine fleet emissions values (Table 3) shows several scenarios for "USA Motors" in which industry-wide BEV sales fall short of EPA's expected 60% in 2030 and are "backfilled" by other technologies such as ICE, HEV, and PHEV. While these scenarios would be good for consumers, it would clearly place automakers in a difficult compliance situation based on factors outside their control. We expect the GHG credit market would not be equipped to resolve this magnitude of compliance shortfall, especially with off-cycle credits proposed to be eliminated. [EPA-HQ-OAR-2022-0829-0620, pp. 27-29]

*includes 6 g/mi AC Efficiency Credits for ICEs]

[EPA-HQ-OAR-2022-0829-0620, pp. 27-29]

The ability to pivot on technology strategies and product plans is already severely limited by the resource shift to electrification and becomes more impractical the longer it takes for unresolvable market problems to surface. The only remedy in such a scenario is to revise the standards, which consumes time and complicates automakers' planning and investments. [EPA-HQ-OAR-2022-0829-0620, pp. 27-29]

EPA Summary and Response

Summary:

Exxon Mobil recommended that EPA "encourage a diversity of technology pathways". In its comment, BorgWarner expressed support for performance-based regulations and opposition to technology mandates. EPA agrees with both of these comments, as that is what our final rule does.

Some commenters (Alliance, AFPM, CEI, Growth Energy, Honda, Illinois Corn Growers, Mass Comment Campaign, RFA, SEMA, Stellantis) imply or assert that there is only one technology that could achieve the standards. Other commenters (e.g., Steven Bradbury) imply that the rule forces electric vehicles; the Alliance claims that EPA's proposed rule is "a de facto battery electric vehicle mandate." AFPM concludes the rule is a de facto ban on ICE vehicles and that EPA's approach "ignores the fact that major automakers are on differing technological paths".

EPA disagrees with these claims. For this rulemaking, we are continuing our longstanding approach (with over 50 years of experience in reducing criteria pollutants and 14 years of history for GHGs) of establishing an appropriate and achievable trajectory of emissions reductions by means of performance-based standards. As we state in section I.A.2 of the preamble, we anticipate that a compliant fleet under the final performance-based emissions standards will include a diverse range of technologies. In section I.B.1. of the preamble we discuss the GHG emissions standards and illustrate multiple potential pathways which demonstrate compliance with varying mixes of non-hybrid ICE vehicles, hybrids, PHEVs and BEVs (Table 4). Additional pathway examples are presented as part of our sensitivity scenarios in preamble section IV.F and G.

The Alliance argues that "By 2032, under the proposed standards, only EVs are likely to meet their individual footprint-based targets."

EPA disagrees with this assessment. As we describe in section IV.C.1 of the preamble: at the time of the proposal, we did not specifically model PHEV architectures for the proposed standards, but we did acknowledge that PHEVs could provide significant reductions in GHG emissions, and that we were considering adding them formally into our modeling for the final rule, which we have now done. Electrification technology, including PHEVs, is feasible and readily available in the market today as we discuss in section IV.C.1 of the preamble. EPA has included PHEVs in its modeling for the FRM, and our analysis shows that PHEVs (with an all-electric driving range approaching that needed to meet ACC II requirements) can achieve their individual 2032 MY footprint-based CO2 targets. In addition, EPA demonstrates that there are many potential pathways to compliance with the final standards that include a wide range of potential technology mixes, including various mixes of non-hybrid ICE vehicles, hybrid vehicles, PHEVs and BEVs. See section I.B.1, Table 4 of the preamble.

API claims that our analysis "is flawed in that it failed to account for non-electrification solutions", that "the stringency of the proposed standards... essentially forces manufacturers to solely focus development efforts on BEVs" and it recommends that "EPA adjust the standards to allow all solutions the ability to compete."

Again, EPA disagrees - our standards do not force any one technology. We agree that to meet the standards, various degrees of electrification – which include a continuum of electrified powertrains, including BEVs, PHEVs, strong hybrids and mild hybrids – will be necessary at some level as consistent with the path that automakers are on, as expressed in public comments from automakers. . Manufacturers may also invest in ICE technology development at varying levels of hybridization to supplement their electrified portfolio. Through continued progress in technology advancement, manufacturers have more technology options than they did in the past, and that is reflected in our feasibility assessment commensurate with the level of stringency in the final standards. However, EPA does find that given the increasing penetration of PEV technologies and manufacturers plans to focus development on such technologies, it would be arbitrary and capricious to not consider PEVs as an available technology.

API (and some renewable fuels groups) claim or imply that the proposed standards are not "technology neutral." In response, EPA notes that no engine design is truly neutral to another engine. All engines exhibit different characteristics that distinguish them in terms of performance and emissions. The same can be said for powertrain architectures as a whole. Across the continuum of powertrain and vehicle designs, some technologies exhibit lower emissions than others. The EPA standards are in fact technology neutral in that they do not require the use of any one technology over another – that decision of technology selection rests with the manufacturer who has the choice to select among the wide range of available technologies to select those best suited for its fleet to meet the fleetwide average standards. Considering that these GHG standards are fleet-average standards, no single vehicle is required to meet its individual footprint targets and so no technology is off the table. A manufacturer can choose any technology for a given vehicle, so long as its fleet as a whole complies with the fleet-average standard. As we demonstrate in the rule, we project that manufacturers will meet the standards through their choice of a mix of technologies that they deem best suited for their fleets.

We received several comments in support (and some, in acknowledgement) of performance-based standards:

In its comments, BlueGreen Alliance (BGA) recognizes that while automakers will need to adopt (some level) of ZEVs to meet the standards, the standards are ultimately performance-based. BGA then lists some complementary technologies in addition to zero-emission vehicles and describes the proposal as "tech-forcing and tech-agnostic". EPA agrees with this comment and considers the technologies as viable options towards meeting compliance for the standards.

Energy Innovation commented that BEVs are the most expedient and effective way to eliminate pollutants. Based on our modeling, EPA agrees that manufacturers may find the most cost-effective technology to be BEVs, however, it does not preclude any other technologies from being adopted by manufacturers to meet compliance.

Some commenters provided analyses which corroborated EPA's "multiple pathways" findings after they added PHEVs to their modeling for the final standards. In its comments, Consumer Reports described their own modeling of various technology combinations and found "many reasonable compliance pathways to comply with either EPA's proposed standards or the stronger Alternative 1."

EPA agrees with these comments, and notes that the central case pathway in the proposed standard was modeled as the lowest cost of compliance and is not "the" only approach. As we show, there are varying levels of electrification that may be used to achieve compliance. In fact, in its comments, EDF noted "Because EPA's OMEGA 2 model is designed to show only the most cost-effective compliance pathways, it does not capture the full range of possible pathways automakers may choose to take based on the numerous factors that influence product lines," after which EDF provided a detailed summary of three alternative pathways – with varying levels of advanced ICE technology, PHEV and BEV sales – it independently evaluated using EPA's OMEGA 2 model (but with EDF's independent technology and cost assumptions) that each showed compliance with the proposed standards. We agree with these commenters' assessments.

While affirming that the proposal is technology-neutral, CARB concluded from EPA's modeling that ZEVs will be the most likely pathway towards compliance. EPA agrees with CARB's assessment that the standards are technology-neutral, however we emphasize that the modeling in the proposal is OMEGA's representation of the most cost-effective pathway to compliance but it is one of many potential pathways to compliance for the industry, and for each manufacturer.

In its comments, Environmental and Public Health Organizations noted that "an automaker could improve the emissions performance of its vehicles simply by shifting sales within a nameplate to versions with cleaner powertrains." They show that for some high-volume models, they estimate potential GHG reductions from those models of up to 20% by shifting sales to the cleanest option. EPA agrees that this could be one viable part of a compliance strategy– within a manufacturer's portfolio of trim levels, it could conceivably change the sales mix of its powertrain offerings without requiring significant new investment. However, we recognize that there may be some practical limits to shift all sales to the cleanest trim level, based on, for example, production capacity and consumer demand.

ICCT provided analysis and commentary on potential GHG reductions still available in ICE technology, including lesser levels of electrification such as mild and strong hybridization of the ICE fleet. EPA agrees with this analysis, and while some of these technologies were not modeled due to lack of available inputs (cost and detailed engine efficiency maps) necessary to incorporate into our ALPHA and OMEGA models, EPA agrees that these technologies may be available to manufacturers and provide further evidence of multiple technology pathways. Of course, it will be up to each manufacturer to determine the most appropriate compliance pathway for their business case.

12.5.4 – Sensitivities

<u>Comments by Organizations</u>

Organization: Alliance for Automotive Innovation

Relatedly, <u>we also recommend that the EPA show a full cost-benefit analysis for each of its sensitivity cases,</u> including for high and low battery cost cases, and also for varying assumptions on IRA tax credit eligibility, phase-out, or elimination. [EPA-HQ-OAR-2022-0829-0701, p. 67]

Organization: Institute for Policy Integrity at New York University School of Law

II. While EPA Robustly Analyzes the Proposed Rule's Benefits and Costs, It Should Conduct Additional Analysis Around Key Parameters

Using OMEGA, EPA conducts a thorough and robust analysis of the benefits, costs, and net benefits of the proposed program and its alternatives. EPA's modeling is the product of extensive analysis and reasonably concludes that the benefits of the proposed program and all of its alternatives greatly outweigh their costs. [EPA-HQ-OAR-2022-0829-0601, p. 12]

EPA's analysis is commendable in many ways. The agency estimates many key analytical parameters—such as the rebound rate for ICE vehicles and the elasticity of demand for new vehicles—consistent with the best available evidence. Nonetheless, EPA could perform more analysis around key parameters. For instance, whereas EPA conducted more than sixty sensitivity analyses72 around numerous parameters in the 2020 Rule,73 it presents only seven sensitivity analyses for the Proposed Rule.74 For some key analytical parameters—such as the discount rate and the social cost of carbon—additional valuations reflecting the state-of-the-art economic literature exist and would ensure a more complete presentation of benefits and costs. EPA should conduct additional analysis around these parameters, which generally show that the net benefits of the proposed program and its alternatives are even greater than EPA projects. [EPA-HQ-OAR-2022-0829-0601, p. 12]

72 In regulatory impact analysis, "sensitivity" analysis refers to analysis that "reveal[s] whether, and to what extent, the results of the analysis are sensitive to plausible changes in the main assumptions and numeric inputs." OFF. OF MGMT. & BUDGET, CIRCULAR A-4: REGULATORY ANALYSIS 3 (2003).

73 Final Regulatory Impact Analysis The Safer Affordable Fuel-Efficient (SAFE) Vehicles Rule for Model Year 2021–2026 Passenger Cars and Light Trucks 1769–71 tbl.VII-471 (2020).

74 RIA at 13-43 to -48 (five sensitivities for light-duty vehicles), 13-54 to 13-55 (two sensitivities for medium-duty vehicles).

Specifically, EPA should conduct additional analysis around the social cost of greenhouse gases, discount rate, analytical baseline, BEV rebound rate, safety modeling, and energy security. This section explores each of these issues in turn. [EPA-HQ-OAR-2022-0829-0601, p. 12]

EPA Summary and Response

In its comments, the Alliance requested that EPA conduct a benefit-cost analysis for each of its sensitivity cases provided in the NPRM and requested additional sensitivities and benefit-cost analyses for varying assumptions on the levels of available IRA subsidy. For reasons described at length in RTC 8.1, EPA disagrees with this recommendation and does not provide additional benefit cost analyses for each sensitivity. Regarding IRA sensitivities specifically, EPA worked very closely with DOE and NHTSA in determining the appropriate assumptions regarding the impacts of the IRA on the industry and vehicle market. EPA agrees that additional sensitivities could be conducted on a number of input assumptions, including this one. However, EPA did not have a persuasive reason for determining that the value of the IRA incentives would differ significantly from the central case assumptions. Further, EPA notes that the impact of deviations in the IRA assumptions from the central case, higher or lower, would impact the results through the same mechanism as several of the other sensitivities conducted by EPA; namely that both the battery cost sensitivity and consumer acceptance sensitivity influence the relative consumer preference for the various powertrain technologies, and in the case of the battery costs sensitivity, the producer compliance costs. Therefore, EPA determined that a sensitivity around the IRA assumptions would not provide substantially different information than already provided by the current sensitivities.

The Institute for Policy Integrity (IPI) commented that EPA should conduct a greater number of sensitivity analyses, expanding on those presented in the NPRM. IPI recommended sensitivities around discount rates and the social cost of carbon, as well as possible sensitivities for safety, the rebound rate, the analytical baseline and energy security. In response, EPA notes that for the NPRM and again for this final rule, costs and benefits are presented at both 3 and 7 percent discount rates, and a range of values is used for the social cost of greenhouse gases. More detailed discussion of the choice of discount rates and social cost of carbon values is provided in RIA Chapter 9. EPA has analyzed several new sensitivity cases for this final rule in addition to cases presented in the NPRM. These include cases for more prevalent PHEVs, no additional BEVs beyond already existing models, and no GHG credit trading between manufacturers. Regarding the analytical baseline, the sensitivities included in this final rulemaking analysis cover a wide range of No Action case projections. This range is illustrated in terms of the market penetration of PEVs across the various sensitivity cases in preamble Section IV.B and also by the tables of incremental costs for the sensitivity cases presented in RIA Chapter 12.

12.5.5 - Modeling of MDVs

Comments by Organizations

Organization: Environmental. and Public Health Organizations

a. EPA’s modeling should better reflect the favorable economic case for electric pickup trucks.

A recent report by Roush examined the potential for electrification of MDVs under a range of scenarios, finding that electrification is cost-competitive in the great majority of them. 188 It is clear that some amount of the difference between the uptake of Class 2b-3 pickups and vans in the OMEGA2 modeling stems from the far lower range assumed for vans (150 miles) compared to that of pickups (300 miles). But as illustrated in Table VI.A-1 below, 189 Roush finds that by 2030, even when comparing a low-cost combustion powertrain to the most costly battery chemistry (NMC811) deployed in a 400-mile electric Class 3 pickup, 190 the electric pickup still achieves total cost of ownership (TCO) parity within the typical loan length for a new vehicle (7 years). And when comparing a Class 3 pickup with a low-cost battery (LFP) to a high-cost internal combustion engine powertrain, a 400-mile electric pickup would pay off within 1 year, well within the payback period assumed for consumers by manufacturers within EPA’s OMEGA2 model. [EPA-HQ-OAR-2022-0829-0759, p. 69]

188 Saxena et al., Electrification Cost Evaluation at 26.

189 Table VI.A-1 is adapted from Saxena et al., Electrification Cost Evaluation, Tbl. 24, at 145. Scenario 1 represents the adoption of low-cost BEV and high-cost combustion vehicle technologies; Scenario 2,

medium-cost BEV and combustion vehicle technologies; and Scenario 3, high-cost BEV and low-cost combustion vehicle technologies. Id. at 28-29.

190 Roush used an LFP battery for its low-cost BEV, an NMC811 battery for its medium-cost BEV, and a "10% costlier" NMC811 battery for its high-bost BEV. Id. at 30-31.

Table VIII.A-1. Time to achieve TCO parity for Class 2b-3 BEVs with a 2027 and 2030 purchase timeframe [EPA-HQ-OAR-2022-0829-0759, pp. 69-70]

[See original comment for Table VIII.A-1.]. [EPA-HQ-OAR-2022-0829-0759, pp. 69-70]

When accounting for the impacts of the IRA, the economic case for electrification of Class 2b-3 pickups is even clearer, as shown in Table VI.A-2. Here the impact of the full § 30D credit is shown, which is also the maximum allowable limit of the § 45W (commercial clean vehicle) credit for Class 2b-3 vehicles. 191 Roush's analysis finds that purchase price parity is achieved for virtually all BEV classes in the timeframe of the analysis, so the § 45W commercial vehicle credit is not applicable in the later years of their analysis. 192 In fact, Roush finds that, with the application of IRA credits, by MY 2027 all BEVs except the 400-mile pickup will be priced at or below a comparable combustion vehicle 193; and that all MY 2027 BEVs will achieve TCO parity within the first two years of vehicle ownership. 194 Here it is worth noting that, despite the large share of MDVs that are purchased for commercial fleets, EPA did not directly include the § 45W credit in its analysis, instead applying the same combination of the § 30D and § 45W credit as it did for LDVs. 195 Because the § 45W credit is based on the lesser of $7500 or the difference in purchase price, this credit should act to hedge uncertainty in the Agency's analysis, though that is not how it was treated within the OMEGA2 modeling runs. [EPA-HQ-OAR-2022-0829-0759, pp. 69-70]

191 Id. at 175-79. The § 45W credit is based on 30% of the basis of a vehicle not powered by a gasoline or diesel internal combustion engine, or the difference in purchase price between a qualified clean vehicle and a comparable combustion vehicle. In the case of vehicles that have a GVWR less than 14,000 pounds (which includes Class 2b-3 vehicles), the total credit is capped at $7500.

192 Id. at 195.

193 Id.

194 Id. at 197-98.

195 This is not immediately apparent in the text of the preamble or DRIA but can be assessed by comparing the contents of the vehicle_price_modifications_20230314b.csv input files from the LDV and MDV modeling runs, which are identical.

Table VIII.A-2. Time to achieve TCO parity with IRA § 30D credits for MYs 2023 and 2027 196 [EPA-HQ-OAR-2022-0829-0759, p. 70]

196 This table is adapted from Saxena et al., Electrification Cost Evaluation, Tbl. 30, at 193.

[See original comment for Table VIII.A-2.]. [EPA-HQ-OAR-2022-0829-0759, pp. 70-71]

The Roush report is not the only analysis to find a strong economic rationale for the adoption of zero-emission MDVs. A recent report from the National Renewable Energy Laboratory (NREL) found that cost parity will be achieved before 2035 (even in the absence of the IRA) for medium- and heavy-duty vehicles, including Class 3 vans and Class 4-5 vehicles that share a platform with Class 2b-3 pickups (which were not part of that analysis).197 Similarly, a recent

International Council on Clean Transportation (ICCT) report on electric MDVs finds that purchase price parity with diesel MDVs will be achieved prior to 2032 for 300-mile and lower BEVs, even in the absence of IRA funding.198 And when IRA funding is considered, even 400-mile BEV pickups would achieve purchase price parity in the timeframe of this rule.199 [EPA-HQ-OAR-2022-0829-0759, p. 71]

197 Catherine Ledna et al., NREL, Decarbonizing medium- and heavy-duty on-road vehicles: Zero-emission vehicles cost analysis, Mar. 2022, at 2, 46 https://www.nrel.gov/docs/fy22osti/82081.pdf.

198 Eamonn Mulholland, ICCT, Cost of electric commercial vans and pickup trucks in the United States through 2040 (Working Paper 2022-01), Jan. 2022, at 11 (Fig. 5), https://theicct.org/wp-content/uploads/2022/01/cost-ev-vans-pickups-us-2040-jan22.pdf.

199 See id.

There is some difference in costs between EPA's assessment and other studies such as those described above: on average, according to EPA, Class 2b-3 combustion pickups will cost about $5,000 less (from a purchase price standpoint) than a comparable electric pickup. However, with the Agency's application of an average IRA credit of $6,000 in 2032, this would still yield cost parity, on average, so even EPA's higher cost assessment cannot fully explain the reason for Class 2b-3 pickups electrifying at such a reduced rate in the Agency's modeling. Even more than that, this disparity is almost entirely influenced by the relative price difference of gasoline and diesel pickups in EPA's modeling, with the Agency's BEV300 pickups just $1,100 more expensive than diesel pickups without the IRA incentives, not far off ICCT's conclusion that BEV300 pickups will achieve cost parity with diesel pickups by 2031.200 Despite this, the model's conversion rate of combustion vehicle sales to electric vehicle sales is virtually indistinguishable between gasoline and diesel pickups, at roughly 20% for each, seemingly indicating that neither purchase price nor TCO parity have a significant impact on sales. Given that many Class 2b-3 vehicles are purchased for commercial use,201 such modeling behavior is inconsistent with the economically-driven decisionmaking that would be expected to occur in the real world.202 [EPA-HQ-OAR-2022-0829-0759, p. 71]

200 Id.

201 See id. at 1; Saxena et al., Electrification Cost Evaluation, at 49.

202 For example, EPA's own analysis of the heavy-duty market assumed a conversion rate of 80% when cost parity is achieved. 88 Fed. Reg. at 25992, Tbl. II-23. And analysis from NREL finds this number to be nearly 100%; see comparison at pp. 59-60 of EDF, Comment Letter on GHG Standards for HD Vehicles, June 16, 2023, https://downloads.regulations.gov/EPA-HQ-OAR-2022-0985-1644/attachment_1.pdf (data from Ledna et al. 2022).

Based on EPA's own modeling, BEV variants for over 71% of the Class 2b-3 market achieve first cost parity with their combustion-powered equivalent by 2032 when including IRA incentives, including 57% of the Class 2b-3 pickup truck market.203 This is a substantially higher share of vehicles than the model assumes will be deployed. [EPA-HQ-OAR-2022-0829-0759, p. 72]

203 This was established using the output files for the OMEGA2 MDV runs, using the vehicles file (2023_03_14_22_42_30_central_3alts_20230314_Proposal_vehicles.csv) to compare in a given model year BEV variants with their combustion equivalent, sharing a base-year vehicle ID.

For all of these reasons, EPA's modeling does not accurately reflect the favorable economic case for commercial MDV electrification, particularly for pickups. While some of these modeling problems can be ascribed to differences in battery costs and EPA's unreasonable choice to include an artificial 25% production cap on BEV pickups, other problems are intrinsic to assumptions made within the model that do not reflect the Agency's own assessment of likely adoption of electrification for commercial vehicles, particularly considering the incentives available under the IRA. [EPA-HQ-OAR-2022-0829-0759, p. 72]

Organization: International Council on Clean Transportation (ICCT)

Paralleling the limited public MDV data availability, the discussion of MDV technology costs and effectiveness within the Preamble and DRIA is not as robust as that discussion for LDV. While certain MD-specific technologies are mentioned (e.g. the MD Ford 7.3L engine which was not incorporated in the analysis, DRIA 3.5.1.2), it is unclear what engine maps apply to MDV, if any technology costs/effectiveness were borrowed from LDV, how LDV costs/effectiveness were modified for MDV (if at all), and if there are any other modeling parameters specific to MDV. [EPA-HQ-OAR-2022-0829-0569, pp. 62-64]

By examining several OMEGA MD input and output files, there are several areas ICCT finds worthy of comment. [EPA-HQ-OAR-2022-0829-0569, pp. 62-64]

The central "vehicles" output file161 shows that all diesel vehicles throughout MY2021-MY2035 are considered to have Miller cycle engines (MIL) and all gasoline vehicles are GDI only. Only these 2 ICE technology packages are available for MD, and both are without any level of electrification (micro through strong hybrid).162 This lack of additional ICE technology packages suggest EPA is significantly underestimating the possibility for improved ICE-based MD pickups and vans. As there are many cost-effective ICE technologies available, the lack of detail in the analysis likely overstates the cost of compliance. Relatedly, it is unclear which engine (and electric motor) maps were used to develop the technology packages' RSEs, as well as the appropriateness of approximating diesel engines' CO2e emissions with those of Miller cycle engines. The MD cost equations appear identical to the LD costs.163 While this may be appropriate for many technologies that are shared between LD and MD, there are certain performance and utility differences between LD and MD that may lead to differing costs (consider, in particular, costs related to diesel powertrain improvement, which are unassessed in the LD analysis). [EPA-HQ-OAR-2022-0829-0569, pp. 62-64]

EPA Summary and Response

Summary:

Environmental and Public Health Organizations commented that EPA's modeling does not accurately reflect the favorable economic case for commercial MDV electrification, particularly for pickups. In support, they cite several studies finding the total cost of ownership for electric pickups to be lower than their conventional counterparts by the 2030s. The commenter also notes that this is in part due to differences in EPA's cost assessment, and also that EPA did not directly include the 45W credit in its analysis, but instead applied the same combination of the 30D and 45W credit as for LDVs.

ICCT commented that modeling of medium-duty technology costs and effectiveness in the proposal was not as robust as light duty modeling. In particular, engine technology was limited to Miller and GDI engines, and no hybridization was modeled for MDVs. Additionally, medium duty costs appeared to be identical to light duty costs, which is not appropriate in all cases (for example, costs related to diesel powertrain improvement, which were unassessed).

Response:

In response to comments on modeling of electric MDVs, EPA stands by its modeling process. MDV pickups and vans are true work vehicles that are designed for much higher towing and payload capabilities than are light-duty vehicles. The technologies applied to light-duty vehicles are not all applicable to MDVs at the same adoption rates, and the internal combustion engine technologies often produce a lower percent reduction in CO_2 emissions when used in many medium-duty vehicles. For example, electrification of an MDV pick-up designed and used solely for high towing capacity may be more challenging in the earlier years of the program. Conversely, delivery vans or payload-oriented pick-ups that operate over limited distances and daily routes present a significant opportunity for electrification, as evidenced by current last mile delivery companies' announcements and purchase orders for EVs in this segment. Electrification technologies applied to MDVs reflect the expected usage of these vehicles, with fully electric BEVs as the primary electrification pathway for medium duty vans, and both BEV and PHEV technology applied to 2b/3 pickups in roughly equal proportions. It is important to note that this is a projection and represents only one of many possible compliance pathways manufacturers could choose.

Further responses to comments on battery costs are included in section 12.2.1 of this RTC and further responses to comments on modeling of IRA incentives are included in section 12.5.3 of this RTC.

In response to comments on limited modeling of MDV technology, EPA believes that our modeling of MDV technologies was reasonable and sufficiently robust to support the feasibility of the standards. For this final rule, EPA has updated the modeling of MDV and increased the variety of powertrains modeled. In modeling for the final rulemaking, EPA used a diesel engine (rather than the Miller surrogate mentioned by ICCT) and incorporated both turbocharged and naturally aspirated (the Ford 7.3L engine) gasoline engines for MDV modeling, as further explained in the RIA, chapter 3.5.1. In addition, EPA modeled fully electric BEVs as the primary electrification pathway for medium duty vans, and both BEV and PHEV technology applied to 2b/3 pickups in roughly equal proportions, as further explained in the RIA, chapter 3.5.3. While it is true that EPA could have modeled even more technologies for MDV (as for LDV), the modeling that we did perform sufficiently demonstrates the feasibility of the standards.

In response to the comment on MDV costs, EPA stands by its modeling of cost inputs. As noted by ICCT, many technologies that are shared between LD and MD have appropriately shared costs. For those few technologies not shared (for example, the development of the PHEV technology applied to 2b/3 trucks), costs were developed appropriately for the MDV modeling. Powertrain improvements to diesels were not included as a pathway in this analysis, though manufacturers are free to choose this pathway as part of their technology mix under the performance-based standards.

12.5.6 - Modeling of the no action case

Comments by Organizations

Organization: American Council for an Energy Efficient Economy (ACEEE)

EPA's baseline BEV projections are well below estimated penetration rates expected from IRA and IIJA programs and investments (FR 29333, Table 99). Multiple analyses project that the IRA, in particular, will lead to new-vehicle BEV adoption rates of over 60% by the early 2030s, compared to EPA's baseline, "No Action", scenario where BEVs only reach roughly 40% of new vehicle sales between MYs 2030 and 2032.8 EPA's standards should fully account for the impact of activities outside of the federal standards to drive vehicle electrification and set targets more stringent than what the market is expected to deliver. Alternative 1 is the strongest proposed option that EPA can adopt to maximize net benefits. [EPA-HQ-OAR-2022-0829-0642, pp. 2-3]

8 https://theicct.org/wp-content/uploads/2023/01/ira-impact-evs-us-jan23.pdf; https://rmi.org/insight/how-inflation-reduction-act-will-affect-ev-adoption-in-the-united-states/

Organization: American Petroleum Institute (API)

The AEO 202359 contains long term projections based on current laws and regulations in place at the time of modeling. As part of that modeling, the AEO includes projections for vehicle sales and vehicle sales projections include consumer choice modeling60. EIA's consumer choice modeling includes fuel choice, sales penetration among similar technologies, market share among different technology sets, and vehicle attributes (i.e., sales price, fuel economy, battery replacement costs, range, etc.). EIA reported that for the first time since 2010, critical mineral prices increased "significantly" in 2022 resulting in the first year to year increase in electric vehicle battery prices. According to AEO projections, which consider current policies and regulations, and consumer choice, BEV sales penetration remains well below EPA's estimates in the proposed rule, which are induced by its proposed stringent standards. EPA must explain why its projections differ so significantly from EIA. Furthermore, EIA61 projects electric vehicles to be less competitive from a cost standpoint than gasoline powered vehicles in the much larger non-luxury market. [EPA-HQ-OAR-2022-0829-0641, p. 19]

Organization: California Attorney General's Office, et al.

Our States and Cities add three observations to EPA's analysis of costs and lead time. First, EPA's projected costs likely overstate the actual costs attributable to reaching the standards in the allotted lead time, due to conservative assumptions in EPA's no-action case that omit the myriad state and local actions to promote electric vehicle adoption. See supra 18-21; CARB Comment at 16. [EPA-HQ-OAR-2022-0829-0746, p. 33]

However, EPA's conservative methodology for constructing the no-action scenario likely ends up overstating the proposed standards' costs significantly, for two key reasons. [EPA-HQ-OAR-2022-0829-0746, pp. 33-34]

First, EPA assumes that auto manufacturers will produce electric vehicles to comply with standards in a "purely cost-minimizing" way. 88 Fed. Reg. at 29,296. As EPA acknowledges, however, auto manufacturers have planned for far higher rates of electric vehicle sales in response to both policies that recognize the significant role of the internal combustion engine in the climate crisis and the surging demand for electric vehicles. Id. A model of industry behavior that minimizes costs without accounting for these other drivers of electric vehicle adoption likely understates electric vehicle penetration in a no-action scenario.186 And, given that respected organizations like Bloomberg New Energy Finance are estimating battery electric vehicle penetrations rates near 52% by 2030 even without considering EPA's proposed standards,187 EPA's no-action scenario projection of 40% penetration is likely an underestimation. See 88 Fed. Reg. at 29,329 (Table 81). [EPA-HQ-OAR-2022-0829-0746, pp. 33-34]

186 See Consumer Reports Amicus Brief, Doc. No. 1988445 in Texas v. EPA, Case No. 22-1031 (D.C. Cir. Mar. 3, 2023), at 4-15.

187 Ira Boudway, More Than Half of US Car Sales Will Be Electric by 2030, Bloomberg (Sep. 20, 2022), available at https://www.bloomberg.com/news/articles/2022-09-20/more-than-half-of-us-car-sales-will- be-electric-by-2030. Second, EPA's no-action scenario likely underestimates the baseline battery electric vehicle penetration rate, because it does not account for numerous state and local actions that promote electric vehicle adoption. 88 Fed. Reg. at 29,296. As discussed in the Proposal, EPA did not model compliance with California's Advanced Clean Cars II program ("ACCII"), which requires 100% of in-state new vehicle sales to be zero-emission or plug-in hybrid electric vehicles by 2035; as EPA notes, 11 other States have adopted or plan to adopt ACCII by model-year 2027 under Section 177 of the Clean Air Act. Id.; id. at 29,334. EPA's decision not to include ACCII in the no-action scenario is appropriate at this stage, because EPA has not yet granted California's pending waiver application for ACCII under Section 209(b). However, EPA's sensitivity study with ACCII in the no-action scenario demonstrates that ACCII would reduce the costs of EPA's standards if EPA were to grant the waiver. See id. at 29,335. Further, beyond ACCII or other state-law sales mandates, states and their political subdivisions have enacted a host of incentives to promote electric vehicle adoption, which the no-action scenario does not account for either. See supra at 18-21. These omitted state-law incentives mean that, even apart from ACCII, EPA's no-action scenario likely understates electric vehicle adoption without the proposed standards, and thus the proposed standards' costs are likely less than EPA's projected estimates. [EPA-HQ-OAR-2022-0829-0746, p. 34]

EPA's conservative estimates provide the industry and other stakeholders important information on the upper bounds of the proposed standards' costs, and our States and Cities acknowledge the technical challenges of rigorously modeling the above state laws and market dynamics. Nevertheless, EPA should be candid that the real-world costs fairly traceable to the final standards will likely be significantly lower than those disclosed, even apart from ACCII's potential effects, and EPA should consider adopting standards more stringent than the proposed standards. [EPA-HQ-OAR-2022-0829-0746, p. 34]

Organization: Center for American Progress (CAP)

EPA's Baseline is Too Conservative

By 2027, the incentives contained within the IRA will have made a significant impact on domestic EV production while increasing the number of EVs that qualify for consumer facing credits. A subset of the total incentives contained in the IRA is expected to bring the EV market at least in line with EPA's expected compliance path for the proposed rule. Accounting for California's Advanced Clean Cars II standard, the 30D, and 45W credits as well as limited portions of the 45X credit, the International Council on Clean Transportation (ICCT) finds that EVs are expected to achieve 67 percent penetration by 2032.9 This same analysis finds that EVs are expected to achieve price parity with ICE vehicles between 2023 and 2025. This conclusion is supported by analysis by the Rocky Mountain Institute (RMI) which finds that electric sedans will achieve price parity in 2023, electric SUVs between 2023 and 2024, and electric pickup trucks between 2024 and 2025.10 Further, RMI finds that EVs could reach 76 percent market penetration by 2032, which significantly exceeds even the proposed Alternative 1. Organization: Environmental. and Public Health Organizations

b.EPA should more fully account for the impact of state regulations on the adoption of Class 2b-3 ZEV pickups and vans.

In addition to market forces, state regulatory requirements will have a significant impact on the adoption of Class 2b-3 ZEV pickups and vans, not just through ZEV sales requirements but through the corresponding industrial development and production that will occur to meet related demand. EPA does not appear to have considered the relative impact of such state regulations as part of its OMEGA2 modeling.204 [EPA-HQ-OAR-2022-0829-0759, p. 72]

204 While the Agency has conducted a sensitivity analysis around the Advanced Clean Cars II program, for which California has not yet received a waiver, it has not similarly included any sensitivity or analysis incorporating into its compliance modeling the Advanced Clean Trucks regulation, for which California has already been granted a waiver.

Under the Advanced Clean Trucks (ACT) regulation, manufacturers must ensure that 40% of their sales of Class 2b-3 vehicles are ZEVs by 2032, en route to an eventual target of 55% ZEV sales in 2035.205 ACT has already been adopted in eight states as of the date of this comment letter, and these states make up nearly 20% of the heavy-duty market (including Class 2b-3 vehicles) overall.206 While there are no strict requirements on the mix of vehicles a manufacturer must sell in order to achieve these targets, the sheer size of the Class 2b-3 pickup market means that manufacturers cannot simply rely on the widespread deployment of ZEV commercial vans in order to meet the ACT-required level of ZEV adoption. [EPA-HQ-OAR-2022-0829-0759, p. 72]

205 Table A-1, California Code of Regulations § 1963.1.

206 Based on new vehicle registration data from Polk/IHS Markit for 2019-2021 Class 2b-8 trucks, by state, obtained from Atlas Public Policy.

These state regulations will yield a base level of Class 2b-3 ZEVs, even in the absence of EPA standards, that the Agency has not adequately considered in its No Action scenario or in its modeling. As a separate matter, these regulations (and the ZEV development and deployment efforts that manufacturers have already undertaken to achieve compliance with them) also validate the Agency's assessment that electrification will be a critical emissions control technology in the MDV space moving forward. [EPA-HQ-OAR-2022-0829-0759, p. 73]

207 88 Fed. Reg. at 29341-42; DRIA at 3-12–3-18.

Organization: Hyundai Motor America

In addition, state readiness to successfully implement the ACC II ZEV Regulation remains an outstanding question. We are concerned there simply is not enough time to delivery key infrastructure to support the ACC II ZEV Regulations in Section 177 States ("S177 States"). Many of the current S177 States that have adopted the ACC II ZEV Regulation lack the necessary charging infrastructure to support even the MY 2026 ZEV requirements. Further, several states are on track to become first-time S177 States and are significantly even farther behind in terms of infrastructure and other supportive ZEV policies to ensure regulatory success. To the degree the No Action case assumes equal success of the ACC II ZEV Regulations among S177 States, it overlooks the realities on the ground. These assumptions carry forward risk into the Proposed Rule with an overly ambitious objective for BEV penetration ramp from the current starting point nationwide of under five percent BEV sales today.13 For purposes of forecasting the No Action case, we caution against equating compliance credits 1:1 with BEV penetration. Notably, the ACC II ZEV Regulation includes PHEVs and FCEVs – coincidentally consistent with Executive Order 14037. These are just a few assumptions we encourage the EPA to reconsider in its No Action case. [EPA-HQ-OAR-2022-0829-0599, pp. 3-4]

C. EPA Should Update the Baseline to Ensure Full Consideration of the Inflation Reduction Act

In regulatory impact analysis, the baseline refers to "the best assessment of the way the world would look absent the proposed action."90 Developing an accurate baseline is important for conducting benefit-cost analysis, but challenging when baseline conditions are in flux. That is the case here given last year's passage of the Inflation Reduction Act (IRA). [EPA-HQ-OAR-2022-0829-0601, pp. 15-16]

90 Circular A-4, supra note 86, at 15.

To model the baseline for the Proposed Rule, EPA adopts key variables from the Annual Energy Outlook 2021 (AEO 2021), such as fleet size, new vehicle sales shares, fuel prices, electricity prices, and vehicles miles traveled.91 However, AEO 2021 was developed before the IRA's passage and thus does not include the effects of that law. While it was reasonable for EPA to rely on AEO 2021 in this proposal, it should consider adjusting the baseline in the final rule to fully incorporate the IRA's impacts. In particular, according to the 2023 version of Annual Energy Outlook (AEO 2023), the IRA will decrease both short-run and long-run electricity prices relative to the no-IRA case.92 AEO 2023 also projects that the IRA will decrease long-run gas prices, with a minimal short-run impact.93 Gasoline and electricity prices are important modeling inputs, as they affect the relative cost of ownership between ICE vehicles and BEVs and thereby influence the sales of these vehicles. These prices also affect the fuel-cost savings, the rebound effect, and related environmental impacts. [EPA-HQ-OAR-2022-0829-0601, pp. 15-16]

91 See RIA at 9-1.

92 See infra p. 30 fig.2 (difference between AEO 2023 with IRA (solid-blue line) and AEO 2023's "No IRA" case (dotted-blue line)).

93 See infra p. 30 fig.1 (difference between AEO 2023 with IRA (solid-blue line) and AEO 2023's "No IRA" case (dotted-blue line)).

There are several potential options for EPA to consistently account for the IRA across modeling inputs. One option is for EPA to adopt AEO 2023 for parameters where it currently uses AEO 2021. This would presumably also entail updating future BEV penetration, which, although EPA models separately, is based in part on parameters from AEO 2021. If EPA updates its baseline to incorporate AEO 2023, it should beware that AEO 2023 models only certain aspects of the IRA but does not include the producer-side battery tax credit.94 To blunt the resulting potential underestimate of the IRA's full impact, EPA should consider using the "High uptake of the IRA" sensitivity case provided in AEO 2023. [EPA-HQ-OAR-2022-0829-0601, pp. 15-16]

94 U.S. Energy Information Administration, Transportation Demand Module Assumptions 26 (Mar. 2023), https://www.eia.gov/outlooks/aeo/assumptions/pdf/TDM_Assumptions.pdf.

If updating the baseline to AEO 2023 is infeasible, a more feasible alternative may be for EPA to continue to use AEO 2021 as its baseline and then add the IRA's impact on other parameters on top of that. Data within AEO 2023 enables this type of assessment, as AEO 2023 provides sensitivity analysis in which it models the world with and without the IRA.95 This enables a direct comparison to assess the IRA's effect on key parameters, including electricity prices and gas prices.96 As noted above, EPA should consider adopting the "High uptake of the IRA" sensitivity case in AEO 2023 for comparison purposes.97 [EPA-HQ-OAR-2022-0829-0601, pp. 15-16]

95 See Projection Tables for Side Cases, Annual Energy Outlook 2023, https://www.eia.gov/outlooks/aeo/tables_side_xls.php (providing tables for "No IRA" case).

96 EPA acknowledges that it has estimates of future retail electricity prices that account for the IRA and that these estimates exhibit lower prices compared to a scenario without the IRA. But due to the absence of corresponding information on gasoline price estimates under the IRA and a desire for consistency across variables and model components, EPA opts not to use these estimates. RIA at 2-84.

97 See Projection Tables for Side Cases, supra note 95 (providing tables for “High uptake of the IRA” case).

This modeling adjustment could have meaningful effects (though it’s unclear whether this would increase or decrease net benefits overall, and it would almost certainly not change the sign or ordering of net benefits). According to projections from AEO 2023, the retail electricity price for transportation could be lower by an average of 0.45 cents per kWh from 2027 to 2032 under a high-IRA uptake scenario compared to a scenario without the IRA. This could translate to a decrease of about $50 in the “generalized cost,” 98 i.e. the purchase price net of vehicle ownership and operation costs.99 The lower cost of operating an electric vehicle would translate to greater BEV uptake than EPA projects in its baseline fleet. This suggests, among other implications, that the Proposed Rule’s compliance costs may be lower than EPA projects, since automakers may already be closer to complying with the proposed standards under the baseline than EPA recognizes. [EPA-HQ-OAR-2022-0829-0601, pp. 15-16]

98 Considering the average EV efficiency at 3 miles per kWh, a reduction of 0.45 cent per kWh equates to a savings of 0.15 cents per mile. Incorporating EPA’s assumptions for consumer fuel-cost calculations in their purchase decision—with an annual mileage of 12,000 miles, a 2.5-year fuel-cost valuation period, and a fueling efficiency factor of 0.9—this saving translates to around $50 = 2.5(years) ×{0.15(¢/mile)×12,000(miles/year)÷100(¢/$)}÷0.9.

99 Both producers and consumers use this metric in their decisionmaking processes. See RIA at 4-2 to 4-4.

The Appendix below includes four figures illustrating the data presented in this section. [EPA-HQ-OAR-2022-0829-0601, pp. 15-16]

Organization: Southern Environmental Law Center (SELC)

As noted throughout the proposed rulemaking, there are a number of factors that have resulted in increased ZEV adoption in recent years, and ZEV deployment is only expected to continue to accelerate. EPA, however, has developed a somewhat conservative estimate of BEV penetration in its No Action case59 which may mean it is underestimating the feasibility and impact of more stringent regulations. An inaccurate model that assumes artificially low BEV penetration is likely to cause EPA to adopt standards that are too lenient given business-as-usual conditions. [EPA-HQ-OAR-2022-0829-0591, pp. 7-8]

59 See id. at 29296.

Currently, EPA’s modeling of the No Action case does not account for state-level laws and policies that are likely to impact the nationwide deployment of ZEVs regardless of the status of the federal standards.60 For example, EPA did not seem to consider the Multi-State Medium-and Heavy-Duty Vehicle Memorandum of Understanding that has been signed by 18 jurisdictions and sets a goal of having at least 30 percent of all new medium-and heavy-duty vehicle sales be ZEVs by no later than 2030, and 100 percent of sales being ZEVs by no later than 2050.61 Additionally, although EPA used a sensitivity analysis to consider the impact of California’s Advanced Clean Cars II program, it did not include all jurisdictions that are committed to adopting these standards in its analysis.62 EPA also did not consider manufacturer and other private sector commitments to transition to ZEV fleets. These shifts, along with declining costs and other economic forces, are likely to increase baseline ZEV deployment. Finally, it is unclear whether EPA considered impacts of federal funding available under the Bipartisan Infrastructure Law (BIL) on ZEV deployment.63 The BIL and Inflation Reduction Act (IRA) offer significant funding and incentives for states, local governments, private individuals, and businesses related to ZEV manufacturing, charging infrastructure, and vehicles purchases, and many states and localities have made it a priority to maximize funding opportunities under these laws. EPA should therefore assume robust implementation and deployment of funds under these laws in its modeling. [EPA-HQ-OAR-2022-0829-0591, pp. 7-8]

60 Id.

61 Multi-State Medium-and Heavy-Duty Zero Emission Vehicle Memorandum of Understanding, Ne. States for Coordinated Air Use Mgmt., https://www.nescaum.org/documents/mhdv-zev-mou-20220329.pdf (last updated Mar. 29, 2022).

62 Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles, 83 Fed. Reg. 29334-35 (May 5, 2023). For example, EPA does not consider Virginia's adoption of the Advanced Clean Cars II standards. See Sarah Rankin, GOP leaders want to untie Virginia from California EV rule, AP NEWS (Aug. 26, 2022), https://apnews.com/article/technology-california-pollution-climate-and-environment-e661fe8026ab9ed8d5d521a14bee0858.

63 In explaining its No Action case, EPA makes no mention of the BIL and only notes "the availability of economic incentives for electric vehicles for both manufacturers and consumers provided by the IRA." Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles, 83 Fed. Reg. 29334-35 (May 5, 2023).

While there is always uncertainty in modeling, these are factors EPA should consider in the No Action case, rather than taking them into account only when assessing the feasibility of the standards [EPA-HQ-OAR-2022-0829-0591, pp. 7-8]

Organization: Valero Energy Corporation

10. EPA's baseline and sensitivity analysis is flawed.

a) EPA's application of price modifications in the "NTR" and "HDP2" no action scenarios is inconsistent with the Inflation Reduction Act and IRS's proposed implementation of 26 U.S.C. §30D.

In Section IV.B of the Preamble to EPA's proposal,53 EPA describes its approach for assessing the baseline case – or "no action" case – as well as several sensitivity cases. Within the Central Compliance Modeling for LDVs, EPA presents the results of two "no action" modeling runs:54 [EPA-HQ-OAR-2022-0829-0707, pp. 11-12]

53 EPA's Multi-Pollutant LMDV Proposal at 29295-29297.

54 EPA LMDV OMEGA GHG Compliance Modeling Runs (Document ID EPA-HQ-OAR-2022-0829-0486), 2023- 03-25-11-46-49-ld-central-compliance-run.zip.

- "NTR" run, which incorporates modeling of the impacts of the Inflation Reduction Act 55 (IRA) to LDV sales, and

- "NTA_noIRA" run, which does not. [EPA-HQ-OAR-2022-0829-0707, pp. 11-12]

55 117 H.R. 5376 (August 12, 2022).

Similarly, within the Central Compliance Modeling for MDVs, EPA presents the results of two "no action" modeling runs:56

56 EPA LMDV OMEGA GHG Compliance Modeling Runs (Document ID EPA-HQ-OAR-2022-0829-0486), 2023- 03-25-11-46-49-md-central-compliance-run.zip.

- "HDP2" run, which incorporates modeling of the impacts of the IRA to MDV sales, and

- "HDP2_noIRA" run, which does not. [EPA-HQ-OAR-2022-0829-0707, pp. 11-12]

In both the NTR and HDP2 runs, EPA mis-applies the §30D tax credit in the following ways: [EPA-HQ-OAR-2022-0829-0707, pp. 11-12]

- As of April 18, 2023, only 14 light-duty vehicles in the MY 2023 fleet are eligible for any credit amount under §30D.57 Nonetheless, EPA applies a price modification to every BEV in the MY 2023 to MY 2032 analysis fleets, without any consideration of: [EPA-HQ-OAR-2022-0829-0707, pp. 11-12]

57 https://www.politico.com/news/2023/04/17/ev-treasury-department-regulation-00092123 and https://fueleconomy.gov/feg/tax2023.shtml, accessed 4/28/2023.

- Cost of the vehicle – the §30D tax credit is only available for pick-up trucks, vans and SUVs with an MSRP ≤ $80,000 and other qualified vehicles with an MSRP ≤ $55,000. The BEV to which EPA applies the price modification have OMEGA-projected prices ranging from $24,633 to $360,545;58 [EPA-HQ-OAR-2022-0829-0707, pp. 11-12]

- o Location of final assembly – from August 17, 2022, the §30D tax credit is only available for vehicles whose final assembly occurs in North America; [EPA-HQ-OAR-2022-0829-0707, pp. 11-12]

- o Battery components – Starting in 2023, the §30D tax credit requires an increasing percentage of battery components to be manufactured or assembled in North America; [EPA-HQ-OAR-2022-0829-0707, pp. 11-12]

- o Battery critical minerals – Starting in 2023, the §30D tax credit requires an increasing percentage of battery critical minerals to be extracted, processed or recycled in eligible locations; and [EPA-HQ-OAR-2022-0829-0707, pp. 11-12]

- o Purchaser income – the §30D tax credit is only available for taxpayers with adjusted gross income less than thresholds. [EPA-HQ-OAR-2022-0829-0707, pp. 11-12]

58 EPA LMDV OMEGA GHG Compliance Modeling Runs (Document ID EPA-HQ-OAR-2022-0829-0486), 2023- 03-25-11-46-49-ld-central-compliance-run.zip, "2023_03_25_11_46_49_ld_central_compliance_run_Proposal_vehicles/csv," Column AB.

b) EPA incorrectly accounts for the regionality of BEV adoption in its ACC II sensitivity scenario.

In reference to the Central "no action" case, EPA explains that its analysis "does not include the effect of state-level policies [] because many are still not in effect." 59 For the reasons discussed in detail below, we agree that EPA cannot rely upon a scenario in which a waiver is improperly granted for state policies that are unlawful due to Clean Air Act preemption.

Nevertheless, in anticipation of these state-level policies, EPA models an ACC II sensitivity scenario, "which includes the ZEV requirements of the California Advanced Clean Car (ACC) II program for California and other participating states."60 EPA further explains that "if California were to submit a waiver request for the ACC II program and EPA were to subsequently grant the waiver, then it may be appropriate to update the No Action case in the final rulemaking to reflect the ACC II program."61,62 [EPA-HQ-OAR-2022-0829-0707, pp. 12-14]

59 EPA's Multi-Pollutant LMDV Proposal at 29296.

60 EPA's Multi-Pollutant LMDV Proposal at 29296.

61 EPA's Multi-Pollutant LMDV Proposal at 29334, footnote 737.

62 California submitted a waiver request for the ACC II program on May 22, 2023. See https://www.reuters.com/business/autos-transportation/california-seeks-us-approval-end-gas-only-new-vehicle- sales-by-2035-2023-05-23/.

In its development of the ACC II sensitivity modeling, EPA separates the base year fleet into two "regions,"63 such that: [EPA-HQ-OAR-2022-0829-0707, pp. 12-14]

63 EPA's Multi-Pollutant LMDV Proposal at 29334.

- Vehicles sold into ACC II-adopting states ("ZEV regions") are subject to minimum BEV sales share constraints according to Annual ZEV Requirements in ACC II,64 and
- The remaining vehicle sales within a given fleet year ("non-ZEV regions") are subject to a "minimum BEV sales share value of zero."65 [EPA-HQ-OAR-2022-0829-0707, pp. 12-14]

64 EPA's Multi-Pollutant LMDV Proposal at 29334.

65 EPA's Multi-Pollutant LMDV Proposal at 29334.

In the OMEGA modeling to support the ACC II sensitivity scenario, the minimum BEV sales share requirement for each region is applied as a new constraint within the existing model 66 – i.e., for the non-ZEV regions, which have a minimum BEV sales share of zero, the ACC II sensitivity treatment in OMEGA is no different from the underlying base model run.67 [EPA-HQ-OAR-2022-0829-0707, pp. 12-14]

66 EPA LMDV OMEGA GHG Compliance Modeling Runs (Document ID EPA-HQ-OAR-2022-0829-0486), 2023- 03-15-09-58-39-sensitivityACC2-3alts-20230314, "required_sales_share-body_style_zevregions_withACC2_20230222.csv."

67 EPA LMDV OMEGA GHG Compliance Modeling Runs (Document ID EPA-HQ-OAR-2022-0829-0486), 2023- 03-15-09-58-39-sensitivityACC2-3alts-20230314.zip.

The fatal flaw in EPA's logic is that the underlying base model runs – i.e., the Central Case Alt_linear, Alt_minus10, Alt_plus10, NTR, NTR-noIRA, Proposal, and SAFE runs – do not consider the regionality of BEV adoption.68 By attempting to overlay regional constraints in a model that does not otherwise consider regionality, EPA is double-counting the BEV sales share in the high-adopting states. [EPA-HQ-OAR-2022-0829-0707, pp. 12-14]

68 EPA LMDV OMEGA GHG Compliance Modeling Runs (Document ID EPA-HQ-OAR-2022-0829-0486), 2023- 03-25-11-46-49-ld-central-compliance-run.zip.

EPA provides the following data to define the "ZEV regions" and BEV sales share constraints in the ACC II sensitivity scenario.69 [EPA-HQ-OAR-2022-0829-0707, pp. 12-14]

69 EPA's Multi-Pollutant LMDV Proposal at 29334.

Table 104. Sales share of U.S. new light-duty vehicles in states adopting ACC II, by model year

Model Years	Portion of U.S. new light-duty sales	States adopting ACC II
2018 to 2025	12.6%	CA
2026	22.6%	CA, MA, NY, OR, VT, WA
2027 and later	30.4%	CA, CO, CT, MA, MD, ME, NJ, NY, OR, RI, VT, WA

[EPA-HQ-OAR-2022-0829-0707, pp. 12-14]

Table 105. ZEV Percentage sales requirement within states adopting ACC II, by model year

2022	2023	2024	2025	2026	2027	2028	2029	2030	2031	2032	2033	2034	2035
14.5	17.0	19.5	22.0	35.0	43.0	51.0	59.0	68.0	76.0	82.0	88.0	94.0	100.0

[EPA-HQ-OAR-2022-0829-0707, pp. 12-14]

Table 1 summarizes the nationwide BEV sales fractions projected by OMEGA for the "NTR" no action run within the ACC II sensitivity scenario.

Table 1 – BEV sales fraction under ACC II Sensitivity NTR scenario70

Model Year	2027	2028	2029	2030	2031	2032
Nationwide BEV sales fraction	0.325	0.421	0.494	0.523	0.524	0.545

[EPA-HQ-OAR-2022-0829-0707, pp. 12-14]

70 EPA LMDV OMEGA GHG Compliance Modeling Runs (Document ID EPA-HQ-OAR-2022-0829-0486), 2023- 03-15-09-58-39-sensitivityACC2-3alts-20230314.zip, "2023_03_15_09_58_39_sensitivityACC2_3alts_20230314_NTR_summary_results.csv," Columns DU and BBW.

Although the OMEGA model output does not provide a breakout projection of BEV sales in states not adopting ACC II, one can calculate the information using Equations 1 and 2, below:

[See original for equation calculating the breakout projection of BEV sales in states not adopting ACC II] [EPA-HQ-OAR-2022-0829-0707, pp. 14-16]

where:

BEVU.S. = Nationwide BEV sales fraction (Table 1)

BEVACCII = BEV sales fraction in ACC II adopting states (Table 104 from NPRM)71

BEVnon-ACCII = BEV sales fraction in non-ACC II adopting states (Table 2)

salesU.S. = percentage of U.S. new LDV sales occurring in the U.S. (= 100%)

salesACCII = percentage of U.S. new LDV sales occurring in ACC II adopting states (Table 105 from NPRM)72

salesnon-ACCII = percentage of U.S. new LDV sales occurring in non-ACC II adopting states (calculated per Eq-2)

71 EPA's Multi-Pollutant LMDV Proposal at 29334.

72 EPA's Multi-Pollutant LMDV Proposal at 29334.

????????−????? = ??????.?. − ?????????? Eq-2

[EPA-HQ-OAR-2022-0829-0707, pp. 14-16]

Using the EPA data and equations cited above, Table 2 summarizes the BEV sales fractions that must be achieved in non-ACC II adopting states in order to meet the nationwide BEV sales fractions modeled by EPA in the ACC II sensitivity scenario. [EPA-HQ-OAR-2022-0829-0707, pp. 14-16]

Table 2 – BEV sales fractions that would be needed for non-ACC II adopting states73

73 Example calculation for 2027: 0.28 = [(0.325 x 100%) - (0.43 x 30.4%)] / (100% - 30.4%).

Model Year	2027	2028	2029	2030	2031	2032
BEV sales fraction in non-ACC II adopting states	0.28	0.38	0.45	0.45	0.42	0.42

[EPA-HQ-OAR-2022-0829-0707, pp. 14-16]

Inexplicably, the BEV sales fractions that would be needed for the non-ACC II adopting states under the ACC II sensitivity scenario (Table 2) are actually greater than the nationwide BEV sales fractions modeled in EPA's Central NTR scenario, which are provided in Table 3. [EPA-HQ-OAR-2022-0829-0707, pp. 14-16]

Table 3 – BEV sales fractions modeled in EPA's Central NTR scenario74

74 EPA LMDV OMEGA GHG Compliance Modeling Runs (Document ID EPA-HQ-OAR-2022-0829-0486), 2023- 03-25-11-46-49-ld-central-compliance-run.zip, "2023_03_25_11_46_49_ld_central_compliance_run_NTR_summary_results.csv," Columns DL and ALG.

Model Year	2027	2028	2029	2030	2031	2032
Nationwide BEV sales fraction	0.27	0.32	0.41	0.41	0.40	0.39

[EPA-HQ-OAR-2022-0829-0707, pp. 14-16]

What EPA fails to consider in the ACC II sensitivity scenario is that BEVs are already disproportionately adopted by states that have or will adopt ACC II. Eight of the ten top states for EV market share in the first quarter of 2023, as shown in the figure below published by the Alliance for Automotive Innovation (AAI),75 are also identified by EPA as ACC II-adopting states.76 With the LDV sales associated with those states separated into the "ZEV regions" bucket in the ACC II NTR sensitivity scenario, the "no action" BEV sales fraction in the remaining U.S. states must be less than the Central NTR nationwide average. [EPA-HQ-OAR-2022-0829-0707, pp. 14-16]

75 AAI, "Get Connected Electric Vehicle Quarterly Report, First Quarter 2023, https://www.autosinnovate.org/posts/papers-reports/Get%20Connected%20EV%20Quarterly%20Report%202023%20Q1.pdf. In this figure, "EV" refers to the sum of BEV, PHEV and FCEV.

76 EPA's Multi-Pollutant LMDV Proposal at 29334.

[See original for graph titled "EV Market Share by State] [EPA-HQ-OAR-2022-0829-0707, pp. 14-16]

Source: AAI "Get Connected Electric Vehicle Quarterly Report", First Quarter 2023 [EPA-HQ-OAR-2022-0829-0707, pp. 14-16]

The modeled producer and consumer behaviors in response to the ACC II policy are not simply additive to the underlying no action (Central NTR) scenario, and EPA cannot reasonably project the impacts of an ACC II sensitivity case without first regionally disaggregating BEV sales within the Central NTR scenario. [EPA-HQ-OAR-2022-0829-0707, pp. 14-16]

c) EPA's ACC II sensitivity scenario relies on unreasonable assumptions regarding the implementation of the ACC II Program. [EPA-HQ-OAR-2022-0829-0707, pp. 16-18]

EPA fails to recognize and account for the following complexities of the ACC II Program in its ACC II sensitivity scenario modeling:

• ZEVs are not limited to BEVs. EPA assumes for the purposes of the ACC II sensitivity scenario that "ZEV" means "BEV" and fails to consider that FCEVs are also ZEVs.77 [EPA-HQ-OAR-2022-0829-0707, pp. 16-18]

77 California Code of Regulations Title 13, Section 1962.2(i)(18).

• EPA neglects to consider the compliance options and flexibilities available to manufacturers under ACC II. EPA assumes that the Annual ZEV Requirement under the ACC II Program relies wholly on BEV sales, whereas in reality, "manufacturers may meet a portion of their Annual ZEV Requirement with PHEV values, environmental justice values, or early compliance values."78 For instance, [EPA-HQ-OAR-2022-0829-0707, pp. 16-18]

78 California Code of Regulations Title 13, Section 1962.4(e).

- ACC II allows manufacturers to satisfy up to 20 percent of their Annual ZEV Requirement through the sale of qualifying PHEVs;79
- o ACC II offers multiplier incentives of up to 1.5x for vehicles used in certain Environmental Justice programs, up to 5 percent of a manufacturer's Annual ZEV Requirement;80 and

o Manufacturers may earn and apply early compliance credits, up to 15 percent of their Annual ZEV Requirement.81 [EPA-HQ-OAR-2022-0829-0707, pp. 16-18]

79 California Code of Regulations Title 13, Section 1962.4(e)(1).

80 California Code of Regulations Title 13, Section 1962.4(e)(2).

81 California Code of Regulations Title 13, Section 1962.4(e)(3).

A. EPA disregards obstacles to ZEV Penetration.

To support its conclusion that the automotive fleet is rapidly electrifying, EPA selectively references projections by third-party sources, but overlooks the caveats and qualifications that accompany these statements. For example, EPA cites to IHS Markit's prediction of "a nearly 40 percent U.S. PEV share by 2030."92 But IHS Markit also cautions that "specific compliance challenges vary from OEM to OEM"93, and according to Mike Fiske, an Associate Director of North America Powertrain Forecasting at IHS Markit, "manufacturers are also keenly aware of the risks associated with a rapid transition to electrification, [which include] consumer acceptance, vehicle range, and affordability among top concerns."94 [EPA-HQ-OAR-2022-0829-0707, pp. 19-20]

92 EPA's Proposed Rule: Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles [hereinafter "Proposed Rule"] at 29189 (citing to IHS Markit, ''US EPA Proposed Greenhouse Gas Emissions Standards for Model Years 2023– 2026; What to Expect,'' August 9, 2021).

93 IHS Markit, ''US EPA Proposed Greenhouse Gas Emissions Standards for Model Years 2023– 2026; What to Expect,'' August 9, 2021, https://www.spglobal.com/mobility/en/research-analysis/us-epa-proposed- greenhouse-gas-emissions-standards-my2023-26.html.

94 Id.

EPA also relies on "[m]ore recent projections by Bloomberg New Energy Finance[, which] suggest that under current policy and market conditions, and prior to the IRA, the U.S. was on pace to reach 40 to 50 percent PEVs by 2030."95 However, BNEF's 2022 EV Outlook also provides as follows: [EPA-HQ-OAR-2022-0829-0707, pp. 19-20]

95 EPA's Proposed Rule at 29189 (citing to Bloomberg New Energy Finance (BNEF), ''Electric Vehicle Outlook 2022,'' Long term outlook economic transition scenario).

- "Despite the rapid rise in EV adoption, road transport is still not on track for carbon neutrality by 2050. Simply changing out the drivetrain of vehicles may not be the most efficient way to deliver net zero".96 [EPA-HQ-OAR-2022-0829-0707, pp. 19-20]

96 Bloomberg New Energy Finance (BNEF), ''Electric Vehicle Outlook 2022,'' Long term outlook economic transition scenario, Executive Summary at 1.

- "Raw materials supply constraints for batteries also look very tight for the years ahead."97 [EPA-HQ-OAR-2022-0829-0707, pp. 19-20]

Additionally, per EPA, when U.S. ZEV share predictions are “adjusted for the effects of the Inflation Reduction Act, this estimate increases to 52 percent.”104 Yet EPA’s source also caveats that “in 2021, Bloomberg report[ed], [that] less than 5% of new cars sold in the U.S. were electric.”105 EPA also cites to a “another study by the International Council on Clean Transportation (“ICCT”) and Energy Innovation that includes the effect of the IRA estimates that the share of BEVs will increase to 56 to 67 percent by 2032.”106 However, the ICCT’s estimates in this study are inclusive of California’s Advanced Clean Cars program and other Section 177 State adoptions of the Advanced Clean Cars program.107 As such, the scope of the ICCT’s study is not exclusive to an assessment of the IRA’s impact on U.S. ZEV penetration rates. Rather, it encompasses other factors that EPA does not properly account for, thus causing EPA to overestimate the impact of IRA incentives on ZEV penetration. The ICCT study at issue also highlights material context and conditions that EPA does not sufficiently consider in its proposal, including the following statements: [EPA-HQ-OAR-2022-0829-0707, pp. 20-22]

EPA’s DRIA further provides that “Goldman Sachs projects a 50 percent share for BEVs in the U.S. in 2030, 70 percent in 2035 and 85 percent in 2040.”114 But EPA ignores factors outside the control of regulators and OEMs alike that will be material to the feasibility of EPA’s proposal and are highlighted in EPA’s own citational support. Specifically, the Goldman Sachs forecast states that “the EV sector is beset by some major crosscurrents”, which include “ring prices for electrical power” and “inflation for the materials that make up battery components”.115 Further, “[t]he EV sector has some challenges in the near term.” This includes “‘greenflation’, as demand for batteries pushes up prices for key materials involved in making them, according to strategists in Goldman Sachs Research.”116 These strategists “expect battery costs to increase 6% in 2023 from the year before”.117 Collectively, these issues illustrate the neglected assumptions underpinning EPA’s central trajectory for LD ZEV sales and supporting infrastructure. These issues are central to EPA's proposal and make EPA's proposal unreasonable, arbitrary and contrary to law. [EPA-HQ-OAR-2022-0829-0707, pp. 20-22]

117 Id. B. EPA disregards caveats regarding ZEV production capabilities.

EPA cites to “[a] proliferation of announcements by automakers in the past two years[,] signal[ing] a rapidly growing shift in product development focus among automakers away from internal-combustion technologies and toward electrification.”118 Drawing support from these announcements, EPA concludes that it is feasible within the next decade to force transition of the domestic LDV fleet to BEV largely on the basis of third-hand sources and news articles taken out of context. Though EPA acknowledges in passing that “manufacturer announcements such as these are not binding, and often are conditioned as forward-looking and subject to uncertainty[,]”119, EPA’s proposed rule is not characterized by any reciprocal flexibilities to adjust ambitious targets in order to accommodate material realities and uncertainties impacting BEV production. In contrast to EPA’s projections, the same OEMs EPA cites to for support of the Proposed Rule have raised material concerns with an accelerated transition to LD BEVs. [EPA-HQ-OAR-2022-0829-0707, pp. 22-25]

118 EPA’s Proposed Rule at 29190.

119 EPA’s Proposed Rule at 29193.

For example, EPA cites to a May 2021 announcement from Ford, providing that “they expect 40 percent of their global sales will be all-electric by 2030.”120 However, the Ford press release EPA cites to also contains the following laundry list of caveats:121 [EPA-HQ-OAR-2022-0829-0707, pp. 22-25]

“Cautionary Note on Forward-Looking Statements

Statements included or incorporated by reference herein may constitute ‘forward- looking statements’ within the meaning of the Private Securities Litigation Reform Act of 1995. Forward-looking statements are based on expectations, forecasts, and assumptions by our management and involve a number of risks, uncertainties, and other factors that could cause actual results to differ materially from those stated, including, without limitation: [EPA-HQ-OAR-2022-0829-0707, pp. 22-25]

- Ford and Ford Credit's financial condition and results of operations have been and may continue to be adversely affected by public health issues, including epidemics or pandemics such as COVID-19; [EPA-HQ-OAR-2022-0829-0707, pp. 22-25]

- Ford is highly dependent on its suppliers to deliver components in accordance with Ford's production schedule, and a shortage of key components, such as semiconductors, can disrupt Ford's production of vehicles; [EPA-HQ-OAR-2022-0829-0707, pp. 22-25]

- Ford's long-term competitiveness depends on the successful execution of its Plan;

- Ford's vehicles could be affected by defects that result in delays in new model launches, recall campaigns, or increased warranty costs; [EPA-HQ-OAR-2022-0829-0707, pp. 22-25]

- Ford may not realize the anticipated benefits of existing or pending strategic alliances, joint ventures, acquisitions, divestitures, or new business strategies; [EPA-HQ-OAR-2022-0829-0707, pp. 22-25]

- Operational systems, security systems, and vehicles could be affected by cyber incidents and other disruptions; [EPA-HQ-OAR-2022-0829-0707, pp. 22-25]

- Ford's production, as well as Ford's suppliers' production, could be disrupted by labor issues, natural or man-made disasters, financial distress, production difficulties, or other factors; [EPA-HQ-OAR-2022-0829-0707, pp. 22-25]

- Ford's ability to maintain a competitive cost structure could be affected by labor or other constraints; [EPA-HQ-OAR-2022-0829-0707, pp. 22-25]

- Ford's ability to attract and retain talented, diverse, and highly skilled employees is critical to its success and competitiveness; [EPA-HQ-OAR-2022-0829-0707, pp. 22-25]

- Ford's new and existing products and mobility services are subject to market acceptance and face significant competition from existing and new entrants in the automotive and mobility industries; [EPA-HQ-OAR-2022-0829-0707, pp. 22-25]

- Ford's results are dependent on sales of larger, more profitable vehicles, particularly in the United States; [EPA-HQ-OAR-2022-0829-0707, pp. 22-25]

- With a global footprint, Ford's results could be adversely affected by economic, geopolitical, protectionist trade policies, or other events, including tariffs; [EPA-HQ-OAR-2022-0829-0707, pp. 22-25]

- Industry sales volume in any of Ford's key markets can be volatile and could decline if there is a financial crisis, recession, or significant geopolitical event; [EPA-HQ-OAR-2022-0829-0707, pp. 22-25]

- Ford may face increased price competition or a reduction in demand for its products resulting from industry excess capacity, currency fluctuations, competitive actions, or other factors; [EPA-HQ-OAR-2022-0829-0707, pp. 22-25]

- Fluctuations in commodity prices, foreign currency exchange rates, interest rates, and market value of Ford or Ford Credit's investments can have a significant effect on results; [EPA-HQ-OAR-2022-0829-0707, pp. 22-25]

- Ford and Ford Credit's access to debt, securitization, or derivative markets around the world at competitive rates or in sufficient amounts could be affected by credit rating downgrades, market volatility, market disruption, regulatory requirements, or other factors; [EPA-HQ-OAR-2022-0829-0707, pp. 22-25]

- Ford's receipt of government incentives could be subject to reduction, termination, or clawback; [EPA-HQ-OAR-2022-0829-0707, pp. 22-25]

- Ford Credit could experience higher-than-expected credit losses, lower-than-anticipated residual values, or higher-than-expected return volumes for leased vehicles; [EPA-HQ-OAR-2022-0829-0707, pp. 22-25]

- Economic and demographic experience for pension and other postretirement benefit plans (e.g., discount rates or investment returns) could be worse than Ford has assumed; [EPA-HQ-OAR-2022-0829-0707, pp. 22-25]

- Pension and other postretirement liabilities could adversely affect Ford's liquidity and financial condition; [EPA-HQ-OAR-2022-0829-0707, pp. 22-25]

- Ford could experience unusual or significant litigation, governmental investigations, or adverse publicity arising out of alleged defects in products, perceived environmental impacts, or otherwise; [EPA-HQ-OAR-2022-0829-0707, pp. 22-25]

- Ford may need to substantially modify its product plans to comply with safety, emissions, fuel economy, autonomous vehicle, and other regulations; [EPA-HQ-OAR-2022-0829-0707, pp. 22-25]

- Ford and Ford Credit could be affected by the continued development of more stringent privacy, data use, and data protection laws and regulations as well as consumers' heightened expectations to safeguard their personal information; and [EPA-HQ-OAR-2022-0829-0707, pp. 22-25]

- Ford Credit could be subject to new or increased credit regulations, consumer protection regulations, or other regulations. [EPA-HQ-OAR-2022-0829-0707, pp. 22-25]

- We cannot be certain that any expectation, forecast, or assumption made in preparing forward-looking statements will prove accurate, or that any projection will be realized. It is to be expected that there may be differences between projected and actual results. Our forward-looking statements speak only as of the date of their initial issuance, and we do not undertake any obligation to update or revise publicly any forward-looking statement, whether as a result of new information, future events, or otherwise. For additional discussion, see "Item 1A. Risk Factors" in our Annual Report on Form 10-K for the year ended December 31, 2020, as updated by subsequent Quarterly Reports on Form 10-Q and Current Reports on Form 8-K." [EPA-HQ-OAR-2022-0829-0707, pp. 22-25]

Moreover, in March 2023, figures released by Ford highlighted that Ford Motor Co.'s EV business had lost $3 billion before taxes during the past two years and will lose a similar amount this year as the company invests heavily in EV technology.122 Ford's 10-K filed in February 2023 further disclosed: [EPA-HQ-OAR-2022-0829-0707, pp. 22-25]

122 Krishner, Tom, Associated Press, "Ford's electricitv vehicle unit losing billions, as company invests in new technology" (March 23, 2023), https://www.pbs.org/newshour/economy/fords-electric-vehicle-unit-losing- billions-as-company-invests-in-new-technology; see also Ford News Release, "'Refounded' Ford to Show How Customer-Focused Segments Will Drive Value and Growth, Changes in Financial Reporting (March 23, 2023) https://media.ford.com/content/fordmedia/fna/us/en/news/2023/03/23/_refounded_-ford-to-show-how-customer-focused-segments-will-driv.html.

- "We have announced plans to significantly increase our electric vehicle production volumes; however, our ability to produce higher volumes of electric vehicles is dependent upon the availability of raw materials necessary for the production of batteries, e.g., lithium, cobalt, nickel, graphite, and manganese, among others."123 [EPA-HQ-OAR-2022-0829-0707, pp. 22-25]

123 Ford 10-K Annual Report (Feb. 3, 2023) https://shareholder.ford.com/Investors/financials/sec-filings/sec-filings- details/default.aspx?FilingId=16361873 (emphasis added).

- "As a result of the competition for and limited availability of the raw materials needed for our electric vehicle business, the costs of such materials are difficult to accurately forecast as they may fluctuate during the term of the offtake agreements and other long-term purchase contracts based on market conditions. Accordingly, we may be subject to increases in the prices we pay for those raw materials, and our ability to recoup such costs through increased pricing to our customers may be limited. As a result, our margins, results of operations, financial condition, and reputation may be adversely impacted by commitments we make pursuant to offtake agreements and other long-term purchase contracts."124 [EPA-HQ-OAR-2022-0829-0707, pp. 22-25]

124 Ford 10-K Annual Report (Feb. 3, 2023) https://shareholder.ford.com/Investors/financials/sec-filings/sec-filings- details/default.aspx?FilingId=16361873 (emphasis added).

Organization: Western Energy Alliance

EPA relies on rosy market projections, citing a Bloomberg New Energy Finance analysis suggesting that, "under current policy and market conditions, and prior to the IRA, the U.S. was on pace to reach 40 to 50 percent PEVs by 2030. When adjusted for the effects of the Inflation Reduction Act, this estimate increases to 52 percent." (p. 29189) EPA also cites the International Council on Clean Transportation as projecting an increase in new car sales of 67%. EPA should conduct a more robust market analysis with less biased sources if it is to avoid the charge of being arbitrary and capricious. [EPA-HQ-OAR-2022-0829-0679, p. 8]

EPA Summary and Response

Multiple commenters (Hyundai, Environmental and Public Health Organizations) recommended that EPA include California's ACC II and ACT regulations in our No Action case modeling. In response, for this final rulemaking analysis EPA is again including ACT for medium-duty vehicles, but is not including ACC II for light-duty vehicles in the No Action case. At the time of this rulemaking EPA has not issued a waiver for ACC II. This rule is independent from ACC II standards and our feasibility analysis does not depend on the implementation of ACC II, as discussed further in RTC Chapter 2.3. A sensitivity envisioning a fully implemented

ACC II – based on the participating states, and their respective vehicle sales shares – is included in the State-Level Policies sensitivity, as we discuss in preamble section IV.F. This sensitivity assumes nearly 100% of the Section 177 states achieving the ZEV sales share requirements specified in ACC II. And so, the actual effect of ACC II should be something between the No Action case (assuming no state-level policy effects) and 100% of the state-level policy effects. In this way, Hyundai's expectations of actual ACC II realization should fall somewhere between those two cases. EPA's analysis of the medium-duty GHG standards does include California's ACT regulations in the No Action case. This treatment of a state-level policy in the medium-duty central case analysis is different than for light-duty because EPA has granted a waiver for California's ACT program.

California Attorney General's Office et al. commented in support of EPA's decision to not include modeling of ACC II in the No Action case, and observed that if EPA had included it for the NPRM analysis, the estimated costs of the standards would be lower. EPA agrees with this assessment. The commenter is correct that in EPA's "State-level ZEV policies" sensitivity analysis, the No Action case PEV penetrations are higher, and the costs are lower than the central case. Results for this sensitivity are presented in RIA Chapter 12.1.4.

The Center for American Progress and ACEE commented that EPA's No Action case was conservative in terms of the number of BEVs projected for the NPRM. The commenters cited other projections with higher BEV penetrations than the No Action case in EPA's central analysis. The Center for American Progress cited an ICCT study that accounted for the effects of ACC II and IRA incentives, and with BEV penetrations for 2032 that approached the level of EPA's NPRM projections for the Action case. In response, as discussed above, EPA did not include ACC II in the central case for this final rulemaking analysis. EPA's No Action case PEV penetrations are a function of multiple considerations, inputs and assumptions. Among these considerations are various third-party projections of technology penetration rates in the absence of new standards. The particular study cited by the commenter shows projected PEV penetrations that are higher than the range of studies used by EPA in the calibration of the No Action case PEV market, as described in RIA Chapter 4.1. While EPA has concluded that the level of PEVs projected in our No Action case is not overly conservative, we acknowledge that higher levels such as those cited by the commenter may be plausible, as illustrated by several of the sensitivity cases presented in RIA Chapter 12. Such higher PEV levels further support the feasibility of the final standards.

Western Energy Alliance commented that EPA's No Action case BEV projections were based on "rosy market projections," and recommended that EPA should conduct a market analysis using "less biased sources". In response, EPA disagrees that the third-party sources considered when developing the No Action BEV projections were biased, and we note that the commenter does not provide any explanation or evidence for the assertion of bias. EPA has continued to monitor new studies on this topic, and where appropriate incorporate those studies from respected third-party organizations that specialize in analysis and projections for the automotive market. A discussion of the range of studies considered for the analysis of the No Action case in this final rulemaking is provided in RIA Chapter 4.1.

Valero asserted that EPA projections of BEVs in the No Action case for the "State-level ZEV policies" sensitivity case were incorrect because of double-counting of BEVs in the non-ACC II regions. In the words of the commenter, "[b]y attempting to overlay regional constraints in a model that does not otherwise consider regionality, EPA is double-counting the BEV sales share in the high-adopting states." In response, EPA disagrees that BEV sales are double counted in the ACC II sensitivity. The commenter has apparently incorrectly concluded that the single-region National BEV sales from the central case are carried over unchanged into the non-ZEV region of the sensitivity analysis, and that the ZEV-region BEV sales are added to those carried over sales, which, if it were true, would thus generate an inappropriately high level of total BEV sales. Actually, the model does not use this approach. Instead, the sensitivity analysis has unique input files (vehicles.csv and context_new_vehcile_market.csv) which define the overall sales volumes for the analysis context separately for the two regions. As a result, the sales of the non-ZEV region for the ACC II sensitivity case are appropriately only a portion of the National sales for the central case. Accordingly, the overall BEV sales for the non-ZEV region for the ACC II sensitivity will tend to be less National BEV sales of the central case, contrary to the commenter's assertion that central case BEV sales were "simply additive."

13 - Consumer considerations

13.1 - Response to recurrent comments

Among the comments in this section, which appear below, several themes emerged. For brevity and clarity, we address those recurrent comments here in this introduction titled Response to Recurrent Comments. We also note at the outset that the vast majority of comments address consumer considerations regarding light-duty BEVs and PHEVs; a smaller number of comments addressed consumer considerations regarding ICE and hybrid vehicles and medium-duty vehicles.

First, in several comments, the standards are characterized as plug-in electric vehicle (PEV) mandates, using a variety of terminology such as "mandate", "force", "require", "drive consumers to purchase products", "prescriptive policy", and "dictating". Similarly, in many comments, OMEGA estimates of vehicle technology market shares appear to be perceived and described as a "mandate", "requirement", "preferred option", or "single technology pathway." For example, the American Free Enterprise Chamber of Commerce states that the feasibility of the rule "critically depends on the electric-vehicle adoption rates it projects for model years 2027 through 2032." Relatedly, some commenters appear to perceive and describe the standards and the compliance pathway as not being technology neutral. For example, the National Association of Convenience Stores (NACS) et al. asserts that the "proposal … artificially tilts the scale toward electric vehicles." In these and all similar comments, these misunderstandings and misrepresentations of the standards and compliance pathways are incorrect. As a consequence, subsequent arguments based on these mischaracterizations are invalid.

In response, the standards do not mandate PEV adoption; the standards are performance-based emissions standards and manufacturers choose the mix of technologies to comply (e.g., see Preamble I.B.1). In the final rulemaking, we clarify the nature of the standards and demonstrate several alternate pathways for compliance in the RIA in addition to the central case. We have demonstrated multiple potential compliance pathways that include ICE vehicle, hybrids, BEVs, and PHEVs. See sensitivity scenarios in Chapter 4.1 and Chapter 12.1.4 of the RIA. Among alternative pathways, we demonstrate that manufacturers can comply with these standards without increasing the market share of BEVs (i.e., see the No Additional BEVs case, RIA Chapter 12.1.4.4 and Section IV.F.5 of the Preamble).

We respond further by noting that the converse of this faulty PEV mandate argument is also incorrect; the standards and the OMEGA estimates of technology shares do not limit the ability of manufacturers to produce, or for consumer to purchase, ICE vehicles. Likewise, further extensions of this incorrect notion, such as fossil fuel bans, are also incorrect. The central case estimates in the FRM present the most reasonable estimate of vehicle technology market shares according to our analyses. However, within the flexibility of these standards, we expect that manufacturers will choose their respective compliance pathways and match their production portfolio to the highly varied demands of their diverse customers (e.g., households, farmers, ride-hailing drivers, commuters, businesses).

Second, many commenters suggested that EPA's estimates of PEV acceptance (aka demand, attitudes, preferences) and PEV market shares are unreasonable or, for example, "extremely aggressive." In contrast, some commenters assert that EPA's estimates of PEV acceptance and market shares are not sufficiently reflective of state initiatives and manufacturer commitments, and therefore, estimated PEV market shares were too low. According to the California Air Resources Board, "the proposal is not only achievable, but that manufacturers could exceed the standards."

In response, the PEV market shares projected in the FRM central case are reasonable estimates of vehicle technology market shares according to the parameters of our analyses. Our parametrization of PEV acceptance is based on the scientific literature on consumer acceptance, and the resulting central case estimate of future PEV market shares in the No Action case is consistent with third-party estimates that do include projected effects of the IRA and do not include projected effects of this rule (See RIA Chapter 4.1.2). Importantly, we acknowledge the uncertainty inherent in any estimate, and as a result, we have tested the sensitivity of our modeling to different parameterizations of PEV acceptance. Through these sensitivities, we show that compliance does not rely or rest on a specific assumption about PEV acceptance, and therefore, also does not rest upon, for example, the "effect of interacting policies on consumer acceptance." Rather, compliance can be achieved across a broad range of potential developments in consumer acceptance.

Third, some commenters advocate for greater certainty. For example, Consumer Reports states, "By guaranteeing that greater numbers of EVs will be manufactured in the coming years, the new standards will help give private industry the confidence it needs to invest in infrastructure." The corollary is that PEV adoption will also rise since charging access enables PEV adoption. While we agree with this logic, according to our analyses and assuming manufacturers engage in cost-minimizing decision making,[470] EPA's central case projections for vehicle technology shares are likely. As such, we agree with Zero Emissions Transportation Association's (ZETA's) comment that "the adoption of more stringent emissions standards would incentivize the production of more EVs" among the many available technologies that manufacturers may choose in complying with the standards—not guarantee that result. We note that beyond our central case analysis, we have demonstrated through a range of sensitivity

[470] Specifically, OMEGA, incorporates RSEs, technology costs, and other inputs into its algorithms for finding cost-efficient pathways for manufacturers to achieve compliance with desired emissions standards.

scenarios that manufacturers can comply with the standards through a range of technology pathways, including various mixes of ICE, hybrids, PHEVs and BEVs.

Fourth, several commenters stated that these standards would reduce consumer choice, with Competitive Enterprise Institute going so far as to suggest that the standards amount to a "cartelization of the auto industry." We disagree. In response and in contrast to those comments, consumer choice can be preserved and expanded through a variety of combinations of body styles, price points, and powertrains not yet available in today's vehicle market. Greater numbers and diversity of PEVs introduce choices that past consumers did not have, choices that consumers might have made if more PEV options had been available. For example, Forsythe et al. (2023) found that the projected reductions in the BEV price-premium "have driven substantial increases in consumer choices of BEV cars and SUVs over their conventional gasoline vehicle counterparts." Continuing ZETA's comment from above, "the adoption of more stringent emissions standards would incentivize the production of more EVs to meet growing consumer demand while also spurring innovation and increased model availability to meet the needs of an increasingly wider range of consumers." We have seen evidence of a favorable response to increased PEV options, as noted by commenters, enthusiastic response to the introduction of BEV pickup and SUV models. In general, CALSTART expects growth in consumer choice and in "equitable access to clean transportation options."

Regarding non-PEVs, the findings from Consumer Reports (CR) indicate that vehicle options will most likely increase, on the whole, with substantially more vehicle options that meet the desire of the majority of consumers for improved fuel economy. CR states that the remaining non-PEVs "will have to compete with better and better EV offerings," especially in light of "consumer demand for cleaner, more efficient gasoline vehicles." Preference for more efficient vehicles is supported by a preponderance of survey evidence provided by commenters. For example, CR finds that "seven in ten American drivers say that fuel economy is either 'very important' or 'extremely important'" to their purchase decision; "43% of drivers selected improvement in fuel economy" as the attribute of their vehicles that leaves the most room for improvement; and "85% of Americans agree that automakers should continue to improve fuel economy across vehicle types." Relatedly, we have assumed in our modeling that ICE vehicle emissions will not worsen.

Fifth, several commenters, including the Alliance for Automotive Innovation, state that "customers may simply reject new offerings and remain in older vehicles longer, further increasing the rising average age of vehicles on the road and delaying rollouts of other technologies. Any of these outcomes would detract from achieving the agency's overall goals of reduced emissions and improved fuel economy." In response, EPA models the interaction of producer production decisions and consumer purchase decisions, where these decision makers minimize their respective estimation of costs. See RIA Chapter 2.6 and RIA Chapter 4.1. In addition, "OMEGA estimates the effects of a policy on new vehicle sales volumes as a deviation from the sales that would take place in the absence of the standards." See RIA Chapter 4.4.1. As a result, our modeling accounts for consumers who choose not to purchase a new vehicle. Our modeling also accounts for consumers that will not purchase PEVs and purchase ICE vehicles instead. Furthermore, our modeling takes into account the cost and non-cost criteria that influence consumer purchase decisions, many of which were highlighted by commenters. Since our modeling accounts for changes in sales as a result of the standards, we disagree with commenters' claims that an unaccounted for "rejection of new offerings" will yield an aging vehicle fleet, delayed technology rollouts, and fewer emissions reductions. It's worth noting that this is a familiar critique and is called the Gruenspecht Effect. Notably, EPA does in fact model changes in sales as the result of the standards. See RIA Chapter 4.4. Furthermore, given the nature of transportation and vehicle mileage accumulation in the U.S., most existing vehicles will eventually be scrapped and replaced.[471] In the presence of these standards, that future vehicle is likely to be more fuel efficient than it would be otherwise.

We note that commenters further attribute a hypothesized unwillingness or inability of consumers to purchase the vehicles comprising a compliant fleet to a variety of factors such as technology costs, vehicle purchase price, ownership costs, affordability, inconvenience, access, reliability, and durability. In short, some commenters disagree with EPA's characterization of consumer demand, purchase decisions, and behavior. We address assertions regarding the underpinnings of consumer demand, purchase decisions, and behavior in more detail in subsequent sections. We believe that Our representations of ICE vehicle and PEV acceptance and consumer attitudes and preferences, purchase decision, and behavior are based on the scientific literature in the public record, as discussed in RIA Chapter 4.1. The resulting central case estimates of future vehicle technology market shares in the No Action case are consistent with third-party estimates. Our consumer-related modeling assumptions and methods are substantiated and reasonable and based on the best available information including our consideration of the public comments, as are the resulting estimates.

Sixth, many comments cite historical and current statistics (e.g., sales, survey results), prices (e.g., vehicles, fuels), costs (e.g., battery, emissions control technology, infrastructure), and availability (e.g., critical mineral, charging stations and ports) to argue the inaccuracy of EPA's projections. In response, we note that the information provided by commenters comes from a wide variety of sources, some of which agree and some of which do not. These differences and similarities occur for a variety of generally accepted reasons (e.g., timing of the study, survey design, sampling population, sample design) and from a variety of familiar sources (e.g., academic journals, media, public and private sector reports). We question the strength of an argument based on those quantities alone, especially those that do not take into account the dynamic nature of vehicle markets (e.g., See RIA Chapter 4.1 regarding diffusion of innovations). Instead, to commenters for whom these historical or current quantities are at the crux of their argument, we reply that scientific, regulatory, governmental, consumer, and manufacturing communities are in agreement that a significant transition toward PEVs is underway. We project and substantiate changes in vehicle markets over the next 8 years. Throughout the Preamble and RIA, we provide detailed descriptions of the analyses behind the conclusions we reach. We offer our detailed analyses as our response to comments for which historical and current quantities are at the crux of their arguments.

Lastly, consumer characteristics, issues, impacts, and consideration and therefore comments regarding consumers cannot be siloed. Many of the comments addressed here regarding consumer preferences and attitudes, purchase decision, ownership behavior, and savings and

[471] Specifically, EPA projects changes in new vehicle sales as a result of the standards and associated changes in new vehicle purchase prices. EPA also accounts for the distributions of vehicle age and VMT across the vehicle stock. The net effect of this approach is that the small reduction in new vehicle sales tend to increase the portion of miles driven by older vehicles, and therefore tend to increase their overall impacts relative to a case where there is no change in new sales. Our modeling includes a consumer choice element that considers out-of-pocket expenses when purchasing a new vehicle, projected operating savings and incentives available by the IRA.

expenses relate to other aspects of this rule. We also acknowledge that this is especially true for comments regarding PEV acceptance, the consumer-facing nature of PEV technology and the interconnectedness of PEV acceptance and other market conditions. Specifically, many commenters correctly link consumer demand for and acceptance of vehicle technologies, particularly PEV technology, to vehicle attributes such as body style, range, battery durability, and price; fueling and charging conditions such as feasibility of home and work charging, access to public charging, time to fuel and charge, reliability of EVSE; and other factors. In response to all of the comments in this chapter, we address only consumer aspects of the comments here and refer readers to the substantive analyses regarding other related aspects of this rule to the relevant sections of this RTC, the RIA, and the Preamble.

13.2 - Consumer demand

Comments by Organizations

Organization: Alliance for Automotive Innovation

C. Historical Technology Adoption Versus EV Penetration Assumptions

Figure 2 shows the penetration rate of automotive technologies that have been introduced in the last nineteen years. Technologies that follow the most aggressive growth curve are those that are generally transparent to the customer. Eight speed transmissions, gasoline direct injection (GDI) engines, and stop-start have become standard features, and have little or no impact on customer driving behaviors. BEVs, on the other hand, require drivers to make active changes to their driving habits and potentially additional investments (e.g., home charging equipment). In short, BEVs require change, whereas many of the most successful automotive technologies do not. [EPA-HQ-OAR-2022-0829-0701, pp. 29-30]

EPA is assuming that automobile manufacturers can increase BEV production as quickly as they have adopted new transmission or engine technologies, despite the need to build entirely new supply chains and manufacturing facilities. Underlying such rapid growth is also an assumption that the majority of new vehicle buyers will accept BEVs and their inherent changes to driving habits. [EPA-HQ-OAR-2022-0829-0701, pp. 29-30]

[See original comment for Figure 2: Examples of historical automotive technology adoption29 compared to projected BEV market share under the EPA proposal.30]

29 U.S. Environmental Protection Agency, Automotive Trends Report (Mar. 2023), Detailed data. Available at htps://www.epa.gov/automotive-trends/explore-automotive-trends-data#DetailedData. See Detailed Real-World Fuel Economy, CO2 Emissions, and Vehicle Attribute and Technology data.

30 Reflects EPA proposal, central analysis.

EPA has assumed a steep growth in BEV adoption at rates typically only seen in the evolution of disruptive technologies such as the cell phone, the television and microwave ovens, all of which added significant direct convenience and other benefits to customers and that cost substantially less at the time of purchase than an automobile. BEVs, on the other hand, have not thus far experienced such rapid adoption. In terms of convenience or additional new utility, BEVs offer generally superior acceleration performance, home refueling (a convenience not available to all customers), potentially lower fuel costs (that are dependent on where and when a vehicle is charged), and environmental benefits (important to some, but transparent to many). [EPA-HQ-OAR-2022-0829-0701, p. 31]

Thus, EPA makes an extremely aggressive assumption for a nascent technology that has not been fully embraced by the consumer and that faces many additional industrial and market challenges. [EPA-HQ-OAR-2022-0829-0701, p. 31]

Rapid adoption is generally achieved through customer interest and demand for products. According to the latest JD Power EV Index, the percentage of Americans who say they are "very unlikely" to buy an electric vehicle as their next car is growing.34 JD Power has found that the EV-skeptic contingent has steadily grown from 18% to 21% of respondents between January and March 2023. Those "very likely" to go electric has stayed flat this year at 27%.35 These trends are seen across buyer demographics as well. While the majority of baby boomers and pre-boomers are not considering EVs, 33% of Generation Z shoppers also told JD Power they were either "somewhat unlikely" or "very unlikely" to buy an EV.36 [EPA-HQ-OAR-2022-0829-0701, p. 32]

b) Market Concerns

The premise that “Modern vehicles have sufficient power without the use of enrichment”288 is highly subjective and ultimately decided by the customer and their increasing demand for vehicle utility. Such a broad declaration gives the impression that EPA believes that vehicle utility has reached a practical zenith or that any incremental utility can and should now be capped in order to facilitate a new, narrow emissions reduction strategy through the elimination of enrichment. This is in contrast with EPA’s historical practice of setting performance-based standards that generally assume at least maintaining current levels of performance (i.e., not negatively affecting a vehicle’s utility). [EPA-HQ-OAR-2022-0829-0701, pp. 182-183]

288 NPRM at 68.

New vehicle purchasers generally desire increased vehicle features, including power, not less. Power, and the enhanced utility and driving dynamics it enables, are core customer-demanded functional attributes of a vehicle and engine combination. The preference of customers for improved features transcends all price points and vehicle segments. New vehicle purchasers consistently raise the bar on what they decide to be sufficient. [EPA-HQ-OAR-2022-0829-0701, pp. 182-183]

In the past, customers who sought greater vehicle utility or higher performance did so through selection of optional engines with greater displacement. However, industry, driven in part by GHG and fuel economy regulations, has developed entire families of downsized engines that have proven capable of meeting customer demands for power while simultaneously increasing efficiency and lowering GHG emissions. This is exactly the strategy that EPA previously identified as the technological pathway to meeting increasingly stringent GHG emissions regulations while maintaining existing performance levels. [EPA-HQ-OAR-2022-0829-0701, p. 183]

Enrichment is a critical strategy that has enabled this technological shift to lower displacement engines, ensuring their safe and durable operation in transient high-power demand situations. Manufacturers use enrichment to ensure that when customers demand high power, they can do so without the risk of costly damage or interrupted performance. [EPA-HQ-OAR-2022-0829-0701, p. 183]

Customer needs for power include, but are not limited to, the ability to tow a large trailer up an occasional steep grade, to operate the vehicle with a full load of passengers and cargo, and to rapidly accelerate on a short freeway entrance ramp to safely merge into traffic. Other customers, for example those purchasing supercars, expect superior performance and racetrack i. In each case, the power requirement from the engine depends on the customer’s usage, and if its “sufficient power” is inadequate to accomplish their task, then the customer may be exposed to potentially unsafe and inadequate operation and will be dissatisfied with their vehicle’s utility. A sudden reduction or interruption of power in the midst of a driving maneuver (e.g., passing on a grade) could be disruptive to the driver and confusing to other drivers. In some cases, this may create an unsafe traffic condition if the vehicle suddenly loses power, forcing other drivers to take evasive actions. [EPA-HQ-OAR-2022-0829-0701, p. 183]

Customers who seek specific power levels and are dissatisfied with the reduced power of downsized engines due to prohibitions on enrichment would likely revert to seeking out higher displacement engines or shift into larger vehicle segments. Worse yet, customers may simply reject new offerings and remain in older vehicles longer, further increasing the rising average age of vehicles on the road and delaying rollouts of other technologies. Any of these outcomes would detract from achieving the agency’s overall goals of reduced emissions and improved fuel economy. [EPA-HQ-OAR-2022-0829-0701, p. 183]

Organization: American Free Enterprise Chamber of Commerce (AmFree) et al.

The agency’s conclusion that compliance with the proposed rule is feasible critically depends on the electric-vehicle adoption rates it projects for model years 2027 through 2032. EPA expects that by 2032, 67 percent of light-duty vehicles and 46 percent of medium-duty vehicles will be battery-electric. 88 Fed. Reg. at 29,329, 29,331. Those numbers are staggering. Current adoption rates are much lower, and the assumptions that EPA makes to project such sizeable increases are unwarranted. [EPA-HQ-OAR-2022-0829-0683, p. 19]

a. Current Adoption Of Electric Vehicles

Today, battery-electric vehicles make up a small minority of vehicles in both the light- and medium-duty categories. Manufacturers offer a limited number of models, and relatively few consumers buy them. [EPA-HQ-OAR-2022-0829-0683, p. 19]

Although EPA claims that the production of electric vehicles is growing rapidly, see 88 Fed. Reg. at 29,188–89, the U.S. Department of Energy reports that there are only 68 models of light- and medium-duty battery-electric vehi- cles available for the current model year. See U.S. Dep't of Energy, Alternative Fuels Data Ctr., Alternative Fuel and Advanced Vehicle Search, https://ti- nyurl.com/y853dwvt (last accessed June 26, 2023). Thirty-five of them are se- dans or wagons; twenty-nine are SUVs; four are pickup trucks; and none are vans. Id. This limited number of options may be a result of exceedingly low demand. According to the agency, in 2022, battery-electric vehicles accounted for only 807,000 new car sales, or about 5.8 percent of the new light-duty pas- senger-vehicle market. 88 Fed. Reg. at 29,346. Currently, "in most of the United States, the share of EVs is zero or near-zero." Kenneth T. Gillingham et al., Has Consumer Acceptance of Electric Vehicles Been Increasing?, Forthcoming, Am. Econ. Ass'n, at 6 (Jan. 2023) ("Consumer Acceptance"). This is particularly true in rural areas. In Wyoming for example, there were "only 456 electric cars and light trucks registered statewide as of March 2022." Robert N. Charette, The EV Transition Explained: Converting Gasoline Superusers, IEEE Spectrum (Dec. 11, 2022) ("EV Transition"), https://tinyurl.com/5dnry66s. [EPA-HQ-OAR-2022-0829-0683, p. 19]

By and large, the light- and medium-duty sectors have not embraced a shift from internal-combustion-engine vehicles to electric ones. [EPA-HQ-OAR-2022-0829-0683, p. 19]

EPA's projected increase in electric-vehicle adoption also rests on unrealistic expectations of increased future sales. In addition to assuming that "consumer uptake" will increase as more models become available and charging infrastructure develops—issues addressed elsewhere in this comment—the agency asserts that growing interest and satisfaction with electric-vehicle tech- nology, as well as decreasing costs, will play a substantial role in turning the tides toward electrification. See 88 Fed. Reg. at 29,189, 29,312; Draft RIA at 4- [EPA-HQ-OAR-2022-0829-0683, pp. 21-22]

17. Available data, however, demonstrate that these assumptions suffer from critical flaws.

Consumer Interest and Satisfaction. Although nearly 95 percent Americans in the market for a new car chose not to purchase an electric vehicle last year, EPA claims that American consumers are increasingly interested in, and satisfied with, electric-vehicle technology. That assertion rests on a collection of un- justified inferences. [EPA-HQ-OAR-2022-0829-0683, pp. 21-22]

First, EPA cites one recent survey reporting that more than one-third of Americans said that they would either "seriously consider or definitely buy or lease" a battery-electric model today if they were in the market for a new vehicle. 88 Fed. Reg. at 29,189. But other data undermine EPA's reliance on abstract consumer "affinity" (id.) for electric vehicles. Other polls show that, even when there is an expressed interest in purchasing an electric vehicle, consumers often do not follow through. For example, "[a] 2022 CarGurus survey found that 35 percent of new car buyers expressed an interest in purchasing a hybrid, but only 13 percent eventually did." Robert N. Charette, Convincing Consumers to Buy EVs: How Range, Affordability, Reliability, and Behavioral Changes Figure into Purchase Decisions, IEEE Spectrum (Jan. 23, 2023) ("Convincing Consumers"), https://tinyurl.com/3p26536j. "Similarly, 22 percent expressed interest in a battery electric vehicle . . . , but only 5 percent bought one." Id. Just as manu- facturer announcements are not a reliable indicator of actual future production, abstract consumer surveys are not a reliable indicator of actual future purchase. [EPA-HQ-OAR-2022-0829-0683, pp. 21-22]

Second, EPA asserts that most drivers who have opted for electric vehicles in the past have chosen to buy another one and often “express resistance to returning to an [internal-combustion-engine] vehicle.” 88 Fed. Reg. at 29,189. But repeat purchases of electric vehicles by current electric-vehicle owners does not contribute to meaningful growth in electric-vehicle adoption, especially to the extent they purchase new electric vehicles to replace existing ones. Moreo-ver, a significant number of electric-vehicle owners do, in fact, switch back to conventional models. Sean Szymkowski, Surprising Number of EV Owners Switch Back to Gas Power, Study Says, CNET (May 4, 2021), https://ti-nyurl.com/ybt2mxy3. Even in California—which has a high rate of adoption, the most charging infrastructure in the country, and a history of state-law measures designed to incentivize the purchase of electric vehicles—18 percent of electric-vehicle owners traded their electric models in for gas-powered vehicles between 2015 and 2019, largely due to insufficient home charging set-ups. Id. Various factors—such as the price of electricity, safety concerns, and reliability—may cause that trend to continue or even increase in the future. At this early stage in electric-vehicle technology, it is far from clear that any pur-chaser—let alone most of them—will make a permanent switch from tried and true internal-combustion-engine models. [EPA-HQ-OAR-2022-0829-0683, pp. 22-23]

Finally, EPA cites sales data purportedly showing that “some segments” of the market prefer electric vehicles to their internal-combustion-engine counter- parts. 88 Fed. Reg. at 29,189–90. One of the studies the EPA relies on, how- ever, makes clear that those segments are in the “high price brackets”—i.e., generally luxury vehicles—and that “the number of vehicles sold in these high price brackets is relatively small.” Gillingham, Consumer Acceptance at 8; see also Charette, EV Transition (“Battery-electric vehicle owners ‘earn a lot more than not just the U.S. population but [also] the population of new vehicle buyers.’”). EPA offers no reason to believe that the preferences of the limited number of consumers who are interested in and able to purchase those high-end models is a reliable indicator of future purchases by the majority of American drivers. [EPA-HQ-OAR-2022-0829-0683, p. 23]

Perhaps recognizing this weakness, EPA instead suggests that sales data for high-end electric vehicles is indirect evidence that forcing manufacturers to increase their electric-vehicle offerings may result in increased adoption. Citing the asserted preferences for electric vehicles in those high-end “segments,” EPA posits that the lack of widespread penetration in the light- and medium-duty markets at large is “at least partially [] constrained due to the lack of offerings needed to convert existing demand into market share.” 88 Fed. Reg. at 29,190. But EPA’s conjecture that increased offerings would cause increased demand does not follow. Manufacturers already offer low-priced models and the number of drivers that purchase them remain low. For example, the Nissan Leaf, which is “the most affordable new electric car in the United States” (starting at $27,800) was purchased by only 1,276 drivers during the third quarter of 2022. Colin Ryan, 2023 Nissan LEAF, Kelley Blue Book (June 21, 2022), https://ti-nyurl.com/mw2372hc; see also Mark Kane, U.S.: Nissan LEAF Sales Noted the Worst Third Quarter Even, Inside EVs (Oct. 9, 2022), https://ti- nyurl.com/mryu23e7. [EPA-HQ-OAR-2022-0829-0683, p. 23]

In addition, lack of offerings may be merely one among a number of limi- tations that constrains broader adoption of electric vehicles. That purchasers in high-end segments (where electric-vehicle offerings are more available) might prefer electric vehicles to a greater extent does not mean that increasing offerings in other segments will inexorably drive up demand among all consumers with different needs. This is especially true for consumers in rural areas.

See Charette, EV Transition. For example, drivers in states like Idaho, Montana, and South Dakota “are likely to have additional concerns about buying EVs” because of battery life. Charette, EV Transition. One report indicates that a high- mileage driver switching from a Ford-150 to a Lightning and driving it the same number of miles “will find that their battery warranty will expire in about 3.5 years,” with the cost of replacement running between $28,556 and $35,960. Id. Ford’s CEO himself acknowledged that, “in mountainous states, driving re-quirements are ‘different than how we’ve designed (our EV) vehicle so far.’” Id. And “[a]nother potential bump in the road” is that “EVs are designed for over- the-air software service and feature updates, but cell service can be highly un- reliable in rural areas,” making “[l]engthy trips to dealers . . . inevitable.” Id. The Department of Transportation explains that “[r]educed battery perfor- mance and EV range during winter months, as well as protection from the ele- ments while waiting for a vehicle to charge, are a further concern for rural com- munities in cold climates, particularly to those that do not have access to relia- ble electric service.” Implementation Challenges and Evolving Solutions for Rural Communities, U.S. Dep’t of Transp., https://tinyurl.com/3rkwfxpw. [EPA-HQ-OAR-2022-0829-0683, pp. 23-24]

Each of these problems must be resolved before a widespread shift to elec- tric vehicles is plausible. “[E]ven in cases where consumer appetite for ZEVs is high, a lack of adequate charging infrastructure could hold the market back and potentially stall progress.” Marie Rajon Bernard et al., Deploying Charging Infra- structure to Support an Accelerated Transition to Zero-Emission Vehicles, ZEV Tran- sition Council, at 4 (Sept. 2022). And multiple studies report that charging is a top concern among prospective electric-vehicle buyers. See, e.g., Barajas, Cali-fornia’s Rural Areas (“[C]oncerns remain, including hesitant consumers wary of ‘range anxiety,’ the fear of being stranded without the ability to recharge, or in some cases not having access to charging capacity at their apartment complex or work.”); Kampshoff, Building Electric-Vehicle Charging Infrastructure at 1 (“[N]early half of US consumers say that battery or charging issues are their top concerns about buying EVS.”); Nichols, Estimating Electric Vehicle Charging at 1 (“Exactly how much charging infrastructure will be needed and what it will cost are top questions for prospective electric vehicle owners.”). Until ade- quate home, workplace, and public charging infrastructure develops at the rate, in the places, and at the quality desired by consumers, consumers are unlikely to purchase anything close to the volume of electric vehicles that EPA intends to mandate that manufacturers provide. The agency has not offered a reasonable basis for assuming that the necessary expansions and improvements are possible, let alone likely, within less than a decade. [EPA-HQ-OAR-2022-0829-0683, pp. 46-47]

Organization: American Freedom and America First Policy Institute (AFPI)

Most Americans Prefer Gas-Powered Vehicles

EVs have advantages and disadvantages compared to gas-powered automobiles. Charging an EV typically costs owners less than fueling a conventional car, and EVs also have lower maintenance costs and faster acceleration. However, EVs cost substantially more than gas-powered vehicles, have shorter ranges, and can take a while to fully charge. [EPA-HQ-OAR-2022-0829-0699, pp. 2-3]

Although some Americans want EVs, Americans generally prefer conventional vehicles. The Deloitte 2022 Global Automotive Study found that 69% of Americans prefer their next car purchase to be a gas-powered vehicle, 5% prefer an entirely battery-powered car, and 22% prefer a hybrid vehicle. Range and price concerns were particularly important factors for respondents who prefer gas-powered vehicles; most Americans (53%) indicated they would not pay more for an electric vehicle (Edelstein, 2022) (Link: https://www.greencarreports.com/news/1134702_americans-dont-want-ev-yet-half-wont-pay-extra-for-electrified). A recent survey of car dealerships also found that 45% of dealerships reported they would not sell EVs under any circumstances (Lewis, 2023) (Link: https://electrek.co/2023/05/09/us-car-dealers-evs/). [EPA-HQ-OAR-2022-0829-0699, pp. 2-3]

After purchasing an EV, a significant proportion of drivers switch back to conventional vehicles. One study found that one-fifth of California EV owners returned to purchasing gas-powered vehicles, primarily because of the inconvenience of charging EVs (Powell et al., 2022, p. 39) (Link: https://javatar.bluematrix.com/pdf/N8T7PT0N). Another survey looked at all Americans—not just Californians—who purchased a new vehicle in 2017. That study found that about half of EV owners chose not to buy another EV when they bought a new car. Respondents indicated that range, recharging time, and reduced performance in cold weather were key reasons for switching back to gas-powered vehicles (Dua & Bansal, 2021, p. 3) (Link: https://www.kapsarc.org/research/publications/once-consumers-adopt-an-electric-vehicle-do-they-go-back/). [EPA-HQ-OAR-2022-0829-0699, pp. 2-3]

EVs appeal to some Americans, but without substantial government intervention, they would likely remain a niche market. However, EPA proposes to force automakers to primarily produce—and Americans to purchase—EVs. This EV mandate would create significant challenges for energy supply chains, particularly by creating mineral dependencies on foreign powers.2 The EV mandate also threatens many auto manufacturing jobs. [EPA-HQ-OAR-2022-0829-0699, pp. 2-3]

2 China dominates the global market for refined energy minerals, surpassing OPEC's dominance in oil markets. China holds a 40% market share in aluminum, a metal vital for manufacturing electric vehicles. Each EV requires about 400 pounds more aluminum than a conventional gasoline-powered vehicle (Mills, 2022, p. 8) (Link: https://media4.manhattan-institute.org/sites/default/files/the-energy-transition-delusion_a-reality-reset.pdf). Chinese firms can refine minerals for EV batteries at a lower cost than U.S. firms, due in part to less stringent environmental regulations (Chang & Bradsher, 2023) (Link: https://www.nytimes.com/interactive/2023/05/16/business/china-ev-battery.html).

Organization: American Fuel & Petrochemical Manufacturers

EPA offers no support for its conclusion that there will be substantial consumer adoption of ZEVs to achieve the increases projected by the Proposed Rule. To the contrary, recent polling shows that most Americans continue to say that they are unlikely, or will categorically refuse, to buy an EV. As just one example, a Gallup poll conducted in April revealed that only 4 percent of adults owned an EV and just 12 percent are seriously considering buying one. However, 41 percent of adults said they would never buy an EV, raising fundamental questions about how EPA can predict that ZEV sales will reach 67 percent in 2032.136 [EPA-HQ-OAR-2022-0829-0733, p. 31]

136 Megan Brenan, Gallup, Most Americans Are Not Completely Sold on Electric Vehicles (April 12, 2023). Retrieved a https://news.gallup.com/poll/474095/americans-not-completely-sold-electric-vehicles.aspxt .

According to Wards Intelligence, through May 2023, Americans purchased 5.9 million ICEVs, representing 93 percent of all LDVs sold during the first five months.137 At this pace, more than 14 million new ICEVs will be purchased during 2023.138 With the continued sales of ICEVs, this Rule's effort to limit the ability to purchase ICEVs, and more than 50 percent of ICEVs remaining in service, it is mindboggling, as discussed in Section IV.6 below, that EPA never considered the alternative scenarios using vehicle technologies and lower carbon fuels. [EPA-HQ-OAR-2022-0829-0733, p. 31]

Importantly, successful implementation of EPA's Proposed Rule depends on consumer choice as much as it depends on technological improvements. But there is evidence that premature embrace of ZEV may backfire if consumers grow frustrated with inadequate infrastructure. Consumer market demand will not, and cannot, increase to meet the Proposal's required supply. Charging capabilities is a key apprehension for nearly half the U.S. consumer market. [EPA-HQ-OAR-2022-0829-0733, p. 32]

For example, in California, roughly one-fifth of consumers who initially purchased PHEVs or ZEVs subsequently went back to ICEVs based on frustration with convenience factors such as unavailability of charging.143 As the study on discontinuance cited by EPA states, "[R]ange isn't correlated with discontinuance in PHEVs or ZEVs but satisfaction with and access to charging [is]."144 Those with multiple vehicles and a single-family home find it easier to continue ownership than those with fewer vehicles or living in multi-unit dwellings, which could lower ZEV adoption rates as the ZEV market becomes more mainstream.145 Finally, a survey of PHEV owners in California found that current PHEV would not purchase their PHEV without incentives, therefore EVs and PHEVs adoption may face more challenges over time.146 Moreover, EPA ignores that current ZEV sales are linked to mandates that force increased prices of ICEVs to subsidize the mandated ZEV sales. Those mandates are under judicial review. [EPA-HQ-OAR-2022-0829-0733, p. 32]

146 Id. See also JATO Blog, "A breakdown of the US EV market by State shows more incentives equals more sales", April 9, 2019 (latest research shows current tax credits and other incentives in the US are unequal among states, and that EV sales are growing at the fastest rate in states offering financial incentives).

As discussed in more detail below, consumer market demand will not, and cannot, increase to meet the Proposal's required supply. Charging capabilities, which creates range anxiety, is a key apprehension for nearly half the U.S. consumer market. EVs have less range, both technically and practically. As noted by J.D. Power, "[T]he majority of EVs provide between 200 and 300 miles of range on a full charge."147 This same article, however, also noted that EVs with less than 200-mile ranges (such as the 2022 Nissan Leaf at 149 miles or the 2022 Mazda MX-30 at 100 miles) are “either affordable or focused on performance.”148 With respect to longer range vehicles, claimed vehicle ranges of up to 516 miles are available, but this range comes at considerable cost. The number 1 range-rated vehicle by Car and Driver, the 2023 Lucid Air, carries a base price of $113,650. And while three out of the ten top-rated EVs by Car and Driver were more “reasonably priced” from $44,630 to $56,630, all other models within the top 10 cost anywhere from $74,800 to $110,295.149 [EPA-HQ-OAR-2022-0829-0733, pp. 32-33]

EPA requests comment on their approach to determining charging time, as set forth in the DRIA, Chapter 4.155 EPA’s analysis is contingent on unsupported assumptions regarding (1) U.S. consumers’ adoption of and ability to purchase more expensive ZEVs (see Sections IV.B.2 and IV.E.2.ii); (2) the type of ZEV purchased (used ZEVs or PHEVs compatible with slower charging units or new ZEVs that can use DCFC) (Section IV,B.2 addresses charging times); (3) the availability of critical minerals and metals to expand the supply of reliable and renewable electricity (see Section I.B); and (4) the availability of reliable and affordable charging for all users (see Sections IV.B.4). Given the flaws in EPA’s methodology that omits significant data sources and other factors and makes unsupported assumptions, EPA should revise its analysis concerning charging time and continue with promulgating a final rule for future emissions standards, that accounts for the reality of today’s automotive market and not the public pronouncements of the automotive industry, a single state or group of states, or other unsupported estimates of future market growth. [EPA-HQ-OAR-2022-0829-0733, pp. 33-34]

155 88 Fed. Reg. at 29,367.

As previously mentioned, EPA did not fully consider the impact of the rule on fleet turnover. The Agency is aware that the higher purchase price of new ZEVs will keep older cars and trucks on the road longer and that new ZEVs will increase particulate matter (“PM”) emissions through increased tire and road wear. [EPA-HQ-OAR-2022-0829-0733, p. 45]

EPA’s Proposal fails to evaluate how government credits are embedded in vehicle pricing. For example, neither federal or state governments, or auto manufacturers explain how state ZEV credits, EPA GHG multiplier credits, and NHTSA CAFE EV multiplier credits are accounted for in both ZEV and ICEV vehicle price. There is increasing evidence that regulations which mandate EV sales—along with the cross-subsidies from gasoline and diesel vehicle buyers—are leading manufacturers to abandon sales of the least expensive and higher fuel economy gasoline and diesel vehicles that do not receive similar subsidization.236 Cox Automotive found that “in December 2017, automobile makers produced 36 models priced at $25,000 or less. Five years later, they built just 10,” pushing low-income buyers out of the new-car market and into the used- car market. Conversely, in December 2017 automobile manufacturers offered 61 models for sale with sticker prices of $60,000 or higher and in December 2022, they offered 90.237 This is unacceptable. EPA and its sister agencies cannot create credits and then claim they do not affect vehicle price solely because they have not sought to quantify them. [EPA-HQ-OAR-2022-0829-0733, pp. 51-52]

Tellingly, EPA never estimates the annual price of a comparable ZEV and ICEV, for each year in which EPA proposes standards. EPA's bias towards EVs is demonstrated by EPA's statement that its OMEGA modeling "now incorporates a consumer choice element. This means that the impacts of, for example, a $40,000 BEV versus a $35,000 ICE vehicle of similar utility (i.e., a 14 percent increase for the BEV) is a much different consideration than a $6,000 incremental BEV cost versus a $1,000 incremental ICE cost (a 500 percent increase for the BEV)."238 In other words, EPA set up its model to show the consumer price (not the actual real-world cost) of EVs have a lower percentage cost increase than the incremental absolute cost of switching from ICEVs to ZEVs. [EPA-HQ-OAR-2022-0829-0733, pp. 51-52]

v. Costs to upgrade electricity generation, transmission, and distribution

For EPA to achieve its GHG reduction aspirations in this Proposed Rule, all three of these challenges must be met: (1) sufficient materials to manufacture the required EVs, chargers, and grid upgrades, (2) consumer willingness to substitute ZEVs for ICEVs currently for sale, and (3) a low-carbon power generation grid capable of reliably supplying energy for this mode of transportation. Combined with other issues, such as a disorderly transformation of the generation base as conventional units are replaced with intermittent resources, raises questions of the grid's ability to reliably meet consumer demand on a regional basis. Despite these challenges, EPA incredibly assumes no increase in the cost of electricity to consumers (whether EV owners or others) associated with the proposed rulemaking. EPA underestimates the cost of electricity to all consumers, including EV owners, and omits the cost of grid upgrades and distributed energy resources have been excluded from these estimates.260 [EPA-HQ-OAR-2022-0829-0733, pp. 56-57]

260 U.S. Department of Energy, National Renewable Energy Laboratory, "The 2030 National Charging Network: Estimating U.S. Light-Duty Demand for Electric Vehicle Charging Infrastructure." June 2023. https://driveelectric.gov/files/2030-charging-network.pdf.

EPA incorrectly assumes that ZEV owners will pay the national average residential electricity price to charge their vehicles. EPA fails to consider that the majority of ZEVs in the U.S. are located in utility service territories with some of the highest electricity rates in the country and that the average EV owner currently pays a much higher price to charge their ZEV at home than the national average residential electricity rate. Given that EV penetration has varied widely across the U.S., it would be arbitrary to assume that EVs will, unlike in the past, penetrate uniformly across the U.S. and thus that the average electricity price would be representative of the actual cost electricity. For example, California, which has roughly 40 percent of all registered ZEVs in the U.S., has a residential electricity rate that is roughly double the national average. Considering that EPA is modeling its rule after a California-like approach to mandate ZEVs, it would be more appropriate for EPA to assume similar real-world costs (at a minimum, given California's temperate climate). Moreover, EPA fails to consider that mandating such a high ZEV sales rate will necessarily require exponential increases in commercial ZEV charging at rates that are currently three, four or five times higher than the current national average residential electricity rate, depending on location and charging speed. Those customers who are not homeowners and not able to install their own charging stations and take advantage of charging at low-cost times will be adversely impacted. Instead, EPA uses a residential rate for electricity and does not consider peak power or time of use charges. California electric prices rose 42 percent - 78 percent between 2010 and 2020 and are projected to rise an additional 50 percent by 2030 as shown in Figure 9. [EPA-HQ-OAR-2022-0829-0733, pp. 57-58]

SEE ORIGINAL COMMENT FOR Historic and Forecasted Residential Average Rates Based on Most Recent 5-year Average Rate Increase. Figure 9: Source: Michael Shellenberger, Twitter (citing California Public Advocate's Office data), April 27, 2021). [EPA-HQ-OAR-2022-0829-0733, pp. 57-58]

Heaping additional demand for EV charging into this market could exacerbate already high electricity prices. This will be especially impactful to lower-income homeowners who may not be able to install dedicated charging units, forcing them to pay more out of pocket for charging during peak demand periods.265 [EPA-HQ-OAR-2022-0829-0733, pp. 57-58]

265 Hardman, Scott, et al., "A Perspective on Equity in the Transition to Electric Vehicles." MIT Science Policy Review, (Aug. 20 2021), available at https://sciencepolicyreview.org/2021/08/equity-transition-electric-vehicles/ (accessed June 29, 2023).

EPA must revise its analysis to account for realistic electricity prices. The proposed ZEV mandate will require an enormous investment in power generation and distribution, resulting in nationwide increases in electricity bills that EPA has not considered. Of course, considering the additional trillions of dollars in costs would paint a clear picture that the costs of forced electrification far exceed even the inflated benefits EPA presented in the Proposed Rule. [EPA-HQ-OAR-2022-0829-0733, pp. 57-58]

Organization: American Highway Users Alliance

More specifically, EPA's proposal in this docket appears to be premised on huge and rapid growth in the portion of light-duty and medium-duty vehicles that are electric powered (EVs) as well as on rapid transformation of the marketplace in a number of related areas that are not the subject of the proposed regulation. EPA seems to have made favorable assumptions on many issues bearing on the feasibility of the proposal, including as to the issues set forth below. The Highway Users, on the other hand, drawing on the expertise of its members, questions that, within the MY 2027 – 2032 timeframe of the proposed rule, all or most of the following will occur, that -- [EPA-HQ-OAR-2022-0829-0696, pp. 2-3]

• high-speed and other electric charging stations will be sufficiently available to service light-duty and medium-duty EVs in quantities and locations sufficient to encourage customers to buy EVs,

• electric utilities can timely provide connections from the electric grid to those charging stations, or hydrogen fueling stations – and provide the refueling and charging connections at reasonable cost,

• the electric grid will have the capacity to meet the demand for electricity that will be required to support increased electrification of trucks, buses, and passenger cars, even if the connections can be timely made to charging stations (both public and private) that do not yet exist in sufficient numbers,

• charging times can be reduced sufficiently to encourage customers to buy these EVs,

• major industries, including vehicle manufacturers and their suppliers, can implement major changes in vehicles as rapidly as the NPRM assumes (given the limited current market penetration of these EVs),

• there will be an adequate supply of rare earth and other critical minerals, and the ability to process them, with those minerals being so essential to the manufacture of EVs and batteries,

• with a large portion of such minerals being sourced and/or processed overseas, including in China and Africa, whether the national interest in sourcing and processing such minerals in the United States can be met, and

• potential customers of these EVs will proceed to purchase them in sufficient quantity, notwithstanding significantly higher up-front costs, uncertain availability of charging facilities, and other concerns. [EPA-HQ-OAR-2022-0829-0696, pp. 2-3]

This last consideration is highly important because if the potential customers of these EVs do not become actual customers to a sufficient extent, the manufacturers are unlikely to produce the vehicles in the quantities EPA has estimated will be required to be compliant with the regulations, in turn greatly reducing the benefits of the proposal as EPA estimated. [EPA-HQ-OAR-2022-0829-0696, pp. 2-3]

Organization: American Honda Motor Co., Inc.

Over the past decade, the U.S. Environmental Protection Agency (EPA)1 has played a key role in helping successfully pivot the entire auto industry toward an electrified future. Previous debates about whether such a transformation would occur are now merely conversations about when it will happen. In fact, today all of industry is pursuing this transition at a fever pace. [EPA-HQ-OAR-2022-0829-0652, p. 4]

1 Henceforth referred to as "the agency"

Amidst a backdrop of this activity, in May 2023, the agency published what EPA Administrator Michael Regan referred to as "the strongest-ever federal pollution technology standards for both cars and trucks."2 His reference to "technology standards" was decidedly on-point. In contrast to the agency's longstanding approach of setting technology-neutral, performance-based standards, this NPRM proposes to dramatically limit vehicle emissions in the

United States, effectively requiring – according to EPA's own analysis – two-thirds of all new vehicles sold in model year (MY) 2032 to be electric vehicles (EVs). This amounts to a ten-fold increase in electric vehicle adoption nationally, requiring EVs to move beyond today's early adopters, past ubiquity on main street, and extend to small towns and rural areas across the nation – all in a mere eight years. It is an exceedingly ambitious attempt to re-envision Americans' relationship with personal mobility. [EPA-HQ-OAR-2022-0829-0652, p. 4]

2 Davenport, C. E.P.A. Lays Out Rules to Turbocharge Sales of Electric Cars and Trucks. New York Times. April 12, 2023. https://www.nytimes.com/2023/04/12/climate/biden-electric-cars-epa.html

While perhaps well-intentioned, basing standards on an assumed swift and seamless EV market transition – completely unprecedented in nature – strikes us as a questionable choice for policy design. As the agency is well aware, risk management is especially important in the automotive industry due to market uncertainties, high capital expenditures and long lead times needed for the design, development and manufacture of products. By mandating a single path to compliance, the agency shifts a considerable amount of this risk squarely upon automakers and, ultimately, their customers. It is a risky approach that could not only undermine fragile public trust and support for the EV transition, but also create hardships for low income and marginalized communities facing imbalanced infrastructure availability and the still-high cost of technology. [EPA-HQ-OAR-2022-0829-0652, p. 5]

According to S&P Global-IHS Markit data, over the past 12 months, electric vehicles – including all BEV, PHEV and FCEV models – accounted for approximately seven percent of nationwide sales. The agency's proposal, on the other hand, would require ten-fold that level of adoption, all in a mere eight years across all vehicle classes. When examining expected adoption levels based on specific vehicle categories, the EPA analysis assumes these levels of electrification would actually be achieved two years sooner – in 2030 or just six years from now. This is a staggeringly optimistic assumption about the pace of technology transformation in the auto industry. To illustrate how unprecedented this is, consider EPA's own Automotive Trends report. As shown in Figure 3 and the associated table below, there is no historical auto industry analogue to EPA's projected pace of EV adoption, even when generously characterizing EVs today as having already seen "significant use" nationwide for a few years. [EPA-HQ-OAR-2022-0829-0652, pp. 22-23]

All of the technologies shown in Figure 3 took well over eight years to reach 67 percent market adoption and, in some cases, two to three times as long. Even more importantly, none of the identified technologies required any kind of behavioral change on the part of the vehicle owners. For all intents and purposes, apart from experiencing better fuel economy and vehicle performance, it is possible owners may not have even known those technologies existed on the vehicle. In contrast, although electrification has many positive attributes, it does require the owner to embrace a different approach to vehicle use and management, such as ensuring sufficient charging infrastructure is available for a given trip and that sufficient time is available to recharge. These factors are important considerations when evaluating the pace of technology adoption from the general (i.e., non-early adopter) vehicle purchasing population. [EPA-HQ-OAR-2022-0829-0652, p. 23]

iii. Review of Annual Energy Outlook (AEO) data and projections.

EPA's BEV projections differ significantly from other federal agencies and reflect that EPA is improperly mandating that a significant proportion of new LDV and MDV must be powered by electric drivetrains and setting unrealistic tailpipe emission standards. The EIA published market share projections for light-duty BEV and PHEV sales in its Annual Energy Outlook35 2023 (AEO 2023). The AEO 2023 Reference Case modeling includes laws, such as the IRA and the BIL, and other adopted regulations in its analysis. The AEO 2023 incorporates the IRA by adjusting EV purchase prices to account for the Clean Vehicle Credit using offcial estimates of vehicles that will be eligible for tax credits. In addition to the Reference Case, the AEO conducts a range of scenario modeling, that considers different assumptions and uncertainties. Across the range of modelled scenarios in AEO 2023, EIA36 concluded that sales of BEVs and PHEVs do not exceed 29% and the share of the on-road light-duty vehicle stocks comprised of BEVs and PHEVs did not exceed 26%, over the projection period to 2050. [EPA-HQ-OAR-2022-0829-0641, pp. 13-14]

35 U.S. Energy Information Administration. "Annual Energy Outlook 2023." March 2023. https://www.eia.gov/outlooks/aeo/.

36 U.S. Energy Information Administration. "Incentives and lower costs drive electric vehicle adoption in our Annual Energy Outlook." Today in Energy. Accessed May 15, 2023. https://www.eia.gov/todayinenergy/detail.php?id=56480.

Analysis of BEV-only37 sales data from the AEO 2020 (pre-COVID) and 2023 (most recent) editions indicate BEVs sales are projected to increase in comparison to the respective Reference Cases. For example, in 2032, BEV sales are projected to reach 13% in the AEO 2023 Reference Case up from 5% in the AEO 2020 Reference Case. Increased BEV sales in AEO 2023 compared to AEO 2020 likely reflect emerging trends, technological improvements, relative manufacturing costs and purchase prices, subsidies, consumer behavior, and other factors. Also, minimum projections for BEV sales in the AEO 2023 are nearly identical to the AEO 2020 Reference Case (see chart below). However, projections for maximum BEV sales in AEO 2023 reach only 23% in2032. Figure 1 below illustrates BEV sales across a wide range of scenarios as projected by EIA. [EPA-HQ-OAR-2022-0829-0641, pp. 13-14]

37 Transportation supplemental tables for AEO 2020 and AEO 2023 can be found here: https://www.eia.gov/outlooks/aeo/.

BEV sales projected by EPA,38 under a scenario to meet the proposed standards and a "no action" scenario, are included in the chart. BEV sales required to meet EPA's proposed standards or "no action" scenario are significantly higher than any scenario projected by EIA in its AEO 2023 analysis. Differences in trajectories between EPA's proposed standards and the AEO projections illustrate EPA selecting and essentially forcing one technology over others and setting an unrealistic stringency for tailpipe emission standards. Although EIA has projected BEV sales to increase (i.e., AEO 2023 vs. AEO 2020) because of recently enacted federal subsidies and expenditures (i.e., BIL and IRA), along with technological advancements, 2032 BEV sales are projected to reach to only 13% in the AEO 2023 Reference Case compared to EPA's proposed standard at 67%. This is a significant difference in projected BEV sales and the agency has not provided adequate information to explain this major difference. EPA must explain why its projections differ so significantly from its sister agency with far more expertise in such projections than EPA. [EPA-HQ-OAR-2022-0829-0641, pp. 13-14]

38 Table 108, 88 Fed. Reg. 29335 (May 5, 2023).

e. API Supports Consumer Choice for Vehicles.

API 53 supports the concept that different vehicle technologies that reduce greenhouse gas emissions should be allowed to compete equally for consumer and market acceptance and growth. However, API has concerns with regards to the EPA's approach and its effect on consumer choice. [EPA-HQ-OAR-2022-0829-0641, pp. 18-19]

53 https://www.api.org/news-policy-and-issues/blog/2021/05/18/us-consumers-need-balance-choice-in-transportation-policy.

The stringency of the proposed standard is essentially forcing electrification of the transportation sector and is not in alignment with most Americans that, according to a Pew Center survey,54 favor "using a mix of energy sources to meet the country's needs" and a majority of survey respondents oppose phasing out gasoline powered vehicles by 2035. Concerns with charging availability55 could be relieved with vehicle technologies (e.g., PHEVs56) where the length of an average daily trip is approximately 30 miles.57 [EPA-HQ-OAR-2022-0829-0641, pp. 18-19]

56 EPA is proposing a fleet utility factor (FUF) curve that will increase CO2 compliance values for PHEVs. 88 Fed. Reg. 292557 (May 5, 2023).

57 2019 Bureau of Transportation data indicates 49% of 2019 national trips by distance were less 25 miles.

Organization: Betsy Cooper

Today's PHEVs do not have enough range to meet Americans' driving needs. The average American drives 37 miles a day [Link: https://www.kbb.com/car-advice/average-miles-driven-per-year/#miles-per-day]. Moreover, the average American commute may be as high as 41 miles a day [Link: https://www.zippia.com/advice/average-commute-time-statistics/]. Thus, almost no PHEVs on the market will allow the average American commuter to complete their commute without switching on to gas.2 It is no coincidence that the longest electric range mid-tier car, the

Toyota RAV4 – with 42 miles of range – has a wait time of between 5 and 24 months [Link: https://rav4resource.com/rav4-prime-availability/] and dealer markups of more than $10,000! [Link: https://markups.org/search.html?title=RAV4+prime] [EPA-HQ-OAR-2022-0829-0654, pp. 1-2]

2 This is particularly problematic because most EV batteries degrade over time. Our 2019 Volt now gets 45 miles of range—a 15 percent drop. An EV with only 40 miles of range to start will degrade to well below the average commuter's distance.

Organization: California Air Resources Board (CARB) (Part 1 of 5)

Feasibility of proposed standards

California's effective vehicle GHG fleet average emission rate for new vehicles is similar to U.S. EPA's proposal due to similar expected shares of ZEVs entering the market in the 2026 through 2032 MYs and beyond. California's ACC II regulations require that an increasing share of new vehicle sales be zero-emission, ramping up from 35 percent for the 2026 MY to 100 percent for the 2035 MY. As part of the ACC II rulemaking, CARB estimated that 75 percent of new car sales in California in 2032 will be BEVs to comply with the ACC II regulations (with a small percentage of additional fuel cell and plug-in hybrid electric vehicles). In comparison, U.S. EPA projects a 67 percent BEV market share nationwide to comply with the proposed federal GHG standards in the same year. [EPA-HQ-OAR-2022-0829-0780, pp. 12-13]

In establishing its ZEV sales requirement, CARB assessed the technical feasibility and cost of ZEV technologies to determine a feasible pace of ZEV introduction in California. 7 This assessment found several market trends that will drive widespread ZEV penetration in the coming years, including a rapidly expanding number of ZEV models, increasing all-electric range, technological battery and fuel cell advancements, energy efficiency improvements, and declining battery costs. These market trends are also occurring at the national and international levels, and they underpin the technical feasibility of U.S. EPA's proposed standards. Further, as U.S. EPA notes in its proposal, every manufacturer has a public commitment to significant if not full electrification in the next 20 years. 8 Based on public announcements, it is expected that over 100 ZEV and PHEV models will be available to consumers before the 2026 MY. [EPA-HQ-OAR-2022-0829-0780, pp. 12-13]

7 CARB. ACC II ISOR. Appendix G: ACC II ZEV Technology Assessment. April 2022. https://ww2.arb.ca.gov/sites/default/files/barcu/regact/2022/accii/appg.pdf.

8 87 Fed. Reg. at 29,191 - 192.

In addition to these existing market trends, the implementation of ACC II in California and an expanding number of other states will further spur technological development, supporting widespread ZEV deployment and providing additional support that the proposal is not only achievable, but that manufacturers could exceed the standards as proposed. [EPA-HQ-OAR-2022-0829-0780, pp. 12-13]

Organization: California Attorney General's Office, et al.

Finally, consumer demand for electric vehicles has significantly risen, in large part due to environmental concerns, greater vehicle choice, improved battery capacity, and cost savings.124 [EPA-HQ-OAR-2022-0829-0746, p. 21]

124 Javier Colato and Lindsey Ice, Charging into the future: the transition to electric vehicles, U.S. Bureau of Labor Statistics (Feb. 2023), available at https://www.bls.gov/opub/btn/volume-12/charging-into-the-future-the-transition-to-electric-vehicles.htm#ednref4.

Organization: CALSTART

3. Equity

Importantly, this regulation presents an opportunity for greater equity. Rapid expansion of the LD ZEV market through ZEV regulations would not only increase the stock of new ZEVs but would also increase the stock of used ZEVs quickly. Additional stock of used ZEVs would dramatically expand equitable access to clean transportation options, particularly to communities disproportionately burdened by transportation pollution. [EPA-HQ-OAR-2022-0829-0618, p. 4]

Barriers and Solutions

There are several common barriers that arise when discussing more ambitious standards like Alternative 1. Below, we address three commonly discussed barriers and offer some context that helps explain why these perceived barriers should not delay progress. These include concerns related to expected EV deployment timelines, infrastructure, and fleet electrification. [EPA-HQ-OAR-2022-0829-0618, p. 4]

Organization: Ceres BICEP (Business for Innovative Climate and Energy Policy) Network

Existing policies, market trends, and available funding, including the Advanced Clean Cars II (ACC II) rule adopted by California and six other states; manufacturer and corporate zero-emission vehicle (ZEV) commitments; and the significant incentives provided by the Infrastructure Investment and Jobs Act (IIJA) and the Inflation Reduction Act (IRA) for vehicle and battery manufacturers, purchasers, and charging infrastructure, all justify standards supporting greater ZEV sales shares. [EPA-HQ-OAR-2022-0829-0600, p. 1]

Organization: Clean Fuels Development Coalition et al.

III. The Proposed Rule is Not Feasible for Other Reasons.

While the proposal's gross misstatement of vehicle technology costs is the primary reason EPA's proposal is not feasible, the agency also overlooks many other important aspects of the problem. Despite EPA's hopeful projections, very few American want to buy electric vehicles and even fewer will at the prices they will inevitably command. Non-binding company commitments and (unlawful) regulations designed to enforce these commitments do little to change this. Even if consumers did want to purchase these electric vehicles in the volumes EPA projects, the proposal fails to confront several barriers to its rapid electrification plans, including limits on the supply of minerals necessary to manufacture batteries, inadequate charging infrastructure and electrical supplies, and the complex interactions between this rule and other proposed rules all of which will further hinder this development. In light of these many barriers, it is unreasonable for the agency to conclude that compliance with its proposed emission standards is feasible. [EPA-HQ-OAR-2022-0829-0712, pp. 25-26]

A. Very few Americans want to buy electric vehicles.

The projections for battery electric vehicle adoption are based on very few— and very small—real-world data points. See generally 88 Fed. Reg. 29,187–90. Battery electric vehicles made up 5.8 percent of the new light-duty passenger vehicle market in 2022. Id. at 29,189. To comply with its proposed standards, EPA needs these sales to increase ten times over the next 8 years. [EPA-HQ-OAR-2022-0829-0712, pp. 26-27]

But if EPA expects 67 percent of vehicles sold to be electric vehicles, it must point to at least something that suggests 67 percent of Americans would be willing to buy them. Instead, the best the proposal can do is point to "[a] 2022 survey by Consumer Reports [which] shows that more than one third of Americans would either seriously consider or definitely buy or lease a BEV today, if they were in the market for a vehicle." 88 Fed. Reg. 29,189. This is a far cry from the two-thirds of American's EPA needs to want to buy electric vehicles for its proposal to succeed. And of that one third surveyed by Consumer Reports, only 14% said that they would "definitely" buy an electric vehicle. Jeff S. Bartlett, More Americans Would Buy an Electric Vehicle, and Some Consumers Would Use Low-Carbon Fuels, Survey Shows, Consumer Reports (July 7, 2022), https://www.consumerreports.org/hybrids-evs/interest-in-elec- tric-vehicles-and-low-carbon-fuels-survey-a8457332578/. [EPA-HQ-OAR-2022-0829-0712, pp. 26-27]

The studies the proposal cites in support of its projections are also unreasonable. For example, the proposal states that "Goldman Sachs projects a 50 percent share for BEVs in the U.S. in 2030, 70 percent in 2035 and 85 percent in 2040,"15 DRIA 3-14. EPA provides no analysis of why it believes this is correct, or how it can accept projections of 85% electric vehicle adoption across the nation, while simultaneously acknowledging that 20% of early adopters—the most sympathetic group—are already discontinuing electric vehicle usage when purchasing another vehicle. 88 Fed. Reg. 29,189 n.51; Hardiman, S., and Tal, G., Understanding discontinuance among California's electric vehicle owners, 6 Nature Energy 538 (Apr. 2021). [EPA-HQ-OAR-2022-0829-0712, pp. 26-27]

15 N.B.: The 50 percent of sales Goldman Sachs projects is much less than the 60 percent of sales EPA projects. Indeed, those 10 percent of sales that the proposal waves away represent a larger share of the auto market than electric vehicles have ever achieved. While EPA is not required to look into a "crystal ball" in making its projections, it is "subject to the restraints of reasonableness." NRDC v. EPA, 655 F.2d 318, 328 (D.C. Cir. 1981). Assuming an overshot of already unreasonable projections by more sales than have ever occurred leaps over these restraints.

Organization: Competitive Enterprise Institute

II. The Proposed Standards Imperil Consumer Choice, Vehicle Affordability, and Market Liberty

EPA's proposal will restrict consumers' freedom to choose which types of vehicles they want to buy.12 [EPA-HQ-OAR-2022-0829-0611, pp. 4-6]

As the EPA acknowledges, Congress is already providing tens of billions of dollars in EV-related subsidies, such as the IRA's $7,500 tax credit, "effectively making some BEVs more affordable to buy and operate today than comparable ICE vehicles."13 The only purpose for heaping EV mandates on top of EV subsidies is to eliminate choices consumers would otherwise make. [EPA-HQ-OAR-2022-0829-0611, pp. 4-6]

12 Diana Furchtgott-Roth, “Biden’s Plan to Phase Out Gas-Powered Cars Is All Pain for Consumers and No Gain,” The Hill, June 12, 2023, https://www.heritage.org/government-regulation/commentary/bidens-plan-phase-out-gas- powered-cars-all-pain-consumers-and-no. 13 88 FR 29190.

13 88 FR 29190.

EVs have several well-known drawbacks that regulatory mandates do not remove but rather intensify by restricting the supply of ICE vehicles available for purchase. Those disadvantages include the high purchase price,14 price volatility due to supply-chain bottlenecks,15 range anxiety 16(especially in towing mode),17 long recharging times,18 reduced performance in extreme heat and cold,19 and less reliability during blackouts from hurricanes and other disasters. 20 [EPA-HQ-OAR-2022-0829-0611, pp. 4-6]

14 For example, in 2022, the initial purchase price of a conventional Ford F-150 was $40,960, that of the electric Ford-150 Lightning was $54,769. Roberto Baldwin, Sasha Richie, and Dave Vanderwerp, “EV vs. Gas: Which Cars Are Cheaper to Own?” Car and Driver, October 28, 2022, https://www.caranddriver.com/shopping- advice/a32494027/ev-vs-gas-cheaper-to-own/. The authors conclude that overall EV ownership costs are lower than those for gasoline powered vehicles (factoring in expenses for maintenance and fuel). Nonetheless, the higher EV purchase is a disadvantage that undoubtedly matters to many consumers.

The proposed standards would impose disproportionate burdens on low-income, single-vehicle households. My colleague Ben Lieberman explains:

The higher purchase price of an EV is prohibitive enough, but it is only part of the story. Fully one-third of American households are single-vehicle households, including many low-income ones.21 However, the limitations of EVs make them impractical as a household's one and only vehicle. This includes long charging times (especially inconvenient for renters who are less likely to be able to charge at home) as well as limited range. Indeed, nearly 90 percent of EVs currently in use are part of wealthier multi-car households that include one or more gas-powered vehicles.22 Thus, the EV agenda not only involves the higher sticker price relative to gasoline-powered vehicles, but also the additional cost of a conventional vehicle to back it up.23 [EPA-HQ-OAR-2022-0829-0611, pp. 4-6]

23 Ben Lieberman and Donna Jackson, "Costlier cars help the poor, according to EPA," Open Market, June 26, 2023, https://cei.org/blog/costlier-cars-help-the-poor-according-to-epa/.

Government's cartelization of the auto industry via regulations and preferential subsidies poses an insidious threat to consumer welfare. The IRA and the EPA's mandates increase automakers' dependence on political subventions while preventing both industry incumbents and new entrants from competing on price, range, and ease-of-fueling by selling gasoline-powered cars. Energy analyst Robert Bryce recently reported that Ford loses $64,466 on every EV it sells, "and isn't making up for it in volume." 24 Bryce cautions that "if a business isn't profitable, it isn't sustainable." [EPA-HQ-OAR-2022-0829-0611, pp. 4-6]

Organization: Consumer Reports (CR)

4. There is Strong Consumer Demand for Cleaner Vehicles

In January and February 2022, Consumer Reports fielded a nationally representative survey of 8,027 US adults on consumer awareness of BEV and low carbon fuels.17 The survey found that 71% of Americans express some level of interest in buying or leasing an electric vehicle, as shown in Figure 4.1. Within that group, 14% of Americans would "definitely buy" an EV if they were to buy or lease a vehicle today. This translates to approximately 36 million "EV-ready" buyers, which is an increase of 350% between 2020 and 2022. [EPA-HQ-OAR-2022-0829-0728, pp. 10-14]

17 Battery Electric Vehicles & Low Carbon Fuels Survey, Consumer Reports, April 2022, https://article.images.consumerreports.org/image/upload/v1657127210/prod/content/dam/CRO-Images-2022/Cars/07July/2022_Consumer_Reports_BEV_and_LCF_Survey_Report.pdf.

[See original comment for Figure 4.1: Likelihood of Buying or Leasing an Electric-Only Vehicle Today] [EPA-HQ-OAR-2022-0829-0728, pp. 10-14]

Unfortunately, automakers have not kept up with orders. As a result, for every single EV being manufactured, there are 45 consumers ready to buy or lease one.18 The imbalance between supply and demand is resulting in long waitlists and dealer markups. Automakers are making investments to improve supply, but the growth in supply has been lagging the growth in demand. [EPA-HQ-OAR-2022-0829-0728, pp. 10-14]

18 Excess Demand, The Looming EV Shortage, Consumer Reports, March 2023, https://advocacy.consumerreports.org/wp-content/uploads/2023/03/Excess-Demand-The-Looming-EV-Shortage.pdf.

Absent strong action and direction from the federal government, this gap between supply and demand will only continue to widen. This is because the barriers to EV adoption identified in CR's 2022 survey of BEV and low carbon fuels awareness are being addressed: purchase cost for EVs is declining, charging infrastructure is expanding, consumers are gaining more experience with EVs, and automakers are investing in new models and increased production.19 These trends tend to reinforce one another in a virtuous cycle to create even more demand for these vehicles. [EPA-HQ-OAR-2022-0829-0728, pp. 10-14]

19 Battery Electric Vehicles & Low Carbon Fuels Survey, Consumer Reports, April 2022, https://article.images.consumerreports.org/image/upload/v1657127210/prod/content/dam/CRO-Images-2022/Cars/07July/2022_Consumer_Reports_BEV_and_LCF_Survey_Report.pdf.

The EPA's GHG standards can be especially helpful in solving the chicken-and-egg problem with infrastructure. By guaranteeing that greater numbers of EVs will be manufactured in the coming years, the new standards will help give private industry the confidence it needs to invest in infrastructure, knowing that greater demand for reliable charging infrastructure is on the way. Private corporations are already beginning to see the opportunity that EV charging can provide, with Walmart, 7-11, Starbucks, and Subway all recently announcing major EV charging initiatives. This increased private investment combined with the $7.5b in federal investment in charging infrastructure from the Bipartisan Infrastructure Law can help reduce a major barrier to consumer adoption of EVs. As consumers become more confident in the availability and reliability of the charging network, their interest in purchasing an EV is likely to increase. [EPA-HQ-OAR-2022-0829-0728, pp. 10-14]

Another key driver of EV purchase interest is direct experience with EVs. This is illustrated in Figure 4.2, in which the three pie graphs represent low, medium, and high levels of experience with battery electric vehicles.20 CR found that consumers with the most direct experience were almost ten times as likely to say they would "definitely buy" an electric vehicle today as consumers with no direct experience (58% vs 6%).21 More EVs on the road means more opportunities for Americans to gain more direct experience and exposure to EVs. Right now, broad consumer experience with EVs is very limited, but that is likely to change as more people see family, friends, and neighbors bring home their first EV. This data show that as consumers gain that greater familiarity with EVs they will be more likely to consider purchasing them. [EPA-HQ-OAR-2022-0829-0728, pp. 10-14]

20 Id.

21 Experience was measured based upon "yes" answers to four different questions:

1) Have you seen an EV in your neighborhood in the past month

2) Do you know someone with an EV

3) Have you been a passenger in an EV in the past year

4) Have you driven an EV in the past year

[See original comment for Figure 4.2 - Survey Results on EV Demand by Experience with EVs] [EPA-HQ-OAR-2022-0829-0728, pp. 10-14]

Automaker investments and consumer costs have been discussed in other areas of this comment letter, but they also have the potential to drive increased consumer demand. As automakers deliver more volume, economies of scale and intensified competition for customers will further feed cost declines, which will feed back into the cycle, and lead to increased EV demand. [EPA-HQ-OAR-2022-0829-0728, pp. 10-14]

However, it's not just that consumers are showing increased interest in EVs; they're also showing declining interest in conventional gasoline vehicles. CR's car buying survey from March and April 2022 found that 30% of licensed drivers who were then in the market to buy or lease a new (and not a used) vehicle were not even considering a conventional, non-hybrid vehicle.22 This however, isn't just something consumers are telling us, it's also showing up in the market. Sales of new ICE vehicles decreased by 26% from 2019 to 2022, while combined sales of BEVs, PHEVs and conventional hybrids increased by 144%. BEV sales alone increased by 244% over that same period.23 [EPA-HQ-OAR-2022-0829-0728, pp. 10-14]

22 Car Buying: A National Representative Multi-Mode Survey, 2022 Results, Consumer Reports, May 2022, https://article.images.consumerreports.org/prod/content/dam/surveys/Consumer_Reports_Car_Buying_March_2022.pdf.

23 Consumer Reports analysis of Wards Intelligence annual sales data, available with subscription at: https://wardsintelligence.informa.com/datacenter.

Consumers who are still considering gasoline powered vehicles want them to keep getting more efficient. In a 2022 CR survey of 2,161 US adults assessing Americans' beliefs and attitudes about fuel economy, seven in ten American drivers say that fuel economy is either "very important" or "extremely important" to them when considering what vehicle to purchase or lease.24 In addition, when asked which attributes of the vehicle they drive most often have the most room for improvement, 43% of drivers selected improvements in fuel economy, the most commonly selected attribute, which beat out purchase price (30%), maintenance costs (27%), and eleven other features.25 The full results are shown in Figure 4.3. Finally, 85% of Americans agree that automakers should continue to improve fuel economy across vehicle types.26 This underscores the urgency of this rule to ensure that there is a stringent path forward for automakers to not only increase access to EV technology, but to improve the efficiency of conventional vehicles that some consumers will still be buying. [EPA-HQ-OAR-2022-0829-0728, pp. 10-14]

24 CR nationally representative survey of 2,161 US adults in September and October, Consumer Reports, 2022, https://advocacy.consumerreports.org/wp-content/uploads/2023/03/Consumer-Reports-Fuel-Economy-20 22-National-Sample-Report.pdf.

26 Id.

[See original comment for Figure 4.3 - Vehicle Attributes with the Most Room For Improvement] [EPA-HQ-OAR-2022-0829-0728, pp. 10-14]

Unfortunately, the communities most harmed by transportation emissions and pollution are adopting electric vehicles at disproportionately low rates.27 Despite considerable interest in EVs across race and ethnicity, inequities in EV adoption persist. The BEV and low carbon fuel awareness survey found that overall interest in purchasing EVs was high across all demographics, with communities of color showing at least as great a level of interest in purchasing an electric vehicle as white consumers: 33 percent of White, 38 percent of Black, 43 percent of Latino, and 52 percent of English-speaking Asian Americans say they would "definitely" or "seriously consider" purchasing or leasing an EV.28 [EPA-HQ-OAR-2022-0829-0728, pp. 10-14]

27 Survey Says: Considerable Interest in Electric Vehicles Across Racial, Ethnic Demographics, September 2022, Consumer Reports, Union of Concerned Scientists, EV Noire & Green Latinos, https://advocacy.consumerreports.org/wp-content/uploads/2022/09/EV-Demographic-Survey-English-final.pdf.

28 Id.

The same survey found that although exposure to EVs was roughly the same among members of the Black community as white and Latino Americans (either through personal interactions, observations in their community, or through riding or driving an EV), they reported being less familiar with the fundamentals of owning an EV than any other group. This finding further stresses the need to prioritize increasing EV sales in communities that are disproportionately affected by transportation pollution. EPA should therefore consider the needs of consumers in all demographics and income levels. [EPA-HQ-OAR-2022-0829-0728, pp. 10-14]

6. Specific Technical Comments On EPA's Proposal and Modeling

6.1. Internal Combustion Engine Vehicle Backsliding

EPA's modeling accurately considers the high effectiveness of battery EVs at delivering both significant emissions reductions and consumer savings. EPA's modeling finds that EVs are so cost-effective that emissions from the remaining ICE fleet actually increase over the period of the rule by an average of around 4%. This is because EPA's model finds that it would be cost-effective for automakers to remove already developed technology from their ICE vehicles to save money while building more EVs. [EPA-HQ-OAR-2022-0829-0728, pp. 18-20]

However, this modeling result does not seem likely in the real world. Consumer demand for EVs is rapidly increasing, and technology improvements will mean that the remaining gasoline powered vehicles will have to compete with better and better EV offerings.36 In order to continue to find buyers for their remaining gasoline powered vehicles, automakers will need to make them better, not worse. [EPA-HQ-OAR-2022-0829-0728, pp. 18-20]

36 Excess Demand, The Looming EV Shortage, Consumer Reports, March 2023, https://advocacy.consumerreports.org/wp-content/uploads/2023/03/Excess-Demand-The-Looming-EV-Shortage.pdf.

Furthermore, this result ignores consumer demand for cleaner, more efficient gasoline vehicles. Consumer Reports' 2022 fuel economy survey found continued strong consumer demand for more efficient vehicles.37 [EPA-HQ-OAR-2022-0829-0728, pp. 18-20]

37 Fuel Economy: A Nationally Representative Multi Mode Survey, Consumer Reports, November 2022, https://article.images.consumerreports.org/image/upload/v1670867143/prod/content/dam/surveys/Consumer_Reports_Fuel_Economy_National_September_October_2022.pdf.

- 95% of American drivers said fuel economy is at least somewhat important to them when considering what vehicle to purchase or lease, and seven in 10 (70%) say it is very important or extremely important. [EPA-HQ-OAR-2022-0829-0728, pp. 18-20]

- 85% of Americans agreed that automakers should continue to improve fuel economy for all vehicle types. [EPA-HQ-OAR-2022-0829-0728, pp. 18-20]

- 78% of American drivers agreed that they expect each new generation of vehicles available on the market to be more fuel-efficient than the last. [EPA-HQ-OAR-2022-0829-0728, pp. 18-20]

EPA specifically estimates that hybrid vehicles will drop from 4% of the vehicle fleet in 2027 to 0% of the fleet in 2031 and 2032.38 Research from CR has shown that many hybrids on the market today are extremely cost-effective for consumers, delivering a payback on their cost in 3 years or less, with some delivering savings instantly.39 CR's 2022 nationally representative car buying survey of 6,960 US adults found that 32% of consumers planning to purchase or lease a vehicle within a year were considering a hybrid car or truck.40 While consumer demand for EVs is likely to continue to grow rapidly, EVs do not yet work for all consumer lifestyles, and hybrids offer a viable and cost-effective alternative for these consumers to both reduce their emissions and their fuel spending. EPA's modeling that shows that this popular and cost-effective technology will be completely abandoned by the entire market by the end of the decade is at odds with the data on consumer preferences for these vehicles. [EPA-HQ-OAR-2022-0829-0728, pp. 18-20]

38 Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles, Draft Regulatory Impact Analysis, EPA-420-D-23-003, Table 13-68

39 Regardless of Gas Prices, Some Hybrids Pay for Themselves Immediately, Consumer Reports, March 2, 2023, https://www.consumerreports.org/cars/hybrids-evs/hybrids-vehicles-pay-for-themselves-a1092610835/.

40 Fuel Economy: A Nationally Representative Multi Mode Survey, Consumer Reports, November 2022, https://article.images.consumerreports.org/image/upload/v1670867143/prod/content/dam/surveys/Consumer_Reports_Fuel_Economy_National_September_October_2022.pdf.

Finally, over the duration of this proposed rule, EVs will be gaining significant market share. As they do so, ICE vehicles will by necessity be losing market share. Automakers will need to make decisions about which ICE vehicles and powertrains to keep producing and which ones to discontinue. The most logical approach to meeting these standards would be to phase out their oldest and least efficient vehicles and powertrains, while keeping their newest, most advanced, and most efficient powertrains. This process has the potential to result in significant improvements in average vehicle emissions without automakers having to deploy any additional technology. For example, in the 2023 model year, the best selling Ford F150 offers ICE variants that range in emissions from 352 g/mi to 741 g/mi.41 This large range in emissions leaves a lot of room for improving fleet performance by focusing future production on the lowest emitting variants and eliminating the highest emitting variants. A more detailed analysis from the Natural Resource Defense Council found that shifting to the lowest emitting powertrains could result in emissions reductions of between 19 and 65 grams per mile, compared to the current sales weighted average, for the 12 best selling vehicles.42 [EPA-HQ-OAR-2022-0829-0728, pp. 18-20]

41 Fuel Economy of 2023 Ford F150, U.S. Department of Energy, 2023, https://www.fueleconomy.gov/feg/PowerSearch.do?action=noform&path=1&year1=2023&year2=2023&make=Ford&baseModel=F150&srchtyp=ymm&pageno=1&rowLimit=50.

42 Shifting to Cleaner Gas Engines Can Help Reduce Emissions, Natural Resource Defense Council, July 5, 2023, https://www.nrdc.org/bio/kathy-harris/shifting-cleaner-gas-engines-can-help-reduce-emissions

Given the above, CR makes the following general recommendations to improve EPA's modeling: [EPA-HQ-OAR-2022-0829-0728, pp. 18-20]

- EPA's model should not remove technology that automakers have already invested in adding to their existing ICE vehicles.

- As EV market share increases over the course of the rule, EPA should model a reduction in the number of ICE powertrains that automakers continue to build in such a way that the newest and most advanced options are kept, and the oldest and least advanced are phased out over time. [EPA-HQ-OAR-2022-0829-0728, pp. 18-20]

Organization: Countymark

Another issue related to EVs is their weight, ranging from 1,000 to 3,000 pounds more than gas-powered vehicles. This additional weight results in more damage to American roads, necessitating increased infrastructure repair costs funded by taxpayers. Mandating a transition to EVs can lead to increased consumer prices and reduced vehicle choices. It also raises concerns about the financial burden on low-income families and the potential for increased infrastructure repair costs due to the heavier weight of EVs. [EPA-HQ-OAR-2022-0829-0665, p. 2]

Organization: Daniel Hellebuyck

Consumer Choice: There is a large percentage of the population that have no desire for an EV. It may be the extra up-front costs in purchasing an EV, lack of charging stations, limited range, the vehicle not being suitable for long trips or frequent long-distance rural driving, or the time it talks to fully charge an EV compared to an ICE counterpart. In the past, the government has done a poor job of dictating which products or services that customers should purchase and as a result, consumers lost the freedom of choice that made this country so powerful, and employees who provided products and services to these consumers lost their jobs. [EPA-HQ-OAR-2022-0829-0526, p. 1]

Organization: Doug Peterson

Consumer desire for additional range may also put downward pressure on fuel economy. Conventional vehicles have the upper hand with this critical vehicle attribute. Gasoline tanks are sized to provide adequate range. Inadequate range is currently a major convenience drawback for BEVs, and they will not sell in large numbers until range figures increase substantially. Poor range also compounds the convenience drawback of slow refueling because it increases the frequency of charging station visits when travelling far from home. When battery packs are enlarged to provide additional range, fuel economy often suffers. [EPA-HQ-OAR-2022-0829-0500, pp. 10-11]

The relationship between range and electric fuel economy is complex. Higher fuel economy increases range, but automakers can achieve the same result by increasing the size of the battery pack. This approach adds considerable weight to the vehicle and tends to reduce fuel economy. The tradeoff between range and efficiency will shift as engineers improve the gravimetric energy density of battery cells, and impressive breakthroughs appear to be just around the corner. It is also worth noting that some automakers are producing BEV models that deliver impressive range along with outstanding fuel economy. Still, the EPA should be very concerned that its failure to regulate BEV fuel economy will result in the unrestrained upsizing of battery packs. The trend will increase demand for limited supplies of resources like lithium which will also be needed for batteries that store intermittent renewable energy. In the near term, the inability to secure an adequate supply of battery materials will slow BEV proliferation. [EPA-HQ-OAR-2022-0829-0500, pp. 10-11]

Consumer trends favoring larger, more powerful vehicles have undermined regulatory efforts to improve the overall fuel economy of the conventional fleet. The compelling statistics are summarized each year in the EPA’s Automotive Trends Report, and the agency would be wise to not let history repeat itself with the emerging electric fleet. The footprint model was specifically designed so that automakers would not be held accountable for market trends that affect the composition of their fleets. The dubious argument applied here was that automakers have no control over purchasing decisions made by consumers that determine their fleet mix. There is strong evidence that automakers have actively encouraged consumer trends that are known to waste gasoline, and they will do the same thing with BEVs if not held accountable for upstream emissions. The proposed policy will supercharge these wasteful trends just as the electric fleet is taking shape, and it will be very difficult to restore efficiency to the fleet after it has evolved. [EPA-HQ-OAR-2022-0829-0500, pp. 11-12]

There is already a strong public perception that electric fuel economy is environmentally meaningless, and this should be very troubling to the EPA. When automakers advertise their BEVs, MPGe ratings are rarely even cited. The vast disparity between the most efficient BEVs and the least efficient plug-in hybrids is also being blurred in the eyes of the public. If a vehicle is “electrified”, it is marketed as being very environmentally beneficial, but this is often not the case. Plug-in hybrids are sometimes even called “zero-emission vehicles”. Ardent BEV enthusiasts are especially indifferent to MPGe disparities, viewing BEVs as environmentally superior vehicles that are all equally beneficial. The Electric Vehicle Association has no reservations about electron guzzlers, but the EPA certainly should. [EPA-HQ-OAR-2022-0829-0500, pp. 11-12]

Moreover, EVs are not well suited for all of our nation’s climates, especially in states that are rural, are at high altitude, or both. In such areas lon such areas long distance travel in often extreme temperature ranges significantly impact EV range and the ability of Americans to access healthcare, food, and other neg distance travel in often extreme temperature ranges significantly impact EV range and the ability of Americans to access healthcare, food, and other necessities. [EPA-HQ-OAR-2022-0829-0525, p. 2]

Organization: Energy Innovation

As of the first quarter of 2023, the U.S. hit an all-time high of EV sales, which made up just over 8 percent of new car sales.35 And over the last six months, the U.S. has exceeded the 5 percent tipping point for EVs—a trend established by 18 countries, suggesting that a quarter of new car sales could be electric by the end of 2025.36 [EPA-HQ-OAR-2022-0829-0561, pp. 12-15]

[EPA-HQ-OAR-2022-0829-0561, pp. 12-15]

The trajectory for greater electrification follows the trend over the past decade of increasing EV ranges and overall improvements to performance as more models become available. As illustrated in Figure 8, the average EV range has almost tripled over the past 10 years, going from just under 80 miles in 2010 to 220 miles in 2021. These improvements in vehicle performance will continue the positive feedback loop of increased consumer acceptance and vehicle affordability, further accelerating adoption of EVs in this decade. XV. ZEV Penetration in the Absence of the Proposed Standards is Likely to Exceed EPA's Estimates, Supporting the Feasibility of More Stringent Standards.

To support the feasibility of Alternative 1 with a steeper increase in stringency after 2030, we now turn to the market growth of ZEVs and anticipated baseline (or "no action") levels of ZEV penetration. EPA's No Action scenario projected that BEVs will comprise 39% of the LDV fleet in 2032. To assess the reasonableness of this projection, EPA reviewed literature and other analytical projections, which clearly supported ZEV penetration at least as high as EPA's projections. While EPA's approach is reasonable, real-world "no action" levels of BEVs are likely to be even higher than EPA's No Action scenario. This supports making the finalized standards more stringent than proposed. [EPA-HQ-OAR-2022-0829-0759, p. 100]

XIX. Consumer Acceptance of PEVs Is Not a Barrier to Feasibility of EPA's Proposed Standards or More Stringent Standards.

In this section and in Sections XX and XXI, we explain how consumer acceptance considerations support strong final standards. As detailed below, PEVs offer significant economic and performance benefits to consumers, and consumer interest in PEVs continues to grow. [EPA-HQ-OAR-2022-0829-0759, p. 151]

A. EPA has broad discretion in considering consumer preferences when promulgating emission standards but should not give undue weight to that factor.

As explained in EPA's Proposal and Section II of these comments, when promulgating new emissions standards under Clean Air Act § 202(a), EPA must consider the statutory criteria of technological feasibility, cost of compliance, and lead time.412 EPA may consider other factors, and in the past has considered a rule's various impacts on vehicle purchasers.413 [EPA-HQ-OAR-2022-0829-0759, p. 152]

412 42 U.S.C. § 7521(a); 88 Fed. Reg. at 29186.

413 88 Fed. Reg. at 29186.

While EPA has often considered consumer acceptance in its Section 202 rulemakings, the Agency may not let the unique preferences of each and every consumer dictate its consideration of the appropriateness or feasibility of emission standards. In International Harvester Company v. Ruckelshaus, 478 F.2d 615, 640 (D.C. Cir. 1973), the D.C. Circuit Court of Appeals concluded:

We are inclined to agree with the Administrator that as long as feasible technology permits the demand for new passenger automobiles to be generally met, the basic requirements of the Act would be satisfied, even though this might occasion fewer models and a more limited choice of engine types. The driver preferences of hot rodders are not to outweigh the goal of a clean environment. [EPA-HQ-OAR-2022-0829-0759, p. 152]

While International Harvester involved emission requirements for light-duty vehicles under a provision of the 1970 Amendments, the principles the court expressed apply just as well to standards under Section 202(a)(1). As detailed in Section II, Congress intended EPA's standards to push the industry toward greater emission reductions and did not expect them to preserve the market dominance of any particular type of powertrain or power source. EPA should not give oversized weight to arguments questioning consumer preferences, which is not a factor Congress identified in Section 202(a)(1). [EPA-HQ-OAR-2022-0829-0759, p. 152]

While EPA has discretion whether to consider and how much weight to give purchaser acceptance in setting emission standards, that discretion is limited by EPA's primary statutory duty to set standards that adequately protect public health and welfare. An understanding of consumers' willingness to purchase and drive PEVs could inform the feasibility and effectiveness of EPA's regulations. EPA's attention to consumer preferences, however, cannot compromise its overall Clean Air Act mandate to mitigate the automobile's "devastating impact on the American environment," International Harvester, 478 F.2d at 622, or the Agency's primary duty to protect public health and welfare by minimizing harmful air pollution. Most importantly here, however, is that consumer acceptance of PEVs is widespread and growing, and PEVs provide the vehicle features and characteristics that drivers want and need. Thus, as this section will explain, consumer acceptance is not a barrier to PEV penetration at the levels projected by EPA's Proposal or at levels consistent with Alternative 1 with increasing stringency after 2030. [EPA-HQ-OAR-2022-0829-0759, pp. 152-153]

B. Consumer acceptance of PEVs is not a barrier to feasibility because consumer acceptance is widespread and growing.

Under EPA's Proposed Standards and under Alternative 1 with a faster ramp-up after 2030, consumer preferences generally align with the most economically advantageous and cost-effective compliance pathway (increasing the deployment of PEVs within the light-duty fleet) toward meeting strong emission standards that fulfill EPA's statutory mandate. American drivers have shifted and are continuing to shift toward acceptance of—and, increasingly, preference for—PEVs. As several original equipment manufacturers (OEMs) have themselves explained, "[r]educed interest in legacy products due to technology advancements and consumer preference shifts are an inevitable reality of the market and occur in all sectors of the economy." See Initial Brief for Industry Respondent-Intervenors at 13-14, Ohio v. EPA, No. 22-1081 (D.C. Cir. Feb. 13, 2023).414 Here, as PEV technology advances and both the public health and driver-experienced benefits of PEVs become apparent, consumer's preferences are naturally shifting away from combustion vehicles and toward PEVs. [EPA-HQ-OAR-2022-0829-0759, p. 153]

414 Automaker industry respondent-intervenors on this brief include Ford Motor Company, BMW of North America, LLC, Volkswagen Group of America, Volvo Car USA LLC, American Honda Motor Co., Inc., and the National Coalition for Advanced Transportation (whose members include Rivian and Tesla). The Initial Brief for Industry Respondent-Intervenors is available at https://blogs.edf.org/climate411/files/2023/02/Industry-Respondent-Intervenors-Initial-Brief-Feb.-13-2023_.pdf.

EPA's Proposal accurately highlights the already "greatly increased acceptance [of PEVs] by consumers," 88 Fed. Reg. at 29187, and that "consumer affinity for PEVs is strong." Id. at 29189. This market-based consumer acceptance is evidenced at least in part by recent rapid growth in PEV market share—growth that has outpaced historical estimates considered ambitious just a decade ago. EPA's 2012 Rule, for example, assumed electric vehicles would account for only 3% of the car market and 2% of the combined car and light-duty truck market by 2025. 77 Fed. Reg. at 62874, 62875 Tbl.III-52. By 2021, however, combined car BEV and PHEV market share had already outpaced that estimate for 2025, reaching about 4.2% of LDV sales and double the 2020 market share.415 By 2022, electric vehicle market share had again reached a new high, with combined LDV BEV and PHEV market share totaling 7.6% for 2022416—already more than double EPA's 2012 Rule projection for 2025. As of the first quarter of 2023, U.S. light-duty PEV sales were up again, to 8.3%,417 an increase of 60% compared to the same period in 2022.418 As discussed in the Proposal, forecasts based on consumer demand now suggest U.S. passenger car PEV sales percentages of 40% to more than 50% by 2030, 88 Fed. Reg. at 29192, and public announcements by major automobile manufacturers support baseline PEV sales at this level or higher. Id. at 29190-2; DRIA at 3-16.. [EPA-HQ-OAR-2022-0829-0759, pp. 153-154]

Data regarding PEV registrations and preorders also shows strong and growing consumer demand for these vehicles and signals widening consumer acceptance. In the first three months of 2022, registrations for new PEVs increased 60% in the United States, even though overall new car registrations were down 18%.419 Looking at consumer sales shares, however, is likely an inadequate proxy for actual consumer interest in PEVs, given the fact that many consumers do not yet have access to these vehicles. A recent analysis by Sierra Club found that 66% of car dealerships nationwide did not yet have a single EV available for sale.420 When new PEV models enter the market, consumers race to place orders. In late 2022, for example, GMC's new Sierra model electric pickup truck averaged more than 500 reservations per day and reached roughly 20,000 reservations after a little over a month, on top of over 170,000 reservations for GMC's Silverado EV pickup.421 Similarly, the Dodge Ram 1500 REV pickup reached its maximum number of preorders in just 5 days earlier this year.422 [EPA-HQ-OAR-2022-0829-0759, p. 154]

This consumer purchase data shows Americans' increasing desire for PEVs, and is backed up by other data and research. Specifically, as this section will explain, peer-reviewed research and analyses, customer-based surveys, and comparisons with international sales trends provide further evidence of broad and expanding consumer preference for PEVs. [EPA-HQ-OAR-2022-0829-0759, p. 154]

1. Recent peer-reviewed academic literature supports broad and growing consumer acceptance of PEVs.

Several recent peer-reviewed papers have shown that consumers are in fact ready and willing to adopt electric vehicles. EPA references some of these papers in the Proposal, and should also consider additional research on PEV consumer acceptance, including research that is recently published. For example, a recent study by leading academics in this field, and not discussed in EPA's Proposal, examined consumer choices of plug-in electric vehicles (including BEVs and PHEVs) relative to conventional gasoline vehicles.423 The study, Forsythe et al. (2023), found that when consumers' basic demands for vehicle attributes are met, they accept or prefer BEVs to combustion vehicles.424 The analysis was conducted through a nationwide survey-based consumer discrete choice experiment from December 2020 to September 2021, in which new vehicle consumers—weighted to be representative of the U.S. population—chose among potential vehicle options in a manner that mimicked the process of comparing vehicles on an automaker's website.425 In order to examine how consumer preferences might be changing over time, the experiment was designed to be compared to an earlier discrete choice experiment conducted in 2012–2013.426 The Forsythe et al. (2023) experiment was well-designed in that it (1) mitigated typical concerns of stated-preference experiments by "incorporat[ing] multiple features into the survey design that tend to improve the ability for survey responses to reveal comparable preferences as when making true purchase decisions";427 (2) included a substantial number of participants (734 car-buyers and 862 SUV-buyers) recruited using both Amazon's Mechanical Turk (to mirror the earlier comparative study) and Dynata (which includes older and higher-income respondents), and weighted to ensure representativeness of the U.S. new vehicle buying population;428 and (3) evaluated expected technology for a near-future hypothetical vehicle based on extensive research conducted by the National Academies of Sciences, Engineering, and Medicine, thus reflecting what PEV models could realistically be available to consumers in the short term.429 [EPA-HQ-OAR-2022-0829-0759, pp. 154-155]

429 Id. at 2–3; see also National Academies of Sciences, Engineering, and Medicine, Assessment of Technologies for Improving Light-Duty Vehicle Fuel Economy—2025-2035 (2021), https://nap.nationalacademies.org/catalog/26092/assessment-of-technologies-for-improving-light-duty-vehicle-fuel-e conomy-2025-2035.

Forsythe et al. (2023) was the first to examine "the degree to which consumer willingness to trade off relevant vehicle attributes associated with electrification (e.g., range, operating cost, price, etc.) may have changed over time due to technology improvements or other factors and what this could imply for the sales of new vehicles in upcoming years."430 The results indicated that "any perceived disadvantages of BEVs relative to gasoline vehicles are often compensated by the BEV's improved operating cost, acceleration, and fast-charging capabilities, particularly for BEVs with a longer range."431 [EPA-HQ-OAR-2022-0829-0759, pp. 155-156]

430 Forsythe et al. (2023) at 2.

431 Id. at 2.

In short, the study reveals that the attributes consumers look for in their vehicles have most likely stayed consistent between the 2012 stated-preference experiment and Forsythe et al. (2023)'s most recent. As BEVs are able to provide more of those attributes, consumers choose BEVs more often. The authors ultimately concluded that reasonable forecasted improvements of BEV range and price—based on extensive research on technology development by the National Academies of Sciences—show that "consumer valuation of many BEVs is expected to equal or exceed their gasoline counterparts by 2030," resulting in 40% to nearing 60% of consumers choosing BEV powertrain options over combustion powertrain options for the same vehicle.432 Moreover, "[a] suggestive market-wide simulation extrapolation indicates that if every gasoline vehicle had a BEV option in 2030, the majority of new car and near-majority of new sport-utility vehicle choice shares could be electric in that year due to projected technology improvements alone."433 Finally, Forsythe et al. (2023) suggested that, with the assumed technological projections, even if all BEV purchase incentives were entirely phased out, BEVs could still have a market share of about 50% relative to combustion vehicles by 2030, based on consumer choice alone.434 [EPA-HQ-OAR-2022-0829-0759, p. 156]

434 Forsythe et al. (2023) at 6.

As discussed in EPA's Proposal and the Agency's January 2023 literature review of consumer acceptance research,435 other recent studies show a similar trend of increasing consumer preference for PEVs. For example, Carley et al. (2019) found that American consumers were more intent on purchasing PEVs in 2017 than in 2011.436 Gillingham et al. (2023), cited briefly in EPA's Proposal, is especially illustrative of the increasing consumer demand for PEVs. That study used data on all new light-duty vehicles sold in the United States between 2014 and 2020 (a dataset of over 106 million observations), and found that in the vehicle segments and classes where EVs were available, they were competing very successfully with comparable combustion vehicles, with relative market shares "exceeding 30% in recent years."437 The results of this investigation could imply that fleet-wide LDV PEV market share in 2020 was around 2% not because only 2% of buyers wanted PEVs, but at least in part due to “the (near-)absence of EV offerings in many segments of the vehicle market”438 where purchasers are interested in purchasing vehicles. If consumers want to purchase a particular vehicle type and there are no PEVs available within that market segment, they will buy a combustion vehicle. Gillingham et al. (2023) shows that when PEVs are available in those market segments, consumers already often choose the PEV over the combustion vehicle. [EPA-HQ-OAR-2022-0829-0759, pp. 156-157]

Evidence from Microdata on Every New Vehicle Sale in the United States, American Economic Association: Papers & Proceedings 333–334 (May 2023).

438 Id. at 334.

A number of studies in addition to those cited in EPA’s literature review of consumer acceptance have considered the impacts of various factors on consumer acceptance of PEVs, and these—coupled with the current rapid pace of technological development and vast investment in PEV infrastructure—provide additional evidence that consumer acceptance is not a barrier to PEV penetration at levels consistent with EPA’s Proposal or with Alternative 1 with increasing stringency after 2030. One body of research, for example, reveals that consumer demand is responsive to the availability of public charging infrastructure. When this infrastructure is available—as it increasingly is and will be, see Section XVII—consumer acceptance of and demand for PEVs increases. Cole et al. (2023) concluded that for encouraging PEV sales, “[s]pending on charging stations is more effective than spending on rebates,” with shifting spending from rebates to charging station programs increasing projected EV penetration share in 2030 from 48% to 68%.439 Similarly, Li (2017) found that, between 2011 to 2013, the federal income tax credit of up to $7,500 for EV buyers contributed to about 40% of EV sales, but “[a] policy of equal-sized spending but subsidizing charging station deployment could have been more than twice as effective in promoting EV adoption.”440 Using data from Norway, Springel (2021) found that spending on charging station subsidies, at least initially, resulted in more EV purchases than spending on consumer price subsidies.441 Given the extensive investments in PEV infrastructure, detailed in Section XVII, PEV demand would be expected to be responsive to these investments, and increasing. Additionally, Herberz et al. (2022) studied BEV adoption and found that “car owners systematically underestimate the compatibility of available battery ranges with their annual mobility needs and that this underestimation is associated with increased demand for long battery ranges and reduced willingness to adopt electric vehicles.”442 Researchers found that simply providing tailored compatibility information increased consumer willingness to pay for BEVs, even more than information about easy access to charging infrastructure. 2. Consumer surveys also support broad and growing consumer acceptance of PEVs.

Many well-designed, real-world consumer surveys also confirm significant and growing consumer interest in purchasing PEVs. A report on a recent, nationally representative survey of 8,027 Americans conducted by Consumer Reports with input from the Union of Concerned Scientists, GreenLatinos, and EVNoire, conducted between January 27 and February 18, 2022, found that "[o]verall interest in EVs is high" across all racial demographics.443 Between 33% and 52% of respondents (depending on racial demographics) would "definitely" or "seriously consider" purchasing or leasing an EV as their next vehicle.444 Only 28% of Americans would not consider getting an electric-only vehicle if they were to buy or lease a vehicle today.445 Even in rural areas, the survey showed that current interest in EV purchases is high, with up to 29% of rural drivers at least seriously considering buying or leasing an EV.446 Between 2020 and 2022, Consumer Reports surveys have shown a 350% increase in consumer demand for BEVs.447 [EPA-HQ-OAR-2022-0829-0759, p. 158]

Survey responses in the 2022 Capital One Car Buying Outlook also overwhelmingly show that Americans envision a future in which they will be driving PEVs. Over 60% of American car buyers and 84% of American car dealers surveyed agreed that electric vehicles are the future.448

Additionally, 46% of car buyers already believe they will be driving an electric vehicle within the next 10 years.449 The annual global EY Mobility Consumer Index found a similar level of consumer demand for and interest in PEVs, and also emphasized that this is a global trend with which the United States must keep pace in order to remain globally competitive. The investigation, conducted in March 2022, surveyed approximately 13,000 respondents from 18 countries including the United States on themes including EVs, mobility and travel behavior, and car buying. It found that preference for fully electric cars for those surveyed tripled between 2020 and 2022,450 and 52% of global car buyers currently prefer their next car purchase to be an EV, PHEV, or hybrid vehicle.451 [EPA-HQ-OAR-2022-0829-0759, pp. 158-159]

Very recent surveys from this year also show strong consumer interest in PEVs. KPMG's Consumer Pulse Summer 2023 survey of 1,000 Americans showed that nearly half of U.S. combustion vehicle owners are considering switching to PEVs or hybrid electric vehicles, prompted in large part by increasing gas prices and environmental concerns.452 A 2023 online poll of 4,410 Americans by Reuters/Ipsos found that already just over a third of Americans would consider buying an EV for their next car purchase.453 J.D. Power's most recent U.S. Electric Vehicle Consideration Study, released in June 2023, also found high interest in EVs. The study found the number of car buyers "very likely" and "overall likely" to consider purchasing an EV increased over 2002, with 26% of shoppers "very likely" and 61% "overall likely" to consider purchasing an EV.454 [EPA-HQ-OAR-2022-0829-0759, p. 159]

3. A "tipping point" in PEV adoption can signify rapid mass consumer acceptance, and the United States has reached this milestone.

Analysis from other countries shows that once 5% of a country's new car sales are electric—a threshold the United States has crossed—the country has reached an "electric-car tipping point" which "signals the start of mass EV adoption, the period when technological preferences rapidly flip."455 So far, 18 countries have reached this "tipping point," and assuming the United States follows their trend, "a quarter of new car sales could be electric by the end of 2025. That would be a year or two ahead of most major forecasts."456 This "tipping point" occurs because technologies generally follow an S-shaped adoption curve. "Sales move at a crawl in the early-adopter phase, then surprisingly quickly once things go mainstream….In the case of electric vehicles, 5% seems to be the point when early adopters are overtaken by mainstream demand. Before then, sales tend to be slow and unpredictable. Afterward, rapidly accelerating demand ensues."457 This S-shaped pace of technology adoption has been observed for numerous emerging technologies since the early 1900s, including the telephone, the automobile, electricity, refrigeration, clothes washers and dryers, air conditioning, microwaves, computers, cellphones, and the internet, as Figure XIX.B-1 shows.458 [EPA-HQ-OAR-2022-0829-0759, pp. 159-160]

459 This figure is reproduced from id.

Moreover, the pace of adoption has been speeding up consistently across new technologies, as Figure XIX.B-1 also shows. For example, "[i]t took decades for the telephone to reach 50% of households, beginning before 1900. It took five years or less for cellphones to accomplish the same penetration in 1990."460 The automotive industry has not been left out of this increasing speed of technological adoption, with automotive design cycles decreasing from 60 months to 24 or 36 months over a period of five years.461 [EPA-HQ-OAR-2022-0829-0759, p. 161]

460 Id. 461 Rita McGrath, The Pace of Technology Adoption is Speeding Up, Harvard Business Review (Nov. 25, 2013), https://hbr.org/2013/11/the-pace-of-technology-adoption-is-speeding-up.

Between 2021 and 2022, the United States reached this "tipping point" level of PEV penetration, jumping from 4% to over 7.6% PEV sales share.462 As this tipping point is reached, it is likely that Americans' exposure to PEVs increases. Importantly, "studies show that increasing knowledge and exposure to these [electric] vehicles results in lasting, positive impressions."463 A comprehensive literature review regarding consumer adoption of BEVs found that social interactions can influence BEV adoption.464 Some consumers have no interest in purchasing a PEV simply because they lack information about the characteristics of PEVs, but when consumers learn about PEVs, they are more likely to be interested in purchasing one. For example, a study considering hybrid electric vehicle ("HEV") adoption—which "can be used as a proxy for future PEV adoption"—found that there is a strong "direct neighbor effect" by which each consumer's HEV-adoption decision can be influenced by the HEV-adoption decisions of geographic neighbors.465 Another study, using a survey of vehicle customers in California and a spatial and statistical analysis, found that having more neighbors and work colleagues who have EVs increases EV adoption.466 Yet another study using very rich data from Sweden found the same result: having more neighbors and work colleagues who drive EVs increases EV adoption. This study also explored reasons for the effect, finding that information transmission is likely very important.467 [EPA-HQ-OAR-2022-0829-0759, p. 161]

Survey data again corroborates this research. The 2022 Consumer Reports survey found that for all groups of consumers, "experience with EVs strongly correlated to interest in purchasing or leasing an EV."468 The survey found, for example, that "Americans who are more likely to say that they will buy/lease an electric-only vehicle if they were to get a vehicle today have had more exposure to them. They see them where they live and have friends, relatives, or co-workers who own one."469 In fact, 71% of those who said they would definitely buy or lease an EV if they were getting a vehicle today had seen EVs in their neighborhood, compared to 44% of all survey respondents.470 "There is … a strong relationship between having some personal experience with an electric-only vehicle and the likelihood of buying or leasing one."471 Seventeen percent of all survey respondents had been a passenger in an electric-only vehicle in the past 12 months, compared to 39% of people who said they would definitely buy or lease an electric-only vehicle if they were to buy or lease a vehicle today. Only 7% of survey respondents had driven an EV in the past 12 months, but 20% of those who would definitely buy or lease one have driven one.472 Two surveys commissioned by the Consumer Federation of America to study consumer attitudes towards PEVs similarly found that "the more consumers know about PEVs, the more positive their attitudes towards them and the more likely they are to consider acquiring one."473 And J.D. Power's 2023 U.S. Electric Vehicle Consideration Study found that the number of consumers reporting they are "very likely" to consider purchasing an EV was more than double for consumers who had ridden as a passenger in an EV compared to those with no personal experience with EVs.474 [EPA-HQ-OAR-2022-0829-0759, p. 162]

This exposure effect is also evident when reviewing the outcome of events specifically aimed at exposing potential buyers to PEVs. For example, research by CARB has found that “exposure to PEVs through ride and drive events or car-sharing programs seem to result in lasting, positive impressions and serve to be one of the most influential information sources for helping consumers decide on a PEV. Second to a vehicle test drive, another PEV driver is the other most influential information source for new buyers to choose a PHEV or BEV.”475 CARB explained that “[t]he impact of exposure to PEVs through participation in ride and drive events and carsharing programs has been shown to have a positive effect on attitudes towards PEVs and increase interest in PEV adoption.”476 Furthermore, “simply giving consumers more information on PEVs also increases their interest in acquiring one. A study analyzed the effect of providing information on fuel costs of different vehicle technologies for specific commuting patterns on attitudes regarding PEVs,” and found that after utilizing an online tool that allowed users to compare fuel costs for different vehicles based on their own commuting patterns, local fuel prices, and charging opportunities, “[p]articipants reported a significantly greater intention to acquire a PEV.”477 [EPA-HQ-OAR-2022-0829-0759, pp. 162-163]

This “tipping point” concept, and the resulting wider PEV exposure when a location reaches the tipping point, is possibly already playing out in microcosms of high PEV sales within the nation. In California, for example—a state even further past this “tipping point” than the United

States as a whole—sales of EVs reached more than 21% of all new vehicles sold in early 2023,478 and at least one survey shows almost three-quarters of California vehicle shoppers say they are "overall likely" to consider an EV.479 The phase of rapid PEV adoption also has already been underway in several individual cities. For example, 32.9% of monthly new vehicle registrations in the San Francisco metro area were EVs in January 2023, up from 26.7% in January 2022, and 17.2% of new vehicle registrations in Seattle were EVs in January 2023, up from 8.4% in January 2022.480 Passenger EV sales shares for the first quarter of 2023 were 29.1% of sales in San Francisco and 20.7% of sales in Los Angeles.481 In the New York City metro area in 2020, there were about three EVs per 1,000 people; today there are about seven EVs per 1,000 people—growth that has been "propelled by more varied models, more charging stations and lower prices."482 [EPA-HQ-OAR-2022-0829-0759, p. 163]

481 California Energy Commission, New ZEV Sales in California, https://www.energy.ca.gov/data-reports/energy-almanac/zero-emission-vehicle-and-infrastructure-statistics/new-zev- sales (filtered to show ZEV sales in San Francisco and Los Angeles counties).

482 Robin Shulman Agueros, Why the New York Area Is Seeing an Explosive Growth in Electric Cars, New York Times (Mar. 7, 2023), https://www.nytimes.com/2023/03/05/nyregion/electric-vehicles-cars-nyc.html.

This concept could also shed light on one possible reason that PEV sales percentages have been unevenly distributed across the nation, with more sales in cities than rural areas, in a way that minimizes any concerns that rural consumers could have insufficient demand for PEVs. A 2023 survey conducted by the Union of Concerned Scientists and Consumer Reports "uncover[ed] that there isn't sufficient familiarity with EVs in rural areas. The overwhelming majority of respondents—96%—has never owned or leased an EV."483 The survey found that only 6% of rural respondents said they were very familiar with the fundamentals of buying and owning an EV, while 30% said they were somewhat familiar, and concluded that "[o]ne of the reasons for this lack of familiarity could be the scarcity of EVs in rural areas: only 27% of rural dwellers have seen an EV in their neighborhood in the past month compared to more than half of urban dwellers, and even fewer have a friend, relative or co-worker who owns an EV. A whopping 90% of rural dwellers have never been a passenger in an EV, and almost nobody has ever driven one."484 As efforts are made to increase familiarity with PEVs in rural areas, more Americans will learn about the very real benefits and advantages of PEVs, especially for rural drivers, see Section XIX.C.6 below, and this "neighbor effect" will begin to take hold in more places. [EPA-HQ-OAR-2022-0829-0759, p. 164]

C. When considering the attributes consumers care about most, EVs are a great fit.

One of the reasons this "neighbor effect" may occur is because when consumers learn about PEVs, they often realize that PEVs offer a superior fit for the attributes they care about most in their driving and vehicle-owning experience. Forsythe et al. (2023) found that key factors Americans consider when purchasing vehicles and considering PEV options are operating cost, range, fast-charging capabilities, and performance characteristics such as acceleration.485 Consumer surveys and other studies have found the same attributes, along with fuel economy, as key to purchase decisions.486 As explained briefly in this section and in more detail in Sections XIX.C and XX, PEVs offer superior satisfaction of these consumer preferences. Any existing or perceived barriers to PEV adoption based on consumer acceptance are either minimal or surmountable, policies are already in place to support rapid elimination of any remaining barriers, and the pace of PEV incorporation into the fleet will allow for consumer preferences to be fulfilled. [EPA-HQ-OAR-2022-0829-0759, pp. 164-165]

1. PEVs are increasingly favorable from a total cost of ownership perspective and save drivers money over the life of the vehicle. As more models become available, this benefit will be accessible to more consumers.

First, PEVs are increasingly favorable from an operating cost and total cost of ownership (TCO) perspective—a factor that is very important to U.S. consumers when deciding which vehicles they want to buy. A 2020 nationally representative survey of potential vehicle purchasers found that 94% of potential purchasers considered fuel economy to be important when purchasing a vehicle.487 PEVs excel in the area of fuel cost savings. As EPA's Proposal shows, the incremental costs of PEVs over combustion vehicles are increasingly insignificant or nonexistent—especially in light of various state and federal incentives—resulting in PEVs saving drivers money in very short periods of time. And as operating costs are reduced, consumers are willing to pay more for their vehicles. Forsythe et al. (2023) found car buyers willing to pay upfront an additional $1,960 per 1 cent/mile reduction in operating cost, and SUV buyers willing to pay an additional $1,490.488 The paper also found that any perceived PEV disadvantages were made up for by favorable operating costs (along with fast-charging capability), and that lower operating costs "can help increase consumer adoption."489 Forsythe et al. (2023) further found that reductions in the BEV price-premium, which are projected to occur, "have driven substantial increases in consumer choices of BEV cars and SUVs over their conventional gasoline vehicle counterparts."490 A March 2023 J.D. Power survey reflected one example of this consumer responsiveness to price, finding that consumer interest in the Ford Mustang Mach-E and Tesla Model Y measurably increased when both manufacturers announced price drops and both models were made eligible for the IRA's $7,500 federal tax credit.491 A June 2023 J.D. Power survey also indicated that consumers are recognizing these savings, finding that "[t]he more miles that vehicle owners drive, the more likely they are to consider an EV. As in prior-year studies, daily commuters faced with higher fuel expenses are trading in their gas-powered vehicles for EVs."492 [EPA-HQ-OAR-2022-0829-0759, pp. 165-166]

Power, EV Price Pressure Grows as Government Incentives and Lease Deals Wield Outsized Influence on Consumer Demand (Mar. 29, 2023), https://www.jdpower.com/business/resources/ev-price-pressure-grows-as-government-incentives-and-lease-deals-wi eld-outsized-influence-on-consumer-demand#:~:text=At%20the%20current%20trajectory%2C%20J.D.,is%20expec ted%20to%20surpass%2075%25.

492 J.D. Power, Action Needed to Keep Charging from Short Circuiting EV Purchase Consideration, J.D. Power Finds (June 15, 2023), https://www.jdpower.com/business/press-releases/2023-us-electric-vehicle-consideration-evc-study.

Up until recently, nearly all PEV models on the market were sedans or hatchbacks, or vehicles in the luxury car segment of the market,493 leaving vehicle purchasers looking for other types of vehicles without many options. But dozens of new models are entering the market in the next year, in all vehicle segments.494 Additional PEV model availability will provide a wider range of price points and greater diversity of vehicle types and features for potential PEV purchasers, further driving down average PEV costs and resulting in a PEV "fit" superior to a comparable combustion vehicle for more consumers. Research by ICCT has shown that "[g]reater availability of models in more vehicle segments and in higher volumes that meet consumers' wide range of needs and preferences is critical to market growth," and "states with greater model availability tend to have higher electric vehicle uptake."495 In recent years, average PEV costs have appeared higher than average combustion vehicle costs because many PEVs have been offered only in the luxury vehicle market. Gillingham et al. (2023)'s review of its dataset containing every new LDV sale in the United States between 2014 and 2020 revealed that, during that time period, "the market share of EVs and PHEVs is quite high in several price brackets at the high end, but the number of vehicles sold in these high price brackets is relatively small," and that "EVs can make up a large market share in the U.S. new car market," and "there is a great deal of untapped product space for EVs in the lower price brackets."496 Drivers of non-luxury vehicles want PEVs—and their benefits—as well. Automakers understand this demand and are expanding their PEV options, and an appropriately stringent rule by EPA will go further to accelerate this trend by offering automakers regulatory certainty. [EPA-HQ-OAR-2022-0829-0759, p. 166]

493 See, e.g., Gillingham et al. (2023) at 329, 332–333 (noting that EVs are overrepresented in the luxury market segments and that in the hatchback category—"a small market segment with a relatively large number of EV offerings"—sales of PEVs have been "close to 15% of the market in some years").

496 Gillingham et al. (2023) at 331–332.

Already, the number of light-duty PEV options has grown dramatically. The Alliance for Automotive Innovation states that at the end of 2022, there were 95 PEV models available in the United States.497 More models are forthcoming, including additional truck and SUV models along with the expansion of a wider range of EV sedans.498 EPA's Proposal notes research by EDF and ERM projecting that there will be over 180 PEV models available by the end of 2025, 88 Fed. Reg. at 29190 n.59, but EDF and ERM have since updated their analysis and now project that there will be 197 PEV models available by the end of 2025.499 Many of the world's largest automakers have committed to significantly expanding PEV production in the next few years, even absent additional standards,500 which will naturally lead to a larger array of model choices. For example, BMW, Volkswagen, and Stellantis have each committed to fleets half comprised of zero-emission vehicles by 2030.501 Mercedes-Benz, Ford, and GM have committed to an entirely zero-emission fleet by 2035.502 Volvo announced its fleet will be all electric by the end of the decade.503 J.D. Power's EV Index and EV Consideration Pulse Survey found that half of all new car shoppers will have a viable EV option by the end of 2023, and three out of four shoppers will have a viable EV option by the end of 2026.504 [EPA-HQ-OAR-2022-0829-0759, pp. 166-167]

2. PEVs offer meaningful refueling (charging) benefits to consumers.

Americans are interested in how quickly they can refuel their vehicles. Again, PEVs have real advantages that should not be underestimated. While opponents to PEVs frequently assert what they believe will be fundamental changes to how Americans get to work, school, and run errands, a closer look at the issue reveals that PEVs can offer meaningful benefits. Most trips are well below the average PEV range, and charging for these trips can often be done when vehicles are parked at home, work, or in public in between trips. In fact, recent research has shown that 90% of trips could be completed in vehicles with 124 miles of range—well below the capabilities of the current average EV range in the United States (almost 300 miles).505 Even as of 2016, researchers at MIT found that electric vehicles at the time could handle almost 90% of all car travel in the U.S.506 [EPA-HQ-OAR-2022-0829-0759, p. 167]

505 Mario Herberz, Ulf J. J. Hahnel & Tobias Brosch, Counteracting Electric Vehicle Range Concern with a Scalable Behavioural Intervention, Nature Energy 503 (2022) (finding that 90% of trips could be completed in vehicles with 124 miles of range); Tom Randall, Americans Insist on 300 Miles of EV Range. They're Right, Bloomberg (May 4, 2023), (noting that U.S. EVs have almost reached 300 mile average range).

506 Catherine Caruso, Why Range Anxiety for Electric Cars is Overblown, MIT Technology Review (Aug. 15, 2016), https://www.technologyreview.com/2016/08/15/158319/why-range-anxiety-for-electric-cars-is-overblown/.

Drivers with access to a garage or dedicated overnight parking spot may simply charge at home while they sleep, and most do. EY's Mobility Consumer Index 2022 survey found that 80% of EV owners use home charging,507 and other research has found that more than half of all reported EV charging takes place at home.508 Once a home charger is installed, "the home then has its own permanent home refueling station that can likely be used with all future PEVs."509 Substantial investments in infrastructure incentives will help to reduce any consumer concerns over range or charging availability. About half of Americans (49%) say "discounts to install a home charger" are the incentives that would most encourage them to get an EV.510 The Inflation Reduction Act extended the EV charger credit, which covers 30% (up to $1,000 per unit) of the cost of charging equipment for individual/residential uses. See 26 U.S.C. § 30C. Many states and local jurisdictions offer additional installation incentives that can further reduce costs. [EPA-HQ-OAR-2022-0829-0759, p. 168]

Furthermore, "[e]lectric vehicles have the meaningful advantage of refueling at a far wider array of locations than gasoline stations."511 Gas stations "must be carefully located to achieve scale economies to pay for expensive sturdy buried fuel storage tanks, environmental and safety protection methods, and gas pumps. In contrast, PEVs can charge at millions of potential home, work, or public locations."512 And, with increasing numbers of chargers available in places where drivers otherwise spend their time, "drivers can simply plug in and charge at a variety of locations where they would naturally park their vehicle for long periods of time."513 Recently, Walmart announced plans to install new BEV fast-charging stations at thousands of Walmart and Sam's Club locations across the country, in addition to the 1,300 BEV fast-charging stations the retailer has already made available.514 Other retailers already offering significant levels of BEV charging include 7-Eleven, Cinemark, Ikea, Kohl's, Kroger, Macy's, Starbucks, Subway, Taco Bell, Walgreens, and Whole Foods.515 PlugShare's charger locator can be searched based on various types of charging locations, revealing chargers at hiking, dining, shopping, camping, park, and grocery locations throughout the country.516 As far back as 2015, drivers who parked on the street could access street lights for charging in some dense urban areas,517 and this cost-effective technology518 is expanding in Europe and the United States, with U.S. pilot programs in New York, Charlotte, and Kansas City,519 and a large number of BEV charging stations on streetlight poles in Los Angeles.520 In addition, experts anticipate that charging equipment will increasingly be distributed widely throughout apartment building and multi-family garages.521 Research on parking has found that the average car is parked for 95% of its useful life,522 leaving plenty of time to charge in a large variety of locations. As these public chargers increase, PEVs become a viable and attractive option for more drivers, including those without access to easy home-charging.523 [EPA-HQ-OAR-2022-0829-0759, p. 169]

PEV charging is increasingly taking less time, further enhancing the convenience benefits of PEV ownership. Hyper-fast Level 3 DC fast chargers can charge a BEV in as little as 30 minutes or less, adding up to 10 miles of range for each minute of charging time,524 and consumers have expressed strong willingness-to-pay for this capability.525 Research has shown that availability of more fast-chargers “reduce[s] range anxiety and make[s] it possible to use EVs in the way that drivers now use ICEs.”526 [EPA-HQ-OAR-2022-0829-0759, p. 170]

PEV charging has additional benefits on top of saving drivers money and eliminating weekly trips to the gas pump. First, PEVs with bi-directional charging capability have potential to serve as back-up home generators in temporary power outages, with a typical BEV storing about 67 kWh in its battery—more than three days’ worth of electricity.527 In fact, when a 2021 ice storm in Texas left millions of residents without electricity, Ford “lent out their hybrid F-150s as home generators."528 More makes and models are expected to offer bi-directional charging,529 with the potential that this capability becomes the norm. Additionally, vehicle-to-grid (V2G) charging offers potential benefits for both the grid and PEV owners. RMI found that by 2030, "virtual power plants" including parked vehicles supplying energy to the grid could reduce peak loads in the United States by 60 gigawatts.530 As this capability continues to develop, there could be additional "revenue opportunities for PEV owners for providing these grid services."531 Research in Germany has shown that bidirectional EV charging can generate significant revenue for the typical German household: between 310 and 530 euros per year.532 A recent successful vehicle-to-grid demonstration in North Carolina, taking place over two years, reveals the potential for V2G not only to improve grid optimization and resilience, but also to save consumers money. The North Carolina Clean Energy Technology Center explained that "[q]uantifying the potential value streams from bidirectional charging allows utilities to begin considering incentive payments and other EV program options for customers and members. By demonstrating significant positive value, this study encourages utilities in similar market conditions to help customers overcome the financial barriers to purchasing an EV, particularly in low- and moderate-income areas where these costs may restrict EV adoption."533 The University of Delaware has partnered with local electric utilities and a regional transmission organization to have their vehicles plugged in and available when called upon for grid support, with the transmission organization paying the university the market rate, or roughly $1,200 per year per BEV.534 Research by NREL has also considered net revenue generation from V2G services, including from private LDVs, and found significant potential.535 [EPA-HQ-OAR-2022-0829-0759, pp. 170-171]

3. PEV range has increased enough to meet the demands of nearly all American car trips.

American consumers are interested in how far their cars can travel, as Americans currently drive an above average number of vehicle miles per day (compared to the rest of the world),536 and demand "roughly a third more [range] than the global average."537 While range was therefore once a key challenge for PEV adoption, it is no longer. In fact, "many EVs are approaching the range of an average gasoline vehicle," and "the combined electric and gasoline range for PHEVs often exceeds gasoline-only vehicles."538 [EPA-HQ-OAR-2022-0829-0759, p. 171]

537 Tom Randall, Americans Insist on 300 Miles of EV Range. They're Right, Bloomberg (May 4, 2023).

538 EPA, The 2022 EPA Automotive Trends Report: Greenhouse Gas Emissions, Fuel Economy, and Technology Since 1975 E-2, 60 (Dec. 2022), https://www.epa.gov/system/files/documents/2022-12/420r22029.pdf (finding that the efficiency of EVs has increased by about 18% in the last ten years).

The average BEV range has skyrocketed in recent years, making range issues no longer a real concern. Average BEV range reached 298 miles in MY 2021, "or about four times the range of an average EV in 2011,"539 when range was in fact a real concern. Longer-range BEVs are available for consumers with more substantial driving needs,540 PEVs are becoming more efficient,541 and several PHEVs exceed 500 miles of total range.542 The well-designed stated-preference experiment conducted by Forsythe et al. (2023) found that "[m]ost vehicles with a range of at least 300 miles were valued by consumers equivalently or more than their conventional gasoline vehicle counterparts."543 BEV range is "on the cusp of exceeding 300 miles, a key psychological barrier."544 This level of range handily fulfills the needs and preferences of almost every American driver. The average U.S. one-way commute is about 27.6 minutes,545 and the average single-car American household drives about 30 miles per day546—both well within the range of all PEVs in today's vehicle market. ICCT has explained that "87% of American car drivers drive on average less than 100 kilometers (60 miles) a day—that is, only half the range capacity of the e-Golf, one third of the Leaf's, and less than a quarter of the Tesla's range on a single charge."547 Chakraborty et al. (2021) examined how much PEVs were used within households, and concluded that "BEVs and PHEVs appear to be viable as alternatives to conventional vehicles in terms of meeting the travel needs of households," and that "[s]ince most new and upcoming BEVs are longer-range vehicles, we expect this to mean BEVs will largely be suitable replacements for conventional vehicles in household fleets."548 [EPA-HQ-OAR-2022-0829-0759, pp. 171-172]

As consumer understanding of the capabilities inherent in this amount of range increases, range anxiety would be expected to decline and consumer acceptance of PEVs to match the vehicles' other benefits. Forsythe et al. (2023) explained that range increase is a key advancement in BEV technology that has "driven substantial increases in consumer choices of BEV cars and SUVs over their conventional gasoline vehicle counterparts."549 And Herberz et al. (2022) found that 90% of trips could be completed in cars with less than half of the current U.S. average range, but that most drivers do not understand this.550 Surveys by automakers have also found that range anxiety is the largest factor in consumers refraining from purchasing PEVs, explaining that drivers can be fearful they will run out of power before being able to recharge their vehicles, though some of these surveys were conducted in 2019 or earlier, when average PEV ranges were lower.551 Simply providing tailored compatibility information regarding the ability of BEVs to fulfill drivers' range needs increased willingness to pay for BEVs even more than information about easy access to charging infrastructure.552 [EPA-HQ-OAR-2022-0829-0759, pp. 172-173]

552 Herberz et al. (2022) at 503.

Even for longer travel and trips in excess of the average daily drive—which make up a very small percentage of U.S. driving—PEVs provide a good fit for most consumers' needs and wants. U.S. Bureau of Transportation Statistics data shows that trips longer than 250 miles make up a miniscule fraction of U.S. daily driving. In 2022, U.S. drivers took between 1.3 billion and 1.5 billion vehicle trips per day, with fewer than 2 million trips per day 500 miles or longer and between about 1.5 million and 2.5 million trips per day between 250 and 500 miles.553 Charging infrastructure is rapidly developing to support this small percentage of longer drives. As Section XVII explains, the number of public PEV charging stations is growing rapidly,554 and the BIL and IRA are funding new PEV charging corridors. Alternative Fuels Data Center's map of nationwide PEV charging stations shows that already—with 8.3% PEV sales penetration in the first quarter of 2023555—charging stations are widespread.556 In May, U.S. and Canadian officials announced the first Binational EV Corridor, covering a nearly 900-mile stretch between the United States and Canada, with PEV chargers every 50 miles.557 Similarly, last year four states announced plans to build a 1,100-mile PEV charging circuit along Lake Michigan.558 In Washington, Oregon, and California, the West Coast Electric Highway provides DC fast charging stations every 25 to 50 miles along Interstate 5, Highway 99, and other major roadways.559 Electrify America's DC fast-charging network includes two cross-country routes (one from Los Angeles to Washington, DC, and another from San Diego to Jacksonville), along with a route covering much of the East Coast on Interstate 95 (from Portland, Maine to Miami, Florida), and most of the West Coast along Interstate 5 (from Seattle, Washington to San Diego, California).560 GM and Pilot Company just announced plans to collaborate on a national DC fast charging network of 2,000 charging stalls at up to 500 travel centers across the country, to "help enable long-distance electric travel of people and vehicles across the U.S."561 These chargers will be capable of the fastest 350 kW charging speeds.562 [EPA-HQ-OAR-2022-0829-0759, pp. 173-174]

Infrastructure will continue to build out rapidly on highways with increasing PEV penetration, fulfilling the needs for even these comparatively less frequent longer drives. Survey data from Europe shows that as PEV penetration rates increase and drivers become more experienced with PEV operation, they become comfortable taking longer trips in their vehicles and are "more relaxed" about traveling long distances and when they charge their vehicles.563 In addition, other developing technologies could make both short and longer drives even more seamless, such as possible “electrified” roadways that contain wireless charging infrastructure under the asphalt and wirelessly charge PEVs while driving.564 Such projects are already in development or testing in the United States and Europe.565 [EPA-HQ-OAR-2022-0829-0759, p. 174]

4. PEVs have additional attributes that are superior to combustion vehicles.

PEVs have additional superior attributes related to the driving and ownership experience that are widely attractive to drivers. These include faster acceleration; improved performance; better noise, vibration, and harshness characteristics; and reduced maintenance. Sections XIX.C, XX, and XXI detail these additional superior attributes and the benefits that they provide for drivers and vehicle owners. These attributes will continue to further increase consumer preference for PEVs. [EPA-HQ-OAR-2022-0829-0759, p. 174]

5. American consumers also place high importance on environmental sustainability, and EPA should not ignore these preferences.

When considering consumer preferences, EPA cannot overlook the importance that American consumers place on sustainability. U.S. consumers increasingly place high priority on protecting the environment, and PEVs are well positioned to satisfy this aspect of consumer preference. Numerous consumer surveys, including by YouGov, CarMax, and others have found that protecting the environment is a top consideration in purchasing a vehicle.566 In CarMax’s survey, over 60% of people said a car’s “fuel emissions are moderately or extremely important to them, while only 7.3% of people found fuel emissions not at all important.”567 [EPA-HQ-OAR-2022-0829-0759, p. 175]

6. PEVs are a great fit for the needs and demands of rural drivers.

PEVs are a great fit even for rural drivers. Although rural Americans are currently adopting PEVs at slower rates than urban Americans,568 PEVs actually excel at meeting the demands of rural drivers. “Fuel savings for rural households are larger than for urban households, because trips in rural areas are longer than in urban areas, and vehicles tend to be older and less efficient, requiring more fuel per mile, [P]EVs require fewer trips to a mechanic for repairs and maintenance. Because of the high torque and low center of gravity, they have excellent performance, which is important on rough, curvy and steep roads.”569 A survey by the Union of Concerned Scientists and Consumer Reports found that “there is plenty of interest [in PEVs] in rural areas, but there is a huge knowledge gap about what it is like to own an EV."570 Correcting for this knowledge gap and educating rural consumers on PEVs' real benefits will undoubtedly significantly increase PEV adoption in rural areas, allowing all Americans to reap their benefits. [EPA-HQ-OAR-2022-0829-0759, p. 175]

7. Most PEV drivers purchase or plan to purchase another PEV, indicating high satisfaction.

The appeal of these beneficial PEV attributes is made clear from the fact that most PEV buyers purchase another PEV for their next vehicle and through the ample available information pointing to satisfied PEV drivers. As far back as almost a decade ago, Tesla's Model S had the highest owner satisfaction of any vehicle in the U.S. market.571 A recent analysis of S&P Global Mobility vehicle registration data found that roughly two-thirds of EV-owning households that bought a new car in 2022 purchased another EV.572 Other surveys and analyses have found the same. In 2021, Plug In America surveyed over 5,500 EV owners and more than 1,400 potential EV purchasers and found that 90% of EV owners said that it was "likely" (13%) or "very likely" (77%) that their next vehicle purchase would be an EV.573 In Plug In America's most recent survey (conducted between December 2022 and February 2023), again 90% of EV owners said it is "likely" or "very likely" that their next purchase will be another EV.574 Even as of January 2017, CARB found that over 10% of recent PEV buyers were already driving their second or subsequent PEV.575 [EPA-HQ-OAR-2022-0829-0759, pp. 175-176]

As Forsythe et al. (2023) explain, "technology progress projections are key for future BEV adoption projections used in policy planning and cost–benefit analyses."576 Here, it is clear that technological progress is sufficient to support significant consumer acceptance of (and satisfaction with) PEVs. Even considering consumer acceptance as a relevant and permissible factor in EPA's analysis, EPA should enact standards consistent with Alternative 1 with increasing stringency after MY 2030. Consumer acceptance is not a barrier to PEV sales at a pace consistent with this level of stringency, when desirable vehicles are available—as they are expected to be—and purchasers have information about their benefits.577 [EPA-HQ-OAR-2022-0829-0759, p. 176]

576 Forsythe et al. (2023) at 6.

577 EPA's approach to modeling consumer acceptance through the Global Change Analysis Model ("GCAM"), utilizing an S curve, while by no means the only approach to modeling consumer acceptance, is a reasonable one. Specifically, as recent analyses show, GCAM is a random utility discrete choice model equivalent to a logit model with a particular utility function form. Eric G. O'Rear et al., Projecting Vehicle Sales: A Review of Light-Duty Vehicle Adoption Models, Rhodium Group 15-16 (Mar. 24, 2023), https://rhg.com/wp-content/uploads/2023/03/Projecting-Vehicle-Sales-A-Review-of-Light-Duty-Vehicle-Adoption- Models.pdf.

EV Adoption Projections

Many organizations have made projections using a variety of models and methods to establish forward-looking estimates of ZEV sales. All of the projections included were conducted after the adoption of the Inflation Reduction Act and incorporate the sizable impact the legislation will have on cost and access to charging infrastructure. The projections are from ICCT, Rhodium Group, Energy Innovation, and Bloomberg NEF.106.107,108,109 The first three studies included multiple scenarios. For this analysis the central scenario or one of the central scenarios was chosen as the best representation of each study. The projections for ZEV adoption by 2030 range from 32% to 58% of LDV sales. [EPA-HQ-OAR-2022-0829-0786, p. 37]

109 Ira Boudway. More Than Half of US Car Sales Will Be Electric by 2030. 2022. Bloomberg Hyperdrive, https://www.bloomberg.com/news/articles/2022-09-20/more-than-half-of-us-car-sales-will-be-electric-by-2030.

All of the above demonstrates EPA's projections of baseline levels of ZEV deployment are reasonable (if not conservative) and that there are many factors that are accelerating the growth of ZEV sales apart from EPA's standards. They also show that EPA's proposed standards are reasonable and that even greater levels of reduction are possible (as we discuss below). Notably, across all of the indicators we evaluated, manufacturer investments in vehicle and battery manufacturing capacity show some of the highest levels of ZEV deployment, particularly in the near term. This finding is consistent with historical precedent showing periods of rapid technological change often occur more swiftly than models or secondary indicators are able to predict. [EPA-HQ-OAR-2022-0829-0786, p. 37]

Organization: Exxon Mobil Corporation

Linked fuel and lifecycle vehicle CO2 standards offer a preferred, technology-neutral policy pathway relative to BEV-only mandates. A policy that aims to reduce GHG emissions from existing fuels and that recognizes WTW emissions from new vehicles, can help retain consumer choice for the type of vehicle they prefer to drive, would avoid overdependence on foreign critical minerals, would retain high-paying jobs throughout the transportation sector, could grow the role of agriculture in providing energy feedstocks, and ultimately, would be supported through a credit-based system, not taxes. [EPA-HQ-OAR-2022-0829-0632, p. 4]

ExxonMobil respectfully recommends that EPA consider the role it can play in developing and implementing policy to reduce GHG emissions from both new and existing vehicles through the development of WTW emission standards for new vehicles and complementary support for a federal low carbon fuel standard. We would welcome the opportunity to collaborate with the agency and share in greater detail our views on what a comprehensive policy approach might look like. [EPA-HQ-OAR-2022-0829-0632, p. 4]

Organization: Ford Motor Company

Ford is enthusiastic and optimistic about the ICE-to-ZEV transition, and we are already delivering electrified light- and medium-duty EVs at scale. While we remain optimistic, we are also mindful of the considerable challenges and uncertainties that lie ahead. The pace of electrification has been and may continue to be limited by many factors and forces, many of which are outside the control of vehicle manufacturers. These include the availability of critical minerals for battery manufacturing, the need to allocate finite resources between EV programs and efforts toward incremental reductions in emissions from ICE vehicles, consumer demand especially as we proceed beyond early-adopters to the majority of new vehicle purchasers, economic turbulence, geopolitical events, and, of course, electric vehicle charging infrastructure. [EPA-HQ-OAR-2022-0829-0605, pp. 2-3]

Limits on EV Growth

Ford is already delivering electrified light- and medium-duty EVs at scale. While we remain optimistic that EVs will constitute a steadily growing portion of new vehicle sales in the US, we are also mindful of the considerable challenges and uncertainties that will affect the rate of growth. The pace of electrification has been and may continue to be limited by many factors and forces, many of which are outside the control of vehicle manufacturers. A few deserve mention here. [EPA-HQ-OAR-2022-0829-0605, pp. 6-7]

Consumer preference is difficult to predict out to 2032. While EV adoption is growing quickly, and we are seeing enthusiasm for EVs among the early adopters, we cannot assume the same enthusiasm from the early majority let alone the late majority. Market studies suggest many people are interested in purchasing an EV, but not at any cost and not while charging infrastructure remains at a nascent stage. [EPA-HQ-OAR-2022-0829-0605, pp. 6-7]

Last, economic turbulence and geopolitical events will impact EV adoption rates over the 2027 – 2032 timeframe. At this time, automakers and regulators can only guess how and to what extent. [EPA-HQ-OAR-2022-0829-0605, p. 8]

These and other forces have and will continue to limit the growth of EV production and consumer adoption, regardless of an automaker's commitment to electrification. A more conservative path to achieve the proposed 2032 endpoint better accounts for these considerations. [EPA-HQ-OAR-2022-0829-0605, p. 8]

Organization: GROWMARK, Inc.

Lack of EV Capability for Farmers

Current electric vehicles do not provide the capabilities that farmers rely on to carry out their operations. According to a study recently released by the American Automobile Association (AAA), the Ford F-150 Lightning saw its range decrease by almost a quarter when loaded close to its maximum payload capacity.4 A gasoline-powered truck, however, would only lose 14 percent of its range with the same amount of weight, and of course it would be quicker and more convenient to refuel.5 [EPA-HQ-OAR-2022-0829-0560, p. 2]

4 American Automobile Association. (2023, June). Effect of payload on driving range of battery electric truck. https://urldefense.com/v3/ https:/u7061146.ct.sendgrid.net/ls/click?upn=4tNED-2FM8iDZJQyQ53jATUZvOEO3mirlEl3vtAic9l7ghAOXNRXkwKaKICrDXA3ZoT75TOvo955EZ6-2FJiQG-2FErJaPZeKHTyfflQJiv4TMR5A-3DMLSQ_wwmARy8TMTevifjaQtiXjzeH-2FSc8WPX2ToRxYAJ5XFXCYIVurVZ- 2F7aCPZDngjq-2BQuMDruqnM8cSNwQPzi5UIwwpztKldVzphs52jy6vxI2xgPnkdzJy3C9ftadJYj76WuUf2T26mkgeQA4pLiS2I3PjMzAEYZZu-2BUbgcPfolgmcVfQ7aEf7LxjMjPw-2B8WF3EQEdXTpy-2BAUfR52wN4rM91gx75Pxivc VYDED1S55BpuarlzGYrR-2Bk3PvHnJeb3rGPLd5dXXuQ8SwSjo-2BWWPLN8Jrn1ZD1e0j05qXvdpcFmg7-2FbUtbDUzAhjkGZGxVpfcOxvWD4YC810LuMOxWhv3kzMP1Xq9BQ4VUljZwYsOjU-2BI-3D;!!A1OrVxnpM0w!A Qdah29wRyKcLjIUYyHo21FIzdyG78ee-sIEhfNe4_m8Dkjdh8iAFlUoJGGzPw1xORQ0wI8g1EedoHHou9l8NRN7$

5 Tucker, S. (2023, June 6). Study: EVs lose range to hauling, more than gas trucks. Kelly Blue Book. https://www.kbb.com/car-news/study-evs-lose-range-to-hauling-more-than-gas-trucks/

Additionally, EVs will have worse results when it comes to towing than ICE vehicles. For example, while an ICE Ford F-150 can tow up to 14,000 pounds, the EV Ford F-150 Lightning has a max towing capacity of two tons less than that.6 Furthermore, testing of towing any considerable weights with the EV truck resulted in dramatic decreases in range, up to a 70 percent decrease in one test.7 [EPA-HQ-OAR-2022-0829-0560, p. 2]

6 Brandt, E. (2022, August 18). Payload and towing capacity on electric vehicles. Kelly Blue Book. https://www.kbb.com/car-news/how-far-can-an-electric-truck-tow/

7 Brandt, 2022.

These figures are simply not acceptable to farmers who rely on their vehicles to do their jobs. Farmers use their trucks to take products to market, bring supplies to their fields, and move livestock. Vehicles that have less capability than current ICE technology will lead to decreased efficiency and increased cost at the farm gate, which will lead to further farm consolidation and threaten our nation's food security. [EPA-HQ-OAR-2022-0829-0560, p. 2]

Organization: HF Sinclair Corporation

I. Executive Summary

HF Sinclair believes that such government policies must be technology-neutral and not manipulate the energy market by picking winners and losers. EPA cannot and should not promulgate inequitable regulations that mandate compliance through a single technology pathway. Consumer choice must be allowed in order to drive vehicle manufactures, or original equipment manufacturers ("OEMs"), to provide a fleet mix that meets emission limits sufficient to improve air quality in a reliable and efficient manner. [EPA-HQ-OAR-2022-0829-0579, pp. 1-2]

Finally, EPA has not considered the foreseeable, indirect impacts the Proposed Rule will have on ambient air quality. First, with the high purchase price of new PEVs, consumers will likely hold on to their older, higher-emitting ICE vehicles to avoid the increased purchase price of a PEV. [EPA-HQ-OAR-2022-0829-0579, pp. 9]

Setting aside the fact that the production capacity necessary to meet EPA's proposed adoption rates is not available,62 EPA takes for granted that the average consumer cannot and that nearly half of the population would not purchase a PEV. The average consumer cannot afford an expensive, new PEV or is otherwise not willing to sacrifice the range and convenience provided by an ICE vehicle—especially when the average EV is nearly $15,000 on average more than an ICE vehicle and that cost is increasing.63 Consumer demands and willingness to purchase PEVs are muted given the disparate range and cost differences.64 But EPA overinflates the potential effect of the IRA tax incentives to change consumers' minds, especially because the new PEV tax credit is limited to PEVs that meet certain domestic sourcing requirements and, as discussed below, domestic sourcing of critical battery materials is not currently reliable or practical for a vast majority of OEMs.65 [EPA-HQ-OAR-2022-0829-0579, p. 14]

62 Hong Yang and Lewis Fulton, TRANSPORTATION RESEARCH PART D: TRANSPORT AND ENVIRONMENT 118, "Decoding US investments for future battery and electric vehicle production" (May 2023) available at https://www.sciencedirect.com/science/article/pii/S1361920923000901 ("By comparing announced capacities to EV sales targets, we find that in the most ambitious scenario where US achieves 66% EV sales by 2030, the planned 5.1-million EV production falls short by over half; with tentative plans included, the gap closes to 4.6 million. In a less rapid scenario (40% by 2030), tentative plans are sufficient. Needed investments across these scenarios range from $20 to $143 billion, compared to current firm and tentative commitments of $75 to $108 billion, respectively.").

63 See Bryson Hull, BUSINESSWIRE, "Electric Vehicle Mandates Carry Major Price, Electricity Supply Risks That Must Be Addressed to Avert Potential Harm" (Jun. 8, 2023) available at https://www.businesswire.com/news/home/20230608005281/en/Electric-Vehicle-Mandates-Carry-Major-Price- Electricity-Supply-Risks-That-Must-Be-Addressed-to-Avert-Potential-Harm.

64 Jack Ewing, THE NEW YORK TIMES, "Electric Cars Too Costly for Many, Even With Aid in Climate Bill" (Aug. 8, 2022) available at https://www.nytimes.com/2022/08/08/business/energy-environment/electric-vehicles-climate- bill.html.

65 Ewing, supra n. 2 ("'Right now with our lack of capacity for materials, I don't think there is any product that will meet that today,' Carla Bailo, president of the Center for Automotive Research in Ann Arbor, Mich., said of the standards. "Tesla is probably close, but the rest of the manufacturers, no way.'").

e. EPA Fails to Consider Current PEV Market Demands

EPA improperly relied on the general characterization of recent years of the light-duty and medium-duty market as supplemented by incentives in the BIL and IRA to support its proposition that there will be a sufficiently rapid increase in EV market penetration to achieve compliance with the proposed standards. [EPA-HQ-OAR-2022-0829-0579, p. 14]

As mentioned above, charging capability is a key apprehension for nearly half the U.S. consumer market. 66 Importantly, successful implementation of the Proposed Rule depends on consumer choice as much as depends on technological improvements. But, in California as an example, consumer discontinuance occurs at a rate of 20% for plug-in hybrid electric and 18% for PEVs—once again based on the dissatisfaction with the convenience or availability of charging.67 [EPA-HQ-OAR-2022-0829-0579, pp. 14-16]

66 Phillipp Kampshoff, et al., McKinsey & Co., "Building the electric-vehicle charging infrastructure America needs" (Apr. 18, 2022) available at https://www.mckinsey.com/industries/public-sector/our-insights/building-the- electric-vehicle-charging-infrastructure-america-needs.

67 See EPA-HQ-OAR-2022-0829-0077, Abstract (Content restricted for copyright), available at https://www.regulations.gov/document/EPA-HQ-OAR-2022-0829-0077.

Moreover, this high purchase price of new PEVs relative is an especially important consideration, especially for low-income consumers. Although EPA concedes that the Proposed Rule will result in "increases in upfront purchase costs [that] are likely to be of particular concern to low-income households" EPA discounts this concern because of a hypothetical anticipation that "automakers will continue to offer a variety of models at different price points."68 EPA's next conclusion—that low-income households will save money long-term in decreased fuel costs, will utilize the used-car market, and be cushioned by federal tax incentives69—completely misses the mark and illustrates the vacuum in which EPA is proposing these new standards. For example, the IRA tax credit for used cars would apply only to those sold for $25,000 or less, but less than 20 percent of used PEVs fit that category today.70 [EPA-HQ-OAR-2022-0829-0579, pp. 14-16]

68 Proposed Rule at 29,344.

69 Id.

70 Ewing, supra n. 2.

The current market share illustrates this issue. Although EPA attempts to circumvent these market realities by relying on the rapid increase in number of PEV models available in recent years, the number of PEV models is an improper surrogate for the number of actual units sold and in use.71 In reality, as EPA acknowledges, the facts show that in model year 2021, only between 3 and 5% of all vehicles certified by the agency were electric (including hybrid).72 Thus, the ambitions of even the most aggressive OEM from an PEV adoption rate perspective would require nearly exponential growth over each of the next seven years.73 There is no support for concluding there will be substantial consumer adoption of PEVs to achieve the 40–60% increase by 2030 projected by the Proposed Rule. This nearly 60% anticipated increase would require a similar increase in adoption rates over the same seven year period. For comparison, PEV sales increased from 0.2% to 4.6 over the ten year period between 2011 and 2021.74 EPA's overreliance on the BIL, IRA, and success of California's Advanced Clean Cars II program further underscores the insufficiency of the Proposal's analysis, especially where it is speculative at best whether the Advanced Clean Cars program will be active as currently proposed during the MY27–32 timeframe. [EPA-HQ-OAR-2022-0829-0579, pp. 14-16]

f. EPA Fails to Properly Account for the Cost Impact of the Proposed Rule

As noted above, EPA must consider both feasibility and cost of compliance. In addition to the infeasibility of delivering an electric grid that can support the PEVs that OEMs must now produce, EPA has failed to adequately account for the cost of the Proposed Rule. Namely, EPA has severely underestimated the cost impact on lower-income households. Given the low cost of carbon-based transportation fuel, fluctuations in the electricity market, and higher insurance costs, the “break-even” point for a higher-cost PEV – which may be upwards of $15,000 more than its ICE counterpart – is not a mere few years as EPA predicts, but decades.75 And this calculus is heavily dependent on the $7,500 tax credit provided by the IRA, which will change if future policymakers eliminate it or otherwise require PEVs to compete in the market without a subsidy.76 Not only will this hinder the widespread adoption of PEVs, but it will also drive up the cost used car prices across the country as consumers hold off on buying new cars.77 [EPA-HQ-OAR-2022-0829-0579, p. 16]

75 Id. at 5, 13.

76 This subsidy results in a cost-shifting mechanism from middle-class to wealthy families, id. at 14, which may not be supported by future elected officials.

77 Id. at 6.

Organization: Hyundai America Technical Center, Inc. (HATCI)

The result of these massive investments in new and expensive technology, upgraded ICE engine development, and construction of new testing facilities will undoubtedly result in higher prices for new vehicles, which increases the cost of both new low-emission ICE vehicles and ZEVs. These increased costs could lead consumers to reject purchasing new vehicles, extend the life of the used car market, and reduce the environmental gains desired by the EPA with these proposed regulations. [EPA-HQ-OAR-2022-0829-0554, p. 3]

Organization: Illinois Corn Growers Association

Thus, even if in the next eight years automakers, suppliers and retailers can retool their businesses to supply an estimated 7.5 million new vehicles in 2032 and beyond, it is far from assured that: [EPA-HQ-OAR-2022-0829-0756, p. 3]

-The marketplace is willing to buy that many vehicles in spite of their higher purchase cost, charging requirements, limited utility and extremely high batery replacement costs. [EPA-HQ-OAR-2022-0829-0756, p. 3]

Organization: Illinois Farm Bureau (IFB)

Illinois farmers share the societal goal of reduced greenhouse gas ("GHG") emissions across the broader economy and, specifically from energy production, transportation, and use by society. IFB supports federal policies that accomplish these goals, but also believes it is critical to preserve consumers' access to affordable, dependable, and efficient transportation. We are advocates for clean air and believe the environment is in better condition than it was 50 years ago, but we must also balance additional regulation and its impacts on our industries and communities. [EPA-HQ-OAR-2022-0829-0532, p. 2]

Per IFB Policy, "[w]e support policies that keep agriculture viable and address the costs and benefits of those programs using sound, economic analysis." USEPA's proposal inhibits the marketplace from identifying the most efficient, lowest cost opportunities to reduce GHG emissions from vehicles and restricts consumer choice. We are concerned that such a prescriptive policy is not in the best interest of the consumer or the U.S. economy. [EPA-HQ-OAR-2022-0829-0532, p. 2]

Organization: Institute for Policy Integrity at New York University School of Law

G. EPA Should Further Explain Its Choices Around Scrappage, Pass-Through, and Vehicle Sales

EPA should provide additional explanation around certain modeling choices—namely scrappage, pass-through, and sales. [EPA-HQ-OAR-2022-0829-0601, pp. 22-23]

"Scrappage" refers to the rate of which drivers discard old automobiles. OMEGA treats scrappage as exogenous, meaning that the rate of scrappage does not depend on the Proposed Rule's other effects.144 This choice is reasonable: While economic theory and evidence suggest that scrappage depends in part on the Proposed Rule's other effects (most notably the rate at which the Proposed Rule affects new vehicle prices and sales),145 this effect is very difficult to model due to data limitations, and past attempts by EPA and NHTSA to model scrappage have fared poorly.146 Moreover, the increasing movement to electric vehicles provides even more reason to treat scrappage as exogenous, as virtually no analysis on the scrappage of BEVs exists. However, the Proposed Rule provides no discussion of scrappage or EPA's choice not to model it. Particularly since EPA endogenously modeled scrappage in the 2020 Rule, the agency may wish to explain its decision not to follow this approach in the Proposed Rule and a discussion of how it may affect the results. Moreover, to the extent feasible, EPA should attempt to model scrappage in future standards. [EPA-HQ-OAR-2022-0829-0601, pp. 22-23]

144 See RIA at 9-3 to 9-5.

145 See Howard K. Gruenspecht, Differentiated Regulation: A Theory with Applications to Automobile Emissions Control (1982); Howard K. Gruenspecht, Differentiated Regulation: The Case of Auto Emissions Standards, 72 Am. Econ. Rev. 328 (1982); ENV'T PROT. AGENCY, THE EFFECTS OF NEW-VEHICLE PRICE CHANGES ON NEW- AND USED- VEHICLE MARKETS AND SCRAPPAGE 3-6 to 3-11 & 5-7 to 5-7 to 5-12 (2021).

146 Inst. for Pol'y Integrity, Comments on the Safer Affordable Fuel-Efficient (SAFE) Vehicles Rule for Model Years 2021–2026 Passenger Cars and Light Trucks 66–71 (Oct. 26, 2018), https://policyintegrity.org/documents/Emissions_Standards_EPA_NHTSA_Comments_Oct2018.pdf.

"Pass-through" refers to the degree to which manufacturers pass on cost increases to consumers. EPA in prior tailpipe rules has assumed 100% pass-through to consumers in the vehicle market—meaning that every dollar of additional cost to the automaker is ultimately borne by the purchaser.147 EPA appears to repeat this assumption in the Proposed Rule. That approach is also reasonable given consistency with the agency's prior approach and the very limited economic evidence on vehicle pass-through. Nonetheless, that limited available evidence (from a 2010 paper) indicates that pass-through in the vehicle market may be below 100%.148 Accordingly, EPA should discuss and provide a rationale for its approach. EPA should also support further research in this area, given its potential importance. [EPA-HQ-OAR-2022-0829-0601, pp. 22-23]

147 E.g. 2020 Rule, 85 Fed. Reg. at 24,594–95.

148 Using regression analysis, Hellerstein and Villas-Boas (2010) find only partial pass through for the vehicle industry with an average pass-through rate of 38%. Rebecca Hellerstein, & Sophia B. Villas-Boas, Outsourcing and Pass-Through, 81 J. INT'L ECON. 170, 175 (2010).

Finally, with regard to sales, EPA should clarify how OMEGA treats how producers expect consumers to value fuel costs. Within the model, consumers and producers shape their preferred new vehicle mix independently,149 each informed by their unique perspectives on fuel costs: Consumers weigh their expected fuel expenses, whereas producers consider how they think consumers will weigh their expected fuel expenses. In the RIA, EPA explains that consumers are assumed to factor in fuel costs of 12,000 miles annually for 2.5 years.150 However, the OMEGA input files suggest that producers expect consumers to consider fuel costs up to 15,000 miles annually.151 Although this difference is not inherently problematic, especially if EPA posits imperfect information between consumers and producers,152 EPA should explain this difference. This might also be a minor programming error, such that EPA intended for producers to accurately peg consumer valuation of fuel costs at 12,000 miles annually. [EPA-HQ-OAR-2022-0829-0601, pp. 22-23]

149 The model then searches for solutions for a set of vehicle attributes, purchase prices, and quantities such that the sales and production shares match.

MARKET READINESS

The global transition to zero-emission vehicles is accelerating. The U.S. is the third largest electric vehicle market, behind China and Europe. In 2022, new U.S. plug-in electric vehicle sales reached nearly 1 million units, representing over 7% of new light-duty vehicle sales.1 This growth is expected to continue, as evidenced by the more than $1.2 trillion in announced automaker spending on electric vehicles, widespread consumer demand, and billions of dollars in new federal tax credits, incentives, and investments.2 Many electric vehicles have multi-month long wait times, indicating that demand is outpacing supply, and consumer research surveys show that demand for BEVs in the United States continues to increase and that 30% of licensed drivers aren't even considering gasoline vehicles for their next purchase or lease.3 Substantial public and private sector investments and state and federal policies have primed the market for a rapid shift to electric vehicles. [EPA-HQ-OAR-2022-0829-0569, p. 6]

Organization: Jeremy Michalek et al.

The EPA assesses the potential for future demand for electric vehicles by first simulating a ”No Action” scenario, representing a future scenario without the proposed policy but accounting for other policies such as the IRA. They then simulate a future scenario that includes the additional effects of the proposed policy. In both cases, the consumer demand model's parameters (the ”share weights,” which we refer to as alternative specific constants to be consistent with the discrete choice literature) are calibrated so that future shares in the ”No Action” scenario match those projected in an IHS report (Fiske et al., 2021), resulting in the projections summarized in Figure 1. We compare these projections to new results from our research based on an empirical investigation of (1) past trends in consumer preferences and (2) expected technology trends. [EPA-HQ-OAR-2022-0829-0705, p. 4]

[See original for graph titled “Graphical summary of EPA's assessment of expected BEV adoption by vehicle class in the proposed rule (US Environmental Protection Agency, 2023)”] [EPA-HQ-OAR-2022-0829-0705, p. 4]

1.1 Cars and SUVs

In an attached study, published this year in Proceedings of the National Academy of Sciences, we compare results from a discrete choice survey experiment conducted with over 1500 people in 2020-2021 with those of a similar survey conducted in 2012-2013 (Forsythe et al., 2023a). This experiment importantly investigates the likelihood of mainstream U.S. new vehicle consumers choosing BEVs, where our sample is weighted to be representative of the U.S. new car and SUV buying population across household income, age, education, gender, marital status, and household size. We find that technological improvements in battery electric vehicles (BEVs) - particularly increasing range of these vehicles - have driven increases in consumers' likelihood of choosing these vehicles over their conventional gasoline vehicle counterparts. We find that the consumer preference parameters defining what consumers want in vehicle characteristics and what they are willing to pay for have not changed (in to- day's dollars) enough to identify statistically significant trends over this 8 year period. This implies that consumer preferences (independent of technology improvements) have been relatively static. The findings suggest that consumers are buying more electric vehicles today because the technology has improved, and that as BEV technologies continue to improve in the future, it will further increase consumer likelihood of choosing BEVs over conventional vehicle counterparts. [EPA-HQ-OAR-2022-0829-0705, p. 4]

Using the consumer preferences estimated from the choice experiment, we examine consumers' likelihood of purchasing a BEV when choosing between two vehicles: one that has a conventional gasoline powertrain and one that has a battery electric powertrain, but otherwise have very similar characteristics (such as the BMW i4 and the BMW 4-Series Gran Coupe, and the Nissan Leaf and the Nissan Versa). We find that, if consumer prefer-ence parameters continue at today's values and if the technology for range and cost improve to levels predicted by the National Academies (NASEM, 2021), then consumers will become roughly indifferent, on average, between electric and gasoline versions of several car and SUV models by 2030 (see Figure 2 from Forsythe et al. (2023a)). [EPA-HQ-OAR-2022-0829-0705, p. 5]

We further simulate market shares for BEVs across the full U.S. new car and new SUV markets. We find that in a case where BEVs are equally available as conventional gasoline vehicles (every conventional gasoline vehicle has a counterpart BEV with the same body style, brand, and other characteristics important to consumers), BEV technology improvements follow those projected by the National Academies (NASEM, 2021), and consumer preference parameters remain steady at today's values, we find that simulated BEV market shares of both new cars and new SUVs would be approximately 50% by 2030 (see Figure 3 from (Forsythe et al., 2023a)). [EPA-HQ-OAR-2022-0829-0705, p. 5]

Our findings support that large increases in consumer demand for BEVs in the near future is feasible. The research suggests that mainstream consumer demand for BEVs is likely to sharply increase due to expected BEV technology improvements alone. It also supports that BEV demand could grow high enough by 2030 so that BEVs become the majority of new passenger cars, and SUVs nearly the majority, through expected BEV technology improvements and equal availability of BEVs and conventional vehicles. It is important to note that these findings do not incorporate the reduced cost of maintenance and repair or the cost of at-home charger installation. If the net balance of these provides cost savings to consumers as the EPA predicts, then we would expect consumer demand for BEVs would be even larger than predicted in our study. [EPA-HQ-OAR-2022-0829-0705, p. 5]

The proposed EPA rule may further increase consumer demand for BEVs trends by (1) encouraging automakers to shift price margins to encourage more BEV sales, (2) encouraging automakers to reduce gasoline vehicle offerings in favor of increasing BEV offerings, (3) encouraging automakers to invest in electrification technology advancement, potentially exceeding National Academy projections, (4) triggering network effects, such as vehicle buyers being more likely to purchase a BEV as they know more friends and family who own them, and (5) encouraging other efforts - including advertising, dealership practices, and other actions - that would increase consumers' likelihood of purchasing BEVs over conventional vehicles. [EPA-HQ-OAR-2022-0829-0705, p. 5]

In a working paper, we conducted a similar discrete choice experiment of 52 pickup truck owners across the U.S. to characterize their preferences. This sample represented a range of pickup truck consumer household incomes, ages, education, gender, and household size and was weighted to be representative of the U.S. new pickup truck buying population. We find that most pickup truck owners (78%) are open to purchasing electric pickup trucks if the technology provides sufficient performance attributes, including range, operating cost, towing capacity and payload capacity. We find that the largest group, representing 43% of our consumers, choices between a BEV or conventional gasoline pickup truck are driven primarily by what the vehicle can do, rather than its powertrain type (we call this group "tech indifferent" because the don't value the powertrain technology in and of itself, only what it can deliver). Another group, representing an additional 13% cared about payload capacity and operating cost, but did not otherwise value the powertrain technology in and of itself. 17% of pickup truck owners were "BEV enthusiasts" who were willing to pay significantly more for a BEV pickup truck than a conventional gasoline pickup truck, even if they had identical characteristics (including operating costs, towing, payload, and brand). We find that 22% of pickup truck owners are strongly opposed to all types of electrification, including hybrid, plug-in hybrid and battery electric pickup trucks. For this group, a substantial change in consumer preferences would be necessary for the group to opt for electric pickup trucks over gasoline pickup trucks. [EPA-HQ-OAR-2022-0829-0705, p. 8]

We simulate market shares for BEVs across the full U.S. new pickup truck market. We find that in a case where BEV pickup trucks are equally available and diverse as conventional gasoline pickup trucks (every conventional gasoline and diesel truck has a counterpart BEV with the same towing, payload, brand, and other characteristics important to consumers), BEV technology improvements follow those projected by the National Academies (NASEM, 2021), and consumer preference parameters remain steady at today's values, where all gasoline or diesel pickup trucks offer a BEV powertrain option and technology trends match those suggested by the National Academies (NASEM, 2021), we estimate that, despite the notable group opposed to electrification of pickup trucks, over half of pickup truck owners would choose the electric powertrain by 2030 (Figure 4), exceeding EPA's assessment of expected BEV pickup truck adoption in 2030 (Figure 1). [EPA-HQ-OAR-2022-0829-0705, p. 8]

Implications for EPA. Our findings support that large increases in consumer demand for BEV pickup trucks in the near future is feasible. The research suggests that mainstream consumer demand for new BEV pickup trucks is likely to sharply increase due to expected BEV technology improvements in the future. It also supports that, although some pickup truck owners are strongly opposed to purchasing BEV pickup trucks, the majority of pickup truck owners value BEV pickup trucks equally to conventional gasoline pickup trucks as long as they have sufficient performance characteristics. The research supports that consumer de- mand for BEV pickup trucks may exceed EPA's scenario of BEV pickup truck adoption in 2030. It is important to note that our study does not incorporate the reduced cost of main- tenance and repair or the cost of at-home charger installation. If the net balance of these provides cost savings to consumers as the EPA predicts, then we would expect consumer demand for BEVs would be even larger than predicted in our study. The proposed EPA rule may further increase consumer demand for BEV trucks by (1) encouraging automak- ers to shift price margins to encourage more BEV sales, (2) encouraging automakers to reduce gasoline pickup truck offerings in favor of increasing BEV pickup truck offerings, (3) encouraging automakers to invest in electrification technology advancement, potentially ex- ceeding National Academy projections for pickup trucks, (4) triggering network effects, such as pickup truck buyers being more likely to purchase a BEV as they know more friends and family who own them, and (5) encouraging other efforts - including advertising, dealership practices, and other actions - that would increase consumers' likelihood of purchasing BEV pickup truck over conventional trucks. [EPA-HQ-OAR-2022-0829-0705, pp. 8-9]

[See original for Figure 4, titled "Hypothetical share of BEV pickup trucks for model year 2020 and 2030"] [EPA-HQ-OAR-2022-0829-0705, pp. 8-9]

Organization: John Graham

Tables 82 and 83 in the Preamble (page 29329) show EPA's projected market penetrations for strong HEVs drops to virtually zero in both the proposed standards and the No Action case. The preamble states, [EPA-HQ-OAR-2022-0829-0585, p. 12]

"While manufacturers may in fact choose HEVs, the modeling indicates they are less cost effective than the BEVs which have been subsidized by the IRA and emit 0 g/mi tailpipe CO2." [EPA-HQ-OAR-2022-0829-0585, p. 12]

"In the proposed standards case, the steady decline in projected HEVs is primarily a result of continued projected reductions in battery costs which make BEVs increasingly more cost effective relative to HEVs." [EPA-HQ-OAR-2022-0829-0585, p. 12]

If the results of EPA's OMEGA modeling were correct, we should already observe HEVs weakening in the marketplace. While the proposed rule projects penetration of virtually zero hybrids in 2032,10 the real world reveals hybrids flourishing in the marketplace. [EPA-HQ-OAR-2022-0829-0585, p. 12]

10 Tables 13-65 through 13-94 in the DRIA indicate that 100% of market share is comprised of Turbo12, ATK, and BEV technologies for all cases except for Alterative 1, where 100% of market share includes 6% strong hybrids.

EPA's own analyses confirm the recent large increase in hybrid market share. Section 3.1.1.2 Hybrid Electric Technologies in the DRIA (page 3-3) states:

"Hybrid electric vehicles (HEVs) were first introduced in the U.S. marketplace in model year 2000 with the Honda Insight. As more models and options were introduced, hybrid production increased to 3.8 percent of all vehicles in model year 2010, before declining somewhat over the next several years. However, in model year 2021 hybrid production reached a new high at 9.3 percent and is projected to reach 10.1 percent in model year 2022, as shown in Figure 3-2 (U.S. EPA 2022)." [EPA-HQ-OAR-2022-0829-0585, pp. 12-13]

"The growth of hybrids in the pickup vehicle type is largely due to the introduction of "mild" hybrid systems that are capable of regenerative braking and many of the same functions as other hybrids but utilize a smaller battery and an electrical motor that cannot directly drive the vehicle.

These mild hybrids account for about a third of hybrid production in model year 2021." [EPA-HQ-OAR-2022-0829-0585, pp. 12-13]

Against this recent rapid increase in hybrid sales, note that OMEGA forecasts only 4% hybrids in 2027 for the No Action scenario (preamble Table 83) and 3% for the Proposed Standards (preamble Table 82). [EPA-HQ-OAR-2022-0829-0585, pp. 12-13]

Organization: KALA Engineering Consultants

Comment 5. The Law of Unintended Consequences or Reactions

A. We believe public sentiment toward the obvious potential results of adoption of the Docket ID No. EPA–HQ–OAR– 2022–0829 rulemaking of "forcing" manufacturers to predominately produce BEVs in order to meet the proposed standards may well have a host of unintended consequences.

Despite the glowing polling results reported in the Federal Register rulemaking document regarding eager acceptance of BEVs and polls of PHEV and BEV owners that would be willing to purchase such vehicles again, we believe that most of those respondents fall into several categories such as 'Early Adopters,' electric car zealots and wealthy people who can afford BEVs and want to impress their friends and neighbors with how "Green they are. Seriously, a person who buys an obscenely ostentatious Lucid 1,000 horsepower electric vehicle cannot be considered representative of the majority of people who will be presented with BEVs as, essentially, their only choice in new car showrooms in a few years. We think there may well be elderly people who buy a new car after 2027 that will get the BEV home and be wondering, "Where do I put in the gas for this thing?" [EPA-HQ-OAR-2022-0829-0617, pp. 54-60]

We looked at several polls, as did several other commenters, but the one we chose to discuss here has international representation in several developed countries in Europe as well as the US. The poll was conducted by UK-based Kantar Public in their Journal- 04 publication of polling data on public attitudes towards the environment, sustainability, and climate change. If you go to ResearchGate and request the actual PDF of the research, you will get the graphics and discussion we are about to share with EPA. https://www.researchgate.net/publication/355734467_European_attitudes_to_climate_change_implication s_for_citizens_institutions_and_governments [EPA-HQ-OAR-2022-0829-0617, pp. 54-60]

The Guardian also published excerpts from the polling in 10 countries here:

https://www.theguardian.com/environment/2021/nov/07/few-willing-to-change-lifestyle-climate-survey [EPA-HQ-OAR-2022-0829-0617, pp. 54-60]

From those sources we present the second of two graphics below from the survey and then comment on the results. The most interesting results we found were from the following question "How would you rate in terms of importance, the following measures aimed at preserving the environment and the planet?: [EPA-HQ-OAR-2022-0829-0617, pp. 54-60]

Replacing fossil fuels with renewable energy – 45% say important Reducing people's energy consumption – 32% say important Favoring the use of public transport over cars – 25% say important And most pertinent to this comment's discussion: [EPA-HQ-OAR-2022-0829-0617, pp. 54-60]

Banning fossil fuel vehicles – 22% say important [EPA-HQ-OAR-2022-0829-0617, pp. 54-60]

[See original attachment for poll on how people ranked, in terms of importance, the following measures aimed at preserving the environment and the planet] [EPA-HQ-OAR-2022-0829-0617, pp. 54-60]

Only 22% felt that banning fossil fuel vehicles (22%) was important to preserve the planet. We would characterize this level of response to that question as dismal at best, people do not want to use electric vehicles. [EPA-HQ-OAR-2022-0829-0617, pp. 54-60]

In the US, Transportation accounts for slightly more Greenhouse Gas (GHG) emissions than does electricity generation. However, in most other large emitter countries, the opposite is true with Electricity generation being far greater than Transportation. This is especially true of China (the largest global GHG emitter), where much of the country is still rural in nature, most electrical generation is by exceedingly dirty coal-fired power plants and the thought of a personal vehicle being a birthright is a foreign (i.e. US) notion. The most frightening aspect of what we call the "Lifestyle Gap" is the desire by most people in other countries to have a similar lifestyle to what they observe in the US. Having personal transportation (something bigger and more enclosed than a motor scooter) is very high on that desire list. That implies that as other countries catch up to a US lifestyle, Transportation GHG emissions will continue to rise from that sector. [EPA-HQ-OAR-2022-0829-0617, pp. 54-60]

Most other countries that do not have oil reserves, look to the US for what to do about Climate Change. The reasoning goes, the US is the most technically advanced country in the world and whatever solutions the US comes up with must be the "correct" solutions. These facts make it doubly important for the US to act as the leader of the world on Climate Change with truly "correct" and nearly universally applicable solutions. Yet, we do not have a set of National Climate Change Solution Plans that the Federal Government has endorsed as policy and has committed funding and regulations to implement. So far, there have been "Band Aid" measures on Transportation GHG emissions such as the Biden plan to place electric vehicle charging stations all across the country, a partial solution that KALA disagrees with, not on the viability of electric vehicle charging stations, but the lack of focus on deployment in locations that desperately need reductions in emitted vehicle pollution (these are known as EPA's nonattainment areas such as large cities where most of the pollution that creates the nonattainment condition is from vehicles). The opposite is true in China where big city pollution is mostly from nearby electrical generation. [EPA-HQ-OAR-2022-0829-0617, pp. 54-60]

These dichotomies between nations and their levels of technology and emission profiles also makes it important for the solutions developed by the US be largely applicable to nations with lower levels of technology and wealth. The battery electric vehicle solution so often touted as "THE" solution to transportation GHG emissions, will NEVER apply to the hundreds of millions of motor bikes, motor scooters, motor trikes, motorized boats and various other transport modes, which all use petroleum-based liquid fuels, found all across Asia, India, Indonesia, the

Philippines, the Middle East, Africa and South America. Many countries that are considered "Developed" (I'm thinking Russia and the former USSR vassal states) may not have citizenry that can easily afford a transition to an entirely different vehicle propulsion method, such as battery electric, and will struggle to maintain their existing fleets of vehicles that still use fossil petroleum fuels. In fact, the less developed and lower income nations around the world will balk at implementing the so-called "solution" that seems to be prevalent in the thinking of the United States for Transportation GHG emissions, i.e. Battery Electric Vehicles (BEV). Oil producing states, such as Russia and Saudi Arabia, where oil income is the principal national revenue will be outright hostile to the notion of changing the vehicle propulsion method. [EPA-HQ-OAR-2022-0829-0617, pp. 54-60]

In response to the Kantar polling as to why they would be hesitant to make drastic changes to help with Climate Change: "I need more resources and equipment from public authorities" (69%) together with "I can't afford to make those efforts" (60%) were major responses. [EPA-HQ-OAR-2022-0829-0617, pp. 54-60]

Any policy makers who see these results, especially in the US, MUST rethink where policy making should go on Transportation GHG reductions. When someone says, "I can't afford to make those efforts" what are they most likely talking about? In our view, for most people, they are referring to the cost of replacing their current gasoline vehicle with an electric vehicle. In the US, vehicles are usually the second most costly item of personal ownership, with a home being in first place. For those who cannot afford home ownership, a large percentage of the Democratic Party's base, a vehicle is their most costly personal possession. If those individuals are middle to lower income, their budgets are usually very tight and the thought of being forced to purchase a vehicle that is 20% to 50% more costly than a gasoline vehicle is generally out of the question even with generous tax rebates that actually mostly apply to more wealthy individuals with high personal incomes. We believe that they will instead, choose to buy a replacement vehicle, when needed, from the existing stock of gasoline-burning used cars for as long as they can. [EPA-HQ-OAR-2022-0829-0617, pp. 54-60]

This analysis brings up the issue of how little time we have left to actually make the most significant changes to GHG emissions. We simply do not have time for people to run out of gasoline-burning used car choices, which could amount to 20 years or more, for them to finally buy the supposed "solution" to transportation GHG emissions, a BEV. Related to this lower to middle income demographic is the issue of their vehicle being able to provide "Dual Duty." A Dual Duty vehicle is one that can provide short-distance (short time frame) transportation for daily needs such as grocery getting and the back and forth to work commute AND provide a way to take long trips for such things as vacations and family gatherings. Let me relate an interesting response to a question I posed to a Nissan representative at a Denver car show about the Leaf All-Electric vehicle (BEV). I asked what about trips up into places like Wyoming where they will not be welcoming to electric vehicles in that oil producing state? Incredulously, the Nissan rep said, "Oh, you don't use the Leaf for longer trips – you use your 'Other car' for that." [EPA-HQ-OAR-2022-0829-0617, pp. 54-60]

Such a response shows an unbelievable elitism about lower cost BEVs, such as the Leaf and the Chevrolet Bolt, that the owner of such BEVs will have the financial means to have two or more vehicles, one of which is capable of long-distance trips without the bother of waiting 3 to 7 hours for a recharge after the car's battery is exhausted. This has become known as "Recharge

Anxiety." It is a real thing and represents the problem all BEVs have in public perception of: What happens when you run out of battery charge on a long trip or in a traffic jam? Will it take hours to recharge even if I can find an open and working recharge outlet? Why would I ever try to take a BEV on a long trip when I can "recharge" (i.e. refuel) my gasoline vehicle in less than 10 minutes? BEV makers have tried to address this problem, Tesla for example, by providing a Supercharging option at special recharge stations designed to recharge a half-discharged battery in about 15 minutes. But, even Tesla admits that rapid recharge is not good for the individual cells in the battery pack and should not be done too often. [EPA-HQ-OAR-2022-0829-0617, pp. 54-60]

B. If the EPA attempts to "force" people into BEVs, there may be an unexpected and unforeseen political reaction among people who have traditionally been the base of the Democratic Party who may switch their political allegiance to the other Party who won't force them to drive BEVs.

So, what choices do the lower and middle income people that comprise a large percentage of the Democratic Party base have when it comes to the supposed Transportation GHG emission "solution," the BEV. The answer is not much, because for the ONE car they can afford, they need the Dual Duty vehicle that is represented best by a gasoline-fueled vehicle that can be refueled on longer trips in less than 10 minutes and then they are on their way again. If the Democratic party at the behest of a Democratic president through a regulatory agency attempts to force those people to purchase and deal with all the recharge problems that BEVs have, they might well not be Democrats anymore. Republicans will NEVER support forcing people to buy BEVs (they are in the back pockets of the oil companies after all) and that may well drive people who were reliable Democratic voters into the Republican camp over this single issue. [EPA-HQ-OAR-2022-0829-0617, pp. 54-60]

So, the question to EPA administrators is simple. Do you want to risk political reprisals in the form of election of Republican legislators and the head of the executive branch, the president, because you felt this was your chance to "force" the adoption of a vehicle type, the BEV, down peoples throats that, frankly, we believe we have shown conclusively will not perform the GHG reduction function that the EPA claims it will. [EPA-HQ-OAR-2022-0829-0617, pp. 54-60]

Didn't you see what happened when Donald Trump was president and the EPA was rendered powerless and, now that the Supreme Court is constituted the way it is with ultra-conservative judges, how do you think court cases that make it to SCOTUS will turn out for EPA on this and other regulatory Docket issues? Now look, we are not saying to the EPA to be fearful and hunker down and not do anything about GHG and criteria pollutants from transportation. PLEASE review our set of alternatives in Comment Section 4, which we think makes more sense, especially from a GHG reduction standpoint than trying to "force" adoption of BEVs into the US fleet at unreasonable numbers. Making people buy and drive very different vehicle types may not be the answer, especially for GHG reductions. We think the "Fuel Change Out" approach with high GHG reduction potentials and better criteria emissions profiles is a better way to meet the needs for health risk reductions and more importantly, as we have argued above, for dramatic reduction in GHG emissions by substituting fossil carbon containing fuels for carbon-neutral fuels made from biomass. [EPA-HQ-OAR-2022-0829-0617, pp. 54-60]

We have the technology to make these carbon-neutral fuels that come very close to the properties of gasoline and dramatically reduce GHG emissions if we just have the will and foresight to do so. [EPA-HQ-OAR-2022-0829-0617, pp. 54-60]

C. The consequences that may arise from full implementation of Docket ID No. EPA–HQ–OAR– 2022–0829 rulemaking standards and requirements may produce something that could be described as a quiet rebellion against what many people would view as government overreach via regulation.

To give you a better "feel" or Flavor for the reaction to the docket's provisions, we would invite EPA to look at a YouTube video by long-time YouTube maven on automotive issues, Scotty Kilmer. https://www.youtube.com/watch?v=j1R0wTBsK3I [EPA-HQ-OAR-2022-0829-0617, pp. 54-60]

In this video presentation, Kilmer starts out blaming President Biden and by association the Democratic Party as the villains who want to take your gasoline car away from you and limit your buying choices in the future. Here are some of the comments elicited from the video with many of the obvious Trumpian attitudes filtered out: [EPA-HQ-OAR-2022-0829-0617, pp. 54-60]

"How do we do this when 90% of Americans cannot afford a new car?"

"As someone who has never bought a new car. I can assure you I will never be buying a used electric car." "We can barely get enough minerals to power our phones, and now we want 60%of cars to run on batteries."

"They can build all they want, but you cannot force people to buy them."

"Just where am I supposed to get $61,500 for a car? That is absolutely insane! This is legislation through regulation. Who voted for those EPA bureaucrats? There is exactly ZERO percent probability that I will buy an EV." [EPA-HQ-OAR-2022-0829-0617, pp. 54-60]

"This is the closest thing to government mandating what people get to choose and eliminating a free market based on consumer demand."

"We just need a group of people with the know-how and the financial ability to sue the EPA to stop infringing on our rights to purchase what we want. They're just basically taking our freedom away through regulation without actually saying we don't have the freedom to choose what we want."

"Thanks to Scotty's advice we just bought a 2023 Camry V-6. We're good for 20 years or 300,000 miles." "I have a Tesla but forcing everyone to get an EV is insane. Many don't have the capability to charge at home and a lot of homes need panel upgrades to make room for a EV charger. All of this costs a lot of money for people to afford." [EPA-HQ-OAR-2022-0829-0617, pp. 54-60]

"In our office people are buying hybrid cars instead of EV cars. It make more sense, 500 miles of range, fill the tank in 6 minutes and probably last longer and they are about the same price or less and are proven technology."

"This sounds like used vehicle prices are going to skyrocket worse than before - probably not a good sign for those of us stuck as pizza drivers."

“The EPA doesn't have the authority to change the law or the regulations. The people through congress will make that decision thank you.”

“American people remember you have the power to choose your president and who makes the laws, if it’s affecting you who cannot afford to change your car then get someone who sides with the working classes and will help you make your own choices, the fact that making batteries pollutes more than gasoline engines produce doesn’t matter to these politicians who don’t know what it’s like to have to work for a living.”

“Is it at all possible for congress to stop this insane man [presumably Pres. Biden]? [EPA-HQ-OAR-2022-0829-0617, pp. 54-60]

So, does the EPA get some of the rebellion flavor in those comments? It is our opinion that one of the unintended consequences of implementing this Docket may be to create a rebellion of sorts among millions of Americans. We think that people may decide to hold on to their gasoline vehicles much longer than they otherwise might. We also think that once BEVs are about the only vehicles on dealer’s showroom floors, the price of used gasoline vehicles may well increase dramatically. If that happens, millions of low income people may be priced out of the used car market. What may happen is “Cubanization” of the US used car market. Cuba has long been banned from importing vehicles from the US and elsewhere. With the parts Cubans are able to smuggle in and automotive machine shops making some hard-to-get parts, the car owners in that country are driving around in cars from the Fifties and Sixties with no end in sight. Fortunately, Cuba is a small island, but the idea is that there could be new “cottage industries” like the ones in Cuba pop up all across our country that would be mechanics, auto machine shops, and detailers and upholsterers who keep those old cars in good shape. The very same thing could conceivably happen here in a “Resistance” movement against the regulations the EPA is advocating for. [EPA-HQ-OAR-2022-0829-0617, pp. 54-60]

The temporal upshot of these possible consequences is that the gasoline part of the US fleet will continue to use gasoline and spew the usual GHG and criteria pollutants as time goes by. The problems we foresee are that as engines in those older vehicles that people in the Resistance Movement are holding onto will get tired and transmissions get less efficient, the amount of pollutants and GHGs could go up – exactly what the efforts to implement these new regulations are meant to avoid. [EPA-HQ-OAR-2022-0829-0617, pp. 54-60]

George H. W. Bush stated it best when he said, “The American life-style is non-negotiable.” And in this context, that means that stubborn Americans are not going to be told what they can and can’t drive and they will resist what they might view as an intrusive government trying to alter their “life-style.” [EPA-HQ-OAR-2022-0829-0617, pp. 54-60]

Organization: Kentucky Office of the Attorney General et al.

3. Consumers are not willing to accept the Proposed Rule’s electrification mandate.

All of the above questions whether it is possible to make EVs in the numbers the Proposed Rule dictates. Assuming the Agency could explain away those concerns, another important aspect of the problem would persist: Consumers will not buy that many EVs. [EPA-HQ-OAR-2022-0829-0649, p. 15]

The entire proposal depends on increased—much increased—EV demand. And demand undoubtedly is growing. But it is not likely that sales will "rapidly grow" enough that 67% of new passenger cars, trucks, and SUVs will be electric in the next handful of years. 88 Fed. Reg. at 29,189, 29,329. After all, EVs comprised under 6% of the market last year. Sebastian Blanco, Strict EPA Rules for 2027-2032 Vehicles Announced, Garnering a Range of Reactions, Car and Driver (updated Apr. 13, 2023), https://www.caranddriver.com/news/a43546970/new-strict-epa-mpg-rules-for-2027-2032-vehicles/. Taking another 60% of the market by model year 2032 is unrealistic. Consumers' "vehicles are near and dear to their hearts," so "[f]or most people," EPA's manipulation of the new-vehicle market "could be really problematic." David Ferris, Gasoline car bans: EV savior or 'stupid' idea?, E&E News (Feb. 14, 2020), https://bit.ly/43PIP8I. A March 2023 Gallup survey undercuts EPA's market assumptions, too: Only 12% of U.S. adults are "seriously considering" buying an EV, while 41% "unequivocally" say they would not consider buying one. Megan Brenan, Most Americans Are Not Completely Sold on Electric Vehicles, Gallup (Apr. 12, 2023), https://news.gallup.com/poll/474095/americans-not-completely-sold- electric-vehicles.aspx. Add in recent cuts on tax credits for electric-car buyers, and the indications that the Proposed Rule relies on wildly inaccurate demand projections keep growing. [EPA-HQ-OAR-2022-0829-0649, p. 15]

Organization: Matthew DiPaulo

My company produces motor oil for passenger car vehicles with proprietary formulations which exceed industry specifications, improve fuel economy, reduce emissions, and can be used in hybrid vehicles [EPA-HQ-OAR-2022-0829-1514, p. 1]

The premature rush to transition the U.S. vehicle fleet to EV's will reduce my sales. [EPA-HQ-OAR-2022-0829-1514, p. 1]

The large-scale shift to electric vehicles, which would comprise two-thirds of all new-car sales in the U.S. by 2032 under this proposal, will hurt workers, small businesses, and consumers while doing little to help the environment. The proposed rule would lead to fewer vehicle choices for individuals and families, reducing the selection of vehicles that fit their household budgets and unique needs. [EPA-HQ-OAR-2022-0829-1514, p. 1]

Organization: Mazda North American Operations

The proposed rule is the most stringent light duty vehicle regulation that EPA has promulgated to date. The electrification and carbon reduction goals are incredibly challenging and will require not just a coordinated effort to achieve but also solutions addressing consumer demand, affordability, charging network, power grid capacity, rare earth mineral availability, and striking the right balance regarding China policy [EPA-HQ-OAR-2022-0829-0595, p. 2]

Summary

Mazda is proud of its heritage and contributions to personal mobility, and we celebrated our 100th anniversary in 2020. Mazda has also long been an engineering leader known for innovative powertrains like the rotary engine and Skyactiv technology. [EPA-HQ-OAR-2022-0829-0595, pp. 3-4]

We look at EPA's NPRM and its preferred option through the lens of a company that is already working towards an electrified future. It's not a matter of if this transformation will happen, but when and how. Mazda, like the rest of the industry, faces many challenges: [EPA-HQ-OAR-2022-0829-0595, pp. 3-4]

- Will charging infrastructure be sufficient?

- Can the electric grid handle the increased demands?

- How will EV incentives on the federal and state level impact this shift? [EPA-HQ-OAR-2022-0829-0595, pp. 3-4]

- Will suppliers be able to develop and produce components like batteries (that currently require critical minerals, many from China) quickly enough and in enough volume?

- How might future laws or regulations in trade and re-shoring impact our ability to meet goals?

- Are consumers ready and willing to move away from "tried and true" internal combustion engines in numbers sufficient to meet these goals?

- Can OEMs remain sufficiently profitable to fuel the transition to EVs? [EPA-HQ-OAR-2022-0829-0595, pp. 3-4]

Mazda strongly requests that EPA take these considerations into account and make necessary adjustments to the proposed rule as it works towards a Final Rule. We feel the Final Rule should have more realistic targets and associated ramp ups, include PHEVs, and adopt CARB's current LEV IV for criteria emissions. [EPA-HQ-OAR-2022-0829-0595, pp. 3-4]

Organization: Minnesota Pollution Control Agency (MPCA)

There is strong and growing demand for EVs in Minnesota, especially as the variety of EV options grows. During our Clean Cars Minnesota rulemaking, we heard from Minnesotans that demand for EVs was outstripping supply – Minnesotans were seeking EVs and sitting on long waitlists or going out of state to obtain them. EV sales in Minnesota increased by more than 2.5 times between 2020 and 2022.5 [EPA-HQ-OAR-2022-0829-0557, p. 3]

5 Alliance for Automotive Innovation, 2023, Advanced Technology Sales Dashboard, retrieved June 14, 2023. https://www.autosinnovate.org/resources/electric-vehicle-sales-dashboard

Organization: Mitsubishi Motors North America, Inc. (MMNA)

To determine a realistic maximum volume of EVs the market can support for each of the model years covered by the rule, we believe EPA should consider certain critical factors. Among these factors, we believe EPA must make a thorough and realistic year-by-year assessment of key factors like projected battery costs, projected supply of battery critical-minerals, projected residential and public charging infrastructure availability, projected electrical grid capacity, and consumer acceptance of BEV technology in the broader arena. [EPA-HQ-OAR-2022-0829-0682, p. 2]

Organization: National Association of Convenience Stores (NACS) et al.

Renewable fuels such as ethanol materially lower gasoline's carbon footprint. If properly incentivized, these technologies' capability to reduce emissions can continue to grow alongside other decarbonization technologies such as clean electricity. Pursuing one solution does not require abandoning others. [EPA-HQ-OAR-2022-0829-0628, pp. 1-2]

As articulated in this letter, and in our associations' respective comments in response to the Proposal, we are concerned that EPA is pursuing a single technology as the solution to decarbonize light-duty transportation. The speed at which the Agency appears to anticipate the market and consumers will transition to electric vehicles is divorced from our members' assessment of reality. The Proposed Rule does not appreciate the market obstacles associated with such a massive transition in consumer behavior. It also abandons proven decarbonization technologies, such as higher-octane liquid fuels, that can deliver material emissions reductions using existing infrastructure, existing vehicles, and working with consumers' existing behavior. [EPA-HQ-OAR-2022-0829-0628, pp. 1-2]

Our associations support the Agency's stated goal of improving the emissions consequences of over-the-road transportation. The Proposed Rule's approach toward realizing that objective, however, is flawed. A technology-neutral approach to transportation decarbonization will help to mitigate costs, promote innovation, and address the practical challenges associated with electrification. All fuels and technologies should be treated equally within the context of emissions standards. The Proposal does not do this, but instead artificially tilts the scale towards electric vehicles ("EVs") by only accounting for emissions from one segment of the value chain: vehicle tailpipes. [EPA-HQ-OAR-2022-0829-0628, pp. 1-2]

Organization: National Automobile Dealers Association (NADA)

NADA has long supported continuous vehicle emissions improvements that are technologically achievable and affordable for household and commercial new vehicle customers. As noted above, NADA's franchised dealer members are "all-in" with selling and servicing the new EVs being produced by the OEMs they represent. In fact, nationwide, NADA expects franchised dealers to spend some $5 billion installing EV chargers, buying EV-related equipment, parts, and tools, and investing in EV training for sales and service personnel. As evidenced by these investments and by the EV-related activities at the 2022 and 2023 NADA Shows,22 America's new motor vehicle dealers recognize their importance to the broad, mass market adoption of EVs. However, they also are concerned that EPA's proposal could undermine that adoption. [EPA-HQ-OAR-2022-0829-0656, p. 4]

22 See Exhibit A: "Everything Electric" at NADA Show 2022-2023.

Appropriately structured standards must involve a national, holistic approach to improving tailpipe emissions. EPA claims that it is not proposing to mandate specific technologies or the production of specific vehicle types, but its proposal is anything but technology neutral. Unlike prior rules governing tailpipe emissions, EPA's proposed standards cannot be met by ICE vehicles alone and would phase-out existing credits for ICE vehicle and hybrid technologies that have to date helped OEMs to achieve better emissions compliance. Moreover, they are premised on overly aggressive assumptions regarding future EV market penetration. If adopted, the cumulative practical effect of the proposal would be to greatly reduce the market availability of new ICE vehicles. This “if you build them, they will come” approach ignores the fact that, while franchised dealers are the OEMs’ primary customers, actual emission reductions cannot be achieved unless and until new EVs take to the road. [EPA-HQ-OAR-2022-0829-0656, p. 5]

Unlike for many regulated goods, prospective purchasers of new light-duty vehicles have transportation options, including the used vehicle marketplace, the service and repair of existing vehicles, and alternatives like public transit and micro-mobility. Consequently, vehicle consumer purchase behaviors must be viewed through the lens of an ever-changing marketplace that hinges on the willingness and ability of prospective purchasers to buy ever more expensive new vehicles with enhanced emissions performance. Similarly, new commercial medium-duty vehicle purchase decisions hinge on affordability, cost-efficiency, and reliability (i.e., uptime). At bottom, the market will avoid new vehicles that are too costly, that offer performance comprises, or that pose unacceptable downtime risks. [EPA-HQ-OAR-2022-0829-0656, p. 5]

EPA’s current proposal is flawed in that it disregards these critical demand-side marketplace factors. It also appears aimed at promoting EVs to the exclusion of ICE, hybrid, and other alternative fuel vehicles. It will likely cause OEMs to produce fewer new technology ICE and alternative fueled vehicles and will increase their cost, thereby dissuading consumers from considering their purchase. EPA’s final rule should set truly technology-neutral emissions standards that maximize, not inhibit, fleet turnover. Doing so is critical to maximizing emissions reduction given that, as noted above, regulatory objectives will not be achieved unless and until new vehicles subject to more stringent emissions standards are bought. [EPA-HQ-OAR-2022-0829-0656, p. 5]

Less than 10 percent of new vehicle sales are cash transactions, meaning that over 90 percent of prospective new vehicle purchasers finance their transactions. Today’s high interest rates are compounding the affordability dilemma and driving consumers out of the market.26 As a result, Americans are holding onto their existing vehicles longer, extending the average age of the on-road fleet to 12.5 years.27 And, dealers are selling fewer new vehicles, about 13.9 million in 2022, down 8 percent from 2021 and well down from the 17.2 million sold in 2018.28 [EPA-HQ-OAR-2022-0829-0656, p. 6]

26 See Auto Loan Interest Rates Hit Highest Level Since 2008 and Drive Record Share of $1,000+ Monthly Payments in Q1, | Edmunds.

27 See Average Age of Light Vehicles in the US Hits Record High 12.5 years, | S&P Global (spglobal.com).

28 See Cox Automotive Forecast: U.S. Auto Sales Expected to Finish 2022 Down 8% Year Over Year, as General Motors Reclaims Top Spot, Honda and Nissan Fall Significantly - Cox Automotive Inc. (coxautoinc.com); New- Vehicle Sales Reach 17.3 million; 2019 Less Rosy - Cox Automotive Inc. (coxautoinc.com).

American consumers generally support incremental emissions improvements, and a recent survey shows that 61 percent of new vehicle car shoppers say that they are “overall likely” to consider purchasing an EV.29 But intender surveys are of limited value and often do not reflect what prospective purchasers will do, or what they care about most. For example, polling by Centrist Democrats of America shows that while Americans generally support EVs, they do not support bans on the sale of new ICE vehicles, or prioritizing funding for public EV charging over building schools and police and fire resources.30 Moreover, a recent Gallop poll shows that 41 percent of U.S. adults state that they will not consider purchasing an EV.31 and a recent poll by the Energy Policy Institute at the University of Chicago and the Associated Press-NORC found that 47 percent of respondents are unlikely to purchase an EV.32 In May 2023, J.D. Power reported that 21 percent of U.S. car shoppers are "very unlikely" to consider an EV for their next vehicle purchase, and a GOBankingRates survey found that 22 percent of respondents said they do not ever want to own an EV.33 [EPA-HQ-OAR-2022-0829-0656, pp. 6-7]

29 See 2023 U.S. Electric Vehicle Consideration (EVC) Study | J.D. Power (jdpower.com).

30 See Democrats should be wary of banning gas vehicles | The Hill.

31 See Most Americans Are Not Completely Sold on Electric Vehicles (gallup.com).

32 See 47 percent in new poll say it's unlikely they would buy EV | EPIC (uchicago.edu); 47 percent in new poll say it's unlikely they would buy EV | The Hill.

33 See EV Divide Grows in U.S. as More New-Vehicle Shoppers Dig in Their Heels on Internal Combustion | J.D. Power (jdpower.com); 22% of Americans Never Want To Own an Electric Vehicle | GOBankingRates.

Now, some of these polls focused on Americans generally versus on prospective new vehicle shoppers. But they raise real concerns that EPA must consider when setting standards designed to achieve continuous emission improvements that maximize, not inhibit, fleet turnover. [EPA-HQ-OAR-2022-0829-0656, pp. 6-7]

Now, some of these polls focused on Americans generally versus on prospective new vehicle shoppers. But they raise real concerns that EPA must consider when setting standards designed to achieve continuous emission improvements that maximize, not inhibit, fleet turnover. [EPA-HQ-OAR-2022-0829-0656, pp. 6-7]

1. EPA's Use of a Cost-of-Ownership Payback Analysis Is Flawed and Problematic.

EPA correctly acknowledges that under its proposed standards "the average purchase price of vehicles is estimated to be higher," which it attributes to an anticipated larger share of EVs in the market. However, its assertion that lower EV operating costs and IRA purchase incentives will offset these higher up-front costs is unsound.34 As NADA has explained previously, for most prospective new vehicle purchasers, using a total cost of ownership (TCO) "payback" cost/benefit analysis is flawed and problematic for several reasons. [EPA-HQ-OAR-2022-0829-0656, pp. 7-8]

34 88 Fed. Reg. at 29201, 29328-29, 29344, 29364.

First, consumers shopping for vehicles with better fuel economy35 must be willing and able to pay for it. As noted above, 67 percent of Americans presently cannot afford any new vehicle. And of the 33 percent who can, high interest rates are driving many of them out of the market. NADA takes issue with EPA's projections that its proposal will result in only a small change in total new light-duty vehicle sales and no change in new medium-duty vehicle sales. NADA's projections differ significantly, showing vehicle sales declines corresponding with the higher vehicle costs attributable to EPA's proposed standards. [EPA-HQ-OAR-2022-0829-0656, pp. 7-8]

35 For at least two practical reasons, improved fuel economy performance is a surrogate for better emissions performance. First, strategies for improving a vehicle's fuel economy often result in improved emissions performance, especially with respect to GHGs. Second, while some prospective purchasers seek

and are willing to pay for improved fuel economy performance, few seek and are willing to pay for improved emissions performance.

Second, consumer demand for fuel efficiency fluctuates with fuel prices. Prospective purchasers form expectations of the net present value of future fuel savings that are related, but not closely related, to a standardized financial calculation.36 During dramatic upward fuel price swings followed by heavy media coverage, consumers place a large value on fuel economy, as revealed by shifts in demand to more fuel-efficient segments of the market. But during slow and steady increases in the price of liquid fuels with little or no media attention, consumer demand reveals a diminished value for fuel economy. [EPA-HQ-OAR-2022-0829-0656, pp. 7-8]

36 See Exhibit B, Walton & Drake, Willingness to Pay for MY 2025 Fuel Economy Mandates: Government Estimates v. Economic Reality, February 2012.

Third, a consumer's willingness to purchase improved fuel economy must be viewed in the context of other vehicle attributes. When assessing the value of fuel economy improvements to prospective purchasers, the financial benefits of future fuel savings cannot be separated from the utility lost by necessary reductions to other vehicle qualities and performance. A study released earlier this year examined the tradeoff between fuel economy and vehicle performance in connection with NHTSA's most recent round of fuel economy mandates.37 It found evidence that consumers and OEMs undervalued fuel economy compared to the predictions of a rational-choice model. However, it also found that fuel economy mandates resulted in foregone performance, upon which consumers placed a value approximately equal to that of any fuel-savings benefits resulting from the standards. And it found that models attempting to assess the new vehicle buying public's willingness to purchase fuel economy, without controlling for performance tradeoffs, likely suffered from omitted variables bias. [EPA-HQ-OAR-2022-0829-0656, p. 8]

37 Leard, Linn, Zhou; How Much Do Consumers Value Fuel Economy and Performance? Evidence from Technology Adoption, The Review of Economics and Statistics (2023); 105(1), 158-74.

EPA assumes that consumers value any fuel savings associated with new vehicle purchases over a 30-month period (at most) but suggests erroneously that there is no consensus regarding how consumers value fuel efficiency. EPA also made no real attempt to assess how new light-duty vehicle consumers actually value emissions reduction/fuel economy technology when making purchase decisions.38 Instead, EPA made reference to a so-called "energy efficiency gap" and asserted that the issue will become less relevant as the share of EVs in the market increases.39 But the aforementioned study suggests that the proper approach for setting fuel economy mandates designed to maximize the achievement of regulatory objectives is to control for consumer willingness to purchase changes in both a vehicle's performance and fuel economy. EPA's failure to do so undermines its ability to set emissions reduction mandates premised on realistic and accurate conclusions. [EPA-HQ-OAR-2022-0829-0656, p. 8]

The historic passage of the Bipartisan Infrastructure Law and Inflation Reduction Act underscores the immense public investment now available for ZEVs and associated infrastructure. This public support is being further met with significant private investment from manufacturers and associated entities, while interest in EVs and ZEVs at the individual consumer level is expanding year after year. For instance, more than a quarter million battery-electric vehicles were sold in the first quarter of 2023 alone — a nearly 45% increase over the same period last year.17 Unlike past EPA efforts that may have relied on expected future improvements in technologies, EVs and ZEVs are here now and are growing as a share of the LDV and MDV market. While ZEV technology will continue to improve and evolve, a rapid transition to ZEVs is already the clear option when it comes to the on-road vehicle technology that achieves the greatest degree of emission reductions. [EPA-HQ-OAR-2022-0829-0607, p. 4]

17 Cox Automotive, Another Record Broken: Q1 Electric Vehicle Sales Surpass 250,000, as EV Market Share in the U.S. Jumps to 7.2% of Total Sales (Apr. 12, 2023), https://www.coxautoinc.com/market-insights/q1-2023-ev-sales/.

Organization: Nebraska Corn Board (NCB) and Nebraska Corn Growers Association

Expecting rural Americans who have a lower median income than those in urban areas to pay $10,000 -$20,000 for an electric vehicle is out of touch and does not benefit the consumers. Today, out of the 267 million light-duty vehicles on the road only 1% of them are battery-powered. As we have seen post-pandemic, legacy vehicles are becoming more common as consumers are holding onto their car longer and are going further in mileage. [EPA-HQ-OAR-2022-0829-0583, pp. 1-2]

Organization: Nissan North America, Inc.

Nissan appreciates the Administration's focus on and support for advancing electrification and carbon neutrality and shares the same long-term goal of transitioning to zero emission vehicle society. However, Nissan believes that market realities, infrastructure needs, consumer impacts, and lack of battery critical mineral availability necessitate an adjustment of the GHG standard stringency in this rulemaking timeframe. [EPA-HQ-OAR-2022-0829-0594, p. 1]

Beyond the significant market and governmental challenges posed by such a drastic implementation timeline, consumer adoption will be critical to success. Consumer adoption of EVs has historically lagged behind expectations, leaving a significant hurdle to encourage a large and swift shift to EVs. Consumers need to be convinced not only of the appeal, safety, affordability, and reliability of EVs themselves, but they need to adopt the necessary community and home charging equipment to facilitate their use. Consumers will need to adapt their trip planning and driving behavior to allow for vehicle charging needs. The only way to drive these significant behavioral changes is to assure consumers that charging infrastructure is available and reliable. This is simply not a reality today and is unlikely to be a reality in time to drive such a significant shift within the timeline of the Proposed Multi-Pollutant Rule. These challenges are magnified due to the unclear and uncertain benefits under the Inflation Reduction Act, which place significant limitations on EV consumer incentive programs and charging infrastructure programs. Moreover, many consumers are reluctant or unable to purchase EVs due to their significant price premium. The Proposed Multi-Pollutant Rule will only exacerbate these inequalities, with EV prices likely to increase even more due to extreme investments required by all market sectors involved. Driving too much change too quickly will shut out many communities who need clean vehicles the most. It will likely force consumers who are uncertain about ZEV adoption to continue to operate aging ICE vehicles much longer. This is contrary to the intent of the proposal. [EPA-HQ-OAR-2022-0829-0594, p. 5]

Organization: Paul Bonifas and Tim Considine

Moreover, the EPA claims unrealistically low residential electricity charging rates while simultaneously admitting that low-income households won't have access to, nor be able to afford installation of, residential charging ports. The EPA admits that low-income households will have to rely on commercial charging ports that cost 2-3 times more3, yet they don't consider this in their net impact calculations. The EPA's rule will have a negative impact on the entire population but will disproportionately negatively impact the poorest Americans. Correcting for these EPA oversights leads to a more realistic fuel "savings" of NEGATIVE $108 billion, a $998 billion cost increase from the EPA's calculations. [EPA-HQ-OAR-2022-0829-0551, pp. 2-3]

F. Plug-in Hybrid Electric FFVs (PHEV FFVs) Provide a Key Compliance Solution that Must be Incentivized.

EPA has recognized the need to incentivize emerging technologies under its vehicle GHG program. With the proper incentives, PHEVs can rapidly scale up to dramatically reduce GHGs while providing consumer friendly fuel flexibility to adjust low carbon fuel choices to market conditions. For instance, a PHEV FFV allows consumers to maximize the bioethanol blend used in a vehicle or rely more heavily on the vehicle battery, depending on the varying costs and availability of biofuels, electricity, and electric charging infrastructure. [EPA-HQ-OAR-2022-0829-0609, pp. 19-20]

Various technical analyses show that bioethanol flex-fuel paired with hybrid electric technology can reduce lifecycle emissions just as effectively as comparable BEVs.64 At a minimum, PHEVs provide a supplemental means to meeting the Proposed Rule's significant GHG reduction targets. [EPA-HQ-OAR-2022-0829-0609, pp. 19-20]

64 See ePure, New research confirms important role for renewable ethanol in reducing car emissions (September 1, 2022), finding that "plug-in hybrid vehicles running on E85 ethanol blend are at least as climate-friendly as battery electric vehicles," available at https://www.epure.org/press-release/new-research-confirms-important-role-for- renewable-ethanol-in-reducing-car-emissions/. See also, Mueller and

Unnasch, High Octane Low Carbon Fuels: The Bridge to Improve Both Gasoline and Electric Vehicles (March 22, 2021), p. 1, available at https://erc.uic.edu/wp-content/uploads/sites/633/2021/03/UIC-Marginal-EV-HOF-Analysis-DRAFT- 3_22_2021_UPDATE.pdf. Here, this Mueller and Unnasch study found that "High octane fuel vehicles with ethanol provide very similar GHG savings compared to EVs (within 5 gCO2e/MJ of each other) for many states" and "E85 and HOF-plug-in hybrids are the lowest GHG emitting technology as these vehicles are both able to take advantage of the low carbon intensity of ethanol in their combustion engine and the low carbon intensity of the electricity grid in hybrid mode of operation."

The Proposed Rule correctly explains, "PHEVs may help provide a bridge for consumers that may not be ready to adopt a fully electric vehicle."65 The Proposed Rule specifically "requests comment on the types of PHEVs EPA could consider in our analysis for the final rulemaking."66 The same emissions credit for FFVs discussed above (e.g., the 0.15 Volumetric Conversion factor or a comparable incentive based on the real-world lifecycle benefits of bioethanol) could apply to PHEV FFVs for that portion of those hybrid vehicles that operate on bioethanol E85, MLEBs, or other higher-level ethanol blends. [EPA-HQ-OAR-2022-0829-0609, pp. 19-20]

65 See 88 Fed. Reg. at 29298.

66 Id.

EPA also assumes that customers will prefer BEVs over conventional ICE vehicles without sufficient support or much analysis into the many different factors that affect consumer choices apart from just the costs of BEVs compared to conventional ICE vehicles.101 [EPA-HQ-OAR-2022-0829-0609, p. 24]

101 Id. at 8.

EPA's vehicle GHG program is unlike most EPA programs that rely on manufacturers or other industry participants being directly regulated (under command and control regulations) or undertaking certain actions in response to a price imposed on industry. The success of EPA's vehicle GHG program ultimately depends on the willingness of consumers to buy vehicles. The Proposed Rule cites an EPA and national lab study purporting to support EPA's expansive "anticipation" of two-thirds of new car purchasers suddenly going electric, but this report EPA cites also states that the "experiences of current PEV adopters . . . do not fully reveal the mechanisms that will lead to large scale PEV adoption" and "access in the United States" to PEVs is "low in general."102 Similarly, EPA relies on an ICCT modeling regarding projections of consumer demand but that ICCT report states that "it does not account for . . . barriers such as lead time for vehicle manufacturing and charging infrastructure development."103 The ICCT report further states "should battery prices not decline as predicted or consumer acceptance of electric vehicles stalls, our forecasts could be overly optimistic."104 Those reports EPA relies on in the Proposed Rule in fact undermine EPA's overly optimistic projections about BEV adoption in the United States. [EPA-HQ-OAR-2022-0829-0609, p. 24]

102 See 88 Fed. Reg. at 29342, n. 744, citing Jackman et al, Jackman, D K, K S Fujita, H C Yang, and M Taylor. Literature Review of U.S. Consumer Acceptance of New Personally Owned Light Duty Plug-in Electric Vehicles (2023), and pages 52, 54 within that report.

103 See 88 Fed. Reg. at 29346, footnote 761, citing ICCT, "Analyzing the Impact of the Inflation Reduction Act on Electric Vehicle Uptake in the US," and the Executive summary, p. iii, in that ICCT report.

104 ICCT report, supra, at 17.

OnLocation also identifies factual issues that call into question the robustness of EPA's assumptions regarding future EV penetration rates. For instance, EPA's projections of BEV sales are almost nine times higher than those of EIA.122 EPA may also be making overly optimistic assumptions regarding battery manufacturing capacity and domestic lithium production.123 [EPA-HQ-OAR-2022-0829-0609, p. 27]

122 Id. at 2.

123 Id.

Consumer acceptance of BEVs is another important issue related to BEV penetration with or without the Proposed Rule. U.S. EPA discusses consumer acceptance of BEVs at length in Chapter 4.1 of the DRIA and purports to perform a sensitivity analysis of its assumptions in that regard using two cases it labels as "faster BEV acceptance" and "slower BEV acceptance). In describing the faster acceptance case U.S. EPA states (DRIA Chapter 4.1.3): [EPA-HQ-OAR-2022-0829-0609, pp. 60-61]

We acknowledge, however, that a very rapid transition to electric vehicles may be underway as appears to be reflected in the popular media. In a Faster BEV Acceptance case, BEV acceptance could rise very quickly and exceed acceptance of ICE vehicles by orders of magnitude. For sedans and wagons this could mean that within just a few years BEV acceptance will match that of an ICE vehicle. In fact, recent evidence suggest that BEVs may already be preferred all else equal. [EPA-HQ-OAR-2022-0829-0609, pp. 60-61]

In contrast, in describing the slower adoption case U.S. EPA states (DRIA Chapter 4.1.3):

Though we believe it to be very unlikely given the thoroughness of the Central case and evidence of BEV acceptance discussed throughout this chapter, we acknowledge that BEV acceptance may be slower than characterized in the Central case. [EPA-HQ-OAR-2022-0829-0609, pp. 60-61]

And

…acceptance begins to grow less rapidly in the early to mid-2030's, roughly coincident with the expiration of the IRA produce and consumer incentives. [EPA-HQ-OAR-2022-0829-0609, pp. 60-61]

The results of the consumer acceptance "sensitivity analysis" on BEV penetration are presented in Chapter 13 of the DRIA. The results relevant to the proposed standards for the combined light-duty fleet (passenger cars and trucks) are shown in DRIA Tables 13-49, 13-73, 13-110, 13,-111, 13-114, and 13-115. Under the faster acceptance case, MY 2032 incremental vehicle costs drop from $1,164 to $712 and BEV penetration increases from 67 to 75%. Under the slower acceptance case, MY 2032 incremental costs increase from $1,164 to $1,498 and BEV penetration is actually increased from 67% to 68%. Perhaps not surprisingly given the descriptions of the two cases, U.S. EPA's sensitivity analysis concludes that regardless of consumer acceptance of BEVs, BEV penetration, at least in MY 2032 will be equal to or higher than that forecast for the Proposed Rule. A reasonable conclusion is that U.S. EPA has assumed, without proper support, that consumers will prefer BEVs to conventional ICE vehicles and as a result failed to perform a meaningful sensitivity analysis of consumer acceptance. [EPA-HQ-OAR-2022-0829-0609, pp. 60-61]

Organization: RV Industry Association (RVIA)

RVIA strongly opposes EPA's overreaching proposed rule for the reasons discussed below and requests the agency exclude motor homes from having to comply with the proposed medium- duty vehicle standards. [EPA-HQ-OAR-2022-0829-0629, pp. 1-2]

In contradiction to this NPRM, the EPA has already proposed, in the Phase 3 GHG rule (see 88 FR 25996), to establish standards for motor homes that correctly acknowledge the reality that motor homes are not well-suited for electrification. Under the proposed Phase 3 GHG rules, the EPA would establish a CO2 standard of 226 g/mi for MY2027 and later motor homes. As discussed in the Phase 3 GHG NPRM, the agency has proposed this standard given the negative implications of electrifying the motor home chassis. To power a motor home, the batteries would take up space that is otherwise necessary for housing the various elements of a motor home. It would also add significant amounts of weight to the motor home making it no longer capable of being equipped with the components typically found in a motor home. It makes no difference whether a motor home falls under the MD/HD Phase 3 GHG rules or the LD/MD rules, the issues are the same. Standards which can only be met by battery-powered vehicles are not practicable for motor homes. EPA staff who authored the Phase 3 GHG rule have acknowledged this. In establishing standards for medium-duty vehicles within this rule, staff need to be consistent and exclude motor homes from standards that would force them to be electrified. [EPA-HQ-OAR-2022-0829-0629, pp. 1-2]

Motor homes are often operated in locations where there is no electricity. This is known as "boondocking." Frequently, motor homes will be operated for weeks at a time at such locations. When motor homes are operated in a boondocking scenario, there is no possibility of EV charging. Electrification simply does not work for this operating use case. [EPA-HQ-OAR-2022-0829-0629, pp. 1-2]

Unlike medium-duty vehicles that might be conveniently recharged overnight, motor homes are routinely driven 500 miles or more a day making it necessary to fully recharge mid-trip. A multi- hour charging event is simply not something the typical motor home driver would find acceptable. [EPA-HQ-OAR-2022-0829-0629, pp. 1-2]

Motor homes are typically a discretionary purchase by families who tend to be very cost sensitive. Large increases in price for a vehicle that is operated on average only 20 days per year and that travels on average only 4,000 miles will not be viewed favorably by potential buyers. [EPA-HQ-OAR-2022-0829-0629, pp. 1-2]

The ability to recoup higher vehicle costs through refueling savings is minimal given motor homes are driven sparingly by their owners. [EPA-HQ-OAR-2022-0829-0629, pp. 1-2]

If finalized, EPA's rule will severely limit the use and affordability of motor homes. As a result, it will severely hurt motor home manufacturers, dealers, their employees and their families. [EPA-HQ-OAR-2022-0829-0629, pp. 1-2]

Regarding the certification of medium-duty motor homes powered by internal combustion engines, as well as vehicles used to tow RVs, RVIA supports the concerns raised by the Alliance for Automotive Innovation in its comment letter. Such concerns include: [EPA-HQ-OAR-2022-0829-0629, pp. 1-2]

• EPA's proposed rule is neither reasonable nor achievable in the timeframe provided.

• EPA's proposed rule is a de facto battery electric vehicle mandate.

• EPA outstrips Biden administration's own 50 percent light-duty electrification executive order from 2021.

• EPA underestimates battery costs and makes unrealistic battery electric vehicle (BEV) sales assumptions.

• EPA makes no concurrent requirements to support the infrastructure and battery critical minerals for the required EVs or the drivers that must buy them. [EPA-HQ-OAR-2022-0829-0629, pp. 1-2]

Organization: Senator Shelley Moore Capito et al.

Perhaps the most conspicuous flaw that will leap out to the American public is that these proposed actions were taken with complete disregard to consumer choice or affordability. In addition to potentially lacking access to charging at home, work, or public charging stations, consumers looking to purchase a new car may be unable to purchase these vehicles due to the higher purchase price or lack of availability. Today, the average purchase price of EV cars in 2022 was approximately $65,000-which is more than what 46 percent of American households earn in income in a year.8 Adding demand to the grid amid the confluence of other EPA regulations referenced above will drive up the cost of electricity, making powering these vehicles less affordable and undermining the EPA' s claims of savings for consumers that ignore or understate the increase in vehicle and energy prices. Taken together, the erosion of choice and affordability of vehicles will have profound impacts on how American families run errands, get to school, commute to work, and recreate. Additionally, there are serious concerns about the range of electric vehicles and the performance in rural areas of the country, where people may have to drive much longer distances to reach a charger, especially in locations where cold weather can impact the range the vehicle can drive. [EPA-HQ-OAR-2022-0829-5083, p. 3]

Organization: South Coast Air Quality Management District

3. Set a minimum range for ZEVs. ACC II requires a minimum certification range of 200 miles for zero emission vehicles. This is to ensure that new ZEVs will provide useful EV miles to meet the everyday needs of consumers, which will lead to higher acceptance and uses, and greater reductions of emissions from on-road vehicles. This range is also easily achievable with technologies that are currently available. We concur with the need for a minimum range requirement and recommend a similar range limit for the proposed rule. Setting a 200-mile range minimum threshold will prevent manufacturers from producing ZEVs with limited ranges simply for the sake of compliance with State and federal regulations, including the Corporate Average Fuel Economy (CAFÉ) standards. [EPA-HQ-OAR-2022-0829-0659, p. 3]

Organization: South Dakota Department of Agriculture and Natural Resources (DANR)

Electric Vehicle Battery and Range Limitations

South Dakota is a large state with significant driving distance between many of our communities. Although several new electrical vehicles indicate they have a 200 mile or greater range (note - it is 224 miles one way from Pierre to Sioux Falls), a recent study shows electric vehicles (EVs) do not consistently achieve EPA's range estimates. In addition, all batteries degrade over time. Reports indicate EV vehicle batteries will degrade between 10 and 40 percent over a 10-year life span. To maintain the battery's life, manufactures recommend batteries are not frequently depleted below 10 percent capacity or charged above 90 percent capacity. This means that an electrical vehicle should be limited to 80 percent of its capacity range to maintain the battery's life. In addition, cold, hot, and windy weather conditions may reduce an EV vehicle's range between 20 to 40 percent and may further impact the reliability of EV. South Dakota is known to have cold and windy winters and hot and windy summers, which, with current EV ranges, batteries conditions, and availability of charging stations, makes widespread use of EVs impractical in South Dakota. [EPA-HQ-OAR-2022-0829-0523, p. 2]

Cost

EPA acknowledges the cost of an electrical vehicle will be greater than a gasoline powered vehicle but justifies the additional expense by stating the "purchase price could be reduced by any state and federal purchase incentives available to consumers. Under the Inflation Reduction Act, consumers are eligible for up to $7,500 for the purchase of an electric vehicle." DANR disagrees with EPAs efforts to use the proposed emissions standards and incentives to force consumers into purchasing vehicles that may not meet their actual driving needs or budget. In fact, EPA's approach along with the cost of EVs may encourage South Dakota car owners to hold on to their older, less efficient vehicles in perpetuity to avoid purchasing a vehicle that will not meet their driving needs. The proposed rules may also encourage a person to own more than one vehicle to meet their actual needs. [EPA-HQ-OAR-2022-0829-0523, pp. 2-3]

Organization: Specialty Equipment Market Association (SEMA)

Vehicle Choice and Cost for Consumers

The EPA’s multipollutant proposal flies in the face of consumers having the freedom to purchase the vehicles that best suit their personal needs and those of their family. The EPA’s rush to further limit tailpipe emissions in the U.S. will cause great economic harm to many consumers across the country. According to an April 2023 report from Kelley Blue Book, the average cost of a BEV is $58,000, which is over 20% more than the average cost of a non-BEV.8 The average cost of a BEV outpaces the median salary in 2022 in the United States of $54,132 as reported by the Bureau of Labor Statistics.9 In addition to the increased up-front costs to consumers to purchase a BEV, J.D. Power reported that approximately 28 million American homeowners must spend on average an additional $1,300 to install at home chargers, putting additional financial burden on American consumers.10 [EPA-HQ-OAR-2022-0829-0596, pp. 4-5]

Organization: Stellantis

Electrification Rates Misaligned to Market and Exceed Commitments

Stellantis fully supports comments submitted through The Alliance for Automotive Innovation (AAI or the Auto Innovators) detailing the challenges associated with EPA's overly optimistic expectation for EV market growth. Stellantis remains steadfast to delivering on our commitments to achieve an electrified future, and we acknowledge EPA's efforts with this rulemaking to help support this difficult yet critical transition. However, the proposed rule significantly underestimates the actions needed to build the targeted EV market. Addressing concerns such as manufacturing capacity, battery production, charging infrastructure, and consumer acceptance of EVs will be paramount to the success of this ambitious proposed regulation. [EPA-HQ-OAR-2022-0829-0678, pp. 2-3]

Organization: Steven G. Bradbury

EPA's notices of proposed rulemaking (NPRMs) discuss the possibility of alternative adjustments to its proposed emissions limits for different pollutants, but those alternatives fall within a narrow band above and below EPA's proposed levels. They do not encompass any true alternative approaches, and they do not even leave room for automakers to rely on the various different powertrain modalities that consumers have shown a greater willingness to embrace, such as hybrid vehicle technologies and bio-fuel options, to achieve improved environmental performance. [EPA-HQ-OAR-2022-0829-0647, p. 3]

Where does EPA purport to find this authority in the Clean Air Act?

The logic is as follows:

Because most automakers have announced ambitious timetables for transitioning to the production of EVs going forward and have pledged to make large capital investments to finance this gradual switchover,13 and because Congress has recently approved generous federal subsidies for some EV purchases and charging infrastructure,14 EPA says it can now declare that battery-electric vehicle technology is a “feasible” alternative to the tradi- tional internal-combustion engine (ICE) powertrain.15 And on that basis, EPA is proposing to treat EVs as an available “control technology” for achieving compliance with the tailpipe emissions restrictions under Clean Air Act section 202.16 [EPA-HQ-OAR-2022-0829-0647, pp. 6-8]

13 See 88 FR at 29191, Figure 1 (reproducing a chart prepared by the Environmental Defense Fund depicting the automakers’ announced goals for future electrified vehicle sales as a percentage of total sales); id. at 29193-94 (summarizing automakers’ announced plans for investments in EV technology).

14 See id. at 29195-96; Infrastructure Investment and Jobs Act, Public Law 117–58, 135 Stat. 429 (2021), https://www.congress.gov/117/plaws/publ58/PLAW117publ58.pdf; Inflation Reduction Act of 2022, Public Law 117–169, 136 Stat. 1818 (2022), https://www.congress.gov/117/bills/hr5376/BILLS117hr5376enr.pdf.

15 See 88 FR at 29194 (light-duty and medium-duty vehicles); 88 FR at 25972 (heavy-duty trucks).

16 See 88 FR at 29284 (for light-duty and medium-duty vehicles); 88 FR at 26015 (for heavy-duty trucks).

This reasoning obviously depends on a kind of feedback loop. The automakers are pledging to invest in the transition to EVs because governments around the world—like China, the EU, the Biden White House, and Governor Gavin Newsom and his climate regulators in California—are demanding that they do so. But everyone knows there is a large looming impediment to this Green Dream: resistance from American consumers. [EPA-HQ-OAR-2022-0829-0647, pp. 6-8]

The American public is not jumping on the electric bandwagon. EVs are expensive— beyond the reach of many American families—and most Americans remain skeptical that EVs will reliably serve the full range of their needs, that quick and convenient charging stations will be widely available, that EVs will maintain their promised driving range over time or in cold weather, that they will have any significant resale or trade-in value down the road, and that insurance carriers will cover the huge costs of battery replacement when the battery wears out or is damaged in a minor accident.17 [EPA-HQ-OAR-2022-0829-0647, pp. 6-8]

17 See Nick Carey, Paul Lienert, and Sarah McFarlane, “Scratched EV battery? Your insurer may have to junk the whole car,” Reuters, March 20, 2023, https://www.reuters.com/business/autos-transportation/scratched-ev-battery-your-insurer-may-have-junk-whole-car-2023-03-20/ (“For many elec- tric vehicles, there is no way to repair or assess even slightly damaged battery packs after accidents, forcing insurance companies to write off cars with few miles—leading to higher premiums and under-cutting gains from going electric.”).

To push the automakers to convert to EV production in the absence of sufficient mar- ket demand, EPA plans to ratchet down the emissions limits for carbon dioxide and for the traditional criteria and other pollutants associated with smog (such as unburned hydrocar- bons, particulate matter, oxides of nitrogen, and ozone) to super-stringent levels that are technologically impossible for gas-powered vehicles (even hybrids) to satisfy.18 At the same time, EPA is proposing to phase out certain regulatory buffers that allow automakers to report better emissions compliance results, such as “off-cycle credits” for the addition of onboard technologies that improve the fuel efficiency of ICE vehicles.19 [EPA-HQ-OAR-2022-0829-0647, pp. 6-8]

18 See, e.g., 88 FR at 29237-38; id. at 29257-61.

19 See id. at 29249-50.

The automakers' only recourse will be to replace more and more of the ICE vehicles in their fleets (including hybrids) with the "alternative control technology" of battery-electric vehicles. [EPA-HQ-OAR-2022-0829-0647, pp. 6-8]

And here is the trick: For enforcement purposes, EPA applies the emissions limits to each automaker on a fleetwide average basis, and it proposes to reduce these fleetwide averages dramatically each model year from 2027 through 2032 on a ramp rate calculated to achieve the Biden administration's desired percentage mix of EVs in the U.S. auto fleets. [EPA-HQ-OAR-2022-0829-0647, pp. 6-8]

In other words, EPA is now proposing to set fleetwide average tailpipe pollution limits that are intended by design to apply increasingly over time to vehicles that have no tailpipes and that EPA says emit none of the pollutants covered by the regulations.20 [EPA-HQ-OAR-2022-0829-0647, pp. 6-8]

20 Automakers can avoid violating the average emissions limits in certain circumstances with regulatory "credits," earned by producing vehicles, like EVs, that outperform the limits. Under the EPA's rules, credits can be "banked" from one model year to another within limits, "transferred" from one fleet to another (for example, from the automaker's light truck fleet to its passenger car fleet), or "traded" between automakers, which usually involves a privately negotiated purchase. Tesla, which manufactures nothing but EVs and accounts for approximately 70 percent of the U.S. EV market, receives a large portion of its income from selling emissions credits to the other automakers. Predictably, the EPA is proposing to retain this credit system to continue the subsidization of EV manufacturing. See 88 FR at 26245-46.

The 39-40 percent no-action baseline also assumes that American car buyers will suddenly drop their resistance to EVs. In effect, EPA is banking on a near-term future in which market demand for the new fleet of EVs will be just as high as it currently is for the most popular brands of ICE and hybrid vehicles, like the Ford F-150 pickup, the Chevy Silverado pickup, or the Toyota Camry. That assumption is highly suspect: the average price of an EV today is $61,000 (24 percent higher than the average ICE vehicle),30 and EVs come with limitations and question marks that concern many buyers.31 EPA is untroubled; it casually predicts that the price of EVs will fall and buyer demand will rise greatly in the years ahead, assumptions that are critical to EPA's ability to minimize the true cost effects of its proposals. [EPA-HQ-OAR-2022-0829-0647, p. 12]

30 See https://www.kbb.com/car-news/average-new-car-price-tops-49500/.

31 For example, reports suggest that some electric pickups may have a greatly reduced effective range when towing heavy loads—a limitation likely to be of concern to prospective pickup buyers. See https://www.motortrend.com/reviews/ford-f150-lightning-electric-truck-towing-test/.

In the real world of the marketplace, the automakers cannot manage the huge capital costs of EPA's assumed production switchover to battery-electric technology unless con- sumer demand for EVs is strong. Without sufficient market demand, at levels far more robust than currently seen, the effective costs of these rules will be much higher than EPA recognizes and will not be sustainable for the automakers. It is not always true that "if you build it, they will come"—just ask Facebook about the Metaverse. [EPA-HQ-OAR-2022-0829-0647, p. 12]

EPA also undercounts the cost of electricity charging over the life of the EV. EPA relies on a pricing model that claims to show that electricity prices will somehow not rise significantly in a world where EVs comprise more than half of new cars sold in the U.S., but that claim is wholly unrealistic. Even absent high EV penetration, the Bureau of Labor Statistics reports that electricity prices are steadily rising in the U.S.38 Increased EV charging demand will only cause those prices to rise even faster. Driving a single EV 15,000 miles per year and charging it at home could raise the annual electricity bill for the average family by 50 percent or more.39 If the nation converts to EV ownership at the rates EPA is aiming for, such a large increase in overall electricity demand will inevitably cause electricity rates to rise significantly. [EPA-HQ-OAR-2022-0829-0647, pp. 14-15]

38 See generally https://data.bls.gov/pdq/SurveyOutputServlet (allowing user to generate graph showing the rise from 2003 to the present in the average price of electricity in the U.S.).

39 The Energy Information Agency reports that the average American household uses about 886 kilowatt hours of electricity per month, https://www.eia.gov/tools/faqs/faq.php, and the EPA says the average EV consumes 36 kilowatt hours of electricity per every 100 miles driven, https://www.epa.gov/greenvehicles/comparison-your-car-vs-electric-vehicle. If the family's EV is driven 15,000 miles per year, or 1,250 miles per month, it would consume 450 kilowatt hours of electricity every month.

The EPA's glib premise that car buyers in the U.S. will respond with strong demand for the supposed flood of future EVs (notwithstanding the practical concerns, cost consid- erations, and other uncertainties that surround EVs in the minds of American consumers), is typical of the consistently rosy—almost relentlessly rosy—assumptions about cost factors and consequential risks that underlie all parts of EPA's supporting analysis. [EPA-HQ-OAR-2022-0829-0647, pp. 14-15]

EPA fails to consider the negative societal consequences and second-order cost effects of its proposals. [EPA-HQ-OAR-2022-0829-0647, pp. 15-16]

In putting forward regulatory proposals designed to force upon the American people a vast and rapid industrial transformation, EPA has an obligation to go further than just considering the direct cost effects of its proposals (which are themselves woefully under- estimated, as highlighted above); it must also consider the broader indirect economic con- sequences and negative societal costs that would follow if these rules are finalized as pro- posed. So far in these rulemakings, the Agency has either ignored or deliberately down- played these second-order effects. [EPA-HQ-OAR-2022-0829-0647, pp. 15-16]

Some of the most consequential burdens and negative ramifications of the proposed rules that EPA hides, disregards, or minimizes include the following: [EPA-HQ-OAR-2022-0829-0647, pp. 15-16]

• Stifling consumer choice at the dealership. Many of the vehicle models most pop- ular with American families will no longer be sustainable under the EPA's proposed rules. Automobiles have long been America's favorite freedom machines. When the models of ICE vehicles Americans love the most disappear from dealerships, that will represent an enormous drop in consumer welfare (in basic happiness and well- being) for the average American family and for the U.S. economy as a whole. For many of these ICE vehicle models, there is no EV option likely to be available that could provide the same performance, utility, or recreational value at a comparable price (or at all). EPA makes no real effort to quantify this generational loss of consumer welfare. [EPA-HQ-OAR-2022-0829-0647, pp. 15-16]

• Increasing the purchase price of all new vehicles. Notwithstanding EPA's gaming of the numbers, the true costs of the industrial transformation forced by the EPA's proposed rules will be spread across the automakers' fleets, resulting in a significant increase in the prices of all new vehicles, with greater price increases concentrated on those vehicles for which the demand is highest relative to supply. All Americans will be harmed by these price increases, but the biggest losers will be lower-income Americans who cannot afford to buy an EV or to pay more for a gas-powered vehicle at the dealership, as well as those who live in rural areas and need to drive longer distances and for whom EVs are impractical. [EPA-HQ-OAR-2022-0829-0647, pp. 15-16]

• Destroying jobs in the U.S. auto industry. The loss of popular new vehicle options and the significant price increases at the dealership will mean that fewer new vehicles will be purchased—almost certainly far fewer than EPA is predicting. This drop-off in demand will challenge the profitability of the auto industry and lead to a loss of jobs for tens of thousands of America's autoworkers, as well as a loss of jobs in the many U.S. companies that supply inputs for the production of auto- mobiles and heavy trucks.40 The United Auto Workers union has warned of the potential for job losses from the transition to EVs,41 as automakers announce more plant closures and layoffs due to the costs of electrification.42 [EPA-HQ-OAR-2022-0829-0647, pp. 15-16]

40 See Technality, "Ford Just Proved How Far Ahead Tesla Really Is: Profitability May Continue to Be a Struggle for All Legacy Automakers," May 10, 2023, https://medium.com/tech-topics/ford-just-proved-how-far-ahead-tesla-really-is-6a4d95cff519 ("Despite wanting to be a fully-electric brand by 2035, as of Q4 2022, Ford's average net margin on the Mustang Mach-E was -40.4%. Unfortunately, that's a figure that's only gotten worse since, to the point where Ford is now losing an average of $58,000 for every EV sold.").

41 See Press statement, United Auto Workers, "UAW Statement on Job Cuts at Stellantis," April 26, 2023, https://uaw.org/uaw-statement-job-cuts-stellantis.

42 See Michael Wayland, "Stellantis to indefinitely idle Jeep plant, lay off workers to cut costs for EVs," CNBC.com, December 9, 2022, https://www.cnbc.com/2022/12/09/stellantis-to-idle-jeep-plant-lay-off-workers-to-cut-costs-for-evs.html.

• Causing more deaths and serious injuries on America's highways. As new vehicle models become unaffordable or unappealing, many American families will be left driving older and older used cars, and the age of the nation's auto fleet will rise dramatically. Already, the average age of a car on the road in the United States is approaching 13 years, and many cars are on their fifth or sixth owners. The aging of the American fleet has very negative safety consequences, as NHTSA statistics show that older vehicles are much less safe than newer models in an accident.43 [EPA-HQ-OAR-2022-0829-0647, pp. 15-16]

43 See https://www.nhtsa.gov/sites/nhtsa.gov/files/documents/newer-cars-safer-cars_fact-sheet_010320-tag.pdf.

If U.S. consumers do not embrace EVs as quickly and enthusiastically as the EPA assumes they will, or if even one of the EPA's other overly optimistic assumptions comes a cropper, the consequences of these rules will be catastrophic—for America's industrial base, our nation's workforce, and the safety and wellbeing of Americans, particularly medium- and lower-income Americans. [EPA-HQ-OAR-2022-0829-0647, p. 21]

Organization: Strong Plug-in Hybrid Electric Vehicle (PHEV)

Also, we think that willingness to pay is the correct question to ask regarding PHEV cost. As long as there is consumer demand, some car and truck makers will target this market. That consumers pay very high prices for luxury vehicles today illustrates this point. A Strong PHEV especially offers many compelling benefits to consumers even if they are priced higher than a BEV. [EPA-HQ-OAR-2022-0829-0646, p. 22]

The experience of the last fifteen years has shown that many residential and commercial users of vehicles will first adopt a PHEV instead of a BEV. In addition, we believe that long range PHEVs are a no-regrets solution for EPA to encourage in the long term. In other words, uncertainty in speed of adoption of battery EVs and fuel cell EVs, especially by fast followers and late adopters, requires agencies such as EPA to be fuel and technology neutral in their regulations. Including in the rule additional alternatives such as Strong PHEVs results in a faster path to a net zero carbon future.25 [EPA-HQ-OAR-2022-0829-0646, p. 25]

25 Bistline, J.E.T., Blanford, G., Grant, J., Knipping, E., McCollum, D. L., Nopmongcol, H.S., Shah, T., and Yarwood, G. (2022). Economy-wide evaluation of CO2 and air quality impacts of electrification in the United States. Nature communications, 13, 6693, https://doi.org/10.1038/s41467-022-33902-9

Strong PHEVs provide the flexibility that is key to convincing the hard-to-convince individuals and fleets to adopt advanced technology. Many consumers for political or personal reasons are very skeptical about BEVs and FCEVs, but we have found that Strong PHEVs appeal to them. [EPA-HQ-OAR-2022-0829-0646, p. 28]

Organization: The Heritage Foundation (Kevin Dayaratna and Diana Furchtgott-Roth)

Almost three-quarters of vehicles sold are previously owned cars.7 In 2022, the last year for which complete data on used car sales are available, Americans bought 36 million used cars8 and 14 million new cars.9 But people do not want to buy used electric vehicles, because it is difficult to evaluate how long the battery will last. Replacing an EV battery can cost anywhere from $5,000 to $20,000.10 The poor and middle class will suffer most from higher prices for used vehicles, because they cannot afford the new electric vehicles. EPA has not fully discussed the effects on the used car market. [EPA-HQ-OAR-2022-0829-0674, p. 3]

10 Recurrent, "Updated: Electric Car Battery Replacement Costs," March 26, 2023, https://www.recurrentauto.com/research/costs-ev-battery-replacement (accessed April 28, 2023).

Battery-powered vehicles lack sufficient range to satisfy some customers. Although 60 to 70 miles of range is enough for most trips, people buy cars for all circumstances, including vacations and cold weather. Moreover, batteries lose up to 40% of their range in cold climates.13

A study by Autocar14 shows that electric vehicles lose, on average, a third of their range in the winter, which reduces the typical 240-mile range to 160 miles. If a heat pump is added to the car, the loss is less, but still the 240-mile range would shrink to 180. The effects of the cold are not sufficiently accounted for by EPA. [EPA-HQ-OAR-2022-0829-0674, p. 4]

13 Ellen Edmonds, "Icy Temperatures Cut Electric Vehicle Range Nearly in Half," AAA News Room, February 7, 2019, https://newsroom.aaa.com/2019/02/cold-weather-reduces-electric-vehicle-range/ (accessed April 28, 2023).

14 Move Electric, "Electric Vehicle Range Test Reveals Up to 20% Drop in Winter," Autocar, March 17, 2022, https://www.autocar.co.uk/car-news/move-electric/electric-vehicle-range-test-reveals-20-drop-winter (accessed April 28, 2023).

Car results varied. The Fiat 500 42kWh Icon lost 40% of its range in the winter.15 The Ford Mustang Mach-E Extended Range RWD lost 35%, and the Porsche Taycan 4S Performance Battery Plus, with heat pump, lost 22% (the Taycan costs between $83,000 and $166,000).16 The loss of range in cold weather is one reason why, at the end of 2021, the latest full year available, North Dakota had 380 electric vehicle (EV) registrations, the fewest in the United States, according to the Energy Department.17 [EPA-HQ-OAR-2022-0829-0674, p. 4]

In addition, if people choose not to buy the mandated electric vehicles, carmakers will have to reduce their prices and raise prices of popular pickup trucks and SUVs to stay profitable.27 Lower-income and Americans in rural areas will be paying more for their preferred vehicles, subsidizing better-off residents in cities and California, who are the main purchasers of electric vehicles. EPA does not account for this. [EPA-HQ-OAR-2022-0829-0674, p. 6]

Organization: Transfer Flow, Inc

Consumers are more likely to adopt near-zero technologies if given a menu of near-zero emission technologies to choose from. [EPA-HQ-OAR-2022-0829-0496, pp. 3-5]

Many consumers disapprove of the government dictating which near-zero technologies they're allowed to utilize. Unfortunately, the EPA has not provided for a battery directive such as the UN has required setting sustainability requirements for batteries placed on the market, including responsible sourcing of raw materials, hazardous substances, carbon footprint, and measures to improve the collection, treatment, and recycling of these waste batteries ensuring materials recovery. Many concerned citizens do not support the human rights violations associated with mining cobalt, lithium, and other minerals required for battery manufacturing. [EPA-HQ-OAR-2022-0829-0496, pp. 3-5]

A major concern for consumers is how they would charge an electric vehicle. For citizens living in apartment buildings or utilizing on-street parking, managing an electric vehicle would be inconvenient and challenging. The image below from Deloitte's 2022 Global Automotive Consumer Study17 illustrates consumer powertrain preferences for their next vehicle, which are not aligned with the EPA's proposed Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles. [EPA-HQ-OAR-2022-0829-0496, pp. 3-5]

17 https://www2.deloitte.com/content/dam/Deloitte/global/Documents/Consumer-Business/us-2022-global-automotive-consumer-study-global-focus-final.pdf

[See original attachment for "Consumer powertrain preferences for their next vehicle"] [EPA-HQ-OAR-2022-0829-0496, pp. 3-5]

Electric Vehicles require the ramp-up of many new electricity-generating power plants to provide enough power to charge all the projected electric vehicles, and then those electricity-generating power plants must rely heavily on carbon capture technologies to keep the emissions from these electricity-generating power plants out of the atmosphere. Current carbon capture technologies are experimental and may prove dangerous.22 [EPA-HQ-OAR-2022-0829-0496, pp. 3-5]

22 https://www.huffpost.com/entry/gassing-satartia-mississippi-co2-pipeline_n_60ddea9fe4b0ddef8b0ddc8f

In many places, such as rural environments or for use in utility vehicles, electric vehicles are not a practical solution. Utility companies working on phone lines, power lines, and performing construction work all need reliable power sources that can be used for transporting people and powering equipment, as well as function when the electric power grid may be in need of repair. Electric vehicles do not have a network in remote areas or the energy density to effectively transport and power auxiliary equipment needed to, among other functions, install or perform repairs to electric power lines. [EPA-HQ-OAR-2022-0829-0496, pp. 3-5]

Pacific Gas and Electric (PG&E), two years after the historical Dixie Fire, is still powering affected Californians with diesel-powered generators as the infrastructure required to bring electricity into homes has still not been rebuilt. Citizens living in these affected areas would need to charge electric vehicles using electricity created from diesel generators, and the logistics of that simply do not make sense. [EPA-HQ-OAR-2022-0829-0496, pp. 3-5]

For a myriad of reasons, people may be hesitant to adopt electric vehicle technology. Near-zero technologies are going to be more agreeably adopted if consumers feel they have a choice of which near-zero technology works best for them. In Northern California, many citizens affected by various wildfires still harbor animosity towards PG&E for negligently causing various wildfires that have ruined thousands of people's lives. In 2020 PG&E pled guilty to 84 counts of manslaughter for starting the historically devastating Camp Fire.23 Many citizens affected by these wildfires don't want electric vehicles because they don't believe they can trust PG&E. Not encouraging a choice of which near-zero technology consumers choose to implement runs the risk of having the opposite intended effect. Consumers will likely choose to hold on to their old, dirtier vehicles, defeating the intended purpose. [EPA-HQ-OAR-2022-0829-0496, pp. 3-5]

23 https://www.nytimes.com/2020/06/16/business/energy-environment/pge-camp-fire-california-wildfires.html

Organization: Valero Energy Corporation

Further, EPA does not consider the impact of charger performance and consumer experience on consumer acceptance of electric vehicles. A report by the National Renewable Energy Laboratory (NREL) on electric vehicle charging infrastructure development notes that “This analysis envisions a future national charging network that is strategic in locating the right amount of charging, in the right locations, with appropriate charging speeds. However, this vision is irrelevant if the public concludes that charging infrastructure is ultimately unreliable. Even if a relatively small amount of infrastructure fails drivers, this could negatively impact the public’s perception of electric mobility.”153 There is good reason for NREL to raise this concern. A national survey of 26,500 charging attempts at Level 2 and Level 3 public stations found that 20% failed to obtain a charge.154 Common reasons for failure included software glitches, payment processing errors, and vandalism. In 75% of the failures, the charger was out of service. [EPA-HQ-OAR-2022-0829-0707, p. 31]

Footnoet 153: Id.

154 Hannah Lutz, “Negative Charge: One in Five Charging Attempts Failed in 2022, JD Power Data Shows,” Automotive News, February 13, 2023.

This type of consumer frustration may cause drivers who initially purchase electric vehicles to return to ICE vehicles, a phenomenon known as “discontinuance.” For example, a 2021 UC Davis study found that approximately 20% of California drivers who bought a BEV between 2023 and 2018 replaced that vehicle with an ICE vehicle. Seventy percent of those drivers cited lack of access to charging infrastructure as a basis for their decision.155 [EPA-HQ-OAR-2022-0829-0707, p. 31]

155 Hardmand, S., Tal, G.”Understanding discontinuance among California’s electric vehicle owners.” Nature Energy 6, 538-545 (2021). https://doi.org/10.1038/s41560-021-00814-9

Despite these indications that both the availability and the performance of charging stations may be a significant impact on consumers’ willingness to purchase or to keep EVs, EPA does not consider the limitations of charging infrastructure in determining that the proposed rule is feasible. [EPA-HQ-OAR-2022-0829-0707, p. 31]

I. EPA fails to adequately consider the environmental justice impacts of the proposed rule.

Disadvantaged communities already face significant access barriers to electric vehicles, such as: higher upfront costs to electric vehicle ownership; a lack of existing charging infrastructure available to them in low-income, minority populated, and rural areas; and costlier and time-intensive charging due to a greater reliance on public charging infrastructure, particularly for individuals living in multi-family housing. [EPA-HQ-OAR-2022-0829-0707, p. 55]

EPA’s EJ analysis must be thorough and inclusive of factors that may impact the price of transported goods, such as ZEV affordability, the availability of public charging, reasonable charging practices, and a lifecycle analysis of electric vehicles and power generation emissions. Without doing so, EPA runs the risk of intensifying price disparities and access to transport relative to the baseline for EJ communities. EPA’s EJ analysis must be thorough and inclusive of electric vehicle affordability, the availability of public charging, reasonable charging practices, and a lifecycle analysis of electric vehicles and power generation emissions. Without doing so, EPA runs the risk of intensifying price disparities and access to transport relative to the baseline for EJ communities. These impacts can be both quantitatively and qualitatively characterized.300 EPA's silence on these disparities is especially worrisome given EPA's prior binding commitments to EJ analysis for the benefit of disadvantaged and low-income communities. [EPA-HQ-OAR-2022-0829-0707, p. 55]

300 See, i.e., supra.

To date, the target electric vehicle customer base for OEMs consists of "mostly male, high-income, highly educated, homeowners, who have multiple vehicles in their household and have access to charging at home."301 Additionally, according to the U.S. Department of Transportation (DOT), "the rate of EV adoption in rural areas is roughly 40% lower than it is in urban areas, and EV charging infrastructure expansion has mostly been concentrated in cities and along major highways".302As a result, electric vehicle ownership remains primarily concentrated in affluent, large metropolitan and urban areas.303 By contrast, the supporting electricity generation necessary to support EPA's proposal is predominantly located in more remote, rural regions that are geographically isolated from urban centers. [EPA-HQ-OAR-2022-0829-0707, pp. 55-56]

301 Scott Hardman*, Kelly L. Fleming, Eesha Khare, and Mahmoud M. Ramadan, A perspective on equity in the transition to electric vehicles, MIT SCIENCE POLICY REVIEW (Aug. 30, 2021) available at https://sciencepolicyreview.org/2021/08/equity-transition-electric-vehicles/.

302 U.S. Department of Transportation, Community Benefits of Rural Vehicle Electrification (last updated February 2, 2022), available at https://www.transportation.gov/rural/ev/toolkit/ev-benefits-and-challenges/community- benefits.

303 See, i.e., Shuocheng Guo, Eleftheria Kontou, Disparities and equity issues in electric vehicles rebate allocation, Energy Policy, Volume 154, 2021, 112291, ISSN 0301-4215, available at https://doi.org/10.1016/j.enpol.2021.112291.

EPA's proposal directly impacts EJ communities by contributing to additional, local emissions to meet electric vehicle charging demand. Consequently, in theory, EJ communities incur an incremental burden in exchange for the subsidization of electric vehicles for more affluent consumers. And this subsidy occurs at expense of our most vulnerable communities burdened by emissions as a direct result of the proposal, with no corresponding benefit, since electric vehicles are likely to remain concentrated in affluent areas. Further, these communities remain unable to afford EPA's chosen mode of transport and are particularly vulnerable to rising electricity costs. [EPA-HQ-OAR-2022-0829-0707, pp. 55-56]

Notwithstanding EPA's hope that its proposal may serve to incentivize the purchases of electric vehicles, these vehicles are significantly more expensive on average than their ICE vehicle counterparts and unaffordable for many households. These are costs are also likely understated as each electric vehicle already enjoys thousands of dollars' worth of Federal and state subsidies, which are ultimately funded by taxpayers. Additionally, an automakers' ability to sell electric vehicles to consumers depends on substantial price subsidies in the form of credit support. EPA ignores the reality that many EJ stakeholders are currently unable to afford the upfront costs of purchasing an electric vehicle in the first place. With the cost of transition minerals expected to escalate exponentially in the coming years as a function of limited supply and increasing demand, the costs to manufacture and purchase electric vehicles will likely rise. [EPA-HQ-OAR-2022-0829-0707, p. 56]

EPA should also consider the effects of the proposal on electricity prices, as low-income populations often spend a larger percentage of their earnings on essential utilities compared to the rest of the United States. Reliance on electric vehicles has been shown to spur increases in load and demand during peak periods, which impact electricity prices. Because EPA lacks expertise in the area of electrical grid management and economics, EPA should consult with other agencies and credible experts in these areas in order to adequately evaluate these impacts.304 EPA should ensure that the proposal meets reliability and affordability criteria and helps EJ communities make informed decisions about their own energy needs. Additionally, EPA's EJ assessment fails to acknowledge the likelihood that many owners will lack access to residential charging, which will substantially increase their operating expenses. Consistent reliance on fast charging also shortens electric vehicle battery life, resulting in a need to replace the battery and/or the vehicle more frequently. [EPA-HQ-OAR-2022-0829-0707, pp. 56-57]

304 See, West Virginia, 142 S.Ct. at 2612-13 (stating that EPA admitted that opining on trends in electricity transmission, distribution, and storage requires technical and policy expertise not traditionally needed in EPA regulatory development and finding that there is little reason to think Congress assigned such decisions to the EPA).

If EJ is truly a commitment for EPA, it should carefully consider criticisms like those leveled by The Two Hundred, which point out the disproportionate impacts to working and minority communities as a result of California's climate approach regarding electrified transport; those impacts and concerns remain true, and indeed are magnified under the proposed standards.305 [EPA-HQ-OAR-2022-0829-0707, pp. 56-57]

305 See Plaintiffs' Complaint, The Two Hundred for Homeownership, et al. v. California Air Resources Board, et al., No. 1:22-CV-01474.

It is critical from the outset to design standards to minimize the potential for price shocks and supply disruptions. As written, the proposal ultimately benefits electric vehicle manufacturers at the expense of disadvantaged communities by subsidizing unaffordable transportation that is not fit for the purposes of commuting to and from EJ communities. At minimum, EPA should perform a thorough EJ assessment specific to its LDV proposal that is comprehensive of both transport challenges and impacts faced by EJ stakeholders and the government-wide Justice40 Initiative. [EPA-HQ-OAR-2022-0829-0707, pp. 56-57]

The average purchase price of EV cars in 2022 was approximately $65,000, which is more than what 46 percent of American households earn in income in a year.306 While the average "used" EV sold for $42,895 in March of 2023.307 While EPA's DRIA anecdotally indicates that "emerging consensus suggests that purchase price parity is likely to occur by the mid-2020's for some vehicle segments and models"308, Ford CEO Jim Farley told attendees at its 2023 Capital Markets Days that EV cost parity may not come until after 2030.309 Moreover US auto makers are focusing their efforts on producing higher priced electric SUVs and trucks, including Fords $100,000 F150 Lightening Platinum310 and GM's announcement that its luxury brands, Cadillac and Buick, will be its first all-electric product lineups.311 While smaller EV's like the Chevy Bolt, touted by the Biden Administration as being affordable alternatives, are being discontinued.312 The reality is that most middle- and lower-income families simply cannot afford to purchase a new or used EV, even when taking into account available tax incentives and rebates. In fact, middle – and lower -income families are more likely to purchase older used vehicle, due to their lower upfront costs, and to hold onto those vehicles for longer periods.313 [EPA-HQ-OAR-2022-0829-0707, pp. 56-57]

Organization: Volvo Car Corporation (VCC) (DONE)

In addition, it is also uncertain how complimentary US policies (infrastructure, utility capacity, consumer incentives etc.) could impact consumer demand. [EPA-HQ-OAR-2022-0829-0624, p. 2]

Organization: Western Energy Alliance (DONE in readiness memo and in advantages and disadvantages)

Technical Infeasibility and Impracticalities for Consumers: EPA uses flawed analysis about the technical feasibility of the rule, but the behavior aspects are also seriously deficient. There is little evidence that EVs are being accepted by consumers other than a small niche of high-end, wealthy individuals who can afford to purchase an expensive vehicle with limited range.11 Given the long refueling times and battery drain when operating the heater or air conditioning, only those who can afford a second or third vehicle for exclusive use in-town are currently purchasing EVs. There has been no evidence to date that these problems of limited range and functionality will be overcome soon to achieve the high market penetration EPA hopes with this rule. [EPA-HQ-OAR-2022-0829-0679, p. 6]

11 The Energy Information Administration (EIA) shows that 2/3 of households with EVs have incomes over $100,000. Electrified vehicles continue to see slow growth and less use than conventional vehicles, EIA, May 2018

EPA's assertion is simply not supported by facts:

"The year-over-year growth in U.S. PEV sales suggests that an increasing share of new vehicle buyers are concluding that a PEV is the best vehicle to meet their needs. Many of the zero-emission vehicles already on the market today cost less to operate than ICE vehicles, offer improved performance and handling, have a driving range similar to that of ICE vehicles, and can be charged at a growing network of public chargers as well as at home." (p. 29189) [EPA-HQ-OAR-2022-0829-0679, p. 6]

At only 5.8% of new vehicle sales, EVs has a long way to go to meet the targets EPA is setting of 67%, a more than ten-fold increase that is a far goal from the "increasing share of new vehicle buyers…" Further, asserting that the range is similar to an ICEV is preposterous, especially in anything less than the most favorable mild weather conditions, as EVs lose range in cold and hot weather.12 [EPA-HQ-OAR-2022-0829-0679, p. 6]

12 Winter & Cold Weather EV Range Loss in 7,000 Cars, Recurrent, December 12, 2022.

Organization: Wisconsin Automobile and Truck Dealers Association

The EPA also cites trends showing an increased demand for the EV product. What the EPA does not recognize is huge increases in trends are easy to show when the starting point is single digit percentages. The EPA does not recognize that many families show interest in adding an EV to their household, not forsaking ICE vehicles all together. Consumers recognize that the network will take over a decade to build out. The desired and necessary ranges and convenience can currently only be met by ICE vehicles. Yet the EPA is comfortable in driving the price of both ICE and EV technology to the point of completely unaffordable. The Midwest consumer will be forced to drive their ICE vehicle beyond the average of 12 years, and/or purchase an EV that will not be able to keep their family warm in the winter, achieve the necessary range in the winter, and overwhelm an electrical grid that Northern Wisconsin will not be able upgrade due to numerous reasons. [EPA-HQ-OAR-2022-0829-0494, pp. 1-2]

Organization: Zero Emission Transportation Association (ZETA)

2. There is Strong Consumer Demand for EVs

American consumers are quickly becoming accustomed to EVs, and demand is rising rapidly as EVs become more ubiquitous. From 2020 to 2022, Consumer Reports found there was a 350% increase in consumer demand for EVs.5 A similar ZETA poll found that 71% of Americans are considering an electric vehicle for their next car.6 The best-selling vehicle worldwide in the first quarter of 2023 was Tesla’s Model Y, an all-electric SUV.7 In the U.S., Tesla's Model 3 was ranked 10th for overall vehicle sales, and the Model Y came in 4th–behind the top-3 vehicles which were all pickup trucks.8 [EPA-HQ-OAR-2022-0829-0638, p. 6]

7 “Tesla Model Y Was The World's Best-Selling Car In Q1 2023,” Motor1, (May 25, 2023) accessed June 18, 2023 https://www.motor1.com/news/669135/tesla-model-y-worlds-best-selling-car-q1-2023/

8 “The 25 Bestselling Cars, Trucks, and SUVs of 2023 (So Far),” Car and Driver, (April 10, 2023) https://www.caranddriver.com/news/g43553191/bestselling-cars-2023/

This strong interest in EVs is expected to continue to grow throughout 2023, with more than two million EVs sold in the first quarter of this year. IEA expects more than 14 million EVs will be sold globally this year, which would comprise 18% of total passenger vehicle sales.9 In fact, demand for EVs is expected to exceed supply at the current trajectory. Consumer Reports found there are 45 buyers for every EV produced.10 Today, EV demand is driven by factors that include cost-savings, environmental protection, increasing model availability, and the ability of an EV to meet a driver’s day-to-day needs. The adoption of more stringent emissions standards would incentivize the production of more EVs to meet growing consumer demand while also spurring innovation and increased model availability to meet the needs of an increasingly wider range of consumers. [EPA-HQ-OAR-2022-0829-0638, p. 6]

10 Id. at footnote 5

a. Consumers Prefer to Drive EVs

One of the easiest ways to convert drivers to an EV is to get them behind the wheel of one. EVs have faster acceleration, are a quieter ride, and have a low center of gravity making for a safer and more enjoyable drive.11 As a result, performance is the most frequently cited reason (75%) among drivers who switched to a premium EV. 12 According to J.D. Power, the Rivian R1T ranks highest overall among premium EVs, with a satisfaction score of 794 out of 1,000-points. In particular, owners are pleased with the R1T’s driving performance and style.13 [EPA-HQ-OAR-2022-0829-0638, pp. 6-7]

13 Id. at footnote 12

A study by AAA found that once drivers own an EV, their previously held concerns (e.g., range anxiety, cost, lack of charging) largely disappear. For example, 77% said they had little to no range anxiety after owning an EV.14 This underscores that many of the commonly-cited barriers to EV adoption can be addressed through experience and education. [EPA-HQ-OAR-2022-0829-0638, pp. 6-7]

14 “Owning an Electric Vehicle is the Cure for Most Consumer Concerns,” AAA Newsroom, (January 22, 2020) https://newsroom.aaa.com/2020/01/aaa-owning-an-electric-vehicle-is-the-cure-for-most-consumer-concerns/

In addition to vehicle owners who purchase an EV for personal use, there are a growing number of rideshare operators purchasing or renting EVs. These drivers travel significantly more miles than a typical American, which is on average 40 miles a day.15 Additionally, they have expressed satisfaction with the EV driving experience. Because of the greater distance traveled, rideshare drivers stand to see the greatest fuel and maintenance cost savings. In fact, cost savings were the number one reason ride-share drivers adopted an EV. Not only have EV drivers seen higher earnings, but 94% of drivers have reported a positive experience with their EV,16 and up to 93% of them would choose an EV as their next vehicle according to a survey of Uber drivers.17 Among drivers who do not currently use an EV, more than 60% would switch to an EV.18 [EPA-HQ-OAR-2022-0829-0638, pp. 6-7]

18 Id. at footnote 17

Many consumers prefer to purchase American-made products and vehicles are no exception. Fortunately, some of the top-selling EVs are made in America. In fact, the top two vehicles on Cars.com American Made Index are the Tesla Model Y and Model 3, with the Model X and Model S coming in 5th and 6th place, respectively.19 With increasing domestic production requirements tied to the EV tax credit in the IRA, more EVs will be manufactured in America. Automakers have already announced new EV factories across the country, with new models such as the Rivian R1T, Lucid Air, Ford’s F-150 Lightning, Polestar 3, and Volkswagen ID.4 being produced in the U.S. [EPA-HQ-OAR-2022-0829-0638, pp. 7-8]

19 “2023 Cars.com American-Made Index: Which Cars Are the Most American?,” Cars.com, (June 21, 2023) https://www.cars.com/articles/2023-cars-com-american-made-index-which-cars-are-the-most-american-467465/

Another reason the EV market is growing is simply because consumers prefer the new features and technology in EVs. An article published in June 2023 from Inside Climate News indicated that while some people buy an EV on principle, the rapid rise in sales is poised to continue because consumers like the features that EVs offer.20 This includes features such as longer battery ranges, faster acceleration, lower total cost of ownership, and that EVs have a higher ride quality than comparable ICEV. As more features are added and technology of EVs improves, more consumers are likely to switch just based on those facts, independent of the environmental or climate change incentive to do so. This indicates that the EV market is broadening to a wider consumer base, which further amplifies the trend of greater adoption among consumers that the market is currently experiencing. [EPA-HQ-OAR-2022-0829-0638, pp. 7-8]

20 “It’s the Features, Stupid: EV Market Share Is Growing Because the Vehicles Keep Getting Better,” Inside Climate News, (June 8, 2023) https://insideclimatenews.org/news/08062023/inside-clean-energy-electric-vehicle-market-features/

b. EV Sales are Increasing

Consumer demand for EVs has grown exponentially over the last few years and so too have EV sales. Global passenger EV sales jumped from 1 million in 2017 to over 10 million in 2022. In the first half of the decade, it took the same amount of time for sales to grow from 100,000 to 1 million.27 This is because Consumer demand is increasing, and will continue to do so as more and more models for all different use cases are offered. [EPA-HQ-OAR-2022-0829-0638, p. 9]

27 “Global EV Outlook 2023: Trends in electric light-duty vehicles,” IEA, (2023) https://www.iea.org/reports/global-ev-outlook-2023/trends-in-electric-light-duty-vehicles

In California, EVs comprised more than 21% of new car sales in the first quarter of 2023.28 Much of the growth in the electric vehicle stock has occurred over the last few years, with nearly 10% of all EVs sold in the U.S. occurring in the first quarter of 2023. The U.S. is on pace to sell over 1 million EVs this year.29 The more than 300,000 EVs sold in Q1 is nearly equivalent to the total number sold in the entirety of 2020. Figure 1 depicts the exponential growth in EV sales since 2011. [EPA-HQ-OAR-2022-0829-0638, p. 9]

28 “Record-Shattering EV Sales Continue in Q1 2023 as California Reaches the 1.5 Million EVs Sold Milestone Two Years Ahead of Schedule,” Veloz, (April 21, 2023) https://www.veloz.org/record-shattering-ev-sales-continue-california-reaches-1-5-million-evs-sold/

29 “Chart: EV sales on pace to break 1 million in US this year,” Canary Media, (April 21, 2023) https://www.canarymedia.com/articles/electric-vehicles/chart-ev-sales-on-pace-to-break-1-million-in-us-this-year

[See original comment for Figure 1: EV Sales in California and the U.S. as of April 2023] [EPA-HQ-OAR-2022-0829-0638, p. 9]

30 Id. at footnote 28

c. State Consumer Incentive Programs are Well-Utilized

In the United States, clear evidence exists that consumer incentives drive EV sales. The states with the greatest number of EV registration per thousand people were California, Hawaii, Washington, Oregon, Vermont, and Colorado.31 These states all have relatively generous state and local subsidies in addition to available federal subsidies. However, the surge in EV demand and uptick in applications for state rebates and incentives is leading several states to actually halt their programs due to overwhelming demand. It is evident that consumers are increasingly choosing an EV for their next vehicle, and policy development must keep pace. [EPA-HQ-OAR-2022-0829-0638, pp. 10-11]

31 “These 7 US states lead the nation in EV registrations,” Green Car Reports, (March 12, 2023) https://www.greencarreports.com/news/1138974_these-7-us-states-lead-the-nation-in-ev-registrations

New Jersey

Rebate programs like “Charge Up New Jersey” have contributed to the significant growth in EV sales in the Garden State. In May 2020, New Jersey began to offer a $5,000 rebate for EV purchases. Since then, annual EV sales increased by over 40% in 2020 from 2019, which was the highest growth rate in the nation.32 Over that period, Charge Up New Jersey has dispersed funding for more than 25,000 new EVs in the state. In total, there are more than 91,000 EVs on the roads of New Jersey.33 [EPA-HQ-OAR-2022-0829-0638, pp. 10-11]

32 “Annual Enacted EV Policies More Than Double Between 2015 and 2020,” Atlas EV Hub, (May 7, 2021) https://www.atlasevhub.com/data_story/annual-enacted-ev-policies-more-than-double-between-2015-and-2020/

33 “New Jersey halts electric vehicle rebates; demand too high,” Associated Press, (April 18, 2023) https://apnews.com/article/new-jersey-electric-vehicle-rebate-02c6965ef22f23ffc88fcc4f68857955

However, the program well exceeded expectations and the program was paused three months earlier than planned as it had already exceeded its $35 million annual budget after providing rebates to more than 10,000 New Jerseyans who qualified that year.34 [EPA-HQ-OAR-2022-0829-0638, pp. 10-11]

34 Id. at footnote 33

Oregon

A similar situation occurred in Oregon, as they paused the Oregon Clean Vehicle Rebate program in May of 2023. It surpassed its $15.5 million budget as the program became more popular than anticipated.35 Unless additional funding is provided by the state, the program will not be restarted until the next fiscal year begins March 2024. [EPA-HQ-OAR-2022-0829-0638, pp. 10-11]

35 "Oregon to temporarily suspend popular EV rebate program," OPB, (March 15, 2023) https://www.opb.org/article/2023/03/15/oregon-ev-rebate-program-electric-vehicles-environment-greenhouse-gas-e missions

Next year, the estimated program costs are over $33 million, more than doubling this year's budget.36 While the pause on the credit might be disappointing for EV purchasers in the state, it is a positive sign that EV adoption is growing and federal, state, and local policies need to adopt accordingly. [EPA-HQ-OAR-2022-0829-0638, pp. 10-11]

36 Id. at footnote 35

California

California leads the U.S. in EV sales with over 1 million full BEV registrations as of April 2023– making up 40% of the total US EV fleet. In the first quarter of 2023, EVs comprised 21.1% of all vehicle sales in the state.37 [EPA-HQ-OAR-2022-0829-0638, p. 11]

37 "New ZEV Sales in California," California Energy Commission, accessed June 28, 2023 https://www.energy.ca.gov/data-reports/energy-almanac/zero-emission-vehicle-and-infrastructure-statistics/new-zev- sales

California's success in EV market share is partially due to their Clean Vehicle Rebate Project (CVRP), the first state incentive for EV purchasers. Since 2010, the program has provided more than 500,000 rebates.38 To cut costs, the program was modified to target more lower-income residents by setting income and MSRP caps. This was because the program was oversubscribed, with demand far exceeding the program's budget. Every year, CVRP's funding runs out, with a lengthy waitlist for when more funding becomes available.39 As of June 2023, there was more than $275 million in funding available for the CVRP program.40 [EPA-HQ-OAR-2022-0829-0638, p. 11]

e. EV Production and New Model Availability

EVs are now available in all light- and medium-duty classes, with many presenting owners with a favorable total cost of ownership today. That should be expected to further improve over the MY 2027-2032 time frame covered by these proposed emissions standards and continued innovation by industry will only increase product offerings and vehicle capabilities in the coming years. [EPA-HQ-OAR-2022-0829-0638, p. 70]

While EV manufacturing investments in the U.S. have been ramping up over the past decade, the passage of the BIL and IRA have supercharged investment. Before the passage of these bills, several automakers had already committed to electrify large portions or all of their vehicle offerings. These targets were in recognition of the need to meet environmental goals and a result of the market's movement towards EVs. As EPA notes in the proposed rule, several major automakers set ambitious goals for a 100% electrified fleet. To meet these targets, they have significantly expanded their EV model offerings alongside manufacturing capability. [EPA-HQ-OAR-2022-0829-0638, p. 70]

EPA Summary and Response

Many individuals and institutions spoke to the issues related to demand,[472] including consumer preferences and attitudes, purchase decision, and sales. The following, very general logical sequence applies to these comments. Many factors underpin preferences and attitudes. Preferences and attitudes drive the desire to consider and purchase a particular vehicle or set of vehicles. A purchase of a desired vehicle, or equivalently a sale, takes place if the desired vehicle is available and best matches a consumer's criteria. Comments also vary from general to specific. Some are descriptive and, when substantiated, are derived from survey results, sales statistics, sales projections, or some combination thereof. Some leverage assumed or demonstrated causal relationships (i.e., factors underpinning preferences and attitudes, purchase decision, and sales). We organize our responses to the content of these comments from general to specific, and as a consequence, address sales and market share and projections followed by survey-based comments and assertions about causal relationships.

Before we proceed with our response to demand-related comments, we make three overarching observations. First, as in RTC Chapter 13.1, we note that the vast majority of comments regarding demand relate to light-duty BEVs and PHEVs. A smaller number of demand-related comments address ICE and hybrid vehicles and medium-duty vehicles. This distribution of comments will be evident in the summary and response.

Second, public relations (PR) announcements, news media, and surveys (sometimes referred to as "stated preference"), sales and registration statistics which are direct measures of behavior (sometime referred to as "revealed preference"), and sales projections (often achieved through modeling of some sort) are all generally accepted forms of information or methods that inform this rulemaking. Each has well known advantages and disadvantages. Commenters have tended to focus on disadvantages. For example, people and organizations do not always behave in ways that are consistent with what they say. Historical sales and registration data for PEV adopters has been limited to a small percentage of households and small number of vehicles, and preferences are inferred from sales and registration statistics, not truly "revealed." Models are careful, simplified representations of systems; projections are not predictions. Each of these methods, however, has advantages, too. In response to comments that deride these methods and their applicability to this rulemaking, we note that EPA is mindful of the advantages and disadvantages of different types of information and methods. We integrate information from many sources, including data on PEV adopters, survey information from PEV adopters and non-PEV adopters, manufacturer announcements, public comments, known relationships between

[472] We employ a colloquial definition of "demand" that include preferences attitudes, quantity consumed, purchase behavior, and purchases.

factors underlying consumer purchase and use behaviors, and historical evidence regarding the uptake of technological advancements. EPA's analyses are rooted in the full body of relevant science, and we believe our findings are reasonable and robust as discussed in RIA Chapter 4.

Third, commenters perceive and frame information differently, even when the information is identical. For example, in EPA's review of PEV acceptance, we cite a UC Davis study in which roughly one in five PEV owners replaced their PEV with an ICE vehicle (Hardman & Tal, 2021). Some comments presented this information as evidence of low PEV acceptance and losses in future sales. In contrast, EPA's presentation of that information was positive. We observed 80% continuance under past circumstances that were far less favorable than what exists now and will exist in the future. Given, for example, the smaller number or vehicle models available at the time of the UC Davis study, the lower average range of PEVs during that time, the absence of the BIL and IRA incentives, and less expansive charging infrastructure during that timeframe – all of which are obstacles to PEV adoption and retention – an 80% continuance rate "reveals" a rather high level of consumer satisfaction with PEVs. PEV satisfaction (aka "approval" per (Jackman, Fujita, Yang, & Taylor, 2023)) is a key enabler of PEV adoption. Similarly, while some comments cite recent PEVs sales statistics to argue that EPA's PEV market share projections are "overly optimistic," Energy Innovation offers a very different interpretation. They note that "the U.S. hit an all-time high of EV sales" and proceed with a discussion of how the "U.S. has exceeded the 5 percent tipping point for EVs" and laud the "increasing EV ranges and overall improvement to performance" that "will continue the positive feedback loop … further accelerating adoption of EVs in this decade." Relatedly, some commenters, such as the American Free Enterprise Chamber of Commerce, suggest that EPA has inappropriately described historical growth in PEV production, number and diversity of PEV models, PEV sales, and/or PEV demand as "rapid" or some synonymous wording. While the definition of "rapid" and synonyms may be arguable, we have documented the mathematically exponential growth in PEV production, the number of PEV models, and PEV sales in the Preamble Section IV. Correspondingly, approval of PEVs have grown and are expected to continue to grow exponentially assuming that the number of PEVs that consumers want is at least equal to sales and may be higher if there is unmet demand or supply shortages.[473]

Non-PEV Demand

Several commenters highlight current and future demand for hybrid, PHEV, and ICE vehicles as well as the attributes of these vehicles. These commenters asserted that demand for these vehicles was not adequately reflected in the proposal. For example, Consumer Report states that "CRs's 2022 nationally representative car buying survey of 6,960 US adults found that 32% of consumers planning to purchase or lease a vehicle within a year were considering a hybrid car or truck…. EPA's modeling that shows that this popular and cost-effective technology will be completely abandoned by the entire market by the end of the decade is at odds with the data on consumer preferences for these vehicles." Some of these commenters also claimed that some attributes of ICE vehicles were superior to PEVs. For example, API states that "vehicles powered by internal combustion engines (ICE) offer outstanding drivability and reliability" in contrast to

[473] Relatedly, we apply Roger's (2003) diffusion of innovation framework in estimating future PEV acceptance and adoption. See RIA Chapter 4.1.2.2.2. In this framework, as observed for many technologies, early levels of technology adoption are often low and unpredictable, and also exponential, after which growth in adoption accelerates.

the "reliability issues" of EVs. Regarding comments that EVs are less reliable than ICE vehicles, we note that, as discussed in Chapter 4.3.7 of the RIA, and Section VIII.B.3 of the preamble, research indicates that maintenance and repair costs for PEVs is lower than that for ICE vehicles, and that when issues that may impact the reliability of PEVs arise, they are often covered under warranty and are often related to infotainment or other technology features and not with drivetrain or other major mechanical issues.[474] In response to these and similar comments, we repeat general responses from above. First, we have included PHEVs in our modeling for the FRM. Second, we have demonstrated multiple compliance pathways that include BEVs, PHEVs, hybrids, and ICE vehicles. Third, the standards are technology neutral. Via a logit formulation that includes generalized cost elements (e.g., repair and maintenance costs) and non-cost elements (e.g., perceptions of drivability and reliability) of purchase decisions, the consumer module of OMEGA estimates distributions of consumer purchase decisions across vehicle technologies. Critically, the non-cost elements of OMEGA's representation of vehicle choice include acceptance of different vehicle technologies. As discussed in RIA Chapter 4.1, our parameterization of PHEV acceptance is always lower than ICE vehicle acceptance, and BEV acceptance for sedans, wagons, SUVs, and CUVs is lower than ICE vehicle acceptance until 2030.

A notable subset of comments addressed consumer preferences for vehicle performance related to enrichment. EPA is not finalizing its proposal to limit enrichment, but instead will revisit this issue in a future rulemaking, as discussed in section 4.1.6 of this RTC.

PEV Demand

Regarding PEVs, some commenters assert that consumer demand for PEVs may not or will not be sufficient to match the EPA proposal's Central case estimates of new PEV sales in the 2027 to 2032 timeframe. For example, Stellantis describes EPA's "expectation for EV market growth" as "overly optimistic." American Honda Motor Co., Inc. calls it "a staggeringly optimistic assumption about the pace of technology transformation in the auto industry." Some commenters note historical PEV sales statistics, compare them to EPA's proposed Central case PEV penetrations, and conclude that EPA projections are implausible. They assert that EPA has incorrectly extrapolated current PEV market share (i.e., roughly 9 percent of new vehicle sales in the first quarter of 2023) to unreasonably high market shares for PEVs in 2027 and later. These arguments derive from a few lines of reasoning. Some commenters incorrectly characterize PEV market shares from the Central case as assumptions. Other commenters point to factors underlying demand such as vehicle attributes (e.g., range, purchase price), current and/or future system conditions (e.g., electric grid and EVSE availability, capacity, and reliability), and preferences, needs, and use cases or attributes of consumers or certain groups of consumers (e.g., long distance driving, towing, low income).

In response, first, we note that EPA is finalizing GHG standards that are less stringent than the proposal in the early years of the program to provide additional lead time for manufacturers, and thus, the pace of PEV penetration projected under the final standards is slower than that of the proposed standards. Second, EPA has not "assumed" growth in PEV adoption. Rather, we

[474] Clean Technica, "Adding Context to That Consumer Reports Electric Car Reliability Report", January 2024, https://cleantechnica.com/2023/12/03/adding-context-to-that-consumer-reports-electric-car-reliability-report/ and Green Cars, "Are Electric Cars More Reliable?", July 2023, https://www.greencars.com/expert-insights/are-electric-cars-more-reliable.

have estimated vehicle technology adoption using OMEGA. PEV adoption estimates are model outputs that follow from several modeling inputs, including acceptance, technology costs, and consumer costs. They also follow from the modeled interaction of producer and consumer decision making. See RIA Chapters 8.1, 8.2, and 8.3. Consumer acceptance of PEVs, a precursor of PEV adoption, is represented with shareweight parameters. The parameterization of consumer acceptance is supported by the scientific literature and consistent with third party estimates. See RIA Chapter 4.1. Acceptance parameters for PEVs increase but do not exceed ICE vehicle acceptance in any of the demonstrated compliance pathways except the Faster BEV Acceptance case. We received no comments that negatively assess our parameterization of BEV acceptance but did receive positive support for our parameterization of BEV acceptance (e.g., Jeremy Michalek et al.).

Many commenters, in addition to expressing concerns regarding insufficient demand, point to factors underlying negative or ambivalent attitudes toward PEVs, and therefore insufficient demand for and adoption thereof. In general, commenters attribute the factors limiting demand for PEVs to characteristics of consumers, attributes of vehicles and consumers' perceptions thereof, and market conditions. EPA conducted a thorough review of the scientific literature regarding consumer acceptance of new, light-duty plug-in electric vehicles in the United States and published primarily between 2016 and early 2022 (Jackman, Fujita, Yang, & Taylor, 2023). Based on the scientific literature, we developed a framework to define and evaluate PEV acceptance consisting of four stages – awareness, access, approval, and adoption. This framework facilitated identification of enablers of and obstacles to PEV acceptance among new, light-duty vehicle consumers in the U.S. attributable to consumer characteristics, attributes of vehicles, and market conditions.

The obstacles and corresponding enablers identified via EPA's review of the consumer acceptance literature encompasses the obstacles noted by commenters with few exceptions. Thus, we refer readers to this report and specifically to Figure 8 in Jackman et al. (2023), which provides a summary of enablers identified in the review. Note that PEV acceptance obstacles are the converse of the enablers appearing in Figure 8. Note also that the brevity of the figure relies upon combining concepts. For example, cold weather range is not explicitly shown in the Figure but is encapsulated in location, range, and driving performance enablers and obstacles. With this review in mind, there is significant overlap among the factors that commenters identify as influencing demand and the enablers identified in EPA's review of PEV acceptance, though commenters tend to frame them as obstacles (e.g., the inconvenience of inaccessible charging rather than the convenience of accessible charging). In other words, EPA agrees with commenters that many factors underly demand. EPA has identified the same or similar drivers of demand that commenters identify with few exceptions. A key exception relates to the small number of commenters who disagree with the conclusion that, as automakers have introduced and continue to introduce additional PEV models, the U.S. has and will continue to experience increasing PEV market shares. In response, we point to the evidence supporting the conclusion that the introduction of additional PEV models invites consumers who might not otherwise consider a PEV into the PEV market by virtue of satisfying consumers' non-compensatory, inflexible criteria (e.g., body style) with more than one powertrain (e.g., BEV, PHEV, hybrid, and/or ICE vehicle), which appears to be a more flexible criteria for consumers on average (Fujita, Yang, Taylor, & Jackman, 2022) (Taylor, Fujita, & Campbell, 2024). Forsythe et al. (2023), published in PNAS, show that "when consumers' basic demands for vehicle attributes are met, they accept or prefer BEVs to combustion vehicles." (EPA discusses this paper in further detail in RIA Chapter 4). Furthermore, and more generally, factors identified by commenters which do not appear in this review in some fashion, do not, in EPA's assessment, significantly affect consumer acceptance for PEVs. For example, a commenter's interest in the U.S. as a global policy leader does not significantly affect consumer acceptance of PEVs.

Some commenters challenge EPA's assessment that these enablers are present and growing and that these obstacles have been and are continuing to be fewer and less consequential to PEV adoption. In other words, these comments argue that, for example, charging infrastructure will not grow fast enough, the grid will not be reliable enough, supply chains will not be sufficiently robust, critical minerals will be scarce, or prices will be higher. In summary, some commenters argue that conditions will not be as we estimate in the Central case and will not support the PEV adoption projected in our Central case. In response to those comments, we refer readers to respective sections of the Preamble, RIA, and this RTC for the analyses of the many enablers of PEV acceptance (e.g., grid, infrastructure, battery technology, supply chain, critical minerals). Our conclusion from the most current and best science available, described in those sections, is that the enablers and obstacles of PEV acceptance have been and are likely to continue to evolve over time in a way that is consistent with our Central case representation of consumers' purchase decisions and resulting PEV market shares.

Many comments cite a variety of PEV advantages and disadvantages as impediments to adoption of PEVs, especially among mainstream consumers. In response, we do not agree or disagree uniformly with any of posed advantages or disadvantages. Rather we note that these advantages and disadvantages are not inherent to the vehicle. What is perceived as an advantage or disadvantage depends on the consumer (e.g., driver, household, and user) and on the context, which are heterogenous and dynamic. Thus, we also disagree with commenters who claim that BEVs are or will remain a niche market (e.g., Western Energy Alliance). We note that current PEV owners differ from non-PEV owners – e.g., higher income, technological affinity, pro-environmental – but they are diverse (i.e., not a monolith) and changing (Jackman, Fujita, Yang, & Taylor, 2023). In other words, PEV adopters are starting to look more and more like mainstream consumers and we expect this trend to accelerate as PEV adoption increases (Taylor, Fujita, & Campbell, 2024). In addition, a large number of non-PEV owners appear to be well-positioned and "ready" right now to add a PEV to their households. One study shows that many non-PEV owners share important enabling characteristics with PEV owners (Fujita, Campbell, & Taylor, 2024). This does not include all of the current non-PEV owners who will be drawn into the PEV market via PEVs on-going technological improvements, purchase incentives, exposure to PEVs, experience with PEVs, fuel savings, maintenance and repair savings, charging convenience, expanding infrastructure, increased productions, and more PEV model choices among other enablers.

Different from the evolution of PEV acceptance enablers are consumers' perceptions of themselves, vehicle capabilities, and context. For example, even when vehicle range, charging access, and charging speeds meet or exceed consumers' perceived needs, the "key apprehension" regarding "charging capabilities" that American Fuel & Petrochemical Manufacturers claims is present "for nearly half of the U.S. consumer market" may impede PEV adoption. In this case the key enablers support awareness, that is, exposure to and experience with PEVs and accurate information about PEV technology and the practical aspects of PEV ownership. Environmental and Public Health Organizations highlights the importance of awareness with regard to PEV acceptance in rural areas: “This concept could also shed light on one possible reason that PEV sales percentages have been unevenly distributed across the nation, with more sales in cities than rural areas, in a way that minimizes any concerns that rural consumers could have insufficient demand for PEVs. A 2023 survey conducted by the Union of Concerned Scientists and Consumer Reports ‘uncover[ed] that there isn’t sufficient familiarity with EVs in rural areas. The overwhelming majority of respondents—96%—has never owned or leased an EV.’ The survey found that only 6% of rural respondents said they were very familiar with the fundamentals of buying and owning an EV, while 30% said they were somewhat familiar, and concluded that ‘[o]ne of the reasons for this lack of familiarity could be the scarcity of EVs in rural areas: only 27% of rural dwellers have seen an EV in their neighborhood in the past month compared to more than half of urban dwellers, and even fewer have a friend, relative or co-worker who owns an EV. A whopping 90% of rural dwellers have never been a passenger in an EV, and almost nobody has ever driven one.’ As efforts are made to increase familiarity with PEVs in rural areas, more Americans will learn about the very real benefits and advantages of PEVs, especially for rural drivers …, and this “neighbor effect” will begin to take hold in more places.” EPA logically extends the argument made above to other areas and subpopulations where the primary obstacles to PEV adoption is awareness.

Other commenters indicate that demand for PEVs is very strong, will continue to grow, and perhaps surpass EPA estimates of PEV market penetration. For example, according to California Attorney General’s Office et al., “consumer demand for electric vehicles has significantly risen, in large part due to environmental concerns, greater vehicle choice, improved battery capacity, and cost savings.” Citing “the past decade of increasing EV ranges and overall improvements to performance as more models become available" Jeremy Michalek et al. compared EPA projections to their “empirical investigation of (1) past trends in consumer preferences and (2) expected technology trends.” They find that “large increases in consumer demand for BEVs in the near future is feasible…Mainstream consumer demand for BEVs is likely to sharply increase due to expected BEV technology improvements alone… BEV demand could grow high enough by 2030 so that BEVs become the majority of new passenger cars, and SUVs nearly the majority, through expected BEV technology improvements and equal availability of BEVs and conventional vehicles… These findings do not incorporate the reduced cost of maintenance and repair or the cost of at-home charger installation. If the net balance of these provides cost savings to consumers as the EPA predicts, then [Jeremy Michalek et al.] would expect consumer demand for BEVs would be even larger than predicted in their study.”

Consumer Reports (CR) describes a virtuous circle in which consumer demand for PEVs will continue to grow. “As automakers deliver more volume, economies of scale and intensified competition for customers will further feed cost declines, which will feed back into the cycle, and lead to increased EV demand.” Consumer Reports argues that we have already observed this effect. “This is because the barriers to EV adoption identified in CR’s 2022 survey of BEV and low carbon fuels awareness are being addressed: purchase cost for EVs is declining, charging infrastructure is expanding, consumers are gaining more experience with EVs, and automakers are investing in new models and increased production. These trends tend to reinforce one another in a virtuous cycle to create even more demand for these vehicles.” In response and as is evident in the Central case of the FRM, we agree that PEV demand is strong, growing, and part of a positive feedback loop wherein PEV adoption leads to more PEV adoption. Like Consumer Reports, EPA interprets the large collection of PEV acceptance enablers (and diminishing obstacles) as part of a robust feedback loop. But some commenters, in contrast, provide a different interpretation. In our view, they misrepresent each enabler as a necessary condition. In this interpretation, every single enabler is required for PEV acceptance to increase/for PEV market shares to grow. In other words, the absence of any single enabler entirely undermines PEV acceptance. Relatedly, Volvo Car Corporation highlights the uncertainty of interacting enablers, that is the uncertainty regarding "how complimentary US policies (infrastructure, utility capacity, consumer incentives etc.) could impact consumer demand."[475] In response, we disagree with the interpretation that the system of enablers is fragile. Notably, PEV adoption has already grown primarily based on technology advancement (Forsythe, Gillingham, Michalek, & Whitefoot, 2023). The introduction of more PEV models, especially SUVs and pickups, has brought more new car buyers into the PEV market. Purchase incentives lead to more purchases. Easy, accessible charging leads to higher PEV satisfaction; higher satisfaction correlates with more purchases. Environmental and Public Health Organizations quotes Forsythe et al. (2023) in their comments, "With the assumed technological innovations, even if all purchase incentives were entirely phased out, BEVs could still have a market share of about 50% relative to combustion vehicles by 2030, based on consumer choice alone." While these enablers can enhance each other, the absence of any one of these enablers does not appear to diminish the independent effect of the others. In short, the system doesn't have to be perfect for PEV acceptance to increase and expand.

Consumer Heterogeneity

Many commenters assert that PEVs will not satisfy every consumer.[476] For example, Consumer Reports urges the EPA to "consider the needs of consumers in all demographic and income levels," noting that interest in EVs is strong and diverse but knowledge, exposure, and adoption are uneven. More specifically, commenters often note the challenges associated with PEV adoption for specific use cases and certain groups of consumers. Use cases that appeared frequently in comments include towing, hauling, long distance driving, and cold weather driving. For example, GROWMARK, Inc. notes that "farmers use their trucks to take products to market, bring supplies to their fields, and move livestock." Consumer groups mentioned frequently by commenters include rural households, low-income populations, and used vehicle consumers. For example, American Free Enterprise Chamber of Commerce (AmFree) et al. reminds us that "in most of the United States, the share of EVs is zero or near-zero."

In response, EPA absolutely agrees that consumers are heterogeneous. To the extent that evidence and scientific methods exist to characterize differences among consumers, we have considered "the needs of consumers in all demographic and income levels." See RIA Chapters 4.1 and 4.2. We note, however, that the science of modeling consumer heterogeneity is not sufficiently advanced to include in this rule making. In fact, in their comments Jeremy Michalek et al. advise against attempting to capture additional consumer heterogeneity in our modeling that is not already reflected in aggregate and on average via logit and shareweight parameters. Furthermore, historical, "revealed preference" data on PEV adoption is too limited to support robust distributional analyses. As a result, EPA has looked to survey data and qualitative

[475] We note that uncertainty is inherent in any estimate, by definition, and goes both ways.
[476] We recognize that consumers are heterogenous. We also believe that the vast majority of our commenters also recognize that consumers are heterogeneous, whether they clearly state it or not.

analyses to estimate PEV demand overall and consider differences among various U.S. populations.

Many individuals and organizations provided results from a wide variety of surveys in their comments on this rulemaking. We thank them for their contributions to an ever-growing set of survey results regarding vehicle demand (or lack thereof). We note, however, that those comments were not intended as a contribution to a body of scientific literature, but rather to argue that PEV demand is (not) or will (not) be sufficient to support future PEV market shares projected to be produced by manufacturers under the proposed standards . For example, "Consumer Reports found that '71% of Americans expressed some level of interest in buying or leasing an electric vehicle,' and 14% of Americans within that group would 'definitely buy' an EV if they were in the market for a vehicle." American Fuel & Petrochemical stated that "41 percent of adults said they would never buy an EV, raising fundamental questions about how EPA can predict that ZEV sales will reach 67 percent in 2032." The same survey also stated that "a majority of Americans now say they are at least open to buying an EV in the future," and acknowledged the limitations of surveys for assessing consumer acceptance, noting that "[p]revious Gallup polling has found that Americans aren't always the best judge of their future behavior when it comes to technology. For example, as recently as 2000, a quarter of Americans thought they'd never own a smartphone."[477] A survey from Consumer Reports in 2022 indicates that more than 70 percent of survey respondents felt that BEVs are as good or better than ICE vehicles, up from about 46 percent in 2017 (Bartlett, 2022). One might conclude from this result that 70 percent of respondents would have been willing to purchase a BEV in 2022, noting, at minimum, that the percentage has grown significantly since 2017 and possibly also concluding that the percentage will continue to grow dramatically after 2022. Furthermore, Consumer Reports (CR) "car buying survey from March and April 2022 found that 30% of licensed drivers who were then in the market to buy or lease a new (and not a used) vehicle were not even considering a conventional, non-hybrid vehicle. This however, isn't just something consumers are telling us, it's also showing up in the market. Sales of new ICE vehicles decreased by 26% from 2019 to 2022, while combined sales of BEVs, PHEVs and conventional hybrids increased by 144%. BEV sales alone increased by 244% over that same period." As illustrated with these examples, survey results reflect a snapshot in time. They vary depending on many factors including survey design and frame, sample population, sample, sampling design, and timing. In short, none of the survey results provided by commenters were surprising or provocative. They fit within the breadth of survey results with which we were already familiar. In addition, EPA is well versed in the many pros and cons of survey design, sample design, data collection, statistical summaries and inferences. Consistent with our intention to consider the full breadth and depth of the scientific literature on PEV acceptance, many surveys as well as the survey statistics provided by commenters informed EPA's parameterization of PEV acceptance in the Central case as well as the sensitivity analysis of those parameters included in the final rule making.[478] While the Central case estimates of market share are the most plausible and cost minimizing

[477] https://news.gallup.com/poll/474095/americans-not-completely-sold-electric-vehicles.aspxt

[478] Our modeling assumptions regarding PEV acceptance and consumer demand are based on the scientific literature which we cite throughout the RIA, particularly in RIA Chapter 4, Chapter 8, and Chapter 9.

pathway, we have demonstrated multiple, potential feasible compliance pathways that manufacturers could choose .

In addition to acknowledging consumer heterogeneity, we also acknowledge that PEV acceptance will occur at different rates for different consumers, and possibly not at all for some. These differences among consumers are reflected in OMEGA. While OMEGA does not directly represent different types of new vehicle consumers, the consumer module of OMEGA does capture heterogeneity in new vehicle consumer choice in any given year (i.e., via the logit parameters) and over time (i.e., via the shareweight parameters). OMEGA models the distribution of choice across vehicle technologies via a generalized logit formulation that includes generalized cost and non-cost elements of purchase decisions. See RIA Chapter 4.1. We also note that all of the demonstrated compliance pathways in this FRM project that some consumers will not purchase PEVs.

The modeling approach employed in OMEGA applies broadly to all use cases and consumer groups. Our modeling does not exclude any use cases or consumer groups from the option of choosing a PEV or any other available technology. EPA notes that PEV ownership is feasible and acceptable to many consumers for towing, hauling, long distance driving, and cold weather driving. EPA also notes that many consumer groups, including lower income buyers and non-white consumers purchase PEVs and indicate interest in PEVs (Consumer Reports, 2022). Furthermore, there appears to be no evidence that PEVs cannot meet the demands of many rural consumers. Instead, there is evidence that information about, exposure to, and access to PEVs and EVSE has been less in rural areas than in urban areas, and the resulting lack of awareness and access has been the primary cause of lower adoption rates in rural areas. According to comments from Environmental and Public Health Organizations, "A 2023 survey conducted by the Union of Concerned Scientists and Consumer Reports 'uncover[ed] that there isn't sufficient familiarity with EVs in rural areas. The overwhelming majority of respondents—96%—has never owned or leased an EV.' The survey found that only 6% of rural respondents said they were very familiar with the fundamentals of buying and owning an EV, while 30% said they were somewhat familiar."[479] Environmental and Public Health Organizations also note that "although rural Americans are currently adopting PEVs at slower rates than urban Americans, PEVs actually excel at meeting the demands of rural drivers. 'Fuel savings for rural households are larger than for urban households, because trips in rural areas are longer than in urban areas, and vehicles tend to be older and less efficient, requiring more fuel per mile, [P]EVs require fewer trips to a mechanic for repairs and maintenance. Because of the high torque and low center of gravity, they have excellent performance, which is important on rough, curvy and steep roads.' A survey by the Union of Concerned Scientists and Consumer Reports found that 'there is plenty of interest [in PEVs] in rural areas, but there is a huge knowledge gap about what it is like to own an EV.'"[480]

Regarding low income and used vehicle market consumers emphasized by many commenters, EPA recognizes that most consumers want and some really need both lower purchase price and lower operating costs, and that different customers have different abilities to purchase vehicles at any given price points. Not every consumer will be able to purchase a new motor vehicle, whether that is a PEV or an ICE vehicle. At the same time, we expect that PEVs will generate

[479] [EPA-HQ-OAR-2022-0829-0759, p. 164]
[480] [EPA-HQ-OAR-2022-0829-0759, p. 175]

large savings for consumers over the lifetime of the vehicle, and we also see a significant trend toward decreasing consumer upfront costs for purchasing PEVs. First, purchase incentives are available for eligible new and used PEVs for buyers who qualify (See RIA Chapter 2.6.8). Second, the price difference for BEVs is widely expected to narrow or disappear as the cost of batteries and other components fall in the coming years.[481] Among the many studies that address cost parity of BEVs vs. ICE vehicles, an emerging consensus suggests that purchase price parity is likely to begin occurring by the mid- to late-2020s for some vehicle segments and models, and for a broader segment of the market on a total cost of ownership (TCO) basis (ICCT, 2022) (EDF and ERM, 2022). Specifically, the International Council on Clean Transportation (ICCT) projects that price parity with conventional vehicles will "occur between 2024 and 2026 for 150- to 200-mile range BEVs, between 2027 and 2029 for 250- to 300-mile range BEVs, and between 2029 and 2033 for 350- to 400-mile range BEVs" (ICCT, 2022). The Environmental Defense Fund notes that "most industry experts believe wide-spread price parity will happen around 2025" (EDF and ERM, 2022). By some accounts, a compact car with a relatively small battery (for example, a 40 kilowatt-hour (kWh) battery and approximately 150 miles of range) may already be possible to produce and sell for the same price as a compact ICE vehicle (Walton, 2020). Many expect total cost of ownership (TCO) parity to precede purchase price parity by several years, as it accounts for the reduced cost of operation and maintenance for BEVs (ICCT, 2022) (EDF and ERM, 2022). See Preamble Sections IV.C.1 and IV.C.6. Third, in our modeling, we assume that a mix of technologies will be used to meet the standards. Our assessment projects there will be variation in the types of technologies that automakers adopt to meet the standards, providing consumers increased fuel economy and associated fuel savings via PEV and ICE vehicle technologies in the new vehicle market and eventually also in the used vehicle market. We expect that automakers recognize the diversity of their consumers and will leverage the flexibilities built into the standards to provide consumers with PEV and ICE vehicle choices over a wide range of utility and price points.

Uptake of technological advancements

In concluding our response to comments related to consumer demand, we acknowledge the comments regarding the projected pace of PEV adoption. Most of those commenters indicated that the pace was too rapid and not justified by available evidence. Some commenters conjectured that the actual pace of PEV adoption will outpace EPA’s projections as has been observed in the past. As with any scientific or modeling endeavor, we agree with these commenters that our Central case projections are not predictions. They may be too high or too low. However, our Central case projections are the best estimate of technology market shares based on our analyses of consumer demand and factors underlying consumer demand. Our Central case projections are consistent, though more conservative as described in Section IV.C.6 of the preamble, with third party estimates. In other words, other researchers have reached the same conclusion regarding likely rates of PEV uptake as the EPA. Nevertheless, we provide an additional response to concerns about the projected demand for PEVs. We also note, that in addition to our central case estimates, we present numerous sensitivity scenarios which demonstrate that the standards can be met through various mixes of technologies including ICE, hybrids, PHEV and BEVs, and thus a wide range of PEV levels.

[481] International Council on Clean Transportation, "Assessment of Light-Duty Electric Vehicle Costs and Consumer Benefits in the United States in the 2022-2035 Time Frame," October 2022.

By most accounts, vehicle markets are in transition. In the words of American Honda Motor Co., Inc., “Previous debates about whether such a transformation would occur are now merely conversations about when it will happen. In fact, today all of industry is pursuing this transition at a fever pace.” Honda continues, however, by misrepresenting and exaggerating proposed, projected PEV market shares as “requiring EVs to move beyond today's early adopters, past ubiquity on main street, and extend to small towns and rural areas across the nation – all in a mere eight years.” They characterize these projections an “assumed swift and seamless EV market transition.” Furthermore, they state that “there is no historical auto industry analogue to EPA’s projected pace of EV adoption” and provide examples. They also highlight that “apart from experiencing better fuel economy and vehicle performance, it is possible owners may not have even known those technologies existed on the vehicle” which is, admittedly, different from the consumer-facing nature of PEV technology and the “different approach to [PEV] use and management”.

In response, we acknowledge that it took several years for the PEV technologies to achieve current levels of adoption, while also emphasizing that growth in PEV market share “has outpaced historical estimates considered ambitious just a decade ago” according to comments from Environment and Public Health Organizations. We also agree that it is important to consider technology-specific factors when projecting technology adoption, particularly the behavior changes and awareness and access challenges associate with PEVs that have been identified by commenters as well as the EPA. We respond to the behavioral component of PEV adoption in four ways. First, as noted about, we are aware of and have accounted for the challenge of awareness and access in our estimates, as stated above. Second, unprecedented public and private investment in vehicle electrification, separate from this rulemaking, has occurred and is expected to continue. Third, EPA has engaged in similarly unprecedented analyses, for example, regarding infrastructure, grid, supply chains, critical mineral availability, related to PEV acceptance, as is clearly evidenced in the Preamble, RIA, and other sections of this RTC. Fourth, we apply Rogers’ robust theory of technology diffusion in our modeling of PEV market shares. As Environmental and Public Health Organizations describes, “’sales move at a crawl in the early-adopter phase, then surprisingly quickly once things go mainstream… Before then, sales tend to be slow and unpredictable. Afterward, rapidly accelerating demand ensues.’ This S-shaped pace of technology adoption has been observed for numerous emerging technologies since the early 1900s, including the telephone, the automobile, electricity, refrigeration, clothes washers and dryers, air conditioning, microwaves, computers, cellphones, and the internet.” Though Honda notes this pattern as well, they compare the longer transition of these technologies to the shorter, roughly decade-long transition to roughly two-thirds of new vehicle sales being PEVs in EPA proposal. It is important to remember that EPA’s proposal projects new vehicle sales, not fleet composition. Statistics on telephones, microwaves, etc. are more comparable to the later metric. It is also important to know that the pace of technological innovation and diffusion in the 21st century is much faster than in the 20th century. According to Environmental Public Health Organizations, “the pace of adoption has been speeding up consistently across new technologies … “‘[i]t took decades for the telephone to reach 50% of households, beginning before 1900. It took five years or less for cellphones to accomplish the same penetration in 1990.’ The automotive industry has not been left out of this increasing speed of technological adoption, with automotive design cycles decreasing from 60 months to 24 or 36 months over a period of five years.” We discuss diffusion of innovation, PEV adoption, and PEV acceptance in See RIA Chapter 4.1.

13.3 - Vehicle ownership behavior

Comments by Organizations

Organization: American Fuel & Petrochemical Manufacturers

EPA's total cost of EV ownership incorrectly assumes each vehicle type of all new ICEV and ZEV will travel the same miles each year.249 EVs have less range, both technically and practically. As noted by J.D. Power, "the majority of EVs provide between 200 and 300 miles of range on a full charge."250 Studies show that the average electric car is driven 9,059 miles per year, compared with 12,758 miles for ICEVs.251 By overestimating VMT, EPA compounds all other errors in its assumptions that all work in favor of ZEVs and to the detriment of ICEVs. [EPA-HQ-OAR-2022-0829-0733, p. 55]

249 DRIA at 4-20, Table 4-7 (e.g., EPA assumes EV and ICEV sedans/wagons will both travel 15,700 miles per year).

2. EPA's consumer demand module isn't explained and leads to strange results

EPA's analysis includes an estimate of consumer demand of vehicles by powertrain, which it describes as "the share weight parameter changes over time to account for factors that are not included in the generalized costs, such as greater access to charging infrastructure or greater availability and awareness BEVs". EPA does not explain how they built their S curve or how it behaves and relies on a single paragraph in its draft RIA to describe this approach (it reserves conversation of the 'cost' metrics for a different section of the RIA). More importantly, EPA does not explain why consumer demand increases because of their proposal across the alternatives when their proposal shouldn't impact these considerations. EPA's proposal does not increase the amount of chargers available or reduce range anxiety. If these things are assumed to change because of EPA's rule, the explanation should be clear in EPA's analysis, and EPA should also carry the costs of forcing increases to the grid and charger access as a cost to their rule. [EPA-HQ-OAR-2022-0829-0565, p. 3]

In considering costs, EPA states "consumers assume that approximate annual VMT is 12,000 miles, annual non-fuel ownership costs for BEVs are $1,600, and annual non-fuel ownership costs for ICE vehicles are $2,000" but does not explain where those assumptions come from and deprives commenters from being able to meaningfully comment and contribute. This basis of non-fuel costs for ICE vehicles being higher by 20% leads to ICE vehicles being disadvantaged. [EPA-HQ-OAR-2022-0829-0565, p. 3]

EPA analysis also seems to gloss over range anxiety which is a leading consideration for many consumers in whether to purchase a BEV (https://www.caranddriver.com/news/a40119553/survey-range-anxiety-evs/#:~:text=The%20bad%20news%3F,list%20their%20top%20three%20concerns) or the time it takes to charge a vehicle, in their analysis of consumer demand. These oversights seriously undermine the value of EPA's model. [EPA-HQ-OAR-2022-0829-0565, p. 3]

Ironically, EPA also assumes 0% rebound for BEVs. Rebound is a sign that consumers value driving a vehicle more and will do so as cost decreases. However, EPA's assumption assumes that there is no additional value to driving a BEV as it becomes more efficient. So on the one hand, BEVs confer the same or better benefits to their drivers, on the other, consumers do not value additional BEV miles. [EPA-HQ-OAR-2022-0829-0565, p. 3]

Organization: Delek US Holdings, Inc.

b. BEV charging consumes significantly more time than refueling ICE- powered vehicles.

The Proposed Rule fails to consider the impact that increased charging times will have on consumer adoption rates and whether end users will be willing to such disruptions to daily travel in addition to the increased prices and upfront costs. According to DOT, Level 1 EVSE, which provides charging through a 120-volt AC outlet, can take 40–50+ hours to fully charge (80%) a BEV from empty; Level 2 EVSE, which offers a higher-rate AC charging and is typically used for home, workplace and public charging, can take 4–10 hours to fully charge a BEV from empty; and direct current fast charging EVSE, which provides rapid charging along heavy-traffic corridors where already installed, can take up to an hour to fully charge a BEV from empty.42 Regardless of fast charging, most PHEVs currently on the market do not work with the DCFC equipment.43 But under any scenario, these ZEVs will incur additional downtime for more frequent, and longer, charging times as compared to the equivalent ICE. And faster charging infrastructure is larger and more expensive, making it difficult for the average consumer to comfortably travel unless there is sufficient access to fast and convenient charging. Yet the Proposed Rule fails to consider whether, in light of these impacts, consumers will purchase ZEVs at the rate necessary to meet EPA's targets regardless of whether a manufacturer can produce them. [EPA-HQ-OAR-2022-0829-0527, p. 9]

The proposed rule in this docket would rapidly accelerate a shift from the use of internal combustion engine vehicles to electric vehicles (EVs). The Alliance for Automotive Innovation has already submitted testimony in this docket that the proposed rule would require 2/3 of vehicles covered by this docket to be battery electric vehicles by 2032. In today's market the share of new light-duty and medium-duty vehicles that are EVs is one-tenth of that share nationally, and far, far lower in our states and many regions of the country. [EPA-HQ-OAR-2022-0829-0525, p. 1]

2) Errors/omissions in the proposal and the RIA.

Not addressed in the RIA is the effect the IRA incentivizing carbon capture and sequestration (CCS) used for enhanced oil recovery (EOR) will have on fuel prices . Setting aside the unsettled question of how much net car- bon is sequestrated after the oil produced in turn emits additional CO2, as not germane to the EV rule15. [EPA-HQ-OAR-2022-0829-0546, p. 5]

What is germane is that the oil will be pro- duced at marginally lower cost. While the rebound effect is taken into con- sideration in the RIA based on increased vehicle milage efficiency, the de- creased cost of fuel from EOR is not. Cheaper fuel will also have a re- bound effect, encouraging more driving, and reducing the pressure to tran- sition to a BEV16. This effect needs to be reflected in the RIA, otherwise the RIA is incomplete and presents a distorted projection. [EPA-HQ-OAR-2022-0829-0546, p. 5]

15 It's estimated a ton of injected CO2 will produce about 2 barrels of oil which when combust- ed, will emit about a ton of CO2

XXV. EPA's Use of a 10% Rebound Effect for Combustion Vehicles, While Reasonable, Is Clearly at the High End of Estimates, Leading to a Possible Overestimation of Costs and Underestimation of Benefits.

This section explores EPA's consideration of rebound effects. As detailed below, while the Agency has justified a 10% rebound effect in its prior rulemakings, it should consider using a lower value here. It is also reasonable for EPA to assume no rebound driving for BEVs. [EPA-HQ-OAR-2022-0829-0759, p. 189]

A. EPA has provided a thorough and sufficient justification for a 10% rebound effect in several prior rulemakings.

EPA's Proposal estimates the vehicle miles traveled (VMT) rebound effect for combustion vehicles to be 10%. DRIA at 4-16. The quantitative estimate of the rebound effect—which indicates the amount of additional driving that will occur as the cost of driving decreases due to fuel economy improvements—significantly influences multiple factors considered in promulgating new GHG regulations for light-duty vehicles. Additional driving leads to more accidents, road congestion, and noise, while also reducing the fuel savings and emission reductions associated with more stringent standards. Therefore, without a reasonable estimate of the rebound effect, the magnitude of a new rule's costs and benefits cannot be properly understood. [EPA-HQ-OAR-2022-0829-0759, p. 189]

The use of a 10% rebound effect is not new. EPA also estimated the rebound effect to be 10% in the 2010 and 2012 Final Rules and the Revised 2023 and Later Model Year Light-Duty Vehicle GHG Emissions Standards finalized in 2021. See 75 Fed. Reg. 25324, 25517 (May 7, 2010); 77 Fed. Reg. 62624, 62716 (Oct. 15, 2012); 86 Fed. Reg. 74434, 74476 (Dec. 30, 2021). During each of these previous rulemakings, EPA considered a large body of both historical and recent literature that reported a very broad range of rebound estimates arrived at through a variety of research methods. EPA understood that simply averaging all of the rebound estimates from all of the studies was an unreasonable and inadequate method for reaching an accurate estimate of rebound for the vehicles subject to the relevant standards.616 For example, many of the studies considered old research, data from other countries with vastly different driving habits, or estimates that were not forward-looking to the years when the covered vehicles would be driven. 77 Fed. Reg. at 62924. Historically, EPA has correctly acknowledged that rebound research should be weighted based on its relevance to GHG emissions regulations in the United States.617 [EPA-HQ-OAR-2022-0829-0759, p. 189]

616 77 Fed. Reg. at 62924; EPA & NHTSA, Joint Technical Support Document, Final Rulemaking for 2017-2025 Light Duty Vehicle Greenhouse Gas Emission Standards and Corporate Average Fuel Economy Standards, EPA-HQ-OAR-2018-0283-0654, at 4-22 to 4-26 (Aug. 2012) (2012 TSD); EPA & NHTSA, Joint Technical Support Document, Final Rulemaking to Establish Light-Duty Vehicle Greenhouse Gas Emission Standards and Corporate Average Fuel Economy Standards, at 4-15 to 4-22 (Apr. 2010).

617 See 77 Fed. Reg. at 62924 (noting a focus on U.S. estimates and declining to use estimates of elasticity of demand for gasoline to measure the VMT rebound effect); 2012 TSD at 4-25 (noting that historical estimates may overstate the rebound effect because the magnitude of the rebound effect declines over time, so more recent studies were entitled to increased weight). See also EPA, Technical Support Document, Proposed Determination on the Appropriateness of the Model Year 2022-2025 Light-Duty Vehicle Greenhouse Gas Emissions Standards under the Midterm Evaluation, at 3-20 to 3-21 (Nov. 2016), available at https://nepis.epa.gov/Exe/ZyPDF.cgi?Dockey=P100Q3L4.pdf (2016 TSD) (finding some rebound estimates in the literature to be more applicable to the standards than others and according those more weight).

In the 2010 Final Rule, EPA concluded that while the historical research dating back to the 1950s suggested higher rebound values, the most recent literature supported a 10% “or lower” rebound effect. 75 Fed. Reg. at 25517. In the 2012 Final Rule, EPA again assumed a 10% rebound effect, and in 2016, EPA confirmed three times that a 10% rebound effect was appropriate. In both the 2016 Draft Technical Assessment Report and the 2016 Final Technical Support Document under the Midterm Evaluation, EPA cited multiple studies demonstrating that the rebound effect shrinks as incomes rise, and again explained that older studies were likely to be less reliable than more recent research.618 Also in 2016, EPA used a 10% rebound effect in adopting standards for heavy-duty pickups and vans.619 [EPA-HQ-OAR-2022-0829-0759, p. 190]

618 EPA & NHTSA, Draft Technical Assessment Report, Midterm Evaluation of Light-Duty Vehicle Greenhouse Gas Emission Standards and Corporate Average Fuel Economy Standards for Model Years 2022-2025, EPA-HQ-OAR-2015-0827-0926, at 10-10, 10-13 & 10-20 (July 2016), available at https://nepis.epa.gov/Exe/ZyPDF.cgi/P100OXEO.PDF?Dockey=P100OXEO.PDF (2016 Draft TAR); 2016 TSD at 3-10 to 3-13, 3-16 & 3-20.

619 Greenhouse Gas Emissions and Fuel Efficiency Standards for Medium- and Heavy-Duty Engines and Vehicles—Phase 2, Proposed Rule, 80 Fed. Reg. 40138, 40453 (July 13, 2015) (“Since [HD pickups and trucks] are . . . more similar in use to large light-duty vehicles, we have chosen the light-duty rebound effect of 10 percent . . .”); Greenhouse Gas Emissions and Fuel Efficiency Standards for Medium- and Heavy-Duty Engines and Vehicles—Phase 2, Final Rule, 80 Fed. Reg. 73478, 73746 (Oct. 25, 2016) (finalizing use of 10%).

The 2020 Rule was the only recent rule to depart from this 10% rebound rate, and the revised MY 2023 and later standards, finalized in 2021, returned to the 10% rebound rate after EPA conducted a rigorous review of the rebound literature in order to prioritize the most relevant rebound studies. EPA's current Proposal refers to the 2021 rule as support for its proposed 10% rebound rate for combustion vehicles. In the 2021 rule, EPA built on well-established precedent, citing much of the same support provided in the 2010 and 2012 rulemakings, along with additional more recent research. EPA also provided even more clarity into the Agency's approach to the broad body of rebound literature spanning many decades. EPA is correct in its belief that "it is important to critically evaluate which studies are most likely to be reflective of the rebound effect that is relevant to the final standards," and that "one cannot just take the 'average' rebound estimates from literature to use for the VMT rebound effect." See EPA, Revised 2023 and Later Model Year Light Duty Vehicle GHG Emissions Standards: Regulatory Impact Analysis (Dec. 2021) ("2021 RIA"), at 3-13. When agencies consider a range of studies, they should focus on those that are similar to the relevant policy context.620 [EPA-HQ-OAR-2022-0829-0759, p. 190]

620 See, e.g., U.S. Office of Management and Budget, Circular A-4 (Sept. 17, 2003) at 25. https://www.whitehouse.gov/sites/whitehouse.gov/files/omb/circulars/A4/a-4.pdf; see also EPA, Science Advisory Board (SAB) Consideration of the Scientific and Technical Basis of the EPA's Proposed Rule titled The Safer Affordable Fuel-Efficient (SAFE) Vehicles Rule for Model Years 2021-2026 Passenger Cars and Light Trucks, EPA-HQ-OAR-2018-0283-7659, at 27 (Feb. 27, 2020) (SAB Report) (stating that "the rebound estimate [should] be reconsidered to account for the broader literature, and that it be determined through a full assessment of the quality and relevance of the individual studies rather than a simple average of results," and "recent papers using strong methodology and U.S. data should be weighted more heavily than older papers, or those from outside the U.S., or those with weaker methodology.").

Specifically, in the 2021 rule reasoning on which EPA continues to rely for its 10% combustion vehicle rebound estimate, EPA appropriately identified factors for weighting rebound studies that reflect their relevance to the proposed rulemaking: (1) geography/timespan relevance (priority given to U.S. studies as opposed to international estimates); (2) time period of study (priority given to recent studies); (3) reliability/replicability of studies (priority given to studies using odometer readings vs. household surveys such as the 2009 National Household Travel Survey); and (4) statistical/methodological basis (priority given to studies employing a strong statistical/methodological basis). 2021 RIA at 3-13. EPA further explained why these factors are important and why they lead to more accurate estimates of the rebound effect. As a result, the Agency provided a clear and well-reasoned basis for its decision to give more weight to studies based on these four key criteria, and thus to conclude that the seven papers listed in Table 3-4 of the 2021 RIA should be given the most significant weight in developing the rebound estimate used in the Proposal. See 2021 RIA at 3-14 to 3-15. [EPA-HQ-OAR-2022-0829-0759, p. 191]

B. Even the 10% rebound effect is too high, and EPA should consider using a rebound effect of a lesser magnitude.

The two most reliable rebound estimates based on U.S. national data from EPA's preferred studies are 10% (Greene (2012)) and around 4% (Hymel and Small (2015)).621 Hymel and Small (2015) noted that their data indicated that fuel economy rebound could be lower than fuel price rebound, meaning that even the 4.0% and 4.2% values could be too high.622 Moreover, another paper in the list of EPA's seven preferred studies, Gillingham et al. (2015), estimates the rebound effect at 10%. But the study also found that "a high percentage of vehicles are almost entirely inelastic in response to gasoline price changes" and that "the lowest fuel economy vehicles in the fleet drive the responsiveness, with higher fuel economy vehicles highly inelastic with respect to gasoline price changes."623 While Gillingham et al. (2015) does not offer an alternative best rebound estimate for higher fuel economy vehicles, it is fair to assume that the 10% estimate is at the high end of reasonable estimates for the vehicles impacted by this rulemaking. [EPA-HQ-OAR-2022-0829-0759, p. 191]

621 See Kenneth A. Small, Comment Letter on Proposed MY 2021-2026 Standards, NHTSA-2018-0067-7789, at 1 (Sept. 14, 2018) ("A better characterization of the most recent study would be that it finds a long-run rebound effect of 4.0 percent or 4.2 percent under two more realistic models that are supported by the data.").

622 Hymel K. & K. Small, The Rebound Effect for Automobile Travel: Asymmetric Response to Price Changes and Novel Features of the 2000s, 49 Energy Econ. 93, 97 (2015); see also Greene, D., Rebound 2007: Analysis of U.S. Light-Duty Vehicle Travel Statistics, 41 Energy Pol'y 14 (2012) (although fuel prices "had a statistically significant impact on VMT, . . . fuel efficiency did not.").

623 Kenneth Gillingham et al., Heterogeneity in the Response to Gasoline Prices: Evidence from Pennsylvania and Implications for the Rebound Effect, 52 Energy Economics S41–S52 (2015).

Other factors would also suggest that even the best and most relevant existing studies could lead to a rebound estimate that is too large. For example, the rebound effect's magnitude diminishes over time, largely due to increasing income and decreasing driving costs, a fact that EPA has historically understood.624 As incomes rise over time, any fuel efficiency improvement will have less of an effect on the total vehicle miles traveled, and thus the rebound effect will decline. In both 2010 and 2012, EPA chose to use a 10% rebound effect as "a reasonable compromise between historical estimates and projected future estimates."625 The 2012 Final Rule noted, however, that several high-quality studies indicated that the rebound effect's magnitude is significantly diminishing over time as incomes rise.626 This income effect on rebound makes clear that the projected future estimates are in fact much more accurate than historical estimates. Moreover, more than 15 years will have passed since the 2010 Final Rule found a 10% rebound effect to be a good compromise and the implementation of the Proposed Standards, and income has continued to grow since that time, supporting a substantially diminished rebound effect. [EPA-HQ-OAR-2022-0829-0759, p. 192]

624 See, e.g., 2016 Draft TAR at 10-14 and 10-20; 77 Fed. Reg. at 62924, 62995; accord Small K. & K. Van Dender, Fuel Efficiency and Motor Vehicle Travel: The Declining Rebound Effect, 28 Energy J. 25 (2007); Hymel, K. et al., Induced Demand and Rebound Effects in Road Transport, 44 Transp. Rsch. Part B 1220 (2010).

625 77 Fed. Reg. at 62924.

626 NHTSA, Corporate Average Fuel Economy for MY 2017-MY 2025 Passenger Cars and Light Trucks: Final Regulatory Impact Analysis, at 851-52 (2012) (citing Small & Van Dender (2007) (finding average rebound to be 22% for 1966-2001, but declining to 11% when looking at only 1997-2001); Hymel et al. (2010) (finding that average rebound for 1966 through 2004 was 24%, but rebound by 2004 was only 13%); Greene, D., Rebound 2007: Analysis of Light-Duty Vehicle Travel Statistics (Mar. 2010) (internal EPA research) (estimating the rebound effect would be 10% in 2010 and 8% in 2030, using 1966-2007 data); see also Greene (2012) (same)).

EPA should give more weight to the fact that the rebound effect varies with income over time. In the 2021 rule, the agency cited Gillingham (2014) to assert that the evidence of how the rebound effect varies with income is "mixed," but then also correctly excluded that study from its list of preferred studies. Gillingham (2014) specifically considers the response to the 2008 gasoline price shock in California. EPA is correct to conclude that this was "an unusual period when gasoline prices were particularly salient to consumers." 2021 RIA at 3-6 to 3-7. As EPA noted, Gillingham explained in a follow-up paper in 2020 that the Gillingham (2014) results should not be used for developing an estimate of the VMT rebound effect for fuel economy or GHG standards. 2021 RIA at 3-7. The Gillingham (2014) paper is equally irrelevant to the question of the income effect on rebound. Various papers have confirmed that the rebound effect is declining over time and one study certainly should not be used as the basis for giving this factor “less weight,” especially a study whose own author acknowledges its irrelevance to this rulemaking context and to which EPA gives little to no weight otherwise. Because of this, EPA should more fully consider the impacts of the income effect on rebound, and in doing so, could support a rebound effect of a magnitude lower than 10%. [EPA-HQ-OAR-2022-0829-0759, p. 192]

In fact, the income effect on rebound is particularly important in the context of setting LDV GHG emissions regulations for two reasons. First, even the most recent relevant studies on which rebound estimates are based consider data only from 2013 and earlier. The historical growth rate of per capita personal income was 1.4% between 2001 and 2019,627 and thus income growth since 2013 would indicate a declining rebound effect even in the time since the most recent data utilized were collected. Second, EPA’s final standards will affect the fuel efficiency—and therefore the rebound effect—for vehicles for the next 30 years or more. Private forecasts have estimated approximately 1.6% growth in real personal income per year over the next 30 years, see 85 Fed. Reg. at 24675 n.1763, meaning that when most vehicles subject to the regulations are retired, incomes will be at least 61% higher than they are today (which are already higher than during the time periods in which the available rebound studies were conducted).628 More recent projections in AEO 2023 anticipate incomes rising even more than prior estimates—an average of 2.4% per year through 2050.629 This income growth would be expected to cause a large reduction in the magnitude of the rebound effect, supporting a rebound effect for the vehicles subject to EPA’s final standards of a magnitude well below 10%. [EPA-HQ-OAR-2022-0829-0759, pp. 192-193]

627 See Amicus Brief of Economists at 16 for calculation of 1.4% growth rate.

628 Amicus Brief of Economists at 16.

629 U.S. Energy Information Administration, Annual Energy Outlook 2023, Table 20: Macroeconomic Indicators, https://www.eia.gov/outlooks/aeo/data/browser/#/?id=18-AEO2023&cases=ref2023&sourcekey=0.

C. It is reasonable for EPA to assume no rebound driving for BEVs.

Based on several recent studies looking at VMT for BEVs, and two studies specifically considering BEV rebound, EPA’s Proposed Rule assumes that the rebound effect for BEVs is 0% rather than the 10% value the Agency uses for combustion vehicles. It is reasonable for EPA to assume no rebound driving for BEVs for the reasons stated in the DRIA, see DRIA at 4-14 to 4-17, and because longstanding rebound research indicates that rebound is likely more a response to fuel prices than to fuel efficiency. [EPA-HQ-OAR-2022-0829-0759, p. 193]

The rebound effect relevant to these standards—for all vehicles, but especially with respect to BEVs—is fuel efficiency rebound. A substantial body of research indicates that fuel price or fuel cost rebound effects are higher than fuel economy rebound effects, meaning that rebound may be more responsive to fuel prices than fuel efficiency. Both Greene (2012) and Hymel and Small (2015)—two of EPA’s seven most preferred studies—came to this conclusion. Other studies cited by EPA—Gillingham (2012), Small and Van Dender (2007), West et al. (2015), and Wang and Chen (2014)—also concluded the same. Kenneth A. Small has explained that his studies indicate that the fuel economy rebound effect "is statistically indistinguishable from zero," and that "[t]his is also true of the vast majority of other studies that have tried to measure separately these two responses."630 He further explained that "the most defensible result empirically is that people do respond to fuel prices as expected, but that they do not respond to fuel economy at all," and that "Small and Van Dender (2007) make this point explicitly, and point out that we are therefore assuming a positive [fuel economy] rebound effect when actually we cannot prove that it's greater than zero."631 Greene (2012) also found that the impact of fuel efficiency on VMT was not statistically significant, a point EPA referred to in the 2016 Draft TAR to suggest that the relevant rebound effect for policymaking purposes "could be zero." 2016 Draft TAR at 10-14.632 And Wenzel & Fujita (2018) found that vehicles with the highest fuel economy—but still vehicles significantly less efficient than BEVs—had notably lower rebound rates than vehicles with lower fuel economy, with an average rebound effect well below 10%.633 [EPA-HQ-OAR-2022-0829-0759, pp. 193-194]

630 Kenneth A. Small, Comment Letter at 2.

631 Id. In the 2020 Final Rule, EPA relied on Linn (2016) to support an argument that fuel economy rebound is greater than fuel price rebound. Linn (2016), however, described the separate coefficients for fuel price and fuel economy changes as statistically insignificant. Linn, J., The Rebound Effect of Passenger Vehicles, 37 Energy J. at 277 (2016). Moreover, Linn also explained that self-reported VMT data (as was used for his research) "may be noisy when compared to VMT calculated from multiple odometer readings," and that therefore studies that use VMT based on multiple odometer readings—such as all of those enumerated above—"should have lower measurement error, and yield preferable estimates from a statistical point of view." Joshua Linn, Comment on Proposed MY 2021-2026 Standards, NHTSA-2018-0067-7188, at 2 (Oct. 11, 2018).

632 Additionally, this point is relevant to the discussion above regarding 10% rebound being a maximum estimate for combustion vehicles. Because some of EPA's seven most preferred studies consider fuel prices rather than fuel efficiency, the most accurate rebound estimate would be no higher than—and likely lower than—the average of those studies' best estimates.

633 Tom Wenzel & K. Sydney Fujita, Elasticity of Vehicle Miles of Travel to Changes in the Price of Gasoline and the Cost of Driving in Texas, Lawrence Berkeley National Laboratory (Mar. 2018) at iv (explaining that rebound for "high MPG" vehicles—which are still less efficient than BEVs—is estimated to be 5.2%).

Additional very recent research that has been presented but is not yet published provides further support for EPA's 0% BEV rebound effect. Spiller et al. (2023) investigated the existence of rebound effects in annual miles driven for BEV owners.634 The study "compile[d] household level fleet data in Massachusetts to perform an event-study and difference-in-difference analysis, comparing miles driven after new vehicle purchases" across BEVs and combustion vehicles.635 The analysis distinguished between BEVs purchased as additions to the household fleet versus replacement vehicles, and used propensity score matching to find an appropriate control group. Spiller et al. (2023) "estimate[d] the elasticity of VMT to changes in gasoline prices for households with and without BEVs, using a fixed effect model and instrumenting for the price of gasoline with the price of crude oil in the international markets," and found that "EV households shift VMT to EVs when gasoline prices increase, although the increase in driving after the purchase of a new vehicle does not differ across fuel type, suggesting the absence of a rebound effect."636 EPA should include discussion of Spiller et al. (2023) in its final rule if the research is published or available in a working paper form prior to promulgation of the final rule. [EPA-HQ-OAR-2022-0829-0759, p. 194]

E. EPA Should Consider a Range of Rebound Effect Assumptions for BEVs While Upholding Its Current Assumption for ICE Vehicles

The “rebound effect” refers to “the additional energy consumption that may arise from the introduction of a more efficient, lower cost energy service.”118 In the Proposed Rule, EPA reasonably, and consistently with prior rules, assumes 10% rebound for ICE vehicles119—meaning that for every 1% improvement in fuel efficiency, there is a 0.9% drop in total fuel use and a corresponding increase in vehicle miles traveled. EPA’s adoption of a 10% rebound rate for ICE vehicles is consistent with the literature.120 [EPA-HQ-OAR-2022-0829-0601, pp. 18-20]

118 RIA at 4-13.

119 Id. at 4-16.

120 See generally Inst. for Pol’y Integrity, Comments on Revised 2023 and Later Model Year Light-Duty Vehicle Greenhouse Gas Emissions Standards (Sep. 27, 2021),

While a wealth of economic literature supports a small rebound effect for ICE vehicles, there is comparatively little economic research on the rebound effect for BEVs. Based on the research available, EPA assumes a rebound effect of 0% for BEVs.121 This rebound assumption has two implications. First, it assumes that drivers do not switch their driving behavior when they switch from an ICE vehicle to a BEV,122 despite cost differences.123 Second, it assumes that any change in per-mile cost for BEVs, including from the introduction of more efficient BEVs or fluctuations in electricity prices, does not affect driving behavior. In effect, EPA’s projection of no rebound for BEVs over the long term presumes that there is something fundamentally different about consumer perceptions of BEVs compared to ICE vehicles, and not simply an issue of familiarity or technological constraints that will be overcome in the future. [EPA-HQ-OAR-2022-0829-0601, pp. 18-20]

121 RIA at 4-16.

122 Id. at 4-17 (stating that “BEVs are not driven more than ICE vehicles”).

123 According to predictions from OMEGA, under the Proposed Rule, the average per-mile fuel cost of BEVs is projected to be approximately 62% lower than that of ICE vehicles between 2022 and 2055. This data is sourced from the '20230315_091353_MY_period_costs.csv' file in the '20230315_091353_effects_central' folder, downloadable from the 'Light-and medium-duty effects' section on EPA's website: https://www.epa.gov/regulations-emissions-vehicles-and-engines/optimization-model-reducing-emissions- greenhouse-gases

EPA's assumption of no rebound effect for BEVs relies on the empirical evidence available, namely Chakraborty et al. (2022) and Nehiba (2022).124 Although insightful, these studies leave reason for uncertainty. For instance, both studies employ cross-sectional data and do not fully address the endogeneity between vehicle choices and usage, which is discussed further below. This correlation between consumer vehicle choices and usage could significantly vary between early adopters of BEVs and average ICE vehicle owners, thereby impacting the study conclusions. While these studies contribute to the emerging body of research in this field, their findings should thus be interpreted with some caution. Beyond Chakraborty et al. (2022) and Nehiba (2022), we are aware of several other studies that purport to use better data and identifying assumptions and also find zero rebound for electric vehicles (but do not yet have working papers available).125 [EPA-HQ-OAR-2022-0829-0601, pp. 18-20]

124 RIA at 4-14.

125 Wendan Zhang et al., Brookings Institution Electric Vehicle Adoption and Combustion Mile Displacement Across Demographics: Short Run Evidence and Implications For Policy, 2023 AERE Presentation (finding a negative rebound effect for electric vehicles.); Beia Spiller, Kenneth Gillingham & Marta Talevi. The Electric Vehicle Rebound Effect, 2023 AEA Conference.

While the available research provides some support for a 0% rebound rate for BEVs based on historical evidence, there is reason to believe that effect may not hold in the future. One potential explanation for the current BEV rebound findings is that "[c]onsumers are quite price inelastic, because they are inattentive."126 With the costs of BEV charging often consolidated into electricity bills, this alteration in cost perception could augment price inelasticity, rendering BEV owners less sensitive to per-mile cost variations.127 But this effect may become less pronounced as BEVs become more common. In particular, as infrastructure grows, electricity price salience may increase as gas stations convert to charging stations and prominently display electricity prices. Relatedly, the current literature could be shaped by the demographic profile of past and current BEV owners—predominantly early adopters—who may not reflect the population that purchases BEVs in the future.128 As BEV penetration accelerates, the associated rebound effect could potentially deviate from current estimates: Outside the vehicle context, economic literature documents a small rebound effect as electrical appliances become more efficient,129 which could hint at similar patterns in the future for BEVs. [EPA-HQ-OAR-2022-0829-0601, pp. 18-20]

126 Xavier Gabaix, Behavioral Inattention at 311, in 2 Handbook of Behavioral Economics: Applications and Foundations (2019).

127 See generally Ben Gilbert & Joshua Graff Zivin, Dynamic Salience with Intermittent Billing: Evidence from Smart Electricity Meters, 107 J. ECON. BEHAVIOR & ORG. 176 (2014) (finding that households tend to decrease their consumption in response to billing information—an effect that wanes as the bill's salience fades); Steven Sexton, Automatic Bill Payment and Salience Effects: Evidence from Electricity Consumption, 97 REV. ECON. & STAT. 229 (2015) (finding that automatic bill payments decreases price responsiveness).

128 RIA at 4-14 (acknowledging that the available data is “not likely representative of the current and future general population of car buyers and their driving behavior”).

129 Kenneth Gillingham et al., The Rebound Effect is Overplayed, 493 NATURE 475, 476 (2013) (finding a 10% rebound effect). Later, Gillingham et al. (2016) also highlight that the rebound effect for both gasoline and electricity generally falls within a range of 5% to 40%, with the majority of studies suggesting a rebound effect between 5% and 25%. Kenneth Gillingham et al., The Rebound Effect and Energy Efficiency Policy, 10 REV. ENV’T ECON. & POL’Y 68, 75 (2016).

In light of these complexities and uncertainties, EPA should consider exploring a range of possible rebound estimates for BEVs, including the same 10% assumption used for ICE vehicles. EPA should conduct sensitivity analysis to assess the implications of a range of rebound effects between 0% and 10%. [EPA-HQ-OAR-2022-0829-0601, pp. 18-20]

Notably, such an analysis would have a very limited impact on EPA’s assessment of net benefit. Policy Integrity reran OMEGA using a 10% rebound rate for BEVs and found that this change decreased total net benefits by just 0.43–0.71%, leaving the rule highly net beneficial overall. In fact, when total net benefits were rounded to two significant figures, as EPA does in the Proposed Rule and RIA, they appeared unchanged. (See Table A-1 in the appendix below for full results.) This is likely because additional BEVs resulting from the Proposed Rule make up a small share of the total fleet, particularly in the earlier years in the analysis that are weighted more as a result of discounting. In future standards, the BEV rebound effect could become more significant as BEVs make up a larger share of the vehicle fleet. [EPA-HQ-OAR-2022-0829-0601, pp. 18-20]

G. EPA Should Further Explain Its Choices Around Scrappage, Pass-Through, and Vehicle Sales

EPA should provide additional explanation around certain modeling choices—namely scrappage, pass-through, and sales. [EPA-HQ-OAR-2022-0829-0601, pp. 22-23]

“Scrappage” refers to the rate of which drivers discard old automobiles. OMEGA treats scrappage as exogenous, meaning that the rate of scrappage does not depend on the Proposed Rule’s other effects.144 This choice is reasonable: While economic theory and evidence suggest that scrappage depends in part on the Proposed Rule’s other effects (most notably the rate at which the Proposed Rule affects new vehicle prices and sales),145 this effect is very difficult to model due to data limitations, and past attempts by EPA and NHTSA to model scrappage have fared poorly.146 Moreover, the increasing movement to electric vehicles provides even more reason to treat scrappage as exogenous, as virtually no analysis on the scrappage of BEVs exists. However, the Proposed Rule provides no discussion of scrappage or EPA’s choice not to model it. Particularly since EPA endogenously modeled scrappage in the 2020 Rule, the agency may wish to explain its decision not to follow this approach in the Proposed Rule and a discussion of how it may affect the results. Moreover, to the extent feasible, EPA should attempt to model scrappage in future standards. [EPA-HQ-OAR-2022-0829-0601, pp. 22-23]

144 See RIA at 9-3 to 9-5.

145 See Howard K. Gruenspecht, Differentiated Regulation: A Theory with Applications to Automobile Emissions Control (1982); Howard K. Gruenspecht, Differentiated Regulation: The Case of Auto Emissions Standards, 72 Am. Econ. Rev. 328 (1982); ENV’T PROT. AGENCY, THE EFFECTS OF NEW-VEHICLE PRICE CHANGES ON NEW- AND USED- VEHICLE MARKETS AND SCRAPPAGE 3-6 to 3-11 & 5-7 to 5-7 to 5-12 (2021).

146 Inst. for Pol'y Integrity, Comments on the Safer Affordable Fuel-Efficient (SAFE) Vehicles Rule for Model Years 2021–2026 Passenger Cars and Light Trucks 66–71 (Oct. 26, 2018), https://policyintegrity.org/documents/Emissions_Standards_EPA_NHTSA_Comments_Oct2018.pdf.

"Pass-through" refers to the degree to which manufacturers pass on cost increases to consumers. EPA in prior tailpipe rules has assumed 100% pass-through to consumers in the vehicle market—meaning that every dollar of additional cost to the automaker is ultimately borne by the purchaser.147 EPA appears to repeat this assumption in the Proposed Rule. That approach is also reasonable given consistency with the agency's prior approach and the very limited economic evidence on vehicle pass-through. Nonetheless, that limited available evidence (from a 2010 paper) indicates that pass-through in the vehicle market may be below 100%.148 Accordingly, EPA should discuss and provide a rationale for its approach. EPA should also support further research in this area, given its potential importance. [EPA-HQ-OAR-2022-0829-0601, pp. 22-23]

147 E.g. 2020 Rule, 85 Fed. Reg. at 24,594–95.

148 Using regression analysis, Hellerstein and Villas-Boas (2010) find only partial pass through for the vehicle industry with an average pass-through rate of 38%. Rebecca Hellerstein, & Sophia B. Villas-Boas, Outsourcing and Pass-Through, 81 J. INT'L ECON. 170, 175 (2010).

Finally, with regard to sales, EPA should clarify how OMEGA treats how producers expect consumers to value fuel costs. Within the model, consumers and producers shape their preferred new vehicle mix independently,149 each informed by their unique perspectives on fuel costs: Consumers weigh their expected fuel expenses, whereas producers consider how they think consumers will weigh their expected fuel expenses. In the RIA, EPA explains that consumers are assumed to factor in fuel costs of 12,000 miles annually for 2.5 years.150 However, the OMEGA input files suggest that producers expect consumers to consider fuel costs up to 15,000 miles annually.151 Although this difference is not inherently problematic, especially if EPA posits imperfect information between consumers and producers,152 EPA should explain this difference. This might also be a minor programming error, such that EPA intended for producers to accurately peg consumer valuation of fuel costs at 12,000 miles annually. [EPA-HQ-OAR-2022-0829-0601, pp. 22-23]

149 The model then searches for solutions for a set of vehicle attributes, purchase prices, and quantities such that the sales and production shares match.

150 RIA at 4-2.

151 This information is derived from the 'sales_share_params_ice_bev_pu_b0p4_k1p0_x02031-cuv_b2p0_k1p0_x02029_nu8p0-sdn_b0p4_k1p0_x02020_nu1p0_20230228.csv' file for consumers, and the 'producer_generalized_cost-body_style_20220613.csv' file for producers, both located within the '2023-03-14-22- 42-30-ld-central-run-to2055\all_inputs' folder, downloadable from the 'Light-duty central case (zip)' section on EPA's website: https://www.epa.gov/regulations-emissions-vehicles-and-engines/optimization-model-reducing-emissions-greenhouse-gases

152 EPA, OMEGA Documentation Sec. 4.3.2 (last revised May 8, 2023), https://omega2.readthedocs.io/en/2.1.0/index.html#gl-label-producer-generalized-cost ("The producer, as an independent decision-making agent, will not have perfect information about the internal consumer decision process. Within the Producer Module, OMEGA allows the user to define the consumer decisions from the producer's perspective, which may be different from (or the same as) the representation within the Consumer Module.").

Organization: Kentucky Office of the Attorney General et al.

Furthermore, the Proposed Rule implicates "question[s] of deep economic and political significance," King v. Burwell, 576 U.S. 473, 486 (2015), due to the huge "number of people affected," United States Telecom Ass'n v. Fed. Commc'ns Comm'n, 855 F.3d 381, 423 (D.C. Cir. 2017) (Kavanaugh, J., dissenting from the denial of rehearing en banc). Because "Americans place a high value on car ownership," almost 92% of households have at least one vehicle, and over 22% have access to at least three. Car Ownership Statistics 2023, Forbes (May 8, 2023), https://bit.ly/3NnPXnn. A regulation affecting so many people is bound to collide with "a significant portion of the American economy," West Virginia, 142 S. Ct. at 2608 (cleaned up), and require "billions of dollars in spending by private persons or entities," id. at 2621 (Gorsuch, J., concurring) (quoting King, 576 U.S. at 485). By EPA's own estimate, technology increases "through 2055 are estimated at $260 billion to $380 billion." 88 Fed. Reg. at 29,344. [EPA-HQ-OAR-2022-0829-0649, pp. 6-7]

The Proposed Rule somewhat attempts to deal with this concern by predicting that sales will increase as consumers become more familiar with EVs as they see broader "charging infrastructure" and more electric cars "on the road." 88 Fed. Reg. at 29,189. But that raises another buyer-focused concern that makes it even less likely consumers will change their purchasing habits to the extreme degree EPA predicts. For people who "rely on street parking," park in a garage over 25 feet from a power source, or own a condo where the building association is not willing to "pay for upgrading the electrical panel or service," where and how to charge a new electric car is a real concern. Rachel Kurzius, Considering an electric vehicle? Here's how to prep your home for one, Wash. Post (Sept. 26, 2022), https://bit.ly/3N4Y3zZ. Even for the slowest and most basic "Level 1" charging option, potential EV customers are out of luck; their "home probably can't accommodate" an EV. Id. And those who are able to upgrade their home parking situations may find themselves in a long line as the need for more complex and expensive charging mechanisms grows at a fast clip. See EV Chargers: How many do we need?, S&P Global (Jan. 9, 2023), https://bit.ly/3X1xFeM (predicting that the EV population uptick will require "about 700,000 Level 2 and 70,000 Level 3 chargers deployed, including both public and restricted-use facilities," 1.2 million and 109,000 nationally by 2027, and 2.13 million and 172,000 by 2030, "all in addition to the units that consumers put in their own garages"). [EPA-HQ-OAR-2022-0829-0649, pp. 15-16]

Even those who already own EVs may be in for some unpleasant surprises. A recent study concluded, for example, that "[t]he vast majority of electric vehicle owners [who] charge their cars at home in the evening or overnight" are "doing it wrong" and should instead "move to daytime charging at work or public charging stations" so as to not overwhelm the grids. Golden, supra. But standard electricity pricing "charg[es] commercial and industrial customers big fees based on their peak electricity use." Id. "This can disincentivize employers from installing chargers, especially once half or more of their employees have EVs." Id. Some of these vehicle owners may thus be left in a vehicle-charging no-man's land. [EPA-HQ-OAR-2022-0829-0649, pp. 15-16]

Organization: Marie Gluesenkamp Perez, and Mary Sattler Peltola, Members of Congress, Congress of the United States

We are writing to express our concerns about the impacts the Environmental Protection Agency's (EPA) new proposed rules, Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles and Greenhouse Gas Emissions Standards for Heavy-Duty Vehicles – Phase 3 may have on rural communities. [EPA-HQ-OAR-2022-0829-0522, p. 1]

Like you, we believe climate change is a threat to communities across the country, and the federal government plays a critical role in developing a clean energy apparatus and helping our communities improve air quality. However, in making that transition, we cannot leave rural communities or working families behind. The administration's Executive Order 14037 and subsequent National Blueprint for Transportation Decarbonization set an ambitious goal for 50 percent of new passenger cars to be electric vehicles (EVs) by 2030. Last year's Inflation Reduction Act included many concrete policies promoting EV production that will drive costs down and improve affordability. We are concerned the EPA, along with the Department of Transportation (DOT) and the Department of Energy (DOE), have not done enough work to ensure rural communities will have the necessary charging infrastructure in place to make widespread EV adoption possible. The imposition of additional regulations in the auto market without key infrastructure investments will reduce consumer choice, which is a recipe for disaster in rural America. [EPA-HQ-OAR-2022-0829-0522, p. 1]

Rural communities, like ours, have more unique transportation and service options compared to cities or suburbs. Like many people who live in rural America, we spend a fair amount of time traveling, whether on or off the road system to get where we need to go. When your job, your pharmacy, or your child's daycare is over an hour away, you need to know that your car, snow machine, or ATV, will get you there and back. The ability to refuel a gas-powered vehicle quickly is valuable given the daily realities of rural life. That option is available because our country has a robust network of gas stations, and the requisite gas infrastructure, to support communities of all kinds. An equally robust infrastructure for EV charging must exist before this transition takes place to ensure working people and rural communities have consumer choices similar to cities and suburbs. And that infrastructure, especially fast-charging options, is not being built fast enough in many rural areas. EV charging programs included in the Infrastructure Investment and Jobs Act will help, but federal agencies remain focused on travel corridors along interstate highways, leaving many rural communities behind. [EPA-HQ-OAR-2022-0829-0522, pp. 1-2]

Washington's third congressional district has fewer than 100 level 2 and DC fast chargers available to the public, and they are largely concentrated in just two cities. Alaska has only 60 publicly available EV charging stations. In Congresswoman Gluesenkamp Perez' home county of Skamania, there are only two EV charging stations right now, and both are located at resorts. In Congresswoman Peltola's borough of Bethel, along with all the other boroughs of Western Alaska, there are zero EV charging stations. As DOT has acknowledged, the costs of installing EV chargers in rural areas can be higher, especially for direct current fast charging stations, because they are more likely to require expensive electrical service upgrades. Furthermore, for many working families, installing an EV charger at home remains out of reach, especially for those who don't own their homes. Bottom line: for EVs to be a meaningful and workable emissions reduction solution in rural America, we must have a ubiquitous and affordable charging infrastructure with access to abundant, cheap electricity. That simply does not exist right now. [EPA-HQ-OAR-2022-0829-0522, p. 2]

We are only four years away from model year 2027, and we are concerned the EPA's regulations are not paired with a plan to ensure adequate charging infrastructure on such a short timeline. Installing hundreds of thousands of new EV chargers and upgrading associated electrical infrastructure will also require tens of thousands of electricians. We are already experiencing a nationwide shortage of qualified electricians – anyone who's currently waiting six months for a residential electrician knows this all too well. Workforce shortages, particularly for those in the trades, are even more acute in rural communities. We want to ensure the EPA has considered the significant workforce development challenges that must be addressed to train electricians for a large-scale roll out of EV charging infrastructure. [EPA-HQ-OAR-2022-0829-0522, p. 2]

We request that the EPA, DOT, and DOE respond to the following questions:

1. What have the EPA, DOT, and DOE done to ensure rural communities are not left behind in the transition to electric vehicles?
2. Is there a clear and detailed deployment plan for electric vehicle charging infrastructure in rural areas?
3. How do the EPA and DOE anticipate potential shortages of trained electricians will impact the deployment of charging infrastructure? Further, have agencies evaluated the disparate impacts these shortages may have in rural communities?
4. Beyond using limited Inflation Reduction Act funding, how do the EPA, DOT, and DOE plan to address existing and future shortages of trained electricians?
5. Going forward, how do the EPA, DOT, and DOE plan to work together to ensure public charging infrastructure is abundant and accessible in rural areas? [EPA-HQ-OAR-2022-0829-0522, pp. 2-3]

We also request that you share how you plan to deploy necessary EV charging infrastructure in a timeframe that matches the implementation of the proposed rules. Building out this infrastructure will ensure that rural communities are not disproportionately impacted and left behind in a changing market. While it is critically important that we move toward a clean energy future, it must be a future that works for all Americans, including those in rural areas. [EPA-HQ-OAR-2022-0829-0522, pp. 2-3]

Organization: Nissan North America, Inc.

Beyond the significant market and governmental challenges posed by such a drastic implementation timeline, consumer adoption will be critical to success. Consumer adoption of EVs has historically lagged behind expectations, leaving a significant hurdle to encourage a large and swift shift to EVs. Consumers need to be convinced not only of the appeal, safety, affordability, and reliability of EVs themselves, but they need to adopt the necessary community and home charging equipment to facilitate their use. Consumers will need to adapt their trip planning and driving behavior to allow for vehicle charging needs. The only way to drive these significant behavioral changes is to assure consumers that charging infrastructure is available and reliable. This is simply not a reality today and is unlikely to be a reality in time to drive such a significant shift within the timeline of the Proposed Multi-Pollutant Rule. These challenges are magnified due to the unclear and uncertain benefits under the Inflation Reduction Act, which place significant limitations on EV consumer incentive programs and charging infrastructure programs. Moreover, many consumers are reluctant or unable to purchase EVs due to their significant price premium. The Proposed Multi-Pollutant Rule will only exacerbate these inequalities, with EV prices likely to increase even more due to extreme investments required by all market sectors involved. Driving too much change too quickly will shut out many communities who need clean vehicles the most. It will likely force consumers who are uncertain about ZEV adoption to continue to operate aging ICE vehicles much longer. This is contrary to the intent of the proposal. [EPA-HQ-OAR-2022-0829-0594, p. 5]

Organization: Senator Shelley Moore Capito et al.

Perhaps the most conspicuous flaw that will leap out to the American public is that these proposed actions were taken with complete disregard to consumer choice or affordability. In addition to potentially lacking access to charging at home, work, or public charging stations, consumers looking to purchase a new car may be unable to purchase these vehicles due to the higher purchase price or lack of availability. Today, the average purchase price of EV cars in 2022 was approximately $65,000-which is more than what 46 percent of American households earn in income in a year.8 Adding demand to the grid amid the confluence of other EPA regulations referenced above will drive up the cost of electricity, making powering these vehicles less affordable and undermining the EPA' s claims of savings for consumers that ignore or understate the increase in vehicle and energy prices. Taken together, the erosion of choice and affordability of vehicles will have profound impacts on how American families run errands, get to school, commute to work, and recreate. Additionally, there are serious concerns about the range of electric vehicles and the performance in rural areas of the country, where people may have to drive much longer distances to reach a charger, especially in locations where cold weather can impact the range the vehicle can drive. [EPA-HQ-OAR-2022-0829-5083, p. 3]

8 See Kelley Blue Book and Cox Automotive Average Transaction Prices Reports; and Average, Median, Top 1%, and all United States Household Income Percentiles, DQYDJ.

Organization: Zero Emission Transportation Association (ZETA)

A common misconception is that range anxiety continues to pose a significant barrier to adoption across all vehicle classes. The average U.S. household travels 37 miles per day.21 The average range on an electric vehicle is 291 miles. The EV models currently available can meet the needs of most American households.22 Vehicles capable of traveling distances up to 520 miles, such as the Lucid Air Dream Edition R,23 are being produced today and those with ranges greater than 600 miles are expected after 2023.24 [EPA-HQ-OAR-2022-0829-0638, p. 8]

EPA Summary and Response

Comments regarding vehicle ownership behavior includes three broad categories: what people do with vehicles (i.e., buy, lease, sell, scrap), how people use their vehicles (i.e., vehicle miles traveled, rebound, and use case like commuting, towing, long trips), and activities they undertake to support use of their vehicles (e.g., trip planning, charging, maintenance and repair). Among ownership behaviors, we do not discuss type of purchase (i.e., buy and lease) or sell/trade-in decisions in this section. We note that we have responded to purchase-related comments in Chapter 13.2 of this RTC where we discuss demand-related comments and there were no comments on selling and trading in a vehicle. We also defer responses to comments regarding maintenance and repair comments to Chapter 13.4 of this RTC where we discuss consumers’ savings and expenses. In addition, where a comment addresses topics other than vehicle ownership behavior – such as PEV demand in rural communities, charging availability, program design, sales, consumer purchase and producer decision making, affordability– we refer readers to the appropriate sections of the Preamble, RIA, and this RTC where those topics are addressed.

What people do with vehicles

The Institute for Policy Integrity at New York University Law School comments on vehicle scrappage. They note that “OMEGA treats scrappage as exogenous” and describe “this choice is reasonable.” They suggest, however, the EPA provide a discussion of our “choice not to model it.” In response, we agree and have briefly discussed this choice in RIA Chapter 4.2.3.

How people use their vehicles

Some commenters called attention to people who live and work in rural environments, stating that “people who live in rural America … spend a fair amount of time traveling.” Relatedly, they expressed “serious concerns about the range of electric vehicles and performance in rural areas of the country, where people may have to drive much longer distances to reach a charger” as well as concerns that government entities “have not done enough work to ensure rural communities will have the necessary charging infrastructure in place to make widespread EV adoption possible.” One commenter asserted that “the ability to refuel a gas-powered vehicle quickly is valuable given the daily realities of rural life.” Relatedly, Green Diesel Engineering LLC simply states that BEVs are a “good solution for local driving patterns. It is not good for long distance runs, or pulling loads and does suffer in range in extreme cold or heat." While these comments focus on number of miles, we know from comments in Chapter 13.2 of this RTC, that consumers use their vehicles in a variety of ways that have greater energy requirements, like hauling and towing, which may be especially important to rural communities. We also know that extreme conditions like very cold temperatures and heavy towing, affect the performance (e.g., fuel or energy efficiency) of PEVs and ICE vehicles. In response, we repeat some of what we discuss in RTC Chapter 13.2. All of the compliance pathways presented in the FRM show a substantial market share of new ICE vehicles. We expect that automakers will continue to produce vehicles, from ICE to hybrids to PEVs, that meet the needs of rural consumers. Second, the so-called advantages and disadvantages of any vehicle are not inherent to the vehicle. What is perceived as an advantage or disadvantage depends on the consumer and on the context, which are heterogenous and dynamic. While rural drivers may drive more miles on average per day, "the average U.S. household travels 37 miles per day," "the average electric range on an electric vehicle is 291 miles," and "U.S. Bureau of Transportation Statistics data shows that trips longer than 250 miles make up a miniscule fraction of U.S. daily driving." Even in cold weather or under high energy demands, average PEV range will likely prove adequate most of the time to "run errands, get to school, commute to work, and recreate" without recharging, as well as make long trips. While the range of PEVs will satisfy many rural drivers, rural or other drivers who log a lot of miles may also enjoy the savings associated with vehicle operation. Also, consumers who purchase PEVs are able to choose between vehicles with different range capabilities that suit their needs. With respect to comments about BEV use in extreme temperatures, just as with ICE vehicles, cold and hot weather can increase EV energy consumption due to use of cabin heating and cooling and defrosting. Because EVs are more efficient, less waste heat is available to heat the cabin so the energy must come from the battery. However, climate control requires only a fraction of the energy needed to drive a vehicle, and most of today's EVs have a substantial driving range of about 300 miles or more that can easily accommodate climate control needs. Also, we note that under these standards, ICE vehicles will still be available to purchase for those consumers who continue to prefer ICE vehicles.

In another section, one commenter stated that EPA "glossed over range anxiety." We disagree. While limited range used to be a practical concern to many households due to the much lower range of early PEVs, technology has advanced and will continue to do so. Households are no longer subject to the range limitations of early PEVs. While range anxiety persists today, it is unlikely to remain a concern as consumers gain experience with and exposure to the realities of PEV ownership. We also expect charging infrastructure to advance, increase in availability, and expand geographically. PEV range, range anxiety, charging behavior, charging availability and access are among the factors that influence PEV acceptance and are included in our analyses and representation of PEV acceptance. See Preamble Section IV.C.6, RIA Chapter 4.1, and RTC 13.1 and 13.2 regarding PEV acceptance. See Chapter 17 of this RTC and RIA Chapter 5 regarding charging infrastructure.

In addition to vehicle miles and use cases, Environmental and Public Health Organizations and Institute for Policy Integrity at New York University School of Law comment extensively on rebound. The former generally provided support for EPA's assessment of rebound for ICE vehicles and BEVs. The later provided more cautious support for EPA's BEV rebound assumptions, suggesting that "the associated rebound effect could potentially deviate from current estimates" as BEV penetration accelerates and recommended that "EPA should conduct sensitivity analysis to assess the implications of a range of rebound effects between 0% and 10%." Environmental and Public Health Organizations made three clear recommendations. First, they recommend that EPA consider an abstract on BEV rebound, Spiller et al. (2023) which "provides further support for EPA's 0% BEV rebound effect." In response to these rebound relevant recommendations, we have reviewed the Spiller et al. 2023 abstract. The results stated in the abstract are not directly relevant to BEV rebound as we have defined it, and the paper appears not to have been published. Second, they suggest that "EPA should consider using a rebound effect [for ICE vehicles] of a lesser magnitude" and relatedly that "EPA should more fully consider the impacts of the income effect on ICE vehicle rebound." As discussed in Chapter 8.3.3 of the RIA, as in the 2021 rule and our proposal, we to continue our estimate of a 10% rebound for ICE vehicles in the final rule analysis. The Institute for Policy Integrity recommended that EPA test a range of rebound estimates for BEVs, but then also noted that their own analyses show very little sensitivity to this assumption. In response, we agree that future measures of BEV use may indicate different rebound than currently assumed. EPA will continue to keep abreast of the literature on this topic. We also appreciate the recommendation to conduct sensitivity analysis of BEV rebound, though we have not done so based on the small effect we expect and the small effect that was found by the commenter.

Regarding rebound, EPA also received comments regarding the effect of IRA incentivizing carbon capture and sequestration (CCS) used for enhanced oil recovery . . . on fuel prices. The commenter states that "oil will be produced at a marginally lower cost" leading to "the decreased cost of fuel" and subsequent rebound. The commenter did not provide any economic analysis of this issue that we could review. At this time, we conclude that there is too much uncertainty to determine how many CCS projects with EOR in the U.S. will result from the IRA legislation over the time frame of analysis of the LMDV rule (2027-2055). We also note that oil prices are set in the global market. The impacts on U.S. fuel prices of IRA provisions on EOR may be very modest. Given these uncertainties, we are not able to quantify this effect. However, we anticipate that the fuel price effect and the subsequent rebound effect would be fairly small. The issue, the impact of CCS on oil prices and, in turn, the rebound effect for LMDVs, is a topic for further study in EPA's view.

Activities people undertake to support vehicle use

In closing out our response to comments regarding vehicle ownership behavior, commenters discussed a few more topics – charging and the behavior necessary to accommodate charging. Delek US Holdings, Inc. commented on the time it takes for BEVs to be fully charged, the additional downtime they claim charging will require, and the discomfort of travel in the absence of "fast and convenient charging." Kentucky Office of Attorney General et al. points out that consumers will need to know "where and how to charge a new electric car" including time of day or night. Nissan also cites charging behaviors and the trip planning and driving behavior to accommodate charging needs.

In response, we first note that most vehicles are in use just a few hours per day. Depending on the vehicle's location when it is not in use, charging could occur when the vehicle is parked. Under those conditions, there is effectively no downtime for charging which is reflected in the refueling time included in the NPRM and in the revised refueling time estimates in the FRM. Mid-trip charging, which the EPA does estimate, is not necessarily uncomfortable or inconvenient. It also does not require fast charging or long duration. For example, in some circumstances, a full charge might be required, in which case fast charging could be preferred. However, depending on one's needs, a driver might not require a full change and either charge for a shorter period of time and/or at a slower rate, stopping before a full charge is reached. There are, of course, exceptions to the above, but, as discussed above, the advantages and disadvantages of any vehicle is not inherent to the vehicle. Rather the perception of vehicle attributes depends on the user and the context. Also as discussed above and throughout this RTC, we have demonstrated multiple example compliance pathways which include various mixes of ICE, hybrids, PHEVs and BEVs. With the flexibility of performance-based standards, we expect that automakers will continue to produce a wide selection of vehicles to meet consumer needs.

We also note that learning and adaptation will occur as PEV markets shares grow and charging infrastructure expands. For consumers who choose a PEV, more exposure and experience, the multiplicative nature of network and neighborhood effects, and people's innate ability to learn and adapt strongly suggest, in combination, that the behaviors associated with charging will emerge and become "second nature" in very much the same way that visiting a gas station is today.

13.4 - Consumers' savings and expenses

Comments by Organizations

Organization: A. Longo

The proposed regulation seeks to impose a number of restrictions on the transportation sector, such as rigorous emissions standards, increased fuel efficiency requirements, and limitations placed on certain modes of transportation. Specifically, the Environmental Protection Agency (EPA), aims to establish new greenhouse gas emissions standards placed upon vehicles that meet the definition of light to medium-duty. These standards seek to achieve an aggressive and sum what arbitrary thirty percent reduction in emissions by 2030 and a fifty percent reduction by 2050. According to the EPA's own analysis, the reduction in emissions would save $1,500 over the life of the vehicle primarily due to savings in fuel costs, and economic value of reduced emissions. However, a number of industry groups have challenged this analysis including the American Trucking Associations, the National Association of Manufacturers, the Alliance of Automobile Manufacturers, the Trucking Alliance, and the Owner- Operator Independent Drivers Association. All have challenged the figure indicating that the analysis does not include the full economic impact. [EPA-HQ-OAR-2022-0829-0517, p. 1]

While these measures target environmental concerns around the improvement in air quality, it is necessary to consider their economic impact. According to a recent study led by the International Council on Clean Transportation (ICCT), implementing more rigorous emissions standards on light to medium-duty vehicles will likely lead to significant increases in manufacturing costs. These increases are routinely passed on to consumers in the form of higher vehicle prices. This would result in decreased affordability and potentially contribute to significant inflationary pressures [1]. Additionally, the American Trucking Association conducted a study indicating that the proposed regulations would increase the cost of manufacturing medium-duty vehicles by $10,000 to $20,000 per vehicle, leading to higher prices for consumers [2]. According to the Department of Transportation, the CPI sub-index for

Transportation reached an all-time high of 284 points in June of 2022 and is holding close to that level, which is well above the last 25-year average. Inflation in the transportation sector increases the price of all consumer goods brought to market and negatively affects our economy. [EPA-HQ-OAR-2022-0829-0517, p. 1]

3. Affordability

The auto industry has made significant progress driving down battery and fuel cell costs. Even still, further research and development investments will be needed to realize cost, utility, and convenience parity between EVs and their internal combustion counterparts. EVs currently cost more to produce than equivalent ICE vehicles, and in many instances are sold at a loss. This divide grows when considering convenience and utility parity, which requires larger batteries to support longer EV ranges commensurate with consumer expectations and needs. Larger vehicles (e.g., pickup trucks and SUVs) used by individuals and businesses for towing or heavy payloads require even higher-capacity batteries to support payload and towing needs. [EPA-HQ-OAR-2022-0829-0701, pp. 80-82]

When discussing affordability, EPA looks at the savings associated with a BEV compared to an ICE vehicle over an eight-year period.140 According to EPA, consumers who chose to purchase a new MY 2032 BEV instead of an ICE vehicle save between $400 and $4,000 at the time of purchase and between $9,000 and $13,000 on operating expenses over the first eight years of vehicle life (DRIA Table 4-7). [EPA-HQ-OAR-2022-0829-0701, pp. 80-82]

140 DRIA at 4-21 (Table 4-8).

First, these costs rely heavily on steep reductions in battery costs reductions in the 2026-2032 timeframe, which as we discuss in Section I.F. (Lithium-Ion Battery Cost) above, are likely unrealistic for a host of reasons, not the least of which is the vast increase in global demand across all sectors for lithium batteries during that same period. Second, the analysis in NPRM Tables 4-7 and 4-8 assume maximum $7,500 IRA tax credits in 2032, which as we've discussed earlier is simply not accurate – all vehicles and all buyers will NOT qualify for the maximum IRA tax credit of $7,500. Moreover, even if they did, what happens in 2033? The standards remain the same but the IRA tax credit is not available. Finally, the differential prices between ICE and BEV are not consistent with at least the current market, where EVs have consistently carried a price premium of close to $10,000 as shown in Figure 30 below. For example, in March 2023, KBB reports the average EV transaction price was $59,553 compared to the average new vehicle transaction price of $48,289.141 [EPA-HQ-OAR-2022-0829-0701, pp. 80-82]

141 https://www.coxautoinc.com/wp-content/uploads/2023/04/March-2023-Kelley-Blue-Book-Average-Transaction- Price-data-tables.pdf

Figure 30: Automotive Vehicle Transaction Price by Segment (Auto Innovators) [EPA-HQ-OAR-2022-0829-0701, pp. 80-82]

The higher EV purchase prices require larger down payments and/or longer-term loans at today's higher interest rates than most people can afford. According to the JD Power EV index report, there are only nine vehicles that reached total cost of ownership parity compared to an ICE as of March 2023.142 [EPA-HQ-OAR-2022-0829-0701, pp. 82-83]

142 htps://www.jdpower.com/business/resources/ev-divide-grows-us-more-new-vehicle-shoppers-dig-their-heels- internal-combustion

Consumer interest in EVs is heavily swayed by the purchase price. According to the April 2023 JD Power E-Vision Intelligence report,143 the primary barriers to EV purchase over the past 10 months have been the lack of public charging infrastructure and price (Figure 31). Organization: American Free Enterprise Chamber of Commerce (AmFree) et al.

Decreasing Costs. EPA's claims about the costs of purchasing and owning an electric vehicle also suffer multiple flaws.

EPA acknowledges that retail prices are typically higher for electric vehi- cles, but it asserts that the price difference is expected to "narrow or disappear" in the coming years. 88 Fed. Reg. at 29,190. That prediction rests primarily on EPA's expectations regarding declining costs of batteries and purchase incen- tives provided in the Inflation Reduction Act ("IRA"). EPA overestimates the effect that these factors will have on upfront purchase prices. [EPA-HQ-OAR-2022-0829-0683, pp. 24-25]

EPA also assumes without justification that manufacturers will pass sav- ings on to purchasers in the form of lower vehicle prices. EPA must assess— not guess—the impact that the Advanced Manufacturing Production Credit is likely to have in the relevant years before relying on that credit to justify its determination regarding feasibility. [EPA-HQ-OAR-2022-0829-0683, p. 30]

EPA separately claims that, even if retail prices remain higher, the total cost of ownership for electric vehicles is lower and will in turn incentivize purchasers to buy them despite higher up-front outlays. 88 Fed. Reg. at 29,190, 29,312. According to the agency, electric-vehicle buyers will save "between $9,000 and $13,000 on operating expenses over the first 8 years of vehicle life." Draft RIA at 4-21. But not all consumers can make purchasing decisions based on savings that they hope to experience years later. "Buying a new car is the second most expensive purchase a consumer makes behind buying a house." Charette, Con- vincing Consumers. In many cases, the price for an electric vehicle will amount to “nearly 100 percent of an annual US median household income.” Id. Poten- tial customers “may not be interested” in those operating-cost savings “if meet- ing today’s monthly auto payments is difficult.” Id. In addition, consumers who focus on the total cost of ownership of a vehicle must consider not only day-to- day operating expenses but also other “extra costs” of purchasing an electric vehicle—such as the need to install home charging equipment, “which can add several thousand dollars more,” and higher insurance costs that “could add an extra $500-$600 a year.” Id. The total cost of ownership, therefore, may not be a selling point for many consumers in the vehicle market. [EPA-HQ-OAR-2022-0829-0683, p. 30]

For these reasons, EPA falls far short of supporting the projected adoption rates upon which its analysis of the feasibility of its proposed rule rests. [EPA-HQ-OAR-2022-0829-0683, p. 30]

Second, EPA concludes that the costs of the proposed rule would be offset by a $580 billion reduction—which EPA counts as a “benefit”—in “mainte- nance and repair costs” that it expects consumers to realize by shifting to elec- tric vehicles. 88 Fed. Reg. at 29,372, 29,385. As support for this enormous sum, EPA points to a single study suggesting that lifetime repair-and-maintenance costs for electric vehicles will be less than for combustion-engine vehicles. See Draft RIA at 4-32. In so doing, the agency unreasonably ignores countervailing sources suggesting the opposite. For instance, Consumer Reports has found that consumers report more problems with electric vehicles than combustion- engine vehicles—including issues with battery packs, charging, electric drive motors, and heating and cooling systems unique to electric vehicles. Jake Fisher, Tesla and Nissan Make the Most Reliable Electric Vehicles, Consumer Reps. (Dec. 14, 2022), https://tinyurl.com/mryx9z6c. It also takes longer, and costs more, for problems with electric vehicles to get resolved. Charette, Convincing Consumers. And there are fewer qualified technicians to resolve them: out of 229,000 auto-repair technicians in the United States, only 3,100 are certified for electric vehicles. Id. Moreover, if a manufacturer goes out of business (much more common in the nascent electric-vehicle industry), purchasers of that com-pany’s vehicles will be on their own in seeking to repair the vehicles, without standard manufacturer-servicing support. Beia Spiller et al., Medium- and Heavy- Duty Vehicle Electrification: Challenges, Policy Solutions, and Open Research Questions, Res. for the Future, at 13 (May 2023). Any final rule must explain why EPA’s fuel-savings figures are realistic in the face of this contrary evidence. [EPA-HQ-OAR-2022-0829-0683, pp. 62-63]

Third, EPA asserts that consumers will receive $890 billion in fuel savings— in other words, that operating electric vehicles will be cheaper than operating combustion-engine vehicles because consumers will no longer need to purchase fuel directly. See 88 Fed. Reg. at 29,362. But this figure depends on consumers’ choosing to switch from their familiar combustion-engine vehicles to electric vehicles in overwhelming numbers. Even if all of the obstacles to manufactur- ing and charging electric vehicles discussed above could be overcome, the fuel savings EPA posits still would not materialize unless individuals decide to pur- chase those vehicles. For the reasons already noted, there is ample reason to doubt that consumers would do so, including based on concerns about electric vehicles’ higher up-front costs and perceptions that charging and maintenance facilities are inadequate. [EPA-HQ-OAR-2022-0829-0683, pp. 63-64]

To the extent EPA believes that the prospect of fuel and other operational savings itself would motivate consumers to adopt electric vehicles in sufficient numbers, experience thus far indicates otherwise. As EPA acknowledges, if abandoning combustion-engine vehicles in favor of electric vehicles actually resulted in net operating savings, rational users of combustion-engine vehicles would likely already be switching to electric vehicles in much greater numbers than they are today. See 88 Fed. Reg. at 29,397; Draft RIA at 4-38–39 (noting that "[c]onventional economic principles" would lead "people [to] buy [electric vehicles]"). The fact that consumers are not doing so—but instead currently "tend to favor [combustion-engine] vehicles over" the electric vehicles that are available now even "when two vehicles are comparable in cost and capability," 88 Fed. Reg. at 29,342—is a strong indication that EPA's asserted savings do not in reality outweigh the costs of switching to electric vehicles. [EPA-HQ-OAR-2022-0829-0683, pp. 63-64]

EPA attempts to sidestep this problem by invoking a supposed "energy ef- ficiency gap," positing a market failure that is responsible for skewing consum- ers' decisions away from purchasing electric vehicles. 88 Fed. Reg. at 29,397. But EPA provides no evidence demonstrating that low adoption of electric ve- hicles is actually the result of any such market failure, as opposed to well- founded concerns about the drawbacks of the technology. EPA offers only a hope that nothing "immutable within consumers or inherent to" electric vehi- cles will "irremediably obstruct[] acceptance." Id. at 29,312. But in light of the gap between the data and consumer behavior on the one hand, and EPA's rosy savings estimates on the other, any final rule must explain why EPA's fuel- savings figure is realistic and why it is an appropriate offset for the rule's costs. See Am. Pub. Gas Ass'n v. DOE, 22 F.4th 1018, 1027–28 (D.C. Cir. 2022). EPA cannot justify an economy-altering rule by invoking an ill-defined, unsubstan- tiated market failure of its own imagining. [EPA-HQ-OAR-2022-0829-0683, pp. 63-64]

Organization: American Fuel & Petrochemical Manufacturers

Additional barriers to ZEV adoption by particularly low-income stakeholders, include but are not limited to restricted driving/battery range; inability to charge in different housing and work situations; high price points to purchase, maintain, and insure EVs; availability of replacement parts and qualified mechanics, as well as ease and cost of repairs; and unpredictability regarding future electricity costs. EPA cannot ignore these real-world limitations. [EPA-HQ-OAR-2022-0829-0733, p. 33]

EPA also assumes the increased supply of ZEVs—resulting from OEMs' planned production expansions and offering of more ZEV models, charging infrastructure, purchase incentives, and lower battery prices—will lead to lower ZEV prices.239 EPA ignores that battery prices have begun to rise due to limited supply of minerals.240 While there are some affordable EVs, these EVs typically have a range below 200 miles on a full charge.241 If consumers want longer range EVs, they will pay a considerable purchase price as seven of the top ten, range-rated EVs cost anywhere from $74,800 to $110,295.242 EPA's analysis also fails to account for the increased vehicle sales tax and property tax associated with the higher purchase price of ZEVs (even after myriad subsidy programs). [EPA-HQ-OAR-2022-0829-0733, pp. 52-53]

242 See Nicholas Wallace, Austin Irwin, & Nick Kurczewski, Longest Range Electric Cars for 2023, Ranked (Mar. 23, 2023), https://www.caranddriver.com/features/g32634624/ev-longest-driving-range/.

EPA's cost benefit analysis is implicitly built around much longer battery life than is currently achieved, as EPA does not factor in battery replacement costs or the environmental implications of additional battery production, recycling, and disposal. EPA cannot have it both ways – either the batteries are remarkably durable, or the costs of this Proposed Rule are dramatically understated. Even with massive direct and indirect subsidies, EVs are more expensive on average than their ICEV counterparts and unaffordable for many households. In the first calendar quarter of 2022, the average price of the top-selling light-duty ZEV in the U.S. was about $20,000 more than the average price of top-selling ICEV.243 The price disparity has not improved, with the average price of light-duty EVs near $66,000 in August 2022 and continuing to rise.244 [EPA-HQ-OAR-2022-0829-0733, pp. 52-53]

iv. Total cost of ownership

EPA's proposal also vastly underestimates the cost of ownership for ZEV owners by assuming ZEVs achieve real-world fuel economy that is equivalent to EPA's test methods. They do not and it is not close. This error significantly undermines EPA's estimates of costs for both ZEV owners and associated power infrastructure and charging infrastructure requirements. As noted in the environmental benefits discussion above, EPA's proposal is based on performance data estimates of ICEV fuel economy using EPA's "5-cycle method." If EPA's analysis were based on real-world fuel economy testing of ZEVs, it would show they use vastly higher amounts of electricity to travel the same distance, with a corresponding increase in ZEV owner costs for electricity and ZEV maintenance and battery replacement. EPA must account for these real costs. [EPA-HQ-OAR-2022-0829-0733, p. 55]

EPA's total cost of EV ownership incorrectly assumes each vehicle type of all new ICEV and ZEV will travel the same miles each year.249 EVs have less range, both technically and practically. As noted by J.D. Power, "the majority of EVs provide between 200 and 300 miles of range on a full charge."250 Studies show that the average electric car is driven 9,059 miles per year, compared with 12,758 miles for ICEVs.251 By overestimating VMT, EPA compounds all other errors in its assumptions that all work in favor of ZEVs and to the detriment of ICEVs. [EPA-HQ-OAR-2022-0829-0733, p. 55]

249 DRIA at 4-20, Table 4-7 (e.g., EPA assumes EV and ICEV sedans/wagons will both travel 15,700 miles per year).

250 See Sebastian Blanco, List of EVs Sorted by Range (Sept. 1, 2022), www.jdpower.com/cars/shopping-guides/list-of-evs-sorted-by-range.

251 iSeeCars, The Most and Least Driven Electric Cars (May 22, 2023), https://www.iseecars.com/most-driven-evs-study.

Another way that EPA justifies lower EV ownership costs is by failing to fully account for current state excise tax policies and insurance that establish higher costs for ICEV owners and lower costs for ZEV owners. Insurance premiums for PEVs are typically higher than comparable ICEVs because of higher repair and parts cost. The price premium depends on the make and model, age of the driver, geographic location, and state. According to ValuePenguin, insurance on a PHEV, depending on the model, could be 19 percent to 32 percent higher than comparable ICEV.252 Another estimate from an Oct 2022 study from Self Financial concludes PEVs' annual insurance is $1,674, $442 more compared to an ICEV annual insurance premium of $1,232.253 [EPA-HQ-OAR-2022-0829-0733, p. 55]

252 How Much Does Electric Car Insurance Cost? - ValuePenguin.

253 Electric Cars vs Gas Cars Cost in Each State | Self Financial.

Should EPA mandate that most new vehicles will be ZEVs, it will become increasingly untenable for ICEV owners to either further subsidize ZEV owners by paying higher excise taxes, or for states to suffer a shortfall in revenue collections by continuing to give preferential treatment to ZEV owners. EPA must acknowledge these significant costs necessarily must increase for ZEV owners as EPA mandates higher ZEV sales. [EPA-HQ-OAR-2022-0829-0733, p. 55]

Finally, EPA's total cost of ownership analysis assumes dramatically lower retail fuel costs for ZEVs (around 60 percent less) than liquid fuels.254 Real-world data squarely contradicts EPA's cost assumptions on EV charging. For example, California's ZEV mandates have contributed to the inflationary impacts on energy prices and on jobs in certain industries related to traditional fuels and vehicles. According to a 2021 California Public Advocates Office presentation to the California Public Utilities Commission, "it is already cheaper to fuel a conventional internal combustion engine (ICE) vehicle than it is to charge an EV" in the San Diego Gas & Electric Co. service area.255 This is astonishing given that gasoline prices in California are the second highest in the nation, averaging approximately $4.01 per gallon of gasoline in 2021. Future projections afford consumers no relief, as the California Energy Commission projects that both commercial and residential electricity prices will continue to rise, reaching nearly $7 per gasoline-gallon equivalent for the commercial sector. Similarly, many in New England are finding it is costing more to charge up than fill up, paying $0.28 per kilowatt hour (double the price of the national average) in the fall of 2022.256 EPA must revise its analysis to account for realistic electricity prices. [EPA-HQ-OAR-2022-0829-0733, pp. 55-56]

254 DRIA at 4-20, Table 4-7.

256 Irina Ivanova, https://www.cbsnews.com/moneywatch?ftag=CNM-16-10abg0dFor some electric vehicle owners, recharging now more costly than filling up, CBS News Money Watch, Feb. 13, 2023. Available at Electric cars 2023: In some parts of the U.S., recharging now more costly than filling up - CBS News.

Finally, charging pricing has been unpredictable, with some stations charging by the minute instead of charging for electricity consumed.257 Other charging stations offer multiple subscription plans or charge different rates at various times of day, resulting in significant price increases over the past few months.258 Boston charging companies raised charging fees in response to New England utilities increasing their rates to 39 cents per kilowatt-hour in February 2023, from 27 cents a year earlier.259 [EPA-HQ-OAR-2022-0829-0733, p. 56]

258 Id.

259 Id.

However, building more charging stations is not enough. “Electricity purchased at a public charger can cost five to ten times more than electricity at a private one.”278 Lower-income consumers cannot afford to install solar photovoltaics, which proponents claim will allow ZEVs to be charged at home with emissions-free electricity.279 Those who cannot afford private charging will end up paying vastly more for a re-charge than the wealthy. For those who simply cannot afford the upfront costs for a new EV or pay higher public charging rates, they may end up retaining older ICEVs for longer. [EPA-HQ-OAR-2022-0829-0733, p. 60]

Organization: American Highway Users Alliance

We are also concerned that the proposed rule, among other impacts, would increase vehicle costs for consumers. At the end of the first quarter of 2023, the price of an EV was more than double the price of a subcompact car.1 This represents a real financial challenge for middle class mobility; for families that need a basic vehicle to get to work, health care, the grocery store, and other fundamental destinations, and for local business travel, such as meetings and sales calls, particularly for small business. [EPA-HQ-OAR-2022-0829-0696, p. 2]

1 https://www.autosinnovate.org/posts/papers-reports/get-connected-2023-q1 (page 4).

Feasibility of the proposal is highly questionable and benefits are likely overestimated We are skeptical that the GHG and criteria reductions estimated by EPA can be realized in the proposed rule’s timeframe. [EPA-HQ-OAR-2022-0829-0696, pp. 4-5]

We noted above the substantially greater cost of EVs. With such a cost differential (even if the differential is reduced somewhat in coming years), many consumers and businesses can be expected to keep and maintain existing vehicles (average age just over 12 years) rather than pay for new, much more expensive electric vehicles. [EPA-HQ-OAR-2022-0829-0696, pp. 4-5]

Additionally, the cost of the vehicle itself is not the only consideration for a consumer in making a purchasing decision. Many businesses and hard-working families will not purchase a vehicle unless both the vehicle and fuel are cost effective and meet their needs. At this point the availability of charging stations, while increasing, seems unlikely to approach the current ubiquitous availability of fuel at gas stations within the time frame of the rule. That could result from various electricity supply and transmission issues, including the time delay and cost involved in building out more connections between the grid and charging stations.4 [EPA-HQ-OAR-2022-0829-0696, pp. 4-5]

4 A statement submitted to EPA in conjunction with EPA's May 3 hearing in the heavy-duty vehicle Phase 3 docket by ABF Freight System, a major trucking company with over 4,500 Class 8 and Class 6 vehicles, noted a wait of 2 years and counting for added utility infrastructure at a facility to support the company's current EV trucks (only 6) and anticipated EV truck purchases.

Moreover, a recent ATRI study found that electrification of the entire U.S. vehicle fleet would consume 40.3% of the current electricity demand, yet our aging national grid can hardly sustain its current needs.5 [EPA-HQ-OAR-2022-0829-0696, pp. 4-5]

5 Charging Infrastructure Challenges for the U.S. Electric Vehicle Fleet, American Transportation Research Institute, December 2022. https://truckingresearch.org/2022/12/charging-infrastructure-challenges-for-the-u-s-electric-vehicle-fleet/

For such reasons the benefits of the proposed rule as estimated by EPA appear to be overstated, as the vehicle fleet will not turn over to EVs as quickly as EPA estimated. Further, the proposed rule will limit consumer choice and the mobility of the American public. [EPA-HQ-OAR-2022-0829-0696, pp. 4-5]

Organization: American Petroleum Institute (API)

2. ZEV penetration/customer uptake and adoption rates.

LMD ZEVs are currently not available in sufficient quantities or at affordable levels to significantly displace ICEVs. Given the lower costs, current ICEV owners may choose to continue to use and extend the life of their ICEVs to avoid these issues. EPA must address the potential impacts of this likelihood on its emissions projections. [EPA-HQ-OAR-2022-0829-0641, p. 15]

Organization: Anonymous

EPA also incorrectly assumes that the tax credits are free. They use the tax credits to offset the costs of BEVs, but they do not consider the costs to taxpayers to fund the tax credits. This hides the costs of BEVs to the American Population by hundreds of billions. Furthermore, EPA does not address the societal inequities that will be produced by providing tax credits for BEVs. Since BEVs are typically more expensive than basic ICE vehicles and the fact that the tax credits are non-refundable (meaning that you have to carry a tax liability to get the benefits of the tax credit), all taxpayer funds will be going towards funding new BEVs for richer Americans. In this sense, EPA's reduces environmental justice by forcing BEVs. [EPA-HQ-OAR-2022-0829-0565, p. 4]

Finally, EPA's estimates of tax credits overstates their applicability. The Clean Vehicle credit has some restrictions that will limit how many vehicles qualify and how much. EPA should model these restrictions or at the very least make a good faith estimate. For the commercial clean vehicle tax credit, EPA ignores the cost-basis nature of the credit an d assumes that everyone will lease a vehicle to get the EV tax credit while ignoring the lost utility of owning a vehicle. [EPA-HQ-OAR-2022-0829-0565, p. 4]

Organization: California Air Resources Board (CARB) (Part 1 of 5)

The Proposal Will Provide Economic Benefits

Not only would U.S. EPA's proposed standards bring critically important emission reductions to combat climate change, improve air quality, and protect public health, the increased ZEV penetration across the U.S. would also provide important economic benefits such as consumer savings and economic growth in clean technology sectors. As CARB noted in its comments on the DRIA, U.S. EPA's analysis demonstrates considerable net benefits to the nation, and these benefits are likely understated. [EPA-HQ-OAR-2022-0829-0780, p. 65]

U.S. EPA's analysis considers consumer benefits in assessing the impacts of its proposal. Consumers stand to benefit greatly from more stringent emission standards implemented at the national level. CARB notes that ZEV technology costs are rapidly declining, and even today ZEVs are often cheaper for consumers than internal combustion engines when considering the total cost of ownership. 126 In its ACC II rulemaking process, CARB estimated the benefits to individuals associated with ZEV adoption. CARB found that, for BEVs, operational savings will offset any incremental costs over the 10-year period evaluated, with a 300-mile-range BEV providing savings in the first year for the 2026 MY. 127 Statewide, CARB estimated that California vehicle owners would save $11 billion (2020 dollars) from implementation of the regulation, driven primarily by lower fuel costs and dramatic savings in maintenance and repair associated with ZEV ownership. These savings are even greater when paired with incentives that reduce upfront purchase prices like those included in the Inflation Reduction Act. Lower operating and maintenance costs are especially important for lower-income consumers who spend a greater share of their incomes on transportation. U.S. EPA's proposal would help ensure that consumers across the U.S. can realize these cost savings. [EPA-HQ-OAR-2022-0829-0780, p. 65]

Organization: Charles Forsberg

The initial cost of light vehicles must not significantly increase. For the majority of Americans, the biggest barrier to vehicle ownership is the initial cost-not long term fuel costs. Vehicle ownership opens up job opportunities because people can get to many different job sites, creates a competitive market for consumer goods and increases life expectancies. When in the early 1900s Ford developed the manufacturing line that enabled low-cost cars, America rapidly converted to automobiles because the benefits of transportation on demand were so obvious to everyone-and ignored by EPA. [EPA-HQ-OAR-2022-0829-0738, pp. 5-6]

Without vehicle ownership, many jobs are off limits. Without vehicle ownership one is held hostage by the local grocery store that knows its customers can't visit the competition down the road and thus it can raise prices. The proposed EPA solutions are for the wealthiest 5% of the planet and the top 20% of Americans. High-cost vehicles are a health disaster because the strongest correlation in health is with income. To use a recent example, China has terrible air pollution but life expectancies have increased rapidly. The small gains in health that EPA believes will derive from electrifying transportation will be totally overwhelmed by the poor health effects of driving down economic opportunities for the bottom half of society by making light vehicles too expensive. The EPA strategy is an economic disaster to rural America and smaller cities where inexpensive transportation is required. [EPA-HQ-OAR-2022-0829-0738, pp. 5-6]

Recommended EPA action. EPA must consider all of American society-not just the top 20%. Incomes of much of the working class have gone down as a direct consequence of failed government policies with good intensions. Poverty generation needs to stop. EPA must consider all health impacts-not just "cherry pick" a small subset where improvements by those metrics to improve health are overwhelmed by large decreases in life expectancy due to "secondary" effects. [EPA-HQ-OAR-2022-0829-0738, pp. 5-6]

I recommend you read the papers referenced above that go into the details-all open access. Good intentions are not enough. The poster child is Germany where they have invested massively in low-carbon technologies for 20 years without significantly changing greenhouse gas emissions. They chose faith-based feel-good strategies rather than hard-headed engineering analysis. That catastrophic failure should be a warning to EPA. [EPA-HQ-OAR-2022-0829-0738, pp. 5-6]

Organization: Charles Gordon

INCONVENIENCE TO PEOPLE

The rapid elimination of new gas-powered cars creates real inconvenience for ordinary people. Those who live in apartment buildings will have to find charging stations where it will take 30 minutes to recharge. This will particularly hurt the poor and minorities. Long trips by car will require careful planning and 30-minute interruptions to recharge. Towing large trailers will be virtually impossible. This is added to the existing inconvenience of more expensive washing machines which take 60 minutes to wash a load-not 30 and dishwashers which take 2 hours to poorly wash dishes. [EPA-HQ-OAR-2022-0829-0747, p. 7]

It may be hard to put a dollar amount on this inconvenience, but it is real nonetheless. EPA needs to take that inconvenience into account when it reviews the proposed rule. [EPA-HQ-OAR-2022-0829-0747, p. 7]

Organization: Consumer Energy Alliance (CEA)

As consumers become more accepting of electric vehicles (EV), taxpayer-funded incentives expand, and automobile manufacturers produce a greater variety of models, EV purchases are expected to keep growing. Policymakers, however, should be increasingly mindful not to put the cart before the horse when it comes to attempting to drive consumers to purchase products they aren't ready to accept, they can't afford to purchase, and that face significant supply-chain bottlenecks that are already limiting supply and increasing costs. This is an area which we explored in-depth in our report Freedom to Fuel: Consumer Choice in the Automotive Marketplace.1 [EPA-HQ-OAR-2022-0829-0788, pp. 1-2]

1 https://consumerenergvalliance.org/cms/wp-content/uploads/2023/06/CEA EV REPORT 2023.pdf

Should this rule be adopted in its current form - lacking both technological feasibility and economic practicality - the result will be limiting consumer options and thwarting environmental progress through depressing innovation. [EPA-HQ-OAR-2022-0829-0788, pp. 1-2]

Organization: Competitive Enterprise Institute

II. The Proposed Standards Imperil Consumer Choice, Vehicle Affordability, and Market Liberty

EPA's proposal will restrict consumers' freedom to choose which types of vehicles they want to buy.12 [EPA-HQ-OAR-2022-0829-0611, pp. 4-6]

As the EPA acknowledges, Congress is already providing tens of billions of dollars in EV-related subsidies, such as the IRA's $7,500 tax credit, "effectively making some BEVs more affordable to buy and operate today than comparable ICE vehicles."13 The only purpose for heaping EV mandates on top of EV subsidies is to eliminate choices consumers would otherwise make. [EPA-HQ-OAR-2022-0829-0611, pp. 4-6]

12 Diana Furchtgott-Roth, "Biden's Plan to Phase Out Gas-Powered Cars Is All Pain for Consumers and No Gain," The Hill, June 12, 2023, https://www.heritage.org/government-regulation/commentary/bidens-plan-phase-out-gas- powered-cars-all-pain-consumers-and-no. 13 88 FR 29190.

13 88 FR 29190.

EVs have several well-known drawbacks that regulatory mandates do not remove but rather intensify by restricting the supply of ICE vehicles available for purchase. Those disadvantages include the high purchase price,14 price volatility due to supply-chain bottlenecks,15 range anxiety 16(especially in towing mode),17 long recharging times,18 reduced performance in extreme heat and cold,19 and less reliability during blackouts from hurricanes and other disasters. 20 [EPA-HQ-OAR-2022-0829-0611, pp. 4-6]

14 For example, in 2022, the initial purchase price of a conventional Ford F-150 was $40,960, that of the electric Ford-150 Lightning was $54,769. Roberto Baldwin, Sasha Richie, and Dave Vanderwerp, "EV vs. Gas: Which Cars Are Cheaper to Own?" Car and Driver, October 28, 2022, https://www.caranddriver.com/shopping- advice/a32494027/ev-vs-gas-cheaper-to-own/. The authors conclude that overall EV ownership costs are lower than those for gasoline powered vehicles (factoring in expenses for maintenance and fuel). Nonetheless, the higher EV purchase is a disadvantage that undoubtedly matters to many consumers.

The proposed standards would impose disproportionate burdens on low-income, single-vehicle households. My colleague Ben Lieberman explains: [EPA-HQ-OAR-2022-0829-0611, pp. 4-6]

The higher purchase price of an EV is prohibitive enough, but it is only part of the story. Fully one-third of American households are single-vehicle households, including many low-income ones.21 However, the limitations of EVs make them impractical as a household's one and only vehicle. This includes long charging times (especially inconvenient for renters who are less likely to be able to charge at home) as well as limited range. Indeed, nearly 90 percent of EVs currently in use are part of wealthier multi-car households that include one or more gas-powered vehicles.22 Thus, the EV agenda not only involves the higher sticker price relative to gasoline-powered vehicles, but also the additional cost of a conventional vehicle to back it up.23 [EPA-HQ-OAR-2022-0829-0611, pp. 4-6]

21 The Geography of Transport Systems, Percentage of Households by Number of Vehicles, 1960-2020, https://transportgeography.org/contents/chapter8/urban-transport-challenges/household-vehicles-united-states/ (accessed July 5, 2023).

22 Lucas W. Davis. 2019. How much are electric vehicles driven? Applied Economics Letters, Vol. 26, No. 18, 1497- 1502, https://faculty.haas.berkeley.edu/ldavis/Davis%20AEL%202019.pdf.

23 Ben Lieberman and Donna Jackson, "Costlier cars help the poor, according to EPA," Open Market, June 26, 2023, https://cei.org/blog/costlier-cars-help-the-poor-according-to-epa/.

Government's cartelization of the auto industry via regulations and preferential subsidies poses an insidious threat to consumer welfare. The IRA and the EPA's mandates increase automakers' dependence on political subventions while preventing both industry incumbents and new entrants from competing on price, range, and ease-of-fueling by selling gasoline-powered cars. Energy analyst Robert Bryce recently reported that Ford loses $64,466 on every EV it sells, "and isn't making up for it in volume." 24 Bryce cautions that "if a business isn't profitable, it isn't sustainable." [EPA-HQ-OAR-2022-0829-0611, pp. 4-6]

24 Robert Bryce, "Ford Is Losing $64,446 on Every EV It Sells," Substack, May 3, 2023, https://robertbryce.substack.com/p/ford-is-losing-66446-on-every-ev.

Organization: Consumer Energy Alliance (CEA)

While there are clearly many reasons to pursue EVs as a mobility option, there are many real world economic, social, and practical considerations the U.S. EPA should fully review before adopting overly restrictive transportation policies. Consumer impacts -especially the impacts imposed on those with low- and fixed-incomes -need to be front and center in these discussions. [EPA-HQ-OAR-2022-0829-0788, p. 2]

Regarding the vehicles that will be mandated because of this rule, has the U.S. EPA considered affordability of vehicles for low- and middle-income families? The average EV cost $65,041 in 2022 while the overall average automobile cost only $48,681, according to Kelly Blue Book data - a $16,360 upfront price differential. This differential is more than two times the incentives offered by the federal government to purchase qualifying EVs.5 Clearly, even with the incentive, EVs are out of the price range for the average American. [EPA-HQ-OAR-2022-0829-0788, pp. 2-3]

5 https://b2b kbb com/news/view/new-vehicle-pnces-hit-record-high-in-november 2022/

Will low- and middle-income families fare better in the used vehicle market? [EPA-HQ-OAR-2022-0829-0788, pp. 2-3]

A National Automobile Dealers Association study on the cost of ownership estimated that after five years, EVs depreciate $43,515 in value, while ICE vehicles average only $27,883 in depreciation.6 This depreciation almost eliminates any residual value advantage of the higher priced EVs after only a short period of usage. If EVs become a non-viable option as used cars due to substantial depreciation and cost of battery replacement, used car markets operating under EV mandates will see very constrained supply despite sustained demand, eventually making even used cars too expensive for many working-class families. [EPA-HQ-OAR-2022-0829-0788, p. 3]

6 https://www.nada.orfi/nada/nada-headlines/bevond-sticker-price-cost-ownership-evs-v-ice-vehicles

The initial purchase of an EV Is not one that working-class families can often consider As noted earlier, the price differential between an EV and a comparable ICE vehicle is often greater than $15,000. And contrary to popular opinion, the cost of EVs have been steadily increasing since 2015. Today, the average EV costs well over $60,000, a price which can only be considered affordable by the upper quintiles of income earners This is not an option for the average working-class family. [EPA-HQ-OAR-2022-0829-0788, p. 3]

Organization: Consumer Reports (CR)

1.2. The Benefits of Strong Vehicle Standards to Consumers

Inefficient vehicles impact consumers in a number of ways. Consumers face higher transportation costs when using less efficient vehicles. Inefficient vehicles produce higher levels of air pollution and greenhouse gas (GHG) emissions. Criteria pollutants such as ozone and particulate matter cause health issues such as respiratory diseases, lung cancer, preterm births, and neurological damage,1,2 which lead to increased spending on public and individual healthcare. GHG emissions contribute to extreme weather events such as extreme heat, flooding, and drought which cost consumers billions of dollars in property damage and increased insurance premiums.3 [EPA-HQ-OAR-2022-0829-0728, pp. 5-6]

1 Air Pollution: Everything You Need to Know, Natural Resources Defense Counsel, 2021, https://www.nrdc.org/stories/air-pollution-everything-you-need-know.

2 Traffic-Related Air Pollution: A Critical Review of the Literature on Emissions, Exposure, and Health Effects, Health Effects Institute, 2010, https://www.healtheffects.org/publication/traffic-related-air-pollution-critical-review-literature-emissions-exposure-and-health.

3 U.S. Billion-Dollar Weather and Climate Disasters, NOAA National Centers for Environmental Information, 2022, https://www.ncei.noaa.gov/access/billions.

These issues are exacerbated in overburdened communities, such as communities of color, due to redlining and other historically discriminatory policies which place these communities along ports and high-transit corridors. Increasing the supply of electric vehicles (EVs) and other lower emission vehicle technologies can mitigate these impacts and contribute to an equitable transportation ecosystem for all consumers. [EPA-HQ-OAR-2022-0829-0728, pp. 5-6]

Providing consumers with cleaner and more energy-efficient vehicle technologies can significantly lower these costs, and enables consumers to make purchasing decisions that save them money. [EPA-HQ-OAR-2022-0829-0728, pp. 5-6]

The proposed EPA rule would increase the supply of cleaner, cost-saving transportation options, such as EVs and hybrids, available to consumers. This proposal, particularly the more stringent Alternative 1, would support the transition to a cleaner transportation sector, providing cost savings, as well as other benefits that go beyond the pocketbook. This proposal would save consumers money on fuel and vehicle maintenance. It would also reduce emissions, thus contributing to reduced spending on healthcare costs tied to air pollution, and disaster recovery tied to GHG emissions [EPA-HQ-OAR-2022-0829-0728, p. 6].

These savings are particularly important for overburdened communities who overwhelmingly bear the brunt of the negative impacts of air pollution. Not only do these communities face a disproportionate exposure to vehicle tailpipe emissions,4 but lower income households also spend a greater percentage of their income on transportation costs than their wealthier counterparts, making them more sensitive to fluctuation and uncertainty in fuel prices.5 Thus, policies such as the proposed rule, which reduce pollutant exposure and increase accessibility to clean, reliable modes of transportation, are needed [EPA-HQ-OAR-2022-0829-0728, p. 6].

1.3. Consumer Petitions in Support of Proposed Rule

Consumer Reports collected 18,817 signatures from consumers in support of strengthening EPA’s current proposal for greenhouse gas standards.6 [EPA-HQ-OAR-2022-0829-0728, p. 6]

6 Petition: More Clean Vehicles = Better Climate Future, Consumer Reports, 2023, https://action.consumerreports.org/nb-20230425-epa-cleancars-petition.

Petition Text:

“We’re urging the EPA and NHTSA to adopt the strongest possible rules to reduce climate- and health-damaging vehicle emissions and greatly reduce fuel consumption, while helping consumers save an estimated $12,000 over the lifetime of a new vehicle. The rules will rapidly accelerate the number of cleaner vehicles like EVs and hybrids in production over the next decade; save lives due to a dramatic decrease in tailpipe pollution; and put us on the route towards a zero emissions future. These rules are a win-win for the climate, consumers’ wallets, and our health.” [EPA-HQ-OAR-2022-0829-0728, p. 6]

5. 2023 EV Ownership Cost Comparison

Many more EVs have entered the market, and significant changes have been made to the federal EV tax credit since CR released its EV ownership cost study in 2020. Given these changes, updated analysis of current EV ownership costs has been performed and is presented in this section.29 [EPA-HQ-OAR-2022-0829-0728, pp. 14-18]

This analysis uses similar modeling methodology as the 2020 study with the following changes:30 [EPA-HQ-OAR-2022-0829-0728, pp. 14-18]

29 A summary of the results of this analysis can be found in the following fact sheet: CR Fact Sheet: Electric Vehicles Save Consumers Money, Consumer Reports, June 30, 2023, https://advocacy.consumerreports.org/research/cr-fact-sheet-electric-vehicles-save-consumers-money/

30 New analysis from CR finds that the most popular electric vehicles cost less to own than the best-selling gas-powered vehicles in their class, Consumer Reports, October 8, 2020, https://advocacy.consumerreports.org/press_release/new-analysis-from-cr-finds-that-the-most-popular-electric-vehicles-cost-less-to-own-than-the-best-selling-gas-powered-vehicles-in-their-class/.

- Selected vehicles include the 6 mainstream EVs that qualify for at least part of the current federal EV tax credit in June 2023.

- Comparison ICE vehicles are selected with similar utility and features as the EV. Vehicles were selected from the same automaker when possible. When no similar vehicle was available from the automaker, the appropriate trim level of the best selling vehicle in the class was used.

- Energy costs are updated to the reference case from EIA’s Annual Energy Outlook 2023.31

- Public direct current fast charging costs are updated to Electrify America’s current standard charging rate of $0.48/kWh.32

- Average loan interest rates were updated to current (June 2023) average values for prime buyers of 6.4% according to NerdWallet.33 [EPA-HQ-OAR-2022-0829-0728, pp. 14-18]

31 2023 Annual Energy Outlook, US Energy Information Administration, March 16, 2023, https://www.eia.gov/outlooks/aeo/.

32 Electrify America is increasing prices at its DC fast charging stations, The Verge, February 23, 2023, https://www.theverge.com/2023/2/3/23584747/electrify-america-price-increase-ev-charging-stations-march-2023.

33 Average Car Loan Interest Rates by Credit Score, NerdWallet, June 27, 2023, https://www.nerdwallet.com/article/loans/auto-loans/average-car-loan-interest-rates-by-credit-score.

The selected vehicles, along with their current market prices according to TrueCar.com, are shown in Table 5.1. The TrueCar price is used rather than MSRP because it better represents the price consumers are actually paying for these vehicles. [EPA-HQ-OAR-2022-0829-0728, pp. 14-18]

[See original comment for Table 5.1 - Vehicles for Ownership Cost Comparison]34 [EPA-HQ-OAR-2022-0829-0728, pp. 14-18]

34 All vehicles were model year 2023 except for the Chevy Trax which is a 2024 model.

Table 5.2 shows the estimated average market adjustment for the vehicles being compared. The TrueCar price represents the market average transaction prices that consumers are actually paying for the vehicle. This may be higher or lower than MSRP. The market adjustment is the difference between the average transaction price and the MSRP. A positive value of the market adjustment means consumers on average are paying above MSRP and a negative value means that consumers are paying below MSRP. The comparison is made for all four sets of vehicles that are sold at dealers and from the same manufacturer.35 [EPA-HQ-OAR-2022-0829-0728, pp. 14-18]

35 Tesla sells all vehicles at MSRP so they are not included here. Also, the comparison is most useful comparing vehicles sold by the same automaker, which isolates any effects that might occur due to the popularity of specific brands or differences in the behavior of different dealer networks, since both vehicles in a pair are sold at the same dealers.

On average, the four EVs were selling at an average transaction price $2,700 more than MSRP, while on average the four ICE vehicles were selling at an average transaction price $2,200 below MSRP. This means that market adjustments are leading to a net increase of $4,900 in the relative price difference between EVs and their gasoline equivalent, compared to what it would be if both vehicles sold for MSRP. The largest difference is seen on the F150 Lightning, which is transacting with a net difference of over $11,000 more than the difference that would have been if both the EV and ICE version were sold at MSRP. This rather large market price difference is continued evidence that EV demand continues to exceed EV supply in the market. [EPA-HQ-OAR-2022-0829-0728, pp. 14-18]

[See original comment for Table 5.2 - Vehicle Market Adjustments Compared to MSRP] [EPA-HQ-OAR-2022-0829-0728, pp. 14-18]

The results of the ownership cost analysis in Figure 5.1 and Table 5.3 show that despite paying over MSRP for many EVs, the average consumer is still pocketing significant savings by purchasing the EV over the comparable ICE vehicle. All 6 EVs analyzed will deliver savings in the first year to the average American. Overall average savings totaled $4,200 over a 7 year first owner period, and $9,700 over the vehicle lifetime 200,000 miles. Lifetime savings ranged from $6,000-$12,000 for the six vehicles studied. [EPA-HQ-OAR-2022-0829-0728, pp. 14-18]

Although the vehicle comparisons are somewhat different from the 2020 study, the results generally show an increase in savings delivered by EVs, especially for the first owner. It is also worth noting that while in 2020 Tesla was largely competing with other luxury brands like Audi and BMW, their recent price cuts have brought their lowest priced vehicles into direct competition with two of the most popular mainstream vehicles in the country, the Toyota Camry and Toyota RAV4. [EPA-HQ-OAR-2022-0829-0728, pp. 14-18]

[See original comment for Table 5.3 - EV Net Ownership Cost Savings] [EPA-HQ-OAR-2022-0829-0728, pp. 14-18]

[See original comment for Figure 5.1 - EV Net Ownership Cost Savings] [EPA-HQ-OAR-2022-0829-0728, pp. 14-18]

All of this indicates that consumers will not have to wait until some date far into the future in order to achieve significant savings from going electric. For many consumers, big savings can already be pocketed today. As more consumers recognize this fact, EV demand will inevitably continue to grow. [EPA-HQ-OAR-2022-0829-0728, pp. 14-18]

Organization: Countymark

In April 2023, the Environmental Protection Agency (EPA) proposed new emissions standards for passenger vehicles and trucks that are significantly more stringent than previous rules. The new proposed standards would require automakers to meet a tailpipe emissions average of 82 grams of CO_2/mile across a company's production by model year (MY) 2032. Your agency estimated this new regulation would result in electric vehicles (EVs) accounting for 67 percent of recent light-duty vehicle sales and 46 percent of new medium-duty vehicle sales in less than ten years. CountryMark believes that this proposal significantly increases costs for American families, undermines American energy security, and falls short of estimated environmental benefits. [EPA-HQ-OAR-2022-0829-0665, p. 1]

Transitioning to electric vehicles (EVs) as a mandated requirement has several negative consequences. Currently, EVs make up a small portion of new vehicle sales, with approximately 6% in the light-duty vehicle segment and less than 1% in the heavy-duty vehicle segment. This demonstrates that EV adoption is still relatively low. One major concern is the higher cost associated with EVs. On average, EVs are priced over $14,000 more than non-luxury vehicles. This increased cost also affects the used car market, as the demand for used EVs rises, leading to higher prices. These higher costs and limited choices in the vehicle market have a more significant impact on low income and disadvantaged families. [EPA-HQ-OAR-2022-0829-0665, p. 2]

Another issue related to EVs is their weight, ranging from 1,000 to 3,000 pounds more than gas-powered vehicles. This additional weight results in more damage to American roads, necessitating increased infrastructure repair costs funded by taxpayers. Mandating a transition to EVs can lead to increased consumer prices and reduced vehicle choices. It also raises concerns about the financial burden on low-income families and the potential for increased infrastructure repair costs due to the heavier weight of EVs. [EPA-HQ-OAR-2022-0829-0665, p. 2]

Organization: David Manley III

Of course, while the proposed rule benefits China without significantly reducing global temperatures, American consumers are penalized because (a) while gas-powered cars take five or 10 minutes to refill, recharging an electric vehicle can take 45 minutes, and personal mobility, including road trips, will be adversely effected since EVs require longer and more frequent interruptions for charging, (b) The common American cannot afford EVs as EVs were on average $11,981 more expensive than gas-powered cars at the end of 2022, and today, for example, the electric version of the Ford F-150 pickup truck, the best-selling vehicle in America, costs an additional $26,000 over the gasoline-powered one while Tesla's EVs start at $39,000 for a Model 3 and go up to nearly $100,000 for a Model X — prices much higher than most families can afford, and (c) American consumers will have to deal with electric power availability problems (even with bidirectional charging that has a negative aspect) as the power grids will not have the capacity to deal with the increased load. [EPA-HQ-OAR-2022-0829-0513, p. 1]

Organization: Donna Jackson

[*From Hearing Testimony, May 10, 2023*] This new proposed rule has the distinction of harming black people on two continents, in the African nation of Congo as well as here in the United States. In the Congo where 75 percent of the world's cobalt needed for rechargeable EV batteries is located, black slave and child labor is readily being used to mine these minerals. It is well documented that their conditions are deplorable. The need for cobalt and thus the extent of the suffering will increase exponentially as a result of the EPA's proposed rule and if that wasn't bad enough, this new proposed rule will create an economic hardship and serious decline in the standard of living for all Americans but especially black Americans. Blacks have more single parent households, lower medium household income and higher poverty rates than the overall population. According to the 2021 U.S. Census Bureau, the median household income for black Americans was $45,000 compared to $71,000 for white Americans and $101,000 for Asian Americans. As such, they can't afford more expensive EV vehicles nor the higher prices for limited supply of gasoline powered vehicles and as it is, many Blacks have already been priced out of the new vehicles markets and can only afford used ones. Overall the consequences of this rule will remove private car ownership from many if not most black Americans. Even if the EVs weren't so expensive, they still don't fit the lives of many Blacks Americans, for example, more Blacks are renters, so fewer have the chance to charge their vehicles at home. Many black Americans live in apartments where street and parking lots is the norm with no ability to charge. In addition, many black households can only afford one vehicle but the reality is EVs are practical only for multi car households and the list goes on. Suffice to say it is that no EV supporter ever bothered to ask the black community if this is what they want or fits the needs of their family. And for those Blacks who want EV vehicle, they are free to choose one with or without an EPA mandate. The proposed rule here only serves to force more expensive vehicles on everyone whether they like it or not. The truth is that black people like most Americans want to make these choices for themselves. For this reason, I urge the EPA to withdraw the proposed rule and instead start thinking of ways to make personal transportation more accessible. [From Hearing Testimony, EPA-HQ-OAR-2022-0829-5115, Day 2]

Organization: Energy Innovation

Other research from the University of California, Berkeley, Grid Lab, and Energy Innovation, 2035 2.0: Plummeting Costs and Dramatic Improvements in Batteries Can Accelerate Our Clean Transportation Future (April 2021), evaluated the technical and economic feasibility (and associated impacts and benefits) of achieving a future scenario where electric vehicles make up 100 percent of new sales of all vehicles by 2035, combined with a 90 percent clean grid (called the DRIVE Clean Scenario).[iv] Compared with the No New Policy scenario (which was pre-IRA and BIL), the total transportation sector pollutant[v] and carbon dioxide emissions reductions in the DRIVE Clean Scenario would reduce ground transportation sector CO2 emissions by 60 percent in 2035 and by 93 percent in 2050, relative to 2020 levels.9 See Figure 3. The DRIVE Clean Scenario would also avoid approximately 150,000 premature deaths and generate nearly $1.3 trillion in health and environmental savings through 2050.10 Compared to the No New Policy, the DRIVE Clean Scenario would also result in approximately $2.7 trillion in consumer savings through 2050 compared—a household savings of about $1000 per year on average over 30 years.11 [EPA-HQ-OAR-2022-0829-0561, pp. 5-6]

Organization: Environmental. and Public Health Organizations

Looking just at EPA’s analysis (which did not analyze the costs and benefits of any standards more stringent than Alternative 1), standards more stringent than the Proposed Standards are feasible and would produce greater societal benefits. While average incremental vehicle costs increase under Alternative 1, those costs are recouped by the vehicle purchaser through reduced fueling, maintenance, and repair costs. And as EPA notes, “consumer savings would be … somewhat higher under Alternative 1” than under the Proposed Standards. Id. at 29203. The annualized vehicle technology costs through 2055 are $15 billion under the Proposed Standards and $17 billion under Alternative 1, using a 3% discount rate, or a difference of $2 billion. Id. at 29364-65, tbl. 160. But the annualized pretax fuel savings under Alternative 1 are $5 billion higher than those under the Proposed Standards, at $51 billion under Alternative 1 and $46 billion under the Proposed Standards, also using a 3% discount rate. Id. at 19366, tbl. 164. Similarly, consumers’ maintenance and repair costs are further decreased under Alternative 1—from an annualized value of $29.9 billion in savings under the Proposed Standards to $33.3 billion in savings under Alternative 1, both at a 3% discount rate.101 [EPA-HQ-OAR-2022-0829-0759, pp. 24-25]

F. Comparison of Criteria Emissions and Possible Health Benefits

For this part of the analysis, ERM utilized EPA's COBRA model to estimate the public health benefits associated with all the policy scenarios. ERM's analysis shows that stricter standards and increased deployment of clean L/MD vehicles results in greater gains in terms of consumer savings and avoided public health impacts (such as premature death, hospital admissions and emergency room visits, respiratory symptoms, and reduced activity and lost workdays). The policy scenario reflective of our Alternative 1+ recommended approach achieves the most reductions: nearly an 80% reduction in NOx and a 60% reduction in PM in 2040 compared to 2026 levels. An Alternative 1+ approach is also projected to achieve almost $42 billion in monetized value of reductions: nearly $8.5 billion more in monetized value than would occur under EPA's Main Proposal and preferred approach (as shown in Figure V.F-1). [EPA-HQ-OAR-2022-0829-0759, p. 31]

SEE ORIGINAL COMMENT FOR Figure V.F-1: Comparison of Possible Health Benefits112 [EPA-HQ-OAR-2022-0829-0759, p. 31]

112 Id. at 12

ERM's analysis incorporates: EPA's assumed changes in tailpipe emission reductions, EPA's upstream assumptions that rely upon the Integrated Planning Model (IPM) for electricity generated units, and ERM assumptions on changes from reduced demand on refining of finished products for diesel (and gasoline) based on the use of Argonne National Laboratory's Greenhouse Gases, Regulated Emissions, and Energy Use in Technologies (GREET) model. [EPA-HQ-OAR-2022-0829-0759, p. 31]

The benefits associated with the Alternative 1+ approach are further depicted in Table V.F-1, which shows the various scenario criteria emissions (NOx and PM) aggregated from 2026-2040 for each of the policy scenarios, as well as possible reduced health incidents, and the monetized value of these reductions (if realized) compared to EPA's No Action scenario.113 [EPA-HQ-OAR-2022-0829-0759, p. 31]

113 ERM's analysis results in slightly lower cumulative reductions of NOx and PM compared with EPA's net air pollutant impacts for the EPA Main Proposal, Alternative 1, and Alternative 3 policy scenarios (Tables 9-37, 9-38 and 9-40 of the DRIA). However, despite the difference, Alternative 1+ would correspond with approximately a 25% increase in benefits relative to the EPA Main Proposal and a similar increase would be expected under EPA's methodology.

SEE ORIGINAL COMMENT FOR Table V.F-1: Comparison of Possible Health Benefits114 [EPA-HQ-OAR-2022-0829-0759, p. 31]

114 ERM, Impacts Report at 12.

H. Comparison of Incremental Fleet Costs and Savings

While some manufacturers have raised unfounded concerns about the costs associated with shifting to ZEVs, the ERM analysis overall shows that the average BEV reaches life-cycle cost parity with diesel and gasoline vehicles before MY 2027. Additionally, from a cost and savings perspective, purchasing an average MY 2032 BEV would save an owner over $18,000 over the life of the vehicle (as seen in Figure V.H-1). [EPA-HQ-OAR-2022-0829-0759, p. 34]

SEE ORIGINAL COMMENT FOR Figure V.H-1: Possible Net Lifecycle Costs of a BEV vs. a Comparable Diesel or Gasoline Alternative118 [EPA-HQ-OAR-2022-0829-0759, p. 35]

118 Id. at 13.

The analysis depicted in Figure V.H-1 incorporates several different cost categories (including purchasing chargers, charger maintenance, incremental purchase price between combustion vehicles and BEVs, vehicle maintenance savings associated with BEVs, and the difference in fuel costs between purchasing gasoline and diesel fuel versus electricity). For this calculation, fuel and maintenance cost savings are discounted at 3% over 16 years. [EPA-HQ-OAR-2022-0829-0759, p. 35]

1. Comparison of Overall Societal Benefits

The results from ERM's analysis (depicted in Figure V.I-1) show that on a net societal basis––inclusive of the costs to fleets as well as air quality benefits, climate benefits, and reduced utility bills—the greatest benefits are seen with Alternative 1+ at about $125.7 billion through the 2040 timeframe. [EPA-HQ-OAR-2022-0829-0759, p. 35]

SEE ORIGINAL COMMENT FOR Figure V.I-1: Comparison of Possible Annual Net Societal Benefits119 [EPA-HQ-OAR-2022-0829-0759, p. 36]

119 Id. at 15.

This figure depicts net annual societal benefits (which incorporates net incremental fleet cost savings, climate benefits, air quality benefits, and reduced utility bills). [EPA-HQ-OAR-2022-0829-0759, p. 36]

5. New utility rates designed for PEV charging increase the fuel cost savings PEVs can provide.

Gasoline and electricity prices vary across the country, and electricity prices vary depending upon the particular characteristics of the utility rate on which a customer takes service. And many existing commercial and industrial utility rates have "demand charges" that can reduce fuel cost savings for high-powered/low-utilization PEV charging use cases, such as public charging along highways in remote areas. Thankfully, the challenge such demand charges can pose for PEV charging has long been recognized, and across the nation, many utilities and regulators have already implemented solutions or are in the process of doing so. [EPA-HQ-OAR-2022-0829-0759, p. 129]

In fact, the BIL amended the Public Utility Regulatory Policies Act (PURPA) Section 111(d) to require regulators and non-regulated utilities to consider new rates that:

promote affordable and equitable electric vehicle charging options for residential, commercial, and public electric vehicle charging infrastructure; improve the customer experience associated with electric vehicle charging; accelerate third-party investment in electric vehicle charging for light-, medium-, and heavy-duty vehicles; and appropriately recover the marginal costs of delivering electricity to electric vehicles and electric vehicle charging infrastructure.352 [EPA-HQ-OAR-2022-0829-0759, pp. 129-130]

352 H.R.3684. Infrastructure Investment and Jobs Act. 117th Congress. (2021-2022). Section 40431 www.congress.gov/bill/117th-congress/house-bill/3684/text.

This has spurred new regulatory proceedings across the country. But many utilities, regulators, and state legislatures were already acting to address this issue before the BIL became law. [EPA-HQ-OAR-2022-0829-0759, p. 130]

As detailed in a publication of the National Association of Regulatory Utility Commissioners (NARUC) entitled "Best Practices for Sustainable Commercial EV Rates and PURPA 111(d) Implementation," rates designed for EV charging can deliver significant fuel cost savings without relying on cross-subsidies from other utility customers.353 For example, on a new Pacific Gas & Electric rate designed for commercial EV charging that still recovers all associated marginal costs, the San Joaquin Regional Transit District reduced its overall fuel cost per mile from $2.31 to $0.68 (in a utility service territory that has some of the higher underlying marginal costs in the nation).354 The paper also details rates that take a similar approach that were approved for Southern California Edison, San Diego Gas & Electric, and Alabama Power. [EPA-HQ-OAR-2022-0829-0759, p. 130]

353 Nancy Ryan, Alissa Burger, Jenifer Bosco, John Howat, and Miles Muller, Best Practices for Sustainable Commercial EV Rates and PURPA 111(d) Implementation (2022), https://pubs.naruc.org/pub/55C47758-1866-DAAC-99FB-FFA9E6574C2B.

354 Id.

Since the publication of that NARUC paper, many other utilities and regulators have either proposed or secured approval of new rates designed for EV charging. And by the time the standards in this rulemaking take effect in 2027, many more will have followed suit, increasing the fuel cost savings EVs can provide. [EPA-HQ-OAR-2022-0829-0759, p. 130]

C. When considering the attributes consumers care about most, EVs are a great fit.

One of the reasons this "neighbor effect" may occur is because when consumers learn about PEVs, they often realize that PEVs offer a superior fit for the attributes they care about most in their driving and vehicle-owning experience. Forsythe et al. (2023) found that key factors Americans consider when purchasing vehicles and considering PEV options are operating cost, range, fast-charging capabilities, and performance characteristics such as acceleration.485 Consumer surveys and other studies have found the same attributes, along with fuel economy, as key to purchase decisions.486 As explained briefly in this section and in more detail in Sections XIX.C and XX, PEVs offer superior satisfaction of these consumer preferences. Any existing or perceived barriers to PEV adoption based on consumer acceptance are either minimal or surmountable, policies are already in place to support rapid elimination of any remaining barriers, and the pace of PEV incorporation into the fleet will allow for consumer preferences to be fulfilled. [EPA-HQ-OAR-2022-0829-0759, pp. 164-165]

Power, EV Price Pressure Grows as Government Incentives and Lease Deals Wield Outsized Influence on Consumer Demand (Mar. 29, 2023), https://www.jdpower.com/business/resources/ev-price-pressure-grows-as-government-incentives-

and-lease-deals-wi eld-outsized-influence-on-consumer-demand#:~:text=At%20the%20current%20trajectory%2C%20J.D.,is%20expec ted%20to%20surpass%2075%25 ("Consumer interest in EVs is increasingly being heavily swayed by price"); Consumer Reports, Consumer Attitudes Towards Fuel Economy: 2020 Survey Results 6 (Feb. 2021), https://advocacy.consumerreports.org/wp-content/uploads/2021/02/National-Fuel-Economy-Survey-Report-Feb-202 1-FINAL.pdf (finding that 94% of potential vehicle purchasers considered fuel economy to be "extremely important," "very important," or "somewhat important" when purchasing a vehicle).

1. PEVs are increasingly favorable from a total cost of ownership perspective and save drivers money over the life of the vehicle. As more models become available, this benefit will be accessible to more consumers.

First, PEVs are increasingly favorable from an operating cost and total cost of ownership (TCO) perspective—a factor that is very important to U.S. consumers when deciding which vehicles they want to buy. A 2020 nationally representative survey of potential vehicle purchasers found that 94% of potential purchasers considered fuel economy to be important when purchasing a vehicle.487 PEVs excel in the area of fuel cost savings. As EPA's Proposal shows, the incremental costs of PEVs over combustion vehicles are increasingly insignificant or nonexistent—especially in light of various state and federal incentives—resulting in PEVs saving drivers money in very short periods of time. And as operating costs are reduced, consumers are willing to pay more for their vehicles. Forsythe et al. (2023) found car buyers willing to pay upfront an additional $1,960 per 1 cent/mile reduction in operating cost, and SUV buyers willing to pay an additional $1,490.488 The paper also found that any perceived PEV disadvantages were made up for by favorable operating costs (along with fast-charging capability), and that lower operating costs "can help increase consumer adoption."489 Forsythe et al. (2023) further found that reductions in the BEV price-premium, which are projected to occur, "have driven substantial increases in consumer choices of BEV cars and SUVs over their conventional gasoline vehicle counterparts."490 A March 2023 J.D. Power survey reflected one example of this consumer responsiveness to price, finding that consumer interest in the Ford Mustang Mach-E and Tesla Model Y measurably increased when both manufacturers announced price drops and both models were made eligible for the IRA's $7,500 federal tax credit.491 A June 2023 J.D. Power survey also indicated that consumers are recognizing these savings, finding that "[t]he more miles that vehicle owners drive, the more likely they are to consider an EV. As in prior-year studies, daily commuters faced with higher fuel expenses are trading in their gas-powered vehicles for EVs."492 [EPA-HQ-OAR-2022-0829-0759, pp. 165-166]

492 J.D. Power, Action Needed to Keep Charging from Short Circuiting EV Purchase Consideration, J.D. Power Finds (June 15, 2023), https://www.jdpower.com/business/press-releases/2023-us-electric-vehicle-consideration-evc-study.

Up until recently, nearly all PEV models on the market were sedans or hatchbacks, or vehicles in the luxury car segment of the market,493 leaving vehicle purchasers looking for other types of vehicles without many options. But dozens of new models are entering the market in the next year, in all vehicle segments.494 Additional PEV model availability will provide a wider range of price points and greater diversity of vehicle types and features for potential PEV purchasers, further driving down average PEV costs and resulting in a PEV "fit" superior to a comparable combustion vehicle for more consumers. Research by ICCT has shown that "[g]reater availability of models in more vehicle segments and in higher volumes that meet consumers' wide range of needs and preferences is critical to market growth," and "states with greater model availability tend to have higher electric vehicle uptake."495 In recent years, average PEV costs have appeared higher than average combustion vehicle costs because many PEVs have been offered only in the luxury vehicle market. Gillingham et al. (2023)'s review of its dataset containing every new LDV sale in the United States between 2014 and 2020 revealed that, during that time period, "the market share of EVs and PHEVs is quite high in several price brackets at the high end, but the number of vehicles sold in these high price brackets is relatively small," and that "EVs can make up a large market share in the U.S. new car market," and "there is a great deal of untapped product space for EVs in the lower price brackets."496 Drivers of non-luxury vehicles want PEVs—and their benefits—as well. Automakers understand this demand and are expanding their PEV options, and an appropriately stringent rule by EPA will go further to accelerate this trend by offering automakers regulatory certainty. [EPA-HQ-OAR-2022-0829-0759, p. 166]

493 See, e.g., Gillingham et al. (2023) at 329, 332–333 (noting that EVs are overrepresented in the luxury market segments and that in the hatchback category—"a small market segment with a relatively large number of EV offerings"—sales of PEVs have been "close to 15% of the market in some years").

496 Gillingham et al. (2023) at 331–332.

Already, the number of light-duty PEV options has grown dramatically. The Alliance for Automotive Innovation states that at the end of 2022, there were 95 PEV models available in the United States.497 More models are forthcoming, including additional truck and SUV models along with the expansion of a wider range of EV sedans.498 EPA's Proposal notes research by EDF and ERM projecting that there will be over 180 PEV models available by the end of 2025, 88 Fed. Reg. at 29190 n.59, but EDF and ERM have since updated their analysis and now project that there will be 197 PEV models available by the end of 2025.499 Many of the world's largest automakers have committed to significantly expanding PEV production in the next few years, even absent additional standards,500 which will naturally lead to a larger array of model choices. For example, BMW, Volkswagen, and Stellantis have each committed to fleets half comprised of zero-emission vehicles by 2030.501 Mercedes-Benz, Ford, and GM have committed to an entirely zero-emission fleet by 2035.502 Volvo announced its fleet will be all electric by the end of the decade.503 J.D. Power's EV Index and EV Consideration Pulse Survey found that half of all new car shoppers will have a viable EV option by the end of 2023, and three out of four shoppers will have a viable EV option by the end of 2026.504 [EPA-HQ-OAR-2022-0829-0759, pp. 166-167]

2. PEVs offer meaningful refueling (charging) benefits to consumers.

Americans are interested in how quickly they can refuel their vehicles. Again, PEVs have real advantages that should not be underestimated. While opponents to PEVs frequently assert what they believe will be fundamental changes to how Americans get to work, school, and run errands, a closer look at the issue reveals that PEVs can offer meaningful benefits. Most trips are well below the average PEV range, and charging for these trips can often be done when vehicles are parked at home, work, or in public in between trips. In fact, recent research has shown that 90% of trips could be completed in vehicles with 124 miles of range—well below the capabilities of the current average EV range in the United States (almost 300 miles).505 Even as of 2016, researchers at MIT found that electric vehicles at the time could handle almost 90% of all car travel in the U.S.506 [EPA-HQ-OAR-2022-0829-0759, p. 167]

505 Mario Herberz, Ulf J. J. Hahnel & Tobias Brosch, Counteracting Electric Vehicle Range Concern with a Scalable Behavioural Intervention, Nature Energy 503 (2022) (finding that 90% of trips could be completed in vehicles with 124 miles of range); Tom Randall, Americans Insist on 300 Miles of EV Range. They're Right, Bloomberg (May 4, 2023), (noting that U.S. EVs have almost reached 300 mile average range).

506 Catherine Caruso, Why Range Anxiety for Electric Cars is Overblown, MIT Technology Review (Aug. 15, 2016), https://www.technologyreview.com/2016/08/15/158319/why-range-anxiety-for-electric-cars-is-overblown/.

Drivers with access to a garage or dedicated overnight parking spot may simply charge at home while they sleep, and most do. EY's Mobility Consumer Index 2022 survey found that 80% of EV owners use home charging,507 and other research has found that more than half of all reported EV charging takes place at home.508 Once a home charger is installed, "the home then has its own permanent home refueling station that can likely be used with all future PEVs."509 Substantial investments in infrastructure incentives will help to reduce any consumer concerns over range or charging availability. About half of Americans (49%) say "discounts to install a home charger" are the incentives that would most encourage them to get an EV.510 The Inflation Reduction Act extended the EV charger credit, which covers 30% (up to $1,000 per unit) of the cost of charging equipment for individual/residential uses. See 26 U.S.C. § 30C. Many states and local jurisdictions offer additional installation incentives that can further reduce costs. [EPA-HQ-OAR-2022-0829-0759, p. 168]

Furthermore, "[e]lectric vehicles have the meaningful advantage of refueling at a far wider array of locations than gasoline stations."511 Gas stations "must be carefully located to achieve scale economies to pay for expensive sturdy buried fuel storage tanks, environmental and safety protection methods, and gas pumps. In contrast, PEVs can charge at millions of potential home, work, or public locations."512 And, with increasing numbers of chargers available in places where drivers otherwise spend their time, "drivers can simply plug in and charge at a variety of locations where they would naturally park their vehicle for long periods of time."513 Recently, Walmart announced plans to install new BEV fast-charging stations at thousands of Walmart and Sam's Club locations across the country, in addition to the 1,300 BEV fast-charging stations the retailer has already made available.514 Other retailers already offering significant levels of BEV charging include 7-Eleven, Cinemark, Ikea, Kohl's, Kroger, Macy's, Starbucks, Subway, Taco Bell, Walgreens, and Whole Foods.515 PlugShare's charger locator can be searched based on various types of charging locations, revealing chargers at hiking, dining, shopping, camping, park, and grocery locations throughout the country.516 As far back as 2015, drivers who parked on the street could access street lights for charging in some dense urban areas,517 and this cost-effective technology518 is expanding in Europe and the United States, with U.S. pilot programs in New York, Charlotte, and Kansas City,519 and a large number of BEV charging stations on streetlight poles in Los Angeles.520 In addition, experts anticipate that charging equipment will increasingly be distributed widely throughout apartment building and multi-family garages.521 Research on parking has found that the average car is parked for 95% of its useful life,522 leaving plenty of time to charge in a large variety of locations. As these public chargers increase, PEVs become a viable and attractive option for more drivers, including those without access to easy home-charging.523 [EPA-HQ-OAR-2022-0829-0759, pp. 168-169]

PEV charging is increasingly taking less time, further enhancing the convenience benefits of PEV ownership. Hyper-fast Level 3 DC fast chargers can charge a BEV in as little as 30 minutes or less, adding up to 10 miles of range for each minute of charging time,524 and consumers have expressed strong willingness-to-pay for this capability.525 Research has shown that availability of more fast-chargers "reduce[s] range anxiety and make[s] it possible to use EVs in the way that drivers now use ICEs."526 [EPA-HQ-OAR-2022-0829-0759, p. 170]

PEV charging has additional benefits on top of saving drivers money and eliminating weekly trips to the gas pump. First, PEVs with bi-directional charging capability have potential to serve as back-up home generators in temporary power outages, with a typical BEV storing about 67 kWh in its battery—more than three days' worth of electricity.527 In fact, when a 2021 ice storm in Texas left millions of residents without electricity, Ford "lent out their hybrid F-150s as home generators."528 More makes and models are expected to offer bi-directional charging,529 with the potential that this capability becomes the norm. Additionally, vehicle-to-grid (V2G) charging offers potential benefits for both the grid and PEV owners. RMI found that by 2030, "virtual power plants" including parked vehicles supplying energy to the grid could reduce peak loads in the United States by 60 gigawatts.530 As this capability continues to develop, there could be additional "revenue opportunities for PEV owners for providing these grid services."531 Research in Germany has shown that bidirectional EV charging can generate significant revenue for the typical German household: between 310 and 530 euros per year.532 A recent successful vehicle-to-grid demonstration in North Carolina, taking place over two years, reveals the potential for V2G not only to improve grid optimization and resilience, but also to save consumers money. The North Carolina Clean Energy Technology Center explained that "[q]uantifying the potential value streams from bidirectional charging allows utilities to begin considering incentive payments and other EV program options for customers and members. By demonstrating significant positive value, this study encourages utilities in similar market conditions to help customers overcome the financial barriers to purchasing an EV, particularly in low- and moderate-income areas where these costs may restrict EV adoption."533 The University of Delaware has partnered with local electric utilities and a regional transmission organization to have their vehicles plugged in and available when called upon for grid support, with the transmission organization paying the university the market rate, or roughly $1,200 per year per BEV.534 Research by NREL has also considered net revenue generation from V2G services, including from private LDVs, and found significant potential.535 [EPA-HQ-OAR-2022-0829-0759, pp. 170-171]

3. PEV range has increased enough to meet the demands of nearly all American car trips.

American consumers are interested in how far their cars can travel, as Americans currently drive an above average number of vehicle miles per day (compared to the rest of the world),536 and demand "roughly a third more [range] than the global average."537 While range was therefore once a key challenge for PEV adoption, it is no longer. In fact, "many EVs are approaching the range of an average gasoline vehicle," and "the combined electric and gasoline range for PHEVs often exceeds gasoline-only vehicles."538 [EPA-HQ-OAR-2022-0829-0759, p. 171]

537 Tom Randall, Americans Insist on 300 Miles of EV Range. They're Right, Bloomberg (May 4, 2023).

538 EPA, The 2022 EPA Automotive Trends Report: Greenhouse Gas Emissions, Fuel Economy, and Technology Since 1975 E-2, 60 (Dec. 2022), https://www.epa.gov/system/files/documents/2022-12/420r22029.pdf (finding that the efficiency of EVs has increased by about 18% in the last ten years).

The average BEV range has skyrocketed in recent years, making range issues no longer a real concern. Average BEV range reached 298 miles in MY 2021, "or about four times the range of an average EV in 2011,"539 when range was in fact a real concern. Longer-range BEVs are available for consumers with more substantial driving needs,540 PEVs are becoming more efficient,541 and several PHEVs exceed 500 miles of total range.542 The well-designed stated-preference experiment conducted by Forsythe et al. (2023) found that "[m]ost vehicles with a range of at least 300 miles were valued by consumers equivalently or more than their conventional gasoline vehicle counterparts."543 BEV range is "on the cusp of exceeding 300 miles, a key psychological barrier."544 This level of range handily fulfills the needs and preferences of almost every American driver. The average U.S. one-way commute is about 27.6 minutes,545 and the average single-car American household drives about 30 miles per day546—both well within the range of all PEVs in today's vehicle market. ICCT has explained that "87% of American car drivers drive on average less than 100 kilometers (60 miles) a day—that is, only half the range capacity of the e-Golf, one third of the Leaf's, and less than a quarter of the Tesla's range on a single charge."547 Chakraborty et al. (2021) examined how much PEVs were used within households, and concluded that "BEVs and PHEVs appear to be viable as alternatives to conventional vehicles in terms of meeting the travel needs of households," and that "[s]ince most new and upcoming BEVs are longer-range vehicles, we expect this to mean BEVs will largely be suitable replacements for conventional vehicles in household fleets."548 [EPA-HQ-OAR-2022-0829-0759, pp. 171-172]

As consumer understanding of the capabilities inherent in this amount of range increases, range anxiety would be expected to decline and consumer acceptance of PEVs to match the vehicles' other benefits. Forsythe et al. (2023) explained that range increase is a key advancement in BEV technology that has "driven substantial increases in consumer choices of BEV cars and SUVs over their conventional gasoline vehicle counterparts."549 And Herberz et al. (2022) found that 90% of trips could be completed in cars with less than half of the current U.S. average range, but that most drivers do not understand this.550 Surveys by automakers have also found that range anxiety is the largest factor in consumers refraining from purchasing PEVs, explaining that drivers can be fearful they will run out of power before being able to recharge their vehicles, though some of these surveys were conducted in 2019 or earlier, when average PEV ranges were lower.551 Simply providing tailored compatibility information regarding the ability of BEVs to fulfill drivers' range needs increased willingness to pay for BEVs even more than information about easy access to charging infrastructure.552 [EPA-HQ-OAR-2022-0829-0759, pp. 172-173]

552 Herberz et al. (2022) at 503.

Even for longer travel and trips in excess of the average daily drive—which make up a very small percentage of U.S. driving—PEVs provide a good fit for most consumers' needs and wants. U.S. Bureau of Transportation Statistics data shows that trips longer than 250 miles make up a miniscule fraction of U.S. daily driving. In 2022, U.S. drivers took between 1.3 billion and 1.5 billion vehicle trips per day, with fewer than 2 million trips per day 500 miles or longer and between about 1.5 million and 2.5 million trips per day between 250 and 500 miles.553 Charging infrastructure is rapidly developing to support this small percentage of longer drives. As Section XVII explains, the number of public PEV charging stations is growing rapidly,554 and the BIL and IRA are funding new PEV charging corridors. Alternative Fuels Data Center's map of nationwide PEV charging stations shows that already—with 8.3% PEV sales penetration in the first quarter of 2023555—charging stations are widespread.556 In May, U.S. and Canadian officials announced the first Binational EV Corridor, covering a nearly 900-mile stretch between the United States and Canada, with PEV chargers every 50 miles.557 Similarly, last year four states announced plans to build a 1,100-mile PEV charging circuit along Lake Michigan.558 In Washington, Oregon, and California, the West Coast Electric Highway provides DC fast charging stations every 25 to 50 miles along Interstate 5, Highway 99, and other major roadways.559 Electrify America's DC fast-charging network includes two cross-country routes (one from Los Angeles to Washington, DC, and another from San Diego to Jacksonville), along with a route covering much of the East Coast on Interstate 95 (from Portland, Maine to Miami, Florida), and most of the West Coast along Interstate 5 (from Seattle, Washington to San Diego, California).560 GM and Pilot Company just announced plans to collaborate on a national DC fast charging network of 2,000 charging stalls at up to 500 travel centers across the country, to "help enable long-distance electric travel of people and vehicles across the U.S."561 These chargers will be capable of the fastest 350 kW charging speeds.562 [EPA-HQ-OAR-2022-0829-0759, pp. 173-174]

562 Id.

Infrastructure will continue to build out rapidly on highways with increasing PEV penetration, fulfilling the needs for even these comparatively less frequent longer drives. Survey data from Europe shows that as PEV penetration rates increase and drivers become more experienced with PEV operation, they become comfortable taking longer trips in their vehicles and are “more relaxed” about traveling long distances and when they charge their vehicles.563 In addition, other developing technologies could make both short and longer drives even more seamless, such as possible “electrified” roadways that contain wireless charging infrastructure under the asphalt and wirelessly charge PEVs while driving.564 Such projects are already in development or testing in the United States and Europe.565 [EPA-HQ-OAR-2022-0829-0759, p. 174]

4. PEVs have additional attributes that are superior to combustion vehicles.

PEVs have additional superior attributes related to the driving and ownership experience that are widely attractive to drivers. These include faster acceleration; improved performance; better noise, vibration, and harshness characteristics; and reduced maintenance. Sections XIX.C, XX, and XXI detail these additional superior attributes and the benefits that they provide for drivers and vehicle owners. These attributes will continue to further increase consumer preference for PEVs. [EPA-HQ-OAR-2022-0829-0759, p. 174]

5. American consumers also place high importance on environmental sustainability, and EPA should not ignore these preferences.

When considering consumer preferences, EPA cannot overlook the importance that American consumers place on sustainability. U.S. consumers increasingly place high priority on protecting the environment, and PEVs are well positioned to satisfy this aspect of consumer preference.

Numerous consumer surveys, including by YouGov, CarMax, and others have found that protecting the environment is a top consideration in purchasing a vehicle.566 In CarMax's survey, over 60% of people said a car's "fuel emissions are moderately or extremely important to them, while only 7.3% of people found fuel emissions not at all important."567 [EPA-HQ-OAR-2022-0829-0759, p. 175]

6. PEVs are a great fit for the needs and demands of rural drivers.

PEVs are a great fit even for rural drivers. Although rural Americans are currently adopting PEVs at slower rates than urban Americans,568 PEVs actually excel at meeting the demands of rural drivers. "Fuel savings for rural households are larger than for urban households, because trips in rural areas are longer than in urban areas, and vehicles tend to be older and less efficient, requiring more fuel per mile, [P]EVs require fewer trips to a mechanic for repairs and maintenance. Because of the high torque and low center of gravity, they have excellent performance, which is important on rough, curvy and steep roads."569 A survey by the Union of Concerned Scientists and Consumer Reports found that "there is plenty of interest [in PEVs] in rural areas, but there is a huge knowledge gap about what it is like to own an EV."570 Correcting for this knowledge gap and educating rural consumers on PEVs' real benefits will undoubtedly significantly increase PEV adoption in rural areas, allowing all Americans to reap their benefits. [EPA-HQ-OAR-2022-0829-0759, p. 175]

XX. BEVs Provide Additional Economic and Performance Benefits to Consumers.

A. Slightly higher upfront costs are offset by lower operating and fuel costs, saving drivers money.

EPA is correct to conclude that consumers experience net economic benefits when purchasing electric vehicles because lower operating costs offset increases in vehicle technology costs, irrespective of purchase incentives. 88 Fed. Reg. at 29344. EPA projects that aggregate vehicle technology costs through 2055 will range from $260 billion to $380 billion (7 and 3% discount rates). Id. Yet EPA estimates that total fuel savings over the same period will range from $560 billion to $1.1 trillion, while reduced maintenance and repair costs will range from $280 billion to $580 billion. Id. On net, consumers benefit from the Proposed Standards. [EPA-HQ-OAR-2022-0829-0759, p. 177]

These savings also filter down to the individual buyer. Even under the "high battery costs" sensitivity analysis, EPA found that the average incremental vehicle cost for the Proposed Standards was $1,632, and $2,066 for Alternative 1 (6-year average). Table 117, 88 Fed. Reg. at 29337. (Under the "low battery costs" analysis, incremental cost increases are far lower: $441 for the Proposed Standards, and $1,360 for Alternative 1 (6-year average). Id. at 29336.) These upfront costs are quickly eclipsed as the broader picture of overall costs emerges. First, some BEV models would be eligible for the full $7,500 purchase incentive in the Inflation Reduction Act, while others would be eligible for a partial credit. As EPA notes, this means that net purchase expenses are lowest across all body styles for BEVs (assuming the maximum incentive applies). DRIA at 4-20. Moreover, in operating expenses over 8 years (the average length of time a new owner keeps a vehicle), BEV owners save between $9,040 for sedans to $12,880 for pickups. Id. These operating expenses, which include lower maintenance and repair costs, are highly significant, and only grow larger the longer the owner retains the vehicle. [EPA-HQ-OAR-2022-0829-0759, p. 177]

B. Consumers and businesses will appreciate the stability of electricity prices relative to the volatility of gasoline prices.

In addition to providing significant absolute fuel cost savings relative to gasoline or diesel, driving on electricity also provides a significant price-stability advantage. As shown in Figure XX.B-1, for more than the last two decades, driving a passenger BEV on residential electricity prices has been the cost equivalent of driving on dollar-a-gallon gasoline, whereas the price of gasoline itself jumps up and down in response to world events. [EPA-HQ-OAR-2022-0829-0759, p. 177]

SEE ORIGINAL COMMENT FOR Figure XX.B-1: Equivalent Electricity and Gasoline Prices: January 2001-April 2023578 [EPA-HQ-OAR-2022-0829-0759, p. 177

578 Source data: EIA, Short Term Energy Outlook. Electricity prices shown in "eGallons" a Department of Energy metric that "represents the cost of driving an electric vehicle (EV) the same distance a gasoline powered vehicle could travel on one (1) gallon of gasoline." Methodology available at: https://www.energy.gov/articles/egallon-methodology.

While gasoline prices fluctuate wildly due to uncontrollable events, electricity prices are inherently more stable because electricity is produced from a diverse mix of largely domestic energy sources. Electricity prices also are more stable because the power industry is regulated, while the world oil market and petro-dictatorships are not. [EPA-HQ-OAR-2022-0829-0759, p. 178]

Households and businesses both stand to benefit from the predictable savings that driving on electricity can provide. And low-income households that spend a disproportionate share of their disposable income at the gas pump will benefit financially from getting off the rollercoaster of the world oil market. [EPA-HQ-OAR-2022-0829-0759, p. 178]

C. BEVs provide additional performance and handling improvements for consumers, improving their overall driving experience.

In addition to the clear economic benefits of BEV purchase and ownership described in the previous section, there are other "intangible" factors that make the overall BEV experience better for consumers. EPA cites several of these factors, including responsive acceleration, improved performance and handling, and quiet operation. DRIA at 3-15. Many examples confirm these advantages. [EPA-HQ-OAR-2022-0829-0759, pp. 178-179]

As Consumer Reports notes, "most electric cars deliver instant power from a stop, and they are both smooth and quiet when underway. The driving experience is quite different from a traditional gasoline-fueled car because EVs feel like they glide effortlessly."579 Other reviewers have found that the lower center of gravity in BEVs improves their handling by allowing turning and cornering more quickly and smoothly than gas-powered cars.580 In addition, BEVs' regenerative braking capabilities, which captures energy normally lost during braking, may also improve the driving experience by extending the vehicle's range and provide a "smoother and more controlled" braking experience.581 [EPA-HQ-OAR-2022-0829-0759, p. 179]

579 Consumer Reports, Electric Cars 101: The Answers to All Your EV Questions (March 2, 2023), https://www.consumerreports.org/cars/hybrids-evs/electric-cars-101-the-answers-to-all-your-ev-questions-a7130554 728/.

581 Id.

Car and Driver tested dozens of EVs and compared the data with gasoline-powered cars, finding that EVs are quieter at "max-attack acceleration" as well as at 70 miles per hour, have a more even weight distribution due to battery packs positioned low and in the vehicle's center, and accelerate almost as quickly as their combustion counterparts.582 Several other analysts have concluded that EVs accelerate faster than gas-powered vehicles because they provide instant torque to the wheels.583 For example, a Tesla Model S Plaid (with a starting price of around $108,000) accelerates from 0 to 60 miles per hour in just under two seconds, a full second faster than a supercar like the Ferrari Daytona SP3 that starts at $2,226,935 (about 20 times the cost of the Tesla).584 And the same holds for more affordable vehicles. For example, the Volvo EX30 promises to be a full second faster to 60 miles per hour than a comparably priced Chevy Camaro.585 While EPA did not place undue emphasis on these factors when making its assumptions about BEV adoption rates, these benefits are nonetheless significant and support EPA's finding that BEV performance and handling factors will contribute to high rates of adoption in coming years. XXI. Consumers Will Experience Significant Savings Due to Reduced Repair and Maintenance Costs for BEVs.

EPA's Proposal accurately projects significant consumer savings due to reduced repair and maintenance costs for BEVs. EPA relies on comprehensive repair and maintenance cost estimates developed by Argonne National Laboratory (ANL) in 2021 to project per vehicle maintenance and repair savings per year of between $430 (BEV sedan/wagons) and $470 (BEV pickups) in 2032. DRIA at 4–20; see also DRIA at 4–32 to 4–37. Other analyses—both those that have relied on the same underlying ANL cost estimates and those that have relied on other data—have found similarly significant maintenance and repair savings. [EPA-HQ-OAR-2022-0829-0759, p. 180]

A 2022 ICCT study considering LDV costs and benefits in the United States between 2022 and 2035 also relied on the ANL cost estimates and found almost identical reductions in per vehicle maintenance costs.586 The ICCT analysis concluded that maintenance costs for BEVs are expected to be about $2,650 lower than for gasoline vehicles over a six-year period,587 which averages to about $442 savings per year. A survey conducted by Consumer Reports in 2019 and 2020 also found very significant self-reported consumer savings on repair and maintenance. The data from surveys of thousands of Consumer Reports members revealed that "BEV and PHEV owners are paying half as much as ICE owners are paying to repair and maintain their vehicles," with lifetime savings of BEVs and PHEVs over combustion vehicles being approximately $4,600.588 Similarly, a study by UBS estimated that the Chevy Bolt (BEV) has total annual maintenance costs of $255 and the VW Golf (combustion vehicle) has repair and maintenance costs of $610.589 An analysis using U.S. Office of Energy Efficiency and Renewable Energy data regarding maintenance and repair costs and U.S. General Services Administration data regarding federal vehicle use calculated that "a hypothetical full-electric government fleet would have saved just over $78 million in maintenance costs" in one year.590 An analysis of repair and maintenance costs in Canada, which found 47% repair and maintenance cost savings for BEVs over combustion vehicles, noted that U.S. studies have found cost savings in similar ranges, and explained that when looking at the top 10 most common U.S. car repair items, none of the repairs in the list apply to a BEV.591 These significant repair and maintenance savings are expected to occur because "[t]ypical BEV drivetrains have 90% fewer moving parts, require no maintenance such as oil changes or timing belts and their ability to use regenerative braking saves energy and makes their brake pads last longer."592 Thus, U.S. drivers and vehicle purchasers stand to gain significant benefits from reduced automotive repair and maintenance needs for BEV. [EPA-HQ-OAR-2022-0829-0759, pp. 180-181]

XXII. BEV Ownership, Combined with Supportive Policies, Will Benefit Lower-Income Consumers.

EPA describes several expected outcomes of the Proposed Standards on lower-income households: first, that increased upfront purchase costs may impact highly price-sensitive consumers; and second, that decreased fuel and maintenance costs from BEV ownership may benefit these consumers disproportionately. 88 Fed. Reg. at 29368. While upfront BEV cost concerns may serve as an initial barrier to lower-income consumers, a suite of targeted policies can mitigate this concern. [EPA-HQ-OAR-2022-0829-0759, p. 181]

First, several policies may help with the upfront cost concerns, including the (maximum) $7,500 new vehicle purchase incentive and the first-of-its-kind (maximum) $4,000 incentive for used vehicles in the Inflation Reduction Act. These policies may also be supplemented by state-level initiatives that further reduce the purchase cost for buyers falling under defined income thresholds, such as California's Clean Vehicle Rebate Project.593 Also, as EPA notes, for used BEVs, there is evidence that the original purchase incentive is passed on to the next buyer, which reduces the effective price of BEVs. Taken together, these savings bring the initial cost of several BEV models–and undoubtedly more to come in future years–below the purchase price of a comparable combustion vehicle. See DRIA Ch. 4.2.2. [EPA-HQ-OAR-2022-0829-0759, p. 181]

593 California Clean Vehicle Rebate Project, Eligibility & Requirements, https://cleanvehiclerebate.org/en/eligibility-guidelines.

Moreover, because lower-income households spend a disproportionate amount on vehicle repair and fuel costs,594 they should benefit from these savings that come with BEVs, which continue to accrue year after year. This is especially true because fuel economy, and therefore fuel savings, tends not to degrade much as a vehicle ages, even when the vehicle is sold and resold for a lower price over time. 88 Fed. Reg. at 29368. Separately, from an overall ownership perspective, modifications to the Alternative Fuel Refueling Property Tax Credit in the IRA limit applicability to charging infrastructure in low-income areas and areas that are not urban. DRIA at 5-26. This change may help residents in those communities afford home charging or incentivize businesses to install public chargers, which would improve the BEV ownership experience. [EPA-HQ-OAR-2022-0829-0759, pp. 181-182]

594 See, e.g., Hardman, Fleming et al., A Perspective on Equity in The Transition to Electric Vehicles, MIT Science Policy Review (Aug. 30, 2021), https://sciencepolicyreview.org/wp-content/uploads/securepdfs/2021/08/A_perspective_on_equity_in_the_transition_to_electric_vehicles.pdf.

For these reasons, EPA was correct to consider the effects of BEV purchase and ownership on lower-income consumers. Inclusive policies that ease the burden of any potential higher costs on these consumers merit further study, and it is essential that the benefits of BEV ownership are accessible to all and shared equitably. EPA has shown that the cost savings over time make BEV ownership worthwhile for lower-income households, and that additional policies like the IRA purchase incentives can lessen any upfront cost disparities. [EPA-HQ-OAR-2022-0829-0759, p. 182]

101 See 88 Fed. Reg. at 29385-86, tbls. 196 and 197, adding $21 billion in avoided maintenance costs and $8.9 billion in avoided repair costs under the Proposed Standards, and the analogous values of $24 billion and $9.3 billion, respectively, under Alternative 1.

Organization: Environmental Defense Fund (EDF) (1of 2)

C. Consumers are already seeing savings from today's ZEVs.

Consumers will also benefit from protective standards that help ensure additional adoption of ZEVs. As discussed in section III below, the upfront costs and the lifetime costs of ZEVs are declining rapidly and are expected to continue to do so over the timeframe of this rulemaking, which will further increase the savings of owning a ZEV as compared to an ICEV. But consumers are already seeing savings today. WSP performed an analysis for EDF that compares the lifetime costs, over 10 years, of owning and operating a number of the most popular or widely anticipated current EVs compared to gasoline vehicles.8 The costs considered include purchase and financing of the vehicle and home charger (for EVs) and annual vehicle registration, maintenance, insurance, and fuel costs. The analysis accounts for federal and state EV and charger tax credits. WSP compared the Chevrolet Equinox EV to the Equinox RS, the Ford Mustang Mach-E Premium to the Ford Edge ST-Line, the Volkswagen ID.4 Pro to the Tiguan SE and the Ford F-150 Lightning XLT to the gasoline F-150 XLT. The analysis finds that higher upfront purchase price and insurance costs for EVs are outweighed by the lower maintenance and fuel costs. Over 10 years, all of the studied EVs are estimated to be less expensive to own and operate than the comparable gasoline vehicle, with total life-time savings of up to $18,440. As shown in Figure 2, the Chevy Equinox EV has the greatest savings over 10 years at 29% and the VW ID.4 has the lowest savings at 1%. The analysis also concluded that rural EV drivers would see additional lifetime savings than urban drivers. In addition to cost savings, there are other attributes of EVs that consumers value, including better performance and reduced noise. [EPA-HQ-OAR-2022-0829-0786, pp. 8-9]

8 Electric Vehicle Total Cost of Ownership Analysis, Summary Report, WSP for EDF (July 2023), https://blogs.edf.org/climate411/wp-content/blogs.dir/7/files/WSP-Total-Cost-of- Ownership-Analysis-July-2023.pdf (Attachment G).

Source: WSP, Electric Vehicle Total Cost of Ownership Analysis [EPA-HQ-OAR-2022-0829-0786, pp. 8-9]

Organization: Fermata Energy

V2X bidirectional charging is a win-win-win investment: many benefits accrue:

• Achieves EPA's environmental goals. Just like stationary storage, V2X bidirectional charging platforms can reduce carbon and criteria pollutant emissions from generators by shifting electricity consumption to the cleanest hours of the day and removing the need for dirty thermal peaker electricity generation. However, V2X is more cost-effective than stationary storage, as ratepayers don't have to pay for purchase of the EV battery and can accelerate the renewable transition. [EPA-HQ-OAR-2022-0829-0710, pp. 4-6]

• Provides grid services. With V2X bidirectional charging, utilities gain a low-cost energy storage resource to help integrate renewable energy into the electric grid by shifting energy, providing resource adequacy, and ancillary services (Figure 3). For example, modeling by the CPUC currently projects 14,700 MW of new energy storage is needed in CA by 2032 to support the integration of renewables but only 2,185 MW is operational today.9,10 V2X, with supportive policies, can provide many thousands of MW by 2030. [EPA-HQ-OAR-2022-0829-0710, pp. 4-6]

9 CPUC Approves Long Term Plans To Meet Electricity Reliability and Climate Goals, CPUC, 2022 (Link: https://www.cpuc.ca.gov/news-and-updates/all-news/cpuc-approves-long-term-plans-to-meet-electricity-reliability-and-climate-goals)

10 Infographic: Q4'21 US Battery Storage by the Numbers, S&P Global, 2022 (Link: https://www.spglobal.com/marketintelligence/en/news-insights/blog/infographic-q4-21-us-battery-storage-by-the-numbers)

[See original attachment for Figure 3 - Grid services and value from different Vehicle-Grid-Integration technologies]11 [EPA-HQ-OAR-2022-0829-0710, pp. 4-6]

11 California Energy Commission, March 2019, Distribution System Constrained Vehicle-to-Grid Services for Improved Grid Stability and Reliability, (Link: https://www.energy.ca.gov/sites/default/files/2021-06/CEC-500-2019-027.pdf) Figure 42

• Lower vehicle ownership costs. EV owners can earn money by selling electricity back to the grid, significantly cutting the cost of vehicle ownership. Offsetting the cost of owning and maintaining an EV supports equitable access to EVs, particularly those EVs in the used car market, such as the low-income EV driving community. [EPA-HQ-OAR-2022-0829-0710, pp. 4-6]

• Increased resiliency. Unidirectional charging is a grid load. V2X bidirectional charging cost-effectively supports grid resilience. During blackouts and extreme weather events, such as Public Safety Power Shutoffs (PSPS) in CA, EV owners can power their homes, businesses, and critical infrastructure. [EPA-HQ-OAR-2022-0829-0710, pp. 4-6]

• Ratepayer benefits. EV adoption has already been shown to significantly benefit utility ratepayers and V2X technology can further those benefits.12 For example, a 2018 CEC study projects $1 billion in annual ratepayer benefits if 50% of chargers were V2X capable.13 V2X technology also improves driver economics which would likely drive further EV adoption and even greater ratepayer benefits. [EPA-HQ-OAR-2022-0829-0710, pp. 4-6]

Organization: Ford Motor Company

Vehicle purchase price is a core consideration for prospective buyers, and in general there may not be cost parity between new EVs and new ICE vehicles until the middle or end of the 2027 – 2032 time period. While purchasers consider many other factors that favor EVs including lower cost of ownership and vehicle performance, it is uncertain whether enough purchasers will elect for an EV over an ICE vehicle. [EPA-HQ-OAR-2022-0829-0605, p. 7]

Consumer incentives for EVs help to reduce the upfront cost, however the federal Clean Vehicle Credit for retail consumers under section 30D of the tax code will not be available for many new vehicle purchasers. Indeed, this tax incentive is less available now for people who purchase Ford EVs and PHEVs than was the case before the Inflation Reduction Act. Further, the supply chain eligibility criteria will become even more strict in the 2027 – 2032 timeframe. While some states offer incentives to reduce the costs of clean vehicles, and that can provide material benefit in that state, to meet the proposed GHG standards will require widespread adoption of EVs nationwide. [EPA-HQ-OAR-2022-0829-0605, p. 7]

Organization: Fred Reitman

Electric vehicles are unaffordable. New electric vehicles cost about $20,000 more than gasoline-powered vehicles. More than half of Americans are living paycheck to paycheck and cannot afford the higher cost of an electric vehicle (EV). Further, batteries will need to be replaced and the cost of new electric batteries range from $10,000 - $ 15,000. [EPA-HQ-OAR-2022-0829-0432, p. 1]

Organization: Fuel Freedom Foundation

Minimize consumer disruption and cost. Since first being introduced more than 15 years ago, FFVs have been manufactured and sold with no consumer disruption. The functioning and fueling are virtually indistinguishable to drivers, and from a policy perspective are only limited in utility by uneven availability of E85. However, the state of California offers an illuminating example of FFVs fueled by a more robust fueling infrastructure. Due to a long-term sustained discount of E85 relative to regular gasoline (87 RON), California drivers have continued to increase use in the state. E85 consumption in California has been increasing by an average of 33% per year—and 40% from 2021 to 2022.14 The usage rate of E85 in FFVs was 16% in 2022 for a total of 103 million gallons.15 A primary driver of increased E85 use has been its sustained discount relative to retail gasoline. E85 has consistently offered a steady pump price discount of ~$1.00/gallon in California. Further, when gasoline prices spiked after Russia's invasion of Ukraine, FFV drivers in the State were buffered from the impact. Unlike gasoline prices, ethanol prices are not dependent on world oil prices. Consequently, while gasoline prices spiked, E85 prices remained stable, resulting in a discount of up to $2.50/gallon for E85 relative to regular gasoline, and in some cases more. [see Appendix A] [EPA-HQ-OAR-2022-0829-0711, pp. 4-5]

Organization: Green Diesel Engineering LLC

Proposed Emission Standard Guidelines

- Modify the emission standards on gasoline and diesel with the primary emphasis to be on minimizing CO2. [EPA-HQ-OAR-2022-0829-0457, p. 6]

- Increase NOx limit for diesel engines to 3 gram/mile on EPA emission test cycles. This is still cleaner than 1980 standards. With proper engine tuning, the smaller NOx increase allows for a decrease of 100 gram/mile of CO2. [EPA-HQ-OAR-2022-0829-0457, p. 6]

- Maintain the theme of clean diesel and keep particulate filters to prevent PM (particulate matter) emissions. [EPA-HQ-OAR-2022-0829-0457, p. 6]

- Manufacturers could add GPS software to go into low NOx mode when near NOx abatement zones. [EPA-HQ-OAR-2022-0829-0457, p. 6]

- Re-allocate tax incentives for urban residents to purchase BEV (battery electric vehicle) [EPA-HQ-OAR-2022-0829-0457, p. 6]

- Work with states on regional smog issues as these are very limited in geographical area. The top cities are: Los Angeles, Denver, Miami, New York City, Houston, Atlanta, etc. Moving to primarily electric vehicles in dense population zones eliminates point of use emissions. [EPA-HQ-OAR-2022-0829-0457, p. 6]

- Work with bio-fuel producers, farmers, refineries as needed to promote plant- based fuels that do not impact the food system. Hemp would be a good starting point as the entire plant can be utilized. The seed oil produces bio-diesel and the stalk produces ethanol. A robust bio fuel industry could reduce CO2 up to 1000 million metric tons yearly. [EPA-HQ-OAR-2022-0829-0457, p. 6]

- Electric is a good solution for local driving patterns. It is not good for long distance runs or pulling loads and does suffer in range with extreme cold or heat. [EPA-HQ-OAR-2022-0829-0457, p. 6]

- Re-calibrating vehicles in the field for low CO2 will yield the quickest return on investment. [EPA-HQ-OAR-2022-0829-0457, p. 6]

Organization: HF Sinclair Corporation

f. EPA Fails to Properly Account for the Cost Impact of the Proposed Rule

As noted above, EPA must consider both feasibility and cost of compliance. In addition to the infeasibility of delivering an electric grid that can support the PEVs that OEMs must now produce, EPA has failed to adequately account for the cost of the Proposed Rule. Namely, EPA has severely underestimated the cost impact on lower-income households. Given the low cost of carbon-based transportation fuel, fluctuations in the electricity market, and higher insurance costs, the “break-even” point for a higher-cost PEV – which may be upwards of $15,000 more than its ICE counterpart – is not a mere few years as EPA predicts, but decades.75 And this calculus is heavily dependent on the $7,500 tax credit provided by the IRA, which will change if future policymakers eliminate it or otherwise require PEVs to compete in the market without a subsidy.76 Not only will this hinder the widespread adoption of PEVs, but it will also drive up the cost used car prices across the country as consumers hold off on buying new cars.77 [EPA-HQ-OAR-2022-0829-0579, p. 16]

75 Id. at 5, 13.

76 This subsidy results in a cost-shifting mechanism from middle-class to wealthy families, id. at 14, which may not be supported by future elected officials.

77 Id. at 6.

Beyond the cost to the consumer, the Proposed Rule also fails to account for the lost fuel tax revenue that will come from the expected reduction in transportation fuel consumption. In 2020, states brought in over $52.7 billion in motor fuel tax revenue which, combined with over $43 billion collected in federal highway-related excise taxes, funded necessary expenditures on highway and road infrastructure.78 Elimination of ICE vehicles, and the associated transportation fuel consumption revenue, will contribute to a deficit of $741 per household annually. Yet this shortfall is not meaningfully addressed in the Proposed Rule. [EPA-HQ-OAR-2022-0829-0579, p. 16]

"Pass-through" refers to the degree to which manufacturers pass on cost increases to consumers. EPA in prior tailpipe rules has assumed 100% pass-through to consumers in the vehicle market—meaning that every dollar of additional cost to the automaker is ultimately borne by the purchaser.147 EPA appears to repeat this assumption in the Proposed Rule. That approach is also reasonable given consistency with the agency's prior approach and the very limited economic evidence on vehicle pass-through. Nonetheless, that limited available evidence (from a 2010 paper) indicates that pass-through in the vehicle market may be below 100%.148 Accordingly, EPA should discuss and provide a rationale for its approach. EPA should also support further research in this area, given its potential importance. [EPA-HQ-OAR-2022-0829-0601, pp. 22-23]

147 E.g. 2020 Rule, 85 Fed. Reg. at 24,594–95.

148 Using regression analysis, Hellerstein and Villas-Boas (2010) find only partial pass through for the vehicle industry with an average pass-through rate of 38%. Rebecca Hellerstein, & Sophia B. Villas-Boas, Outsourcing and Pass-Through, 81 J. INT'L ECON. 170, 175 (2010).

1. EPA Should Discuss Additional Contributing Market Failures

EPA should describe additional market failures that contribute to the energy efficiency gap. These include dealership incentives, biases, and information asymmetries; institutional myopia; and manufacturer market power. As discussed below, most or all of these market failures apply similarly to electric vehicles as they do to ICE vehicles. [EPA-HQ-OAR-2022-0829-0601, pp. 25-27]

i. Dealership incentives, biases, and information asymmetries

Salespeople's incentives and biases may cause informational asymmetries that prevent consumers from optimizing fuel efficiency.165 Studies show that dealers and salespeople often believe that electric vehicles and other efficient cars have lower profits for dealers than gas-powered cars,166 for various reasons.167 Consumers (and researchers posing as consumers) have often complained of poor dealership experiences when trying to purchase electric vehicles, citing salespeople's limited knowledge; misinformation and dishonesty about vehicle cost, range, and other attributes; inconsistent enthusiasm for electric vehicles; lack of inventory for more efficient and electric vehicles; poor timeliness for completing paperwork and vehicle delivery; limited promotional materials on energy efficiency; and inability to facilitate consumers' cost comparisons of electric versus gas vehicles.168 Some dealerships have admitted that poor sales training is a major barrier to electric vehicle sales.169 [EPA-HQ-OAR-2022-0829-0601, pp. 25-27]

165 See Fred Lambert, After Losing Dealers over Its Electric Move, Cadillac Is Now Gaining New Ones, ELECTREK, Sept. 23, 2021 (reporting that one-fifth of U.S. Cadillac dealers exited from the brand in 2020 rather than commit to selling electric vehicles).

166 Cox Automotive, Evolution of Mobility: The Path to Electric Vehicle Adoption 23 (2019), https://perma.cc/UV7N-42BE (reporting that 54% of surveyed dealers say there is a lower ROI for sales of EVs compared to gas); Eric Cahill et al., New Car Dealers and Retail Innovation in California's Plug-In Electric Vehicle Market (U.C. Davis Inst. Of Transp. Stud., Working Paper UCD-ITS-WP-14-04, 2014), https://perma.cc/DJ7T- SGXT (citing real or perceived profitability concerns, especially for compact or midsized vehicles).

167 Cahill et al., supra note 166, at 10 ("[A]s a category, PEVs may not represent a compelling investment to many dealers."); id. at 9–10 (noting that dealers have the false perception that PEVs entail longer transaction times and lower profits, when in fact dealers make more than average on PEVs in gross profits).

168 Id.; EPA, Draft Technical Assessment Report: Midterm Evaluation of Light-Duty Vehicle Greenhouse Gas Emission Standards and Corporate Average Fuel Economy Standards for Model Years 2022–2025 at 3-14 (2016) at 6-15; Cox Automotive, supra note 166; Gerardo Zarazua de Rubens et al., Dismissive and Deceptive Car Dealerships Create Barriers to Electric Vehicle Adoption at the Point of Sale, 3 NATURE ENERGY 501 (2018); Lindsay Matthews et al., Do We Have a Car for You? Encouraging the Uptake of Electric Vehicles at Point of Sale, 100 ENERGY POL'Y 79 (2017); Zoe Long et al., Consumers Continue to Be Confused About Electric Vehicles: Comparing Awareness Among Canadian New Car Buyers in 2013 and 2017, 14 ENV'T RES. LTRS. 114036 (2019).

169 Cox Automotive, supra note 166, at 30 (citing lack of OEM support).

ii. Institutional myopia and inattention, including short-termism

Though EPA refers to myopia in both the 2021 RIA170 and (more briefly) in the current RIA,171 this applies to both individual and institutional consumers. In particular, economists find that corporate managers can exhibit similar kinds of inattention as individual consumers and so fail to implement energy efficiency initiatives despite positive paybacks.172 Businesses may also face a kind of myopia called short-termism, in which corporate employees have an incentive to favor short-term profits over long-term investments if, for example, their compensation or career prospects are tied to near-term earnings (or if they must meet a particular budget in a given year).173 Employees with such incentives may have reason to purchase cheaper, less efficient vehicles.174 Studies suggest that short-termism can affect managers' choices about energy efficiency specifically,175 and about environmental sustainability broadly.176 [EPA-HQ-OAR-2022-0829-0601, pp. 25-27]

170 2021 RIA at 8-4.

171 RIA at 4-39 (discussing “a lack of foresight [and] an aversion to short term losses relative to longer term gains”).

172 See Suresh Muthulingam et al., Energy Efficiency in Small and Medium-Sized Manufacturing Firms, 15 MFG. & SERV. OPERATIONS MGMT. 596, 612 (2013) (finding that manager inattention contributed to the non-adoption of energy efficiency initiatives, since initiatives that appear lower on a list of efficiency recommendations, and initiatives that require more managerial attention, are less likely to be adopted).

173 A similar dynamic could exist in government, and so affect local, state, and federal government fleet purchases, if officials are rewarded for short-term cost savings rather than long-term fiscal health.

174 This incentive could be muted by a firm’s accounting practices if costs and expenses are amortized over time.

175 See Stephen J. DeCanio, Barriers Within Firms to Energy-Efficient Investments, 21 ENERGY POL’Y 906, 907–08 (1993); Suresh Muthulingam et al., Adoption of Profitable Energy Efficiency Related Process Improvements in Small and Medium Sized Enterprises 1, 7 (Working Paper, 2008) (finding that managers fail to implement energy efficiency improvements with short payback periods for several reasons, including myopia and a stronger focus on upfront costs than on net benefits, attributed partially to short-termism).

176 See Yujing Gong & Kung-Cheng Ho, Corporate Social Responsibility and Managerial Short-Termism, ASIA- PACIFIC J. ACCT. & ECON. (2018).

This market failure should remain prominent as electric vehicles become more widely available, due to the fact that electric vehicles frequently have higher purchasing prices but provide operating-cost savings over time. The limited price salience of electricity, including the use of automatic bill-pay, means that many consumers (including corporate consumers) will not properly factor in long-term operating cost savings. [EPA-HQ-OAR-2022-0829-0601, pp. 25-27]

iii. Manufacturer market power

Though EPA mentions in both the 2021 RIA and the current RIA that strategic marketing choices by manufacturers can result in inefficient under-supply of fuel economy to some consumer segments,177 EPA does not fully connect this inefficient pattern to market power. Because of the limited competition in at least some segments of the vehicle market, manufacturers may be able to act strategically when pricing vehicles and when producing vehicles with combinations of different fuel economy and other vehicle features to push consumers toward purchases that lead to higher manufacturer profits at the expense of optimal fuel economy.178 There is a relatively small number of firms producing several types of vehicles and engines.179 This market failure therefore could influence purchases by all consumer groups and across several vehicle classifications, including electric vehicles. [EPA-HQ-OAR-2022-0829-0601, pp. 25-27]

177 2021 RIA at 8-5; id. at 4-39 to -40.

178 See generally Carolyn Fischer, Res. for the Future, Imperfect Competition, Consumer Behavior, and the Provision of Fuel Efficiency in Light-Duty Vehicles (2010), https://www.rff.org/documents/1472/RFF-DP-10-60.pdf.

179 See id. at 3 (explaining that “the largest four firms accounted for 75.5 percent of the value of shipments in the automobile market and 95.7 percent of the light-duty and utility vehicle market”); Nat’l Acad. of Scis., Assessment of Technologies for Improving Light-Duty Vehicle Fuel Economy—2025–2035 at 11-356 (2021) (citing that the top ten firms accounted for 90% of light-duty sales in 2018); see also Winston Harrington & Alan Krupnick, Res. for the Future, Improving Fuel Economy in Heavy-Duty Vehicles

(2012), https://media.rff.org/documents/RFF-DP-12- 02.pdf (explaining that the heavy-duty trucking industry "is dominated by a small number of large manufacturers" and is even smaller than it would seem at first glance because of "affiliations, partnerships, and outright ownership of one company by another").

2. EPA Should More Clearly State That Its Model's Constant- Performance Assumption Obviates the Need to Estimate Lost Consumer Welfare

As in prior rules, EPA assumes when modeling the Proposed Rule that manufacturers will incur any additional costs necessary to hold vehicle performance constant. While EPA highlighted this fact in the 2021 RIA,180 it should strongly conclude that the constant-performance assumption built into OMEGA obviates the need to estimate any potential lost consumer welfare from forgone attributes. The reason for this is straightforward: Because EPA already models the costs of maintaining vehicle performance, any alleged reductions in vehicle performance resulting from the Proposed Rule would be offset by a reduction in compliance cost relative to EPA's projection. In effect, therefore, EPA's analysis already accounts for the cost of any possible efficiency-performance tradeoffs through its projection of compliance costs. [EPA-HQ-OAR-2022-0829-0601, pp. 25-27]

180 2021 RIA at 8-3.

Thus, while EPA sensibly concludes that "the presence of fuel-saving technologies do not lead to adverse effects on other vehicle attributes,"181 it should more forcefully assert that this conclusion does not increase its estimate of net benefits. [EPA-HQ-OAR-2022-0829-0601, pp. 25-27]

181 RIA at 4-38; see also Davis Noll et al., supra note 155, at 32–33 (discussing how "many fuel economy technologies actually improve various performance attributes").

Organization: Jack Spencer

The proposed rule's impact on low-income Americans is vastly under analyzed in the proposed rule's publication in the Federal Register and the Draft Regulatory Impact Analysis. [EPA-HQ-OAR-2022-0829-0681, pp. 1-2]

Fully Monetize the Proposed Rule's Impact on Low-Income Households

Though the proposed rule acknowledges "that increases in upfront purchase costs are likely to be of particular concern to low-income households," it goes on to state on page 29368 that "we look more closely into, but do not monetize, the effects of the standards on low-income households and on consumers of low priced new vehicles and used vehicles." [EPA-HQ-OAR-2022-0829-0681, pp. 1-2]

Neglecting to fully account for the monetized impact of a proposed rule on disproportionately impacted populations is an inexcusable oversight and matter of gross negligence. Academic research has long demonstrated that environmental regulations impose a higher cost on low-income Americans as compared to the population generally.2 [EPA-HQ-OAR-2022-0829-0681, pp. 1-2]

2 Graham, John D., "Saving Lives Through Administrative Law and Economics," University of Pennsylvania Law Review," P. 521, 2008-2009, (https://biotech.law.lsu.edu/blog/graham157upalrev3952008pdf.pdf)

The reality is that environmental regulations increase vehicle costs substantially. One academic study investigated the combined costs of all National Highway Traffic Safety Administration, Environmental Protection Agency, and California Air Resources Board light duty-regulations and found that they increased vehicle prices by $6,000 to $7,000. Put another way, environmental regulation increases the purchase price of most vehicles by 15-20 percent. [EPA-HQ-OAR-2022-0829-0681, pp. 1-2]

Given that 12.8 percent of Americans live in poverty3 and that the mean income for the lowest two quintiles of American incomes is $13,165 and $34,7674, respectively, low-income Americans are already being financially disadvantaged by environmental regulation. According to Kelly Blue Book, the five least expensive sedans available in 2023 cost between $16,490 and $18,500.5 At current prices, a new car is already beyond the reach of most low-income Americans, which is one reason why only around 17 percent of low-income households purchase new cars.6 Given that, according to Cars.com, the top five least expensive electric vehicles (EVs) range from $27,495 to $35,4857, the proposed rule will undoubtedly make new vehicles unaffordable for nearly all low-income Americans and make purchasing even used vehicles more difficult, if not impossible. [EPA-HQ-OAR-2022-0829-0681, pp. 1-2]

7 "Here are the 11 Cheapest Electric Vehicles You Can Buy," Cars.com, June 23, 2023, (https://www.cars.com/articles/here-are-the-11-cheapest-electric-vehicles-you-can-buy-439849/).

This is an unacceptable outcome for any regulation as research firmly establishes that access to a car comes with a litany of positive social benefits including upward economic mobility, public safety benefits, and healthcare and education opportunities.8 Any public policy that could threaten access to autos for low-income households should be a nonstarter. [EPA-HQ-OAR-2022-0829-0681, pp. 1-2]

8 Klein, N. J., "Subsidizing Car Ownership for Low-Income Individuals and Households," Journal of Planning Education and Research, 2020, (https://doi.org/10.1177/0739456X20950428).

Low Income Americans Accrue Little to No Benefits

The proposed rule suggests, without being monetarily specific, that the rule's additional costs to low-income Americans will be offset with saving on maintenance and fuel savings. Even a cursory look at the academic research on low-income households and car ownership and industry reports demonstrates that none of these claims are legitimate. [EPA-HQ-OAR-2022-0829-0681, pp. 2-3]

The proposed rule states on page 29368 that, “the introduction of more stringent standards leads to higher purchase prices and lower fuel expenditures.” It goes on to argue that the lower fuel expenditures will be of even greater significance to low-income households because fuel costs are a larger portion of the expenses for low-income households, that lower price new cars are generally more fuel efficient, and fuel efficiency does not decline for used vehicles while prices do. [EPA-HQ-OAR-2022-0829-0681, pp. 2-3]

The problem with the EPA’s reasoning is that as demonstrated above, very few low-income households purchase new vehicles and thus will not accrue any of the alleged fuel efficiency savings associated with a new vehicle purchase. This problem will be exacerbated by the proposed rule as more, higher priced EV’s are pushed into the market driving prices even higher, further removing low-income households from the alleged fuel efficiency benefits. [EPA-HQ-OAR-2022-0829-0681, pp. 2-3]

Further, the EPA argues that low-income households will benefit from savings passed on through the used car market. First, buying a used EV is a much different proposition than purchasing a used internal combustion engine vehicle. For instance, much of the cost and value of EVs resides in their batteries, but many used EVs have significantly diminished battery life. A well-maintained internal combustion engine vehicle with 100,000 miles could have a couple hundred thousand miles of life left. An EV with 100,000 miles is a much bigger gamble as most EV batteries are only warrantied for around 100,000 miles.9 Suggesting that low income families saddle themselves with the potential $5,000 to $15,000 costs10 for replacing a lithium ion battery for their newly purchased used EV is hardly a recipe for cost savings. [EPA-HQ-OAR-2022-0829-0681, p. 3]

10 Pratt, Devin, “What Happened to the Old Batteries in Electric Cars?,” Consumer Reports, February 23,2022, (https://www.consumerreports.org/cars/hybrids-evs/what-happens-to-the-old-batteries-in-electric-cars- a1091429417/).

Organization: Jaguar Land Rover NA, LLC (JLR)

Inflation Reduction Act (IRA) Clean Vehicle Tax Credits

Prior to the publication of the IRA last year, our vehicles qualified for the 30D Clean Vehicle Credit. The changing incentive landscape has adversely affected Jaguar Land Rover, with our manufacturing facilities located outside the US, we are now ineligible for the amended 30D credit. Due to the positioning of our vehicles and our customer demographics as a premium luxury vehicle manufacturer, the income and MSRP pre-requisites for the 30D credit also exclude us from claiming. We are fortunately eligible to claim the 45W Commercial Clean Vehicle Credit and we are pursuing this opportunity to potentially benefit our customers. [EPA-HQ-OAR-2022-0829-0744, pp. 9-10]

JLR challenges the assumption made by EPA that: “While the restrictions imposed by the IRA on the 30D credit (income, MSRP, critical mineral content, and manufacturing content) limit the vehicles which are eligible for the full $7,500 incentive under 30D, we believe that manufacturers will work to increase the number of vehicles that qualify over time due to the high marketing value of the credit." Despite the work that manufacturers carry out, factors relating to the critical mineral and battery component requirements are largely out of their control. For example, currently 65% of battery cells and almost 80% of cathodes are manufactured in China.15 Until the US develops a robust battery manufacturing industry, it cannot be guaranteed that a high percentage of the fleet will be able to claim. [EPA-HQ-OAR-2022-0829-0744, pp. 9-10]

15 IEA (2023), Global EV Outlook 2023, IEA, Paris Trends in batteries - https://www.iea.org/reports/global-ev-outlook- 2023/trends-in-batteries License: CC BY 4.0

We suggest that EPA incorporate the following into the final rule analysis and the monitoring reports mentioned previously to ensure that the portion of BEV sales eligible for credit under 30D in OMEGA is appropriate.

• Industry fleet GWh of cell and battery capacity eligible
• Industry fleet battery minerals extraction eligible
• Number of IRS eligible vehicles [EPA-HQ-OAR-2022-0829-0744, pp. 9-10]

JLR requests that EPA amends the central case compliance model to reflect a more accurate and realistic credit utilization of the IRA credits. [EPA-HQ-OAR-2022-0829-0744, pp. 9-10]

Organization: Job Creators Network Foundation (JCNF)

In addition to being unconstitutional, EPA also improperly certifies the proposed rule as not having a significant economic impact on a substantial number of small entities under the Regulatory Flexibility Act. That is false. Millions of small businesses use a car or light-duty truck for their work. Cars are an integral part of certain industries, like limousine or other car service providers. But the local landscaper, caterer, interior designer, or even the hairdresser who sees clients at their homes, will use a car for all or a significant part of their business. [EPA-HQ-OAR-2022-0829-0709, p. 2]

Electric cars are at least $10,000 more than the equivalent gas-powered car. For the small business owner operating on razor-thin margins, $10,000 is a significant increased expense. And that is just the cost represented to purchase the vehicle. It does not include the cost of lost time waiting forty-five minutes for an electric car to charge. Or the fact that if the battery pack of an electric vehicle is damaged in an automobile accident, it likely means the car is totaled and would have to be replaced. [EPA-HQ-OAR-2022-0829-0709, p. 2]

EPA should certify that its proposed rule has a significant impact on a substantial number of small entities under the RFA, prepare the required Initial Regulatory Flexibility Analysis, and conduct the required Small Business Advocacy Review Panel. [EPA-HQ-OAR-2022-0829-0709, p. 2]

Organization: Joshua Linn

2. How Would the Proposed Emissions Standards Affect New Vehicle Consumers?

In Section I.D of the proposed standards, “EPA is seeking comment on three alternatives to its proposed standards.” As described in more detail in a new RFF report [Link: https://www.rff.org/publications/reports/how-would-the-proposed-epa-passenger-vehicle-greenhouse-gas-emissions-standards-affect-new-vehicle-consumers/], I use the RFF light-duty vehicle model to estimate the benefits and costs of the proposed standards and two alternatives. I quantify how the benefits to new vehicle consumers vary across income groups. [EPA-HQ-OAR-2022-0829-0635, pp. 7-10]

Despite the Biden administration’s interest [Link: https://www.whitehouse.gov/environmentaljustice/] in environmental justice and equity, the EPA analysis of the proposed standards does not quantify how effects may vary across consumers. The standards will increase sales of plug-in vehicles while simultaneously making gasoline vehicles more fuel efficient. Both changes reduce fuel costs for drivers, which disproportionately benefits low-income households because they spend a much larger share of their income on gasoline than do high-income households. However, low-income households typically have lower demand for plug-in vehicles than high-income households (even putting aside the high up-front purchase price), and by shifting the market from gasoline to plug-in vehicles, the standards may reduce purchasing options for low-income households. [EPA-HQ-OAR-2022-0829-0635, pp. 7-10]

The model monetizes benefits and costs to new-vehicle buyers by income group, costs to manufacturers, and the GHG benefits of the standards. Table 1 summarizes the main results for two scenarios: a baseline that assumes the standards for year 2026 do not change in subsequent years (this is the same baseline that EPA assumes); and tightening standards by about 40 percent between 2026 and 2030. [EPA-HQ-OAR-2022-0829-0635, pp. 7-10]

Table 2. Aggregate Effects in 2030 of Proposed Greenhouse Gas Emissions Standards

[See original for Table 2] [EPA-HQ-OAR-2022-0829-0635, pp. 7-10]

The baseline market share of plug-in vehicles is about 56 percent in 2030, which is slightly higher than the Biden administration’s target. This market share lies in the middle of the wide range [Link: https://rhg.com/research/climate-clean-energy-inflation-reduction-act/] of recent forecasts. The proposed standards would increase plug-in vehicles’ market share to 62 percent, which is comparable to (though slightly lower than) EPA’s analysis. [EPA-HQ-OAR-2022-0829-0635, pp. 7-10]

Expenditure on plug-in vehicle subsidies under the Inflation Reduction Act is about $45 billion in the baseline and $50 billion in the proposed standards. The baseline number is about 20 times greater than the estimate by the Joint Committee on Taxation, reflecting different assumptions about policies (such as the ZEV standards) and consumer preferences. However, the estimate is similar to recent estimates [Link: https://www.brookings.edu/wp-content/uploads/2023/03/BPEA_Spring2023_Bistline-et-al_unembargoedUpdated.pdf] that have used different computer models. [EPA-HQ-OAR-2022-0829-0635, pp. 7-10]

Panel B shows the consumer benefits of purchasing vehicles in 2030. The consumer welfare number measures the benefits of the vehicles compared with hypothetical purchases of used vehicles instead. The proposed standards would increase consumer welfare by $110 billion. [EPA-HQ-OAR-2022-0829-0635, pp. 7-10]

The tighter GHG standards benefit consumers because people undervalue [Link: https://www.rff.org/publications/working-papers/emissions-standards-and-electric-vehicle-targets-for-passenger-vehicles/] fuel cost savings when they purchase vehicles. Consider a consumer who wants a particular vehicle and is offered the opportunity to purchase an otherwise identical vehicle that has lower fuel costs. Based on purchase choices that consumers make, on average [Link: https://www.rff.org/publications/working-papers/emissions-standards-and-electric-vehicle-targets-for-passenger-vehicles/] a consumer is willing to pay about $35 for a hypothetical $100 reduction in fuel costs—in other words, people don't pay as much as they should for the lower fuel costs. Consequently, they buy vehicles with higher fuel costs than is privately optimal for them. By addressing these mistakes, the standards can increase consumer welfare. [EPA-HQ-OAR-2022-0829-0635, pp. 7-10]

Manufacturer profits are the difference between revenue and costs. The tighter standards reduce manufacturer profits by about $5 billion. This result differs from EPA's since the agency assumes that manufacturers raise prices sufficiently to cover their costs. In contrast, my modeling indicates that competition constrains the extent to which manufacturers can increase their prices. That is, if an individual manufacturer tries to increase its prices enough to offset its higher costs, it will lose customers to other manufacturers. Because vehicle manufacturers cannot coordinate with one another on price changes, this competitive pressure prevents manufacturers from fully passing costs on to consumers. [EPA-HQ-OAR-2022-0829-0635, pp. 7-10]

Panel C shows the GHG emissions (CO2 and methane) from producing and consuming gasoline and electricity to power the vehicles. The emissions numbers represent the emissions from the vehicles sold in 2030 over their lifetimes. The proposed standards reduce climate damages from $72 billion to $49 billion over the lifetimes of vehicles sold in 2030, yielding climate benefits of about $23 billion. [EPA-HQ-OAR-2022-0829-0635, pp. 7-10]

Panel D shows that the proposed standards would increase welfare by about $128 billion, where welfare includes new-vehicle consumer welfare, manufacturer profits, and GHG emissions. The agency's numbers are computed differently from the numbers reported in Table 2, so the two should not be compared explicitly. Rather, the results in Table 2, as well as EPA's analysis, reveal that the proposed standards are likely to yield large welfare gains. [EPA-HQ-OAR-2022-0829-0635, pp. 7-10]

Figure 1 shows how the benefits vary across new vehicle consumers, again comparing the proposed standards with the baseline. The figure plots the average welfare change per household; for example, the blue bar indicates that the proposed standards would benefit the average household in the lowest income group (below $44,000) by about $2,500. These benefits, which include fuel cost savings net of any welfare cost of the policy (such as paying higher vehicle prices) and do not include climate or local air quality benefits, could be substantial. [EPA-HQ-OAR-2022-0829-0635, pp. 7-10]

Figure 1. Change in Consumer Welfare per Household for Proposed Relative to Baseline [EPA-HQ-OAR-2022-0829-0635, pp. 7-10]

[See original for graph, Figure 1] [EPA-HQ-OAR-2022-0829-0635, pp. 7-10]

That the bars diminish in height from left to right in the diagram means that the proposed standards benefit low-income households more than high-income households. This pattern holds for other levels of stringency and assumptions described in the report. Benefits concentrate among lower-income households because they substantially undervalue [Link: https://www.rff.org/publications/working-papers/vehicle-attribute-tradeoffs-and-the-distributional-effects-of-us-fuel-economy-and-greenhouse-gas-emissions-standards/] fuel cost savings, whereas high-income consumers undervalue by a moderate amount. If there were no GHG or fuel economy standards, low-income consumers would buy vehicles that have higher fuel costs than would be optimal for them; the GHG standards benefit these consumers by reducing their fuel costs. In contrast, without standards, high-income consumers would buy vehicles that have only slightly higher fuel costs than would be optimal, and thus the standards give them smaller benefits. [EPA-HQ-OAR-2022-0829-0635, pp. 7-10]

An important factor underlying these results is that the modeling indicates that vehicle manufacturers will introduce many low-price electric vehicle options. If it proves challenging for vehicle manufacturers to produce and market low-price electric vehicles, low-income consumers will likely benefit less from the proposed GHG standards than these results indicate. More generally, whether benefits of plug-in vehicles are widespread across consumer income groups will depend on how consumer interest in those vehicles evolves and whether manufacturers can successfully introduce low-price plug-in options. [EPA-HQ-OAR-2022-0829-0635, pp. 7-10]

Organization: KALA Engineering Consultants

We have some things to say about Electrification Step 3 later. In many of the comments EPA has received for the EPA–HQ–OAR– 2022–0829 Docket, many claim that the existing grid is simply not capable of handling (conductor ampacity) the increased power demands for recharging millions of electric vehicles that will replace much of the 250 million vehicle US fleet. [EPA-HQ-OAR-2022-0829-0617, pp. 31-34]

We have some thoughts on that grid capability issue if we may digress for a moment. The problem with many analyses of electric vehicle switch-out scenarios has been not understanding and taking into account what we call the Most Probable Time-of-Day for Recharge (MPTODR). The scenario put forth by electric vehicle advocates for recharging is everyone who has a BEV will come home from work to their single family home that has been retrofitted with a high-amperage (50 – 70 amps) charging station or stations if the family has more than one BEV. The BEV owner will plug their BEV into the charge station, go inside and enjoy a relaxing evening. That of course, is the elitist part of the whole electrification mythos that other people are like you, being upper middle class people that can easily afford a BEV and the other expenses associated with owning a BEV. [EPA-HQ-OAR-2022-0829-0617, pp. 31-34]

If we take Tesla as a typical BEV example, the Tesla Wall Charger is an outlet that requires more amperage at 240 Volts than most home outlets for an electric dryer or stove can supply. We found a cost estimate for installing a Tesla Wall Charger in the Denver, CO metro area that came in at about $5,000. [EPA-HQ-OAR-2022-0829-0617, pp. 31-34]

[See original attachment for photo of EV calculator] [EPA-HQ-OAR-2022-0829-0617, pp. 31-34]

Remember that the large wire gauge conductors needed for the Tesla charger are usually run in metal or plastic conduit and the straight-line distance between the electric distribution box and a garage is not the installed length because the conduit must be routed around your house to the garage, where the new wires will enter that space and be connected to the wall charger or chargers (if you need multiple chargers, the conduit size and cost is increased to run multiple sets of wires for each charger). [EPA-HQ-OAR-2022-0829-0617, pp. 31-34]

If you want to travel with your Tesla they recommend you should carry recharging gear that will provide flexibility for charging from various outlet types. [EPA-HQ-OAR-2022-0829-0617, pp. 31-34]

[See original attachment for picture of various types of TESLA recharging gear] [EPA-HQ-OAR-2022-0829-0617, pp. 31-34]

It looks to us like that “flexibility” is another $450 or so just to reduce what we call “Recharge Anxiety” for BEV owners. [EPA-HQ-OAR-2022-0829-0617, pp. 31-34]

Notwithstanding the larger initial cost of the vehicle associated with owning a typical BEV, we would argue that for people who live paycheck to paycheck who might be in the middle to lower income economic strata, such expenses are probably out of reach. [EPA-HQ-OAR-2022-0829-0617, pp. 31-34]

Organization: Kentucky Office of the Attorney General et al.

Finally, many consumers may not be able to afford electric cars even if they want them. The average new car now costs nearly $50,000. Average New Car Price Tops $49,500, Kelly Blue Book (January 11, 2023) https://bit.ly/3PcSkKT. The typical new car payment is now nearly $800 a month. New Vehicle Affordability Worse Than Ever, Kelly Blue Book (June 18, 2023) https://bit.ly/3X3F8Kt. EPA admits that the Proposed Rule “will result in a rise in the average purchase price for consumers” from even these rates. 88 Fed. Reg. at 29,364. The Agency estimates increased costs for vehicle manufacturers at $7.5 billion annually by 2027. Id. By 2032, the Proposed Rule will cost manufacturers at least $1,200 per vehicle, which they will no doubt pass to consumers. Id. at 29,201. Prices for used cars will rise as well. Id. at 29,364. [EPA-HQ-OAR-2022-0829-0649, p. 17]

The Agency argues that the benefits of EV ownership will offset these costs. Specifically, EPA insists that “projected vehicle technology costs are offset by the savings in reduced operating costs, including fuel savings and reduced maintenance and repair costs.” 88 Fed. Reg. at 29,364. EPA’s reasoning is flawed. [EPA-HQ-OAR-2022-0829-0649, p. 17]

The alleged savings for reduced fuel consumption are based on layers of speculation. The shift to EVs is projected to “reduce liquid fuel consumption (gasoline and diesel) while simultaneously increasing electricity consumption.” 88 Fed. Reg. at 29,365. EPA is correct to consider the net result of these effects when analyzing the costs and benefits of the Proposed Rule. But a necessary part of that analysis relies on correctly forecasting electricity prices over the coming decades. Simultaneous with the forced electrification of vehicles, EPA is attempting to dramatically restructure America’s power-generating portfolio. Whether such a transformation is possible given resource limitations, geopolitical factors, permitting issues, land-use debates, jurisdictional policy differences, and litigation is still to be determined. Even if it is possible, EPA cannot predict with any accuracy the costs to the retail ratepayer for completing such a drastic transition. In short, no one knows with enough certainty to justify massive regulatory shifts whether charging an EV will be more cost-effective than refueling a gasoline engine. [EPA-HQ-OAR-2022-0829-0649, p. 17]

Moreover, low-income consumers will not be able to afford an EV. Despite the Agency’s best efforts to present EVs as increasingly affordable, at the end of 2022 the average new EV sold for

$61,448. Average New Car Price Tops $49,500, supra. This is why the Agency acknowledges "low-income households are more likely to buy used vehicles and own older vehicles." 88 Fed. Reg. at 29,344. But used EVs offer little savings if the buyer has to replace the battery. According to the Department of Energy's National Renewable Energy Laboratory, advanced batteries "wear out eventually," and today's batteries last only 8 to 15 years. Electric Vehicle Benefits and Considerations, U.S. Department of Energy Alternate Fuels Data Center, https://bit.ly/3PcOn9i. Replacing an EV battery costs anywhere from $5,000 to more than $15,000. Electric Car Battery Replacement Costs, Edmunds (May 2, 2023) https://bit.ly/3NutoNS. Such substantial expenses hardly qualify as "reduced repair and maintenance costs." 88 Fed. Reg. at 29,364. [EPA-HQ-OAR-2022-0829-0649, pp. 17-18]

All of this comes at a time of record inflation, historic gasoline prices, and high utility bills. Since President Biden took office, food prices are up over 18%, and energy prices are up over 37%. Introducing the 'Presidential Inflation Rate': Biden trails only Carter, Roll Call (March 15, 2023) https://bit.ly/3qH63jd. Home prices have also surged. In the first quarter of 2023, the average home price in the United States was $516,500, Average Sales Price of Houses Sold for the United States, Federal Reserve Economic Data, https://bit.ly/3p4BenX—an increase of 27% in less than three years. Agencies cannot ignore context when weighing the costs and benefits of a proposed rule. Here, the broader economic landscape is another strong mark against the Proposed Rule. [EPA-HQ-OAR-2022-0829-0649, pp. 17-18]

Organization: Lillian Davey

Creating credits for those who are using off cycle and air conditioning is a very bold incentive. Incentives are almost vital for this kind of legislation as there may be much opposition. One concern I have is for measuring fuel economy and testing fuel specifications. There would have to be very stringent and clear procedures. There are many people that are going to have vehicles that are not going to fit into the electric vehicle category and are going to need to have fuel specifications for measuring fuel economy to be very clear. Another concern of mine is the incentive multipliers. The nature of these incentives would also need to be very clear. The largest concern of mine will be how to make these vehicles affordable to the average person. I think that the EPA and the government will need to work with companies such as Tesla as well as all other major automotive companies that are planning on leveraging these advances in Clean Car Technology. This is not going to be an easy change and many people are not able to afford a Tesla as it sits. [EPA-HQ-OAR-2022-0829-0489, pp. 1-2]

Organization: Marie Gluesenkamp Perez, and Mary Sattler Peltola, Members of Congress, Congress of the United States

We are writing to express our concerns about the impacts the Environmental Protection Agency's (EPA) new proposed rules, Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles and Greenhouse Gas Emissions Standards for Heavy-Duty Vehicles – Phase 3 may have on rural communities.

Like you, we believe climate change is a threat to communities across the country, and the federal government plays a critical role in developing a clean energy apparatus and helping our communities improve air quality. However, in making that transition, we cannot leave rural communities or working families behind. The administration's Executive Order 14037 and subsequent National Blueprint for Transportation Decarbonization set an ambitious goal for 50 percent of new passenger cars to be electric vehicles (EVs) by 2030. Last year's Inflation Reduction Act included many concrete policies promoting EV production that will drive costs down and improve affordability. We are concerned the EPA, along with the Department of Transportation (DOT) and the Department of Energy (DOE), have not done enough work to ensure rural communities will have the necessary charging infrastructure in place to make widespread EV adoption possible. The imposition of additional regulations in the auto market without key infrastructure investments will reduce consumer choice, which is a recipe for disaster in rural America. [EPA-HQ-OAR-2022-0829-0522, p. 1]

Washington's third congressional district has fewer than 100 level 2 and DC fast chargers available to the public, and they are largely concentrated in just two cities. Alaska has only 60 publicly available EV charging stations. In Congresswoman Gluesenkamp Perez' home county of Skamania, there are only two EV charging stations right now, and both are located at resorts. In Congresswoman Peltola's borough of Bethel, along with all the other boroughs of Western Alaska, there are zero EV charging stations. As DOT has acknowledged, the costs of installing EV chargers in rural areas can be higher, especially for direct current fast charging stations, because they are more likely to require expensive electrical service upgrades. Furthermore, for many working families, installing an EV charger at home remains out of reach, especially for those who don't own their homes. Bottom line: for EVs to be a meaningful and workable emissions reduction solution in rural America, we must have a ubiquitous and affordable charging infrastructure with access to abundant, cheap electricity. That simply does not exist right now. [EPA-HQ-OAR-2022-0829-0522, p. 2]

We are only four years away from model year 2027, and we are concerned the EPA's regulations are not paired with a plan to ensure adequate charging infrastructure on such a short timeline. Installing hundreds of thousands of new EV chargers and upgrading associated electrical infrastructure will also require tens of thousands of electricians. We are already experiencing a nationwide shortage of qualified electricians – anyone who's currently waiting six months for a residential electrician knows this all too well. Workforce shortages, particularly for those in the trades, are even more acute in rural communities. We want to ensure the EPA has considered the significant workforce development challenges that must be addressed to train electricians for a large-scale roll out of EV charging infrastructure. [EPA-HQ-OAR-2022-0829-0522, p. 2]

Organization: Mitsubishi Motors North America, Inc. (MMNA)

Mitsubishi shares EPA's goal of achieving net-zero carbon transportation in the future. To be successful in that future - which represents a major transformation to vehicle electrification - it is imperative that the market conditions be aligned with, and capable of, supporting the massive increase in the market share of electric vehicles that will be needed to meet GHG emissions standards. For the reasons laid-out through our trade association, the Alliance for Automotive Innovation's (Auto Innovators), comments, Mitsubishi believes that the very aggressive rate of vehicle electrification assumed in the proposed rule far outpaces what the market can support in that time frame. If finalized as proposed, our experience in this area to date makes us confident the final rule would significantly increase the cost of new vehicles, and would reduce consumer choice. [EPA-HQ-OAR-2022-0829-0682, pp. 1-2]

Mitsubishi participated in the development of - and supports - the comments submitted by Auto Innovators. [EPA-HQ-OAR-2022-0829-0682, p. 2]

In addition, based on its considerable experience discussed previously with BEV and PHEV leadership, Mitsubishi provides the following recommendations to supplement the comments of Auto Innovators: [EPA-HQ-OAR-2022-0829-0682, p. 2]

1. Closely align the multi-pollutant emissions standards with President Biden's 2030 goal by assuming no more than 40-50% PHEVs and FCEVs by 2030, even though our experience leads us to caution that this itself is very ambitious, and is predicated on the assumption that the necessary supportive policies will be effectively implemented.

2. Consider the many benefits of PHEVs to consumers and the environment during the expected period of constrained battery critical minerals production capacity, and how PHEVs are the perfect stepping- stone to full BEV acceptance.

3. Maintain the current PHEV Utility Factor (UF) and work with industry to identify opportunities to increase PHEV electric operation. This is the ideal stepping-stone technology to encourage long-term BEV acceptance and utilization.

4. Keep the proposed approach to determine the passenger car curves, and consider adjusting the cutpoint and stringency levels of the light-duty trucks during the early years of the program.

5. Maintain the existing GHG program flexibilities, such as Air Conditioning and Off-Cycle technologies credits (including the alternative method to apply off-cycle credits), and allow previously approved technologies to continue receiving credits.

6. Align the Tier-4 (criteria pollutants) with CARB's LEV-IV criteria test procedures and standards.

7. Consider the impact that very aggressive GHG standards will have on vehicle affordability, and especially the detrimental impact to low-to-moderate income families. Regardless of the vehicles that regulation may require us to produce, it is critical that regulators always keep the accessibility of consumers in mind. [EPA-HQ-OAR-2022-0829-0682, p. 2]

The rationale for each one of these recommendations is further explained below. [EPA-HQ-OAR-2022-0829-0682, p. 2]

Mitsubishi also is concerned that the increased vehicle cost associated with EPA's proposed ICE criteria pollutant emissions stringency (particularly the cost to meet proposed PM emissions standards) will likely lead consumers to retain their old vehicles longer, thereby offsetting environmental benefits. [EPA-HQ-OAR-2022-0829-0682, p. 9]

7. Vehicle Affordability

Mitsubishi takes great pride in having the lowest fleet GHG emissions of all mass market vehicle manufacturers11 12 while at the same time offering some of the most affordable vehicles in the US market. Many of our customers own and drive cleaner vehicles because the value of our vehicles is a financially viable option to them. This combination is a win-win for US consumers and for the environment. [EPA-HQ-OAR-2022-0829-0682, pp. 10-11]

11 2022 EPA Automotive Trends Report

12 Excludes BEV-only manufacturers

EVs currently cost significantly more to produce than equivalent gasoline cars or trucks. The average price of a BEV today is about $9,000 higher than that of a comparable ICE vehicle13. That price difference is driven mostly by the cost of the batteries. Battery cost have come down significantly in the past, but, contrary to EPA's assumption that the price of EV batteries will be substantially lower in coming years, that trend is not likely to continue. Given the anticipated exponential growth in demand for battery critical minerals to meet the proposed GHG standards, combined with the continued limited supply of those materials for the foreseeable future (resulting from the long lead time needed to ramp up mining and processing capacity), costs of these materials and batteries are expected to rise, thereby widening the price gap between ICEs and BEVs. Mitsubishi agrees with Auto Innovators' assertion that the Agency has not adequately addressed projected battery critical minerals availability and associated cost. [EPA-HQ-OAR-2022-0829-0682, pp. 10-11]

13 New-Vehicle Transaction Prices Trend Downward as Incentives Rise, According to Kelley Blue Book - Mar.8, 2023 (kbb.com).

Setting a very aggressive multi-pollutant emissions standard will substantially increase the cost of all vehicles and reduce consumer choice. If finalized as proposed, EPA's multi-pollutant emissions standards would require OEMs to prematurely phase-out some of the most affordable/cleaner vehicles and replace them with more expensive battery electric vehicles, thereby limiting consumer choice for clean and affordable vehicles. The potential negative consequence in this scenario is price-sensitive car buyers will likely turn to the used car market, thus driving buyers into older, less environmentally friendly vehicles, exactly the opposite of the intention of the GHG regulation. In addition, the resulting increased demand for used cars would also raise used car prices, leaving a growing segment of the US population – mostly low- to-moderate income families - unable to purchase a vehicle at all. [EPA-HQ-OAR-2022-0829-0682, pp. 10-11]

Organization: National Automobile Dealers Association (NADA)

A. The Proposed Standards Will Increase Vehicle Costs and Constrain Fleet Turnover.

Appropriate emission standards must not undermine vehicle affordability. Whether new vehicles are sold or languish on dealer lots depends on whether consumers are able and willing to purchase them. Affordability is critical, but today, most U.S. households cannot afford to purchase a new light-duty vehicle.23 In May 2023, the average price of a new EV was $55,488,[24] down by almost $9,400 from 2022, but higher than the gross income of most Americans.25 [EPA-HQ-OAR-2022-0829-0656, pp. 5-6]

23 See Buying a new car is becoming an out-of-reach, luxury purchase - The Washington Post.

24 See New-Vehicle Sales Incentives Continue to Climb in May, as Transaction Price Increases Moderate, Kelley Blue Book - Cox Automotive Inc. (coxautoinc.com).

25 See Average, Median, Top 1% Individual Income Percentiles - DQYDJ.

The chart below reflects data on the costs and budgeting for an average new light-duty ICE vehicle purchase. Note that only some 33 percent of American consumers can afford a new light-duty vehicle in today's market. Stated another way, 67 percent of U.S. consumers currently are priced out of the new light-duty market. [EPA-HQ-OAR-2022-0829-0656, pp. 5-6]

Assume Americans Pay 27% of Their Income in Taxes: $109,728

Share of U.S. Households That Can Afford: 33.31%

Number of Households that Can Afford: 43,700,000

Total Households: 131,202,000 [EPA-HQ-OAR-2022-0829-0656, pp. 5-6]

2. EPA's Fuel Savings Analysis Is Unclear and Incomplete.

Despite acknowledging that its proposed mandates will result in increased electricity consumption and expenditures, EPA claims that consumers will nevertheless experience fuel savings that will help offset higher upfront EV purchasing costs.40 EPA appears to have premised its conclusion on the modeling of liquid fuel and electricity consumption levels. EPA does not explain how it converted modeled consumption levels into monetary values to show actual consumer savings, and it makes no comparison of fueling costs and electricity rates based on modeled consumption levels. Nor is information provided on individual consumer savings. Thus, the basis for EPA's consumer fuel savings conclusion is unclear, at best. [EPA-HQ-OAR-2022-0829-0656, pp. 8-9]

40 88 Fed. Reg. at 29365-66.

EPA's savings assertion seems questionable. Conceivably, liquid fuel costs could decrease more than electricity costs increase if the proposal is adopted, but even then, EPA's analysis seems to overstate the fuel savings from switching to EVs. According to the Energy Information Agency (EIA), the average American household uses 886 kilowatt hours of electricity per month,41 and EPA reports that the average EV consumes 36 kilowatt hours of electricity per 100 miles driven.42 If the average household drives an EV 15,000 miles per year, or 1,250 miles per month, and the EV is charged at home to the tune of 450 kilowatt hours of electricity per month, the household's electricity bill will increase by around 50 percent. [EPA-HQ-OAR-2022-0829-0656, pp. 8-9]

41 See Frequently Asked Questions (FAQs) - U.S. Energy Information Administration (EIA).

42 See Comparison: Your Car vs. an Electric Vehicle | US EPA.

Moreover, as EV sales increase, electricity rates are likely to rise due to increased power demands. Higher electricity prices will also reflect the cost of increased transmission and generation infrastructure, which some estimates indicate will need to increase 60 percent by 2030, and even more over the following two decades.43 EPA must account for these higher electricity costs when determining accurately whether, and to what extent, commercial and noncommercial purchasers/lessees operating EVs will benefit from any fuel savings. [EPA-HQ-OAR-2022-0829-0656, pp. 8-9]

43 See Queued Up… But in Need of Transmission | Department of Energy.

3. EPA's Modeling Fails to Account for Insurance Costs.

EPA omitted insurance costs from its TCO payback analysis. According to Consumer Reports, electric vehicles may cost more to insure than gasoline-powered cars44 in part due to the uncertainty associated with their projected repair costs. Consumer Reports also notes that insurance companies are more likely to declare an EV a total loss due to battery repair costs. [EPA-HQ-OAR-2022-0829-0656, p. 9]

44 See Electric Vehicles Cost More to Insure Than Gasoline-Powered - Consumer Reports.

Similarly, Progressive, a national insurance company offering auto insurance, has stated that, "[i]nsurance for an electric car may cost more than insurance for a regular gas-powered car. An electric car's higher price tag and more complex equipment means it may cost more to repair or replace if it's in an accident. That can mean higher rates for policyholders who carry comprehensive and collision coverage."45 [EPA-HQ-OAR-2022-0829-0656, p. 9]

45 See Electric Car Insurance: Is It More Expensive? | Progressive.

Both Consumer Reports and Progressive note that the gap in insurance prices between EVs and ICE vehicles should narrow over time but given that it is unknown if or when this will occur, EPA should factor the higher costs of EV insurance into its modeling [EPA-HQ-OAR-2022-0829-0656, p. 9]

4. EPA's Modeling Values the IRA's EV Tax Credits Inconsistently.

EPA's approach for estimating electrification technology costs for its technical feasibility analysis does not assume that all consumers will receive the full $7,500 value of the IRA's EV tax credits, opting instead to combine portions of the Section 30D and Section 45W tax credits in its modeling.46 The initial value of the credit used in the modeling starts at $3,750 in MY 2027 and increases annually until reaching $6,000 in MY 2032.47 But when elsewhere discussing the TCO savings and expenses for a MY 2032 vehicle, EPA assumes a maximum value of $7,500 when comparing the net purchase price of an EV with that of an ICE vehicle.48 [EPA-HQ-OAR-2022-0829-0656, p. 10]

46 88 Fed. Reg. at 29301; EPA DRIA. p. 2-87.

47 88 Fed. Reg. at 29301; DRIA. p. 2-87, Table 2-50.

48 DRIA. p. 4-20, Table 4-7.

This approach is inconsistent. If EPA's own technical feasibility modeling assumes a credit value of only $6,000, the agency should use this same value in its TCO analysis, even if doing so would result in more favorable average purchase price for an ICE powered vehicle versus a comparable EV. For example, assuming application of a $7,500 credit, an EV CUV/SUV may have a net purchase price $400 lower than its ICE counterpart, but assuming application of a $6,000 credit, the ICE CUV/SUV would be $1,100 less expensive than its EV counterpart. [EPA-HQ-OAR-2022-0829-0656, p. 10]

Organization: National Tribal Air Association (NTAA)

Electrified Vehicles

As noted in the announcement of the proposed standards, "EPA's proposal builds upon a proliferation of announcements by automakers that collectively signal a rapidly growing shift…toward zero-emission technologies, including electrification"5. This anticipated reliance on hybrid, plug-in hybrid, and fully electric power trains may be disproportionately burdensome and costly in Indian country. Far too many homes on many reservations lack access to an electric grid. Further, vehicle reliance on centralized or individual battery charging sites as anticipated in the proposed regulations presents a huge challenge. [EPA-HQ-OAR-2022-0829-0504, p. 3]

5 Biden-Harris Administration Proposes Strongest-Ever Pollution Standards for cars and trucks to Accelerate Transition to a Clean – Transportation Future, USEPA News Release, April 12, 2023

The NTAA is well aware of many initiatives to enhance the deployment of renewable energy technologies to support the nation's electricity demand. We actively participate in meetings, webinars, forums, etc. as programs emerge under the Bipartisan Infrastructure Law, Inflation Reduction Act, and other climate change – related initiatives. The NTAA continues to formally comment on EPA proposals that emerge which have the potential to impact Indian country. NTAA remains concerned about realistic access to funding and other resources that are essential to advance renewable energy in Tribal communities and are necessary to transition vehicle fleets as anticipated by the proposed light-duty and medium-duty vehicle emissions standards. [EPA-HQ-OAR-2022-0829-0504, p. 3]

Organization: Nissan North America, Inc.

Beyond the significant market and governmental challenges posed by such a drastic implementation timeline, consumer adoption will be critical to success. Consumer adoption of EVs has historically lagged behind expectations, leaving a significant hurdle to encourage a large and swift shift to EVs. Consumers need to be convinced not only of the appeal, safety, affordability, and reliability of EVs themselves, but they need to adopt the necessary community and home charging equipment to facilitate their use. Consumers will need to adapt their trip planning and driving behavior to allow for vehicle charging needs. The only way to drive these significant behavioral changes is to assure consumers that charging infrastructure is available and reliable. This is simply not a reality today and is unlikely to be a reality in time to drive such a significant shift within the timeline of the Proposed Multi-Pollutant Rule. These challenges are magnified due to the unclear and uncertain benefits under the Inflation Reduction Act, which place significant limitations on EV consumer incentive programs and charging infrastructure programs. Moreover, many consumers are reluctant or unable to purchase EVs due to their significant price premium. The Proposed Multi-Pollutant Rule will only exacerbate these inequalities, with EV prices likely to increase even more due to extreme investments required by all market sectors involved. Driving too much change too quickly will shut out many communities who need clean vehicles the most. It will likely force consumers who are uncertain about ZEV adoption to continue to operate aging ICE vehicles much longer. This is contrary to the intent of the proposal. [EPA-HQ-OAR-2022-0829-0594, p. 5]

Organization: North American Subaru, Inc.

EVs are still more expensive than vehicles with ICE powertrains. For many consumers today, affording an EV is out of reach. According to Kelley Blue Book4 the average transaction price (ATP) for an EV in May of this year was $55,488. The ATP for all Subaru vehicles in April was $35,330. [EPA-HQ-OAR-2022-0829-0576, p. 3]

4 KBB. 6/12/23. https://mediaroom.kbb.com/2023-06-12-New-Vehicles-Sales-Incentives-Continue-to-Climb-in-May-as-Transaction-Prices-Increase-Moderately,-According-to-Kelly-Blue-Book.

Organization: North Dakota Farmers Union (NDFU)

Slow Turnover of the Vehicle Fleet

Sales of new vehicles displace a small fraction of the existing vehicle fleet each year. EPA estimates that 67% of new vehicles sales will be battery electric in 2032.5 Even if that growth is achieved, large numbers of new vehicles that burn liquid fuels will continue to be produced for many years, and those vehicles will remain on the road well into the future. The table below shows survival rates for cars and light trucks by vehicle age.6 [EPA-HQ-OAR-2022-0829-0586, p. 3]

5 Environmental Protection Agency (2023, April 12). Biden-Harris administration proposes strongest-ever pollution standards for cars and trucks to accelerate transition to a clean-transportation future [Press Release]. Retrieved from https://www.epa.gov/newsreleases/biden-harris-administration-proposes-strongest-ever- pollution-standards-cars-and.

6 Davis, S. C., and Boundy, R. G. (2022, June). Transportation energy data book: Edition 40. Oak Ridge National Laboratory. Prepared for the U.S. Department of Energy. Retrieved from https://tedb.ornl.gov/wp-content/uploads/2022/03/TEDB_Ed_40.pdf.

Based on this data [See original comment for Table 3.15, Survival Rates for Cars and Light Trucks by Vehicle Age], 86% of passenger cars and 78% of light-duty trucks remain on the road for 10 years. Moreover, 16% of passenger cars and 32% of light-duty trucks remain on the road for 20 years. If new electric vehicles are more expensive or less attractive to consumers, it is reasonable to assume older liquid-fueled vehicles will remain on the road even longer. [EPA-HQ-OAR-2022-0829-0586, p. 3]

Organization: Northeast States for Coordinated Air Use Management (NESCAUM) and the Ozone Transport Commission (OTC)

C. Market-Enabling Complementary Policies

Many of the NESCAUM and OTC states have state-specific plans to reduce GHGs and air pollution from on-road transportation and have adopted a diverse set of market-enabling policies and programs designed to advance the market for light-, medium, and heavy-duty ZEVs.

Examples include ZEV sales and purchase requirements as discussed above; ZEV and infrastructure purchase incentives; utility programs and investments in ZEV infrastructure; consumer and fleet outreach and education programs; innovative financing mechanisms; multi-family dwelling and workplace charging programs; and deployment of public charging in communities and along major travel corridors. Many states have established requirements or goals to transition state vehicles and transit fleets to ZEVs. In addition, most states have adopted clean energy or renewable portfolio standards, which require a share of power sold by their utilities to come from renewable sources. Some states have adopted 100 percent renewable energy goals. States recognize that transitioning to renewable energy sources will maximize emissions reductions from ZEVs over time. [EPA-HQ-OAR-2022-0829-0584, p. 7]

Organization: Paul Bonifas and Tim Considine

EPA also assumed unrealistically low electricity rates. Not all households have access to home charging ports. The average rate for charging at a Tesla super-charger is 25 cents per kilowatt hour (Kwh)9. In contrast, EPA assumes electricity rates for EV charging are 10.3 cents per kwh in 2027 and fall to 9.3 cents per kwh by 205510. 63 percent of households in the US have garages or car ports, which provides an upper bound for home charging11. Accordingly, 47 percent of households would be paying much higher commercial rates for EV charging. If we assume Tesla's price, this implies that EPA underestimated electricity rates paid for EV charging by 55%. [EPA-HQ-OAR-2022-0829-0551, p. 4]

9 https://www.leafscore.com/tesla/how-much-does-it-cost-to-charge-a-tesla

10 Page 168 of EPA's Draft Regulatory Impact Analysis - https://nepis.epa.gov/Exe/ZyPDF.cgi?Dockey=P10175J2.pdf

11 https://www.energy.gov/eere/vehicles/fact-958-january-2-2017-sixty-three-percent-all-housing-units-have- garage-or-carport

Moreover, the EPA did not factor in the impact on electricity rates from their recent power plant rule that would essentially force all remaining coal and natural gas power plants to cut emissions by 90%12. [EPA-HQ-OAR-2022-0829-0551, p. 4]

Repair Savings

EPA Claimed Savings: $170 billion

Realistic Savings: NEGATIVE $4 billion [EPA-HQ-OAR-2022-0829-0551, p. 10]

The EPA's "repair savings" also relied on Argonne's study, the same study from which the EPA dubiously reported maintenance costs. Instead of relying on actual consumer data from a reputable organization like Kelley Blue Book, the EPA and Argonne use fancy multi-variable mathematical equations that include a "multiplier" that inherently forces ICE vehicles to be ~50% more expensive to repair than EVs. These equations are used to generate "repair cost curve" diagrams. One must then calculate the integral under their "repair cost curves" to decipher an estimated 5-year repair cost for ICE owners of $1,530 compared to $1,065 for EV owners, a claimed 44% cost increase for ICE owners. [EPA-HQ-OAR-2022-0829-0551, p. 10]

Compare Kelley Blue Book's much more straightforward real-consumer data, and the numbers flip completely. KBB reports five-year repair costs for ICE owners of $1,695 compared to $1,712 for EV owners38. This means that ICE owners save money (-1%) on repairs versus EV owners, and don't pay 44% more like the EPA claims. Scaling back the EPA's claimed ICE repair cost from 44% to -1%, changes the repair value of the EPA's proposed rule from a $170 billion "saving" to a $4 billion cost. [EPA-HQ-OAR-2022-0829-0551, p. 10]

38 https://www.nada.org/nada/nada-headlines/beyond-sticker-price-cost-ownership-evs-v-ice-vehicles

The National Automobile Dealers Association (NADA) also agrees, stating that contrary to popular belief, EV owners pay more for repairs than their ICE counterparts. Though EVs are in the shop less frequently, they're more expensive to repair when they do go in 39. [EPA-HQ-OAR-2022-0829-0551, p. 10]

39 https://www.gobankingrates.com/saving-money/car/experts-factors-to-consider-before-switching-to-ev-electric- car/

Generally, mechanics do not have the training or the technology to work on EVs, causing a supply constraint on EV mechanics for repairs. Because of the lack of options, mechanics that do repair EVs have long wait-times and high prices, as the consumers have no alternative choices. It may also lead to needing to travel for hours to reach a mechanic capable of repairing an EV [EPA-HQ-OAR-2022-0829-0551, p. 10]

Organization: Plains All American Pipeline, L.P.

By 2032—less than 10 years from now—the EPA's Proposal would require nearly 70% of light-duty cars and trucks sold in the U.S. to be electric or "zero tailpipe emission." We have a number of concerns with this approach, a few include: [EPA-HQ-OAR-2022-0829-0713, pp. 1-2]

• By focusing on tailpipe emissions alone, most internal combustion engine vehicles that run on gasoline, diesel and biofuels would be unable to meet the standards set forth in the Proposal. This overlooks critical efforts of the energy and automotive industries to pursue continued innovation and optimization of fuel/vehicle systems to improve efficiency and reduce emissions.1 [EPA-HQ-OAR-2022-0829-0713, pp. 1-2]

• Effectively outlawing most liquid fuel-powered vehicles would undercut U.S. energy security,2 harm our domestic energy industry and leave the U.S. more dependent on foreign-controlled supply chains.3 [EPA-HQ-OAR-2022-0829-0713, pp. 1-2]

• Transferring a significant amount of energy demand to electricity will strain already challenged electrical generation and transmission infrastructure. Without substantial additional investment and significant streamlining of electric transmission permitting, it's unclear whether the electrical grid could support charging new EVs at the level necessary to support the proposed emissions reductions.4 [EPA-HQ-OAR-2022-0829-0713, pp. 1-2]

• Traditional energy sources are essential for ensuring effective evolution of the energy landscape-including the manufacture and growth of renewable energy sources and EVs. However, the Proposal would reduce energy investments and increase costs to consumers for all forms of energy. Furthermore, this policy risks the continued viability of critical domestic energy manufacturing infrastructure, which, if idled, would be very challenging to restore. [EPA-HQ-OAR-2022-0829-0713, pp. 1-2]

• Eliminating most new gasoline and diesel vehicles from the market limits consumer choice. Significantly fewer new affordable vehicles are available for sale today5 than a few years ago. Used cars are also increasing in price6 as some automakers warn that they will be forced to cut back on supplying popular gasoline models because of government regulations restricting sales of traditional vehicles.7 [EPA-HQ-OAR-2022-0829-0713, pp. 1-2]

Organization: POET, LLC

In some instances, U.S. EPA assumes that purchase incentives of $7,500 per BEV apply (see DRIA Table 4-7 for example) but in U.S. EPA's analysis of BEV penetration, somewhat lower values are used which range from $4,750 in MY 2027 to $6,000 in MY 2032 as shown in DRIA Table 2-50.

Organization: Porsche Cars North America (PCNA)

Electromobility will need continued support from public policy.

Recent legislative actions have seeded the ground with support for electric vehicles and the beginning of a robust nationwide charging network. With specifics that continue to be defined, stakeholders are working to maximize the opportunity under these new laws to support customers with valuable purchase incentives, and to help spur the development of new electric vehicle component production and material sourcing. Understandably, the complexity of these laws results in a process that requires careful deliberation with industry representatives working hard to ensure customers have a clear understanding of the support available. Nevertheless, the support within these programs will be critical to the growth rates EPA envisions in this proposal. [EPA-HQ-OAR-2022-0829-0637, p. 3]

Organization: Scott Wilson

Perhaps the most conspicuous flaw that will leap out to the American public is that these proposed actions were taken with complete disregard to consumer choice or affordability. In addition to potentially lacking access to charging at home, work, or public charging stations, consumers looking to purchase a new car may be unable to purchase these vehicles due to the higher purchase price or lack of availability. Today, the average purchase price of EV cars in 2022 was approximately $65,000-which is more than what 46 percent of American households earn in income in a year.8 Adding demand to the grid amid the confluence of other EPA regulations referenced above will drive up the cost of electricity, making powering these vehicles less affordable and undermining the EPA' s claims of savings for consumers that ignore or understate the increase in vehicle and energy prices. Taken together, the erosion of choice and affordability of vehicles will have profound impacts on how American families run errands, get to school, commute to work, and recreate. Additionally, there are serious concerns about the range of electric vehicles and the performance in rural areas of the country, where people may have to drive much longer distances to reach a charger, especially in locations where cold weather can impact the range the vehicle can drive. [EPA-HQ-OAR-2022-0829-5083, p. 3]

Organization: Steven G. Bradbury

In addition, the comparative lifecycle costs of owning and operating an EV versus an ICE vehicle are not nearly so different as EPA's NPRMs assert. EPA claims huge cost savings for EV owners over ICE owners from the avoided costs of fuel and maintenance and repairs over the life of the vehicle,33 but EPA's analysis fails to include the full costs of owning an EV: [EPA-HQ-OAR-2022-0829-0647, pp. 13-14]

33 See 88 FR at 29200.

Uncertainty about the remaining life and capacity of the vehicle's battery, com-bined with the high cost of any potential replacement, will likely mean that a used EV will have much lower resale or trade-in value relative to a comparable used ICE vehicle. This loss in value will be a significant cost disadvantage of EV ownership. [EPA-HQ-OAR-2022-0829-0647, p. 14]

Organization: Strong Plug-in Hybrid Electric Vehicle (PHEV)

In the longer term, EPA, the DOE or the national labs should conduct a comparative analysis on PHEV and BEV costs with a stakeholder input or working group). PHEVs can be made in a less costly manner than shown in most analyses. Technical maturity, engineering advances, supply chain issues, changes in mineral prices, war and scale-up issues are impacting the costs of BEV and PHEV up-front and operating costs. Today, costs are rapidly changing, especially for batteries. In addition, Argonne National Lab's recent report6 shows that PHEVs are less expensive than BEVs for cars, and our experts at Strong PHEV coalition assert that several additional technical modifications can lower the cost of PHEVs that most analyses do not consider. We think this likely applies to plug-in hybrid cars and trucks but recognize that more analysis is needed. A common mistake we find in reports is not understanding the difference between a strong PHEV and other PHEVs because a strong PHEV can use the same batteries as a BEV which results in significant cost savings. See Appendix D for a more detailed explanation. [EPA-HQ-OAR-2022-0829-0646, pp. 7-8]

6 https://www.anl.gov/argonne-scientific-publications/pub/167396

The use of away-from-home DC fast chargers should be modestly reduced, and the cost of the PHEV including total cost of ownership should be based on work by Argonne national lab for light-duty PHEVs.7 Finally, bidirectional charging using DC off-board chargers should be assumed in our recommended alternative cost analysis for a reasonable percentage of BEVs and PHEVs in order to further reduce the total cost of ownership. [EPA-HQ-OAR-2022-0829-0646, p. 8]

Tesla also agrees with the agency that there is an “emerging consensus that purchase price parity is likely to occur by the mid-2020s for some vehicle segments and models, and for a broader segment of the market on a total cost of ownership (TCO) basis.”92 Indeed, this parity has already been reached by Tesla. The Tesla Model 3 has a TCO better than a Toyota Corolla.93 Numerous other studies have found that on a TCO basis BEVs are already competitive with ICE vehicles and overall cheaper to own.94 In short, there is a compelling case to be made that BEV costs already favor their adoption over ICE vehicles in the marketplace. Organization: Texas Public Policy Foundation (TPPF)

The LMD Tailpipe Rule Will Unnecessarily Harm Consumers

Similarly, the LMD Tailpipe Rule is regulatory overkill that will harm average Americans and limit innovation. To start, stricter emissions regulations will increase manufacturing costs for automakers. This will lead to higher sticker prices for vehicles, pricing low- to middle-class Americans out of the automotive market, leaving them stranded with little recourse or dependent on public transit, eventually depressing the job market. The government should not place the burden for green energy on the least fortunate Americans, adding yet another obstacle to their economic climb. [EPA-HQ-OAR-2022-0829-0510, pp. 5-6]

Automakers will rush to convert their fleets to feature either all or mostly electric vehicle models, disadvantaging new car buyers in areas without existing electric charging infrastructure. In the same vein, as mentioned above, the strain placed on the electric grid caused by millions of Americans charging their vehicles will cause electric prices to rise markedly and lead to "brown-outs." See, e.g. Nadia Lopez, Race to zero: Can California's power grid handle a 15-fold increase in electric cars?, CALMATTERS (Feb. 6, 2023), https://calmatters.org/environment/2023/01/california-electric-cars-grid/ ("State officials claim that the 12.5 million electric vehicles expected on California's roads in 2035 will not strain the grid. But their confidence that the state can avoid brownouts relies on a best-case — some say unrealistic — scenario: massive and rapid construction of offshore wind and solar farms, and drivers charging their cars in off-peak hours."). [EPA-HQ-OAR-2022-0829-0510, pp. 5-6]

Additionally, electric cars have limited range and require long recharging sessions, and the infrastructure to support the sudden transition to electric vehicles that the LMD Tailpipe Rule would cause simply does not exist. Rural and low-income communities, the people most affected by this regulation, likely will be the last to receive said recharging infrastructure. [EPA-HQ-OAR-2022-0829-0510, pp. 5-6]

Organization: The Heritage Foundation (Kevin Dayaratna and Diana Furchtgott-Roth)

The Rule Would Raise Driving Costs and Inconvenience Americans

New proposed regulations1 on automobile emissions from the Environmental Protection Agency (EPA) would require new car sales to be 60% battery powered electric by 2030 and 67% by 2032, compared to fewer than 6% in 2022. EPA has also proposed new rules for power plants,2 driving up the costs of the electricity needed to charge these vehicles. These rules would raise driving costs for Americans, and poor and middle-class Americans disproportionately would pay the price. EPA has not fully accounted for these price increases. [EPA-HQ-OAR-2022-0829-0674, p. 2]

New electric vehicles cost more than gasoline-powered vehicles. The electric version of the base version of the Ford 150 pickup truck, the best-selling vehicle in America, costs an additional $26,000.3 Tesla's base prices start at about $40,000 for a Model 3 and go up to almost $100,000 for a Model X.4 These are staggering costs to impose on American families. Cars are part of the American Dream for many Americans, a dream that for too many American families is put out of reach by these new regulations. EPA has not analyzed the effects of the increased costs of these vehicles. [EPA-HQ-OAR-2022-0829-0674, p. 2]

The push towards expensive electric vehicles as will be required by the EPA rule, directly contradicts the Department of Transportation's focus on "Health and Equity." According to the Department,26 "households in low-income areas typically own fewer vehicles, have longer commutes, and have higher transportation costs." These are the people who will pay the price for new EPA regulations. Their cars will be older, less safe, and break down more frequently, resulting in higher repair and maintenance costs. [EPA-HQ-OAR-2022-0829-0674, p. 6]

Organization: U.S. Conference of Catholic Bishops (USCCB)

However, there are some aspects of the proposed rule that raise questions and would be the appropriate grounds for considering modification of the rule. The proposed rule requires two-thirds adoption of EVs by 2032. Although a laudable goal in the abstract, it seems plausible that under current economic conditions, such a transition could have a negative impact on lower-income Americans who cannot afford car prices to increase.18 In addition, the incentives for EV use and purchase do not prioritize low-income households, which it should in order to have a greater environmental impact. The EV market in the United States shows increased trends towards larger, heavier and less efficient SUVs and trucks, which in turn are being sold at higher prices.19 Consequently, incentives and rebates for EV purchases are disproportionately allocated to high-income households, which tend to use EVs as a second or third vehicle, with much lower average mileage use.20 EVs that are seldom used may in fact result in larger emissions than ICEV since EVs create more emissions in their production.21 The lower emissions benefits of EVs are only fulfilled when they are used for high numbers of miles that would have been otherwise powered by gasoline.22 Many well intentioned wealthy beneficiaries of EV tax credits may put their vehicles to good use, but studies show that incentives disproportionately benefit high income households that use their cars less.23 A revised proposed rule should address this concern and have a strategy to improve on this outcome. [EPA-HQ-OAR-2022-0829-0540, p. 4]

18 See, e.g., Davis, L. & Knittel, C. 'Are Fuel Economy Standards Regressive?', Dec. 1, 2016. (While fuel emissions standards are slightly progressive when only new vehicles are considered, they are mildly regressive when used cars are taken into account. The EPA's proposed rule, with very stringent emissions

standards and a reliance on incentives for EV's which ignore the used car market will likely have an even greater regressive impact for used car buyers).

19 See, e.g., Zipper, D., June 1, 2023, https://www.theatlantic.com/ideas/archive/2023/06/large-electric-vehicles-road-safety-crashes/674249/ . (Four in five new vehicles purchased in the U.S. are SUVs or light-duty trucks and of only two of 23 EVs for sale in the last two years have a sale price under $35,000. Even with tax rebates, the price is outside the range of middle class and poor Americans, whose median household income was $70,784 in 2021).

23 Burlig, F. et al, 2021. "Low Energy: Estimating Electric Vehicle Electricity Use." AEA Papers and Proceedings, 111: 430-35.

The greater adoption of EVs can be good for society and the environment when incentives are directed to consumers who will use EVs extensively, such as single-vehicle households, ride sharing drivers, used car buyers and middle- and lower-income households.24 In addition, some aspects of EV infrastructure subsidies, such as in the geographical distribution of charging stations, tend to reflect and perpetuate "disparities across race and income."25 A modified proposed rule should address these concerns with a strategy to allocate EV resources to middle- and low-income households, and also favor users who will be inclined to use the EV for the necessary number of miles so that it produces a net environmental benefit. [EPA-HQ-OAR-2022-0829-0540, pp. 4-5]

24 Hardman, S. et al., Aug. 30, 2021, https://sciencepolicyreview.org/2021/08/equity-transition-electric-vehicles/

25 "The result shows a similar overall pattern of access disparities between the race and ethnicity groups, but the access gap is larger than that found for public chargers overall… The odds of having publicly-funded charger access in Black and Hispanic majority CBGs is less than half of that in White-majority CBGs." Hsu, C. & Figerman, K. 'Public electric vehicle charger access disparities across race and income in California', https://www.sciencedirect.com/science/article/pii/S0967070X20309021.

The EPA's numerous regulations that promote human and ecological health, reduce GHG, and promote the common good are commendable. In these times of growing ecological challenges, increased inequality, and fiscal pressures, aggressive environmental standards must also respect economic and social considerations, driving our nation towards an "energy revolution" that provides "not only sustainable, efficient and clean energy, but also energy that is secure, affordable, accessible and equitable."26 For these same reasons, the light-duty vehicle standards should be improved and optimized to benefit primarily low- and middle-income Americans to reduce racial and economic disparities. [EPA-HQ-OAR-2022-0829-0540, pp. 4-5]

2. EPA's analysis of vehicle ownership costs is flawed.

There is a well-developed body of economics literature covering the total cost to the consumer of vehicle ownership (TCO). 157, 158, 159 Such studies include extensive data on powertrain production costs, energy prices, consumption, maintenance and repair costs, depreciation costs, and vehicle miles of travel.160 Rather than draw upon and update this extensive literature, EPA reinvents the wheel and prepares its own TCO analysis without any independent peer review of its approach. [EPA-HQ-OAR-2022-0829-0707, p. 33]

157 Hanna L. Breetz, Deborah Salon, Do Electric Vehicles Need Subsidies? Ownership Costs for Conventional, Hybrid, and Electric Vehicles in 14 U.S. Cities, Energy Policy. 120. September 2018, 238-249.

158 Kate Palmer, Zia Wadud, James E Tate, John Nellthorp, Total Cost of Ownership and Market Share for Hybrid and Electric Vehicles in the UK, US and Japan, Applied Energy. 209. 2018, 109-119.

159 Burnham et al., Comprehensive Total Cost of Ownership Quantification for Vehicles with Different Size Classes and Powertrains, Argonne National Laboratory. ANL/ESD-21/4. April 2021.

160 See supra.

Disadvantaged communities already face significant access barriers to electric vehicles, such as: higher upfront costs to electric vehicle ownership; a lack of existing charging infrastructure available to them in low-income, minority populated, and rural areas; and costlier and time-intensive charging due to a greater reliance on public charging infrastructure, particularly for individuals living in multi-family housing. [EPA-HQ-OAR-2022-0829-0707, p. 55]

Notwithstanding EPA's hope that its proposal may serve to incentivize the purchases of electric vehicles, these vehicles are significantly more expensive on average than their ICE vehicle counterparts and unaffordable for many households. These are costs are also likely understated as each electric vehicle already enjoys thousands of dollars' worth of Federal and state subsidies, which are ultimately funded by taxpayers. Additionally, an automakers' ability to sell electric vehicles to consumers depends on substantial price subsidies in the form of credit support. EPA ignores the reality that many EJ stakeholders are currently unable to afford the upfront costs of purchasing an electric vehicle in the first place. With the cost of transition minerals expected to escalate exponentially in the coming years as a function of limited supply and increasing demand, the costs to manufacture and purchase electric vehicles will likely rise. [EPA-HQ-OAR-2022-0829-0707, p. 56]

EPA should also consider the effects of the proposal on electricity prices, as low-income populations often spend a larger percentage of their earnings on essential utilities compared to the rest of the United States. Reliance on electric vehicles has been shown to spur increases in load and demand during peak periods, which impact electricity prices. Because EPA lacks expertise in the area of electrical grid management and economics, EPA should consult with other agencies and credible experts in these areas in order to adequately evaluate these impacts.304 EPA should ensure that the proposal meets reliability and affordability criteria and helps EJ communities make informed decisions about their own energy needs. Additionally, EPA's EJ assessment fails to acknowledge the likelihood that many owners will lack access to residential charging, which will substantially increase their operating expenses. Consistent reliance on fast charging also shortens electric vehicle battery life, resulting in a need to replace the battery and/or the vehicle more frequently. [EPA-HQ-OAR-2022-0829-0707, pp. 56-57]

304 See, West Virginia, 142 S.Ct. at 2612-13 (stating that EPA admitted that opining on trends in electricity transmission, distribution, and storage requires technical and policy expertise not traditionally needed in EPA regulatory development and finding that there is little reason to think Congress assigned such decisions to the EPA).

If EJ is truly a commitment for EPA, it should carefully consider criticisms like those leveled by The Two Hundred, which point out the disproportionate impacts to working and minority communities as a result of California's climate approach regarding electrified transport; those impacts and concerns remain true, and indeed are magnified under the proposed standards.305 [EPA-HQ-OAR-2022-0829-0707, pp. 56-57]

305 See Plaintiffs' Complaint, The Two Hundred for Homeownership, et al. v. California Air Resources Board, et al., No. 1:22-CV-01474.

It is critical from the outset to design standards to minimize the potential for price shocks and supply disruptions. As written, the proposal ultimately benefits electric vehicle manufacturers at the expense of disadvantaged communities by subsidizing unaffordable transportation that is not fit for the purposes of commuting to and from EJ communities. At minimum, EPA should perform a thorough EJ assessment specific to its LDV proposal that is comprehensive of both transport challenges and impacts faced by EJ stakeholders and the government-wide Justice40 Initiative [EPA-HQ-OAR-2022-0829-0707, pp. 56-57]

The average purchase price of EV cars in 2022 was approximately $65,000, which is more than what 46 percent of American households earn in income in a year.306 While the average "used" EV sold for $42,895 in March of 2023.307 While EPA's DRIA anecdotally indicates that "emerging consensus suggests that purchase price parity is likely to occur by the mid-2020's for some vehicle segments and models"308, Ford CEO Jim Farley told attendees at its 2023 Capital Markets Days that EV cost parity may not come until after 2030.309 Moreover US auto makers are focusing their efforts on producing higher priced electric SUVs and trucks, including Fords $100,000 F150 Lightening Platinum310 and GM's announcement that its luxury brands, Cadillac and Buick, will be its first all-electric product lineups.311 While smaller EV's like the Chevy Bolt, touted by the Biden Administration as being affordable alternatives, are being discontinued.312 The reality is that most middle- and lower-income families simply cannot afford to purchase a new or used EV, even when taking into account available tax incentives and rebates. In fact, middle – and lower -income families are more likely to purchase older used vehicle, due to their lower upfront costs, and to hold onto those vehicles for longer periods.313 [EPA-HQ-OAR-2022-0829-0707, pp. 56-57]

313 Supporting Lower-Income Households' Purchase of Clean Vehicles: Implications From California-wide Survey Results, UCLA Luskin Center for Innovation, 2020

While EPA looks to address fuel saving as a component of the total cost of ownership for BEVs in an effort to portray BEV's as being cost competitive, or even advantageous versus their ICE counterparts, EPA fails to properly address insurance and depreciation, claiming they excluded them because they are quite similar for BEV's and ICE vehicles.314 However, EPA provides no support for these conclusions, while in the actual markets Tesla introduced its own insurance products in 2019 in response to high insurance costs for its EVs. More recently Policygenius.com published its "Electric car insurance 2023 guide", reporting that EV car insurance costs are higher than for non-electric vehicles, averaging 27.2% more expensive, with certain models including Tesla Model 3 and Model Y, averaging 43% and 53% more than the average ICE vehicles in their comparisons.315 Nerdwallet.com attributes the higher cost of EV insurance to higher initial sticker prices and specialized repairs.316 More concerning are recent reports from Car and Driver317 and Reuters318 which highlight an all too common phenomena for EV's in even minor collisions, the sheer numbers of low mileage (under 10,000 miles) vehicles siting in salvage yards as insurance companies elect to salvage the vehicle due to the overwhelming cost of repair/replacement of the battery packs. A trend that is likely to continue as OEM's further integrate larger battery packs into the structural design of EV's chassis. "We're buying electric cars for sustainability reasons," said Matthew Avery, research director at automotive risk intelligence company Thatcham Research. "But an EV isn't very sustainable if you've got to throw the battery away after a minor collision."319 [EPA-HQ-OAR-2022-0829-0707, pp. 57-58]

Organization: Western Energy Alliance

Affordability/Environmental Justice: EPA is assuming that although the retail price of EVs is typically higher than for comparable ICEVs at this time, the price difference will narrow or disappear as the cost of batteries and other components fall in the coming years. EPA is taking a huge leap of faith in the ability of EV manufacturers to innovate in time for the arbitrary deadlines imposed by the president and EPA through this rule. Market projections six months from now are difficult, much less nine years into the future. [EPA-HQ-OAR-2022-0829-0679, p. 7]

Further, a U.K. study has found that EVs depreciate at a rate of 51% compared to 37% for gasoline cars, losing £15,220 ($18,786) versus £9,901 ($12,400).15 Clearly EPA's estimate that

"…the average upfront per-vehicle cost to meet the proposed standards to be approximately $1,200 in MY 2032, as shown in Table 7.131…" is greatly underestimated. EPA mentions but then dismisses the impact on low-income households by just assuming that manufacturers, "will continue to offer a variety of models at different price points…" and that they will save on fuel costs. [EPA-HQ-OAR-2022-0829-0679, p. 7]

13
EV battery costs have soared in 2022, hampering EV affordability," Stephen Edelstein, Green Car Reports, December 8, 2022.

14 Current Strategic Metals Prices, Strategic Metals Invest and D aily Metals Prices, both accessed July 5, 2023.

15 "Electric cars losing value twice as fast as petrol vehicles - drivers may lose £25,000," Felix Reeves, Express, May 3, 2023.

EPA's analysis that EVs have significantly reduced operating costs and would save owners $12,000 versus ICEVs over the life of the vehicle seems to be lacking several aspects. Further, the information EPA relies on to arrive at that number seems cherry picked. First, EPA is not looking at the full refueling costs. Studies call into question EPA's assumption that recharging costs will be lower than the costs of gasoline.16 [EPA-HQ-OAR-2022-0829-0679, pp. 7-8]

16 Comparison: Real World Cost of Fueling EVs and ICE Vehicles, Anderson Economic Group, October 21, 2021.

We wonder at the arrival of EPA's $12,000 lower operating costs, given a Department of Energy study that looked comprehensively at the total cost of ownership and found that after 15 years and found a much lower cost differential. The DOE study compared EV costs to similar gasoline-only models, factoring in the price, maintenance, financing, repairs, federal tax break and fuel costs (emphasis added).17 While it is disingenuous to include subsidies in the calculation, since such are at taxpayer expense, nevertheless the EV version of a small SUV costs $0.4508 per mile, $0.0219 less than the $0.4727 per mile rate of a similar gasoline-based model. Based on the average lifespan of a car of 200,000 miles, the cost of a gasoline-fueled car would be $94,540 while a similar EV would be $90,160. The difference of $4,380 is well short of $12,000. The DRIA references this DOE study but appears to have discounted it. But even assuming EPA is correct about the $12,000 lower operating costs, the $18,000 higher initial cost still results in a net cost to the owner.18 [EPA-HQ-OAR-2022-0829-0679, pp. 7-8]

d. EV Prices are Decreasing

One reason for the explosive growth in EV demand is the increasing cost competitiveness of EV models. In fact, ICCT reported that EVs could be the same cost this year for certain mass market models and are already at parity for a few luxury models due to the purchase and production incentives in the Inflation Reduction Act.41 [EPA-HQ-OAR-2022-0829-0638, pp. 11-12]

41 "Electric Vehicles Could Match Gasoline Cars on Price This Year," The New York Times, (February 14, 2023) https://www.nytimes.com/2023/02/10/business/electric-vehicles-price-cost.html

Cost is the number one cited barrier when it comes to purchasing an EV. Approximately 60% of Americans would purchase an EV if it were the same price as an ICEV.42 The price differential between EVs and ICEVs is rapidly shrinking. In 2020, an EV cost about 42% more than an ICEV.43 Today, an EV costs about 20% more than a similar ICEV, with the average ICEV selling for $48,008, compared to $58,940 for an EV.44 This average selling price is inflated by the popularity of luxury EVs on the market. Out of the top ten best-selling EVs in the U.S., the average starting price is $53,509, which drops to a 10% cost premium over ICEVs.45 [EPA-HQ-OAR-2022-0829-0638, pp. 11-12]

42 "International Electric-Vehicle Consumer Survey 2019," AlixPartners, accessed June 21, 2023 https://www.alixpartners.com/insights-impact/insights/international-electric-vehicle-consumer-survey/

43 "The Average Price of an Electric Car," CarEdge, (September 22, 2022) https://caredge.com/guides/average-price-of-an-electric-car

44 "After Nearly Two Years, New-Vehicle Transaction Prices Fall Below Sticker Price in March 2023, According to New Data from Kelley Blue Book," Kelley Blue Book, (April 11, 2022) https://mediaroom.kbb.com/2023-04-11-After-Nearly-Two-Years,-New-Vehicle-Transaction-Prices-Fall-Below-Stic ker-Price-in-March-2023,-According-to-New-Data-from-Kelley-Blue-Book

45 Id. at footnote 43

Upfront cost parity might be achieved even sooner than anticipated. The tax incentives in the IRA bring down the cost premium even further, with up to $7,500 available from the federal government, in addition to any state and local incentives. After factoring in the $7,500 federal tax incentive under section 30D, the average starting price is $46,009 for the top-10 best-selling EVs, $2,000 cheaper than the average ICEV. [EPA-HQ-OAR-2022-0829-0638, p. 12]

Today, while most EVs are still more expensive than a comparable ICE vehicle, there are a range of models at all different price points. Some of the most affordable EVs start at around $27,495, before factoring in the federal 30D tax credit.46 The Tesla Model 3–one of the most popular models in the world–recently reduced its starting price to $41,880 before any incentives.47 In a similar move, Ford cut the price of its Mustang Mach-E, the third-best selling EV in 2022.48 After two price cuts in 2023, the starting price of the Mach-E premium is $46,995.49 Each year there is a growing number of EV models available under $50,000. [EPA-HQ-OAR-2022-0829-0638, p. 12]

49 "Ford cuts prices of Mustang Mach-E after Tesla moves," Reuters, (May 3, 2023) https://www.reuters.com/business/autos-transportation/ford-cuts-prices-mustang-mach-e-2023-05-02/

The economies of scale and decrease in the cost of components are driving down the price of new models. The production tax credits from the IRA are expected to cut the cost of producing batteries and EVs, savings that can be passed on to customers. With incentives for EV manufacturing, facility upgrades, critical mineral production, and battery manufacturing and assembly, the IRA subsidies could cut costs by up to $9,000 per vehicle.50 The result is record-breaking EV sales every year, driving up the percentage of new car sales that are electric. [EPA-HQ-OAR-2022-0829-0638, p. 12]

50 Id. at footnote 41

b. EVs Have Lower Total Cost of Ownership than Comparable ICE Vehicles

Though a vehicle's total cost of ownership (TCO) depends on several factors, such as the region, driving characteristics, and fuel prices, EVs are consistently cheaper to own than gas-powered cars. A typical driver can expect to save between $6,000 and $12,000 over a vehicle's lifetime by switching to an EV.98 These savings are magnified in rural areas where drivers travel an average of 38% more miles than urban drivers.99 [EPA-HQ-OAR-2022-0829-0638, p. 21]

98 "Electric Vehicles Save Consumers Money," Consumer Reports, (June 2023) https://advocacy.consumerreports.org/wp-content/uploads/2023/06/CR_EVSavings_FACTSHEET_6.2023.pdf

99 "Clean Transportation Strategies for Rural Communities in the Northeast and MidAtlantic States," Union of Concerned Scientists, (November 2020) https://www.ucsusa.org/sites/default/files/2020-11/rural-transportation-opportunities.pdf

EVs have fewer moving parts than their ICE counterparts, which makes them simpler to maintain and reduces the likelihood of a major malfunction.100 Reduced maintenance saves customers both time and money. Notably, the average maintenance costs for an EV are 50% lower than those for a comparable ICEV.101 EVs have significantly fewer components that require regular maintenance like engine oil, transmission fluid, and air filters. According to Argonne National Laboratory, the maintenance costs for an EV averages 6.1 cents per mile, compared to 10.1 cents per mile for a similar ICEV.102 That means for vehicles driven 10,000 miles per year can save $400 per year, totalling $2,000 over five years. Over a vehicle's lifetime, an EV owner can save an average of $4,600 on maintenance costs alone by transitioning away from driving a gas vehicle.103 [EPA-HQ-OAR-2022-0829-0638, p. 21]

100 "Maintenance and Safety of Electric Vehicles" U.S. Department of Energy, accessed June 18, 2023 https://afdc.energy.gov/vehicles/electric_maintenance.html

101 "Consumer Reports Study Finds Electric Vehicle Maintenance Costs Are 50% Less Than Gas-Powered Cars," Great Plains Institite, (November 16, 2020) https://betterenergy.org/blog/consumer-reports-study-finds-electric-vehicle-maintenance-costs-are-50-less-than-gas- powered-cars/

102 "Comprehensive Total Cost of Ownership Quantification for Vehicles with Different Size Classes and Powertrains." (April 2021) https://doi.org/10.2172/1780970

103 "EVs Offer Big Savings Over Traditional Gas-Powered Cars," Consumer Reports, (October 8, 2020) https://www.consumerreports.org/hybrids-evs/evs-offer-big-savings-over-traditional-gas-powered-cars/

The average cost of electricity in the U.S. is 16.5 cents per kWh as of May 2023.104 If electricity costs 16.5 cents per kWh, charging an EV with a fully-depleted 100 kWh battery will cost about $16.50 to reach a full charge. While the range of a 100 kWh battery varies depending on a vehicle's efficiency, a typical Tesla Model S can go up to 400 miles on a single charge.105 Comparatively, the average national gasoline price for regular grade was $3.685 in May 2023.106 Filling up a 12-gallon passenger vehicle with a 30 mpg fuel economy would cost

$45.96 to move the vehicle 360 miles. At $16.50 for a full charge, fueling an EV cuts fuel prices by 64%. [EPA-HQ-OAR-2022-0829-0638, p. 22]

According to AAA, over the course of a year the cost of refueling an EV is around $546, compared to $1,255 per year when fueling a gasoline car.107 [EPA-HQ-OAR-2022-0829-0638, p. 22]

EPA Summary and Response

In the NPRM, EPA prepared a summary of consumer expenses for sales-weighted average vehicles by body style and powertrain for sales-weighted average new, light-duty model year 2032 light-duty vehicles. That summary is an aggregation of analysis substantiated elsewhere in the RIA from which we make several observations. This portion of this RTC is intended to respond to comments directly related to the summary and observations provided in RIA Chapter 4.2.2 and 4.2.3. Some of those comments relate to the derivation of the values that appear in Chapter 4.2.2 but were computed in OMEGA and documented elsewhere. We refer readers to RTC Chapter 12 for responses to comments regarding values estimated using OMEGA as well as to RIA Chapter 2, in which Table 2-1 lists OMEGA topics and their location in the RIA. We refer readers to the cited sources for other values. Other comments suggest that the summaries presented in RIA Chapter 4.2.2 "does not include the full economic impact."[482] In response to such comments, we refer readers to the benefit cost analysis presented in RIA Chapters 9 and 4.3 as well as responses to comments regarding benefit cost analyses in Chapter 8 of this RTC. Also, as clearly stated in the RIA, the summary of consumer expenses for sales-weighted average vehicles by body style and powertrain presented Chapter 4.2.2 of the RIA is not intended to be a total cost of ownership analysis and is not a benefit cost analysis. See RIA Chapter 4.2.2 for clarity regarding the intent and purpose of these summaries. Lastly, other topics evoked in the comments and related to the savings and expense summaries are addressed elsewhere in the RTC, RIA, and Preamble, such as the following: charging infrastructure and battery durability (RTC Chapter 17), power sector and grid reliability (RTC Chapter 18), supply chain and critical minerals (RTC Chapter 15), modeling (RTC Chapter 12), vehicle cost and cost parity (RTC 12.2, RIA Chapter 2.5), environmental justice (RTC Chapter 9), consumer heterogeneity (RTC Chapter 13.2), battery costs (RIA Chapter 2.5.2.1), advances in PEV technology (RIA Chapter 3.1.1 and Preamble Section IV), supply chain and critical minerals (RIA Chapter 3.1.4 and Preamble Section IC.C.7), GHG emissions control technologies (RIA Chapter 3.5), fuel and electricity prices (RTC Chapter 19, RIA Chapters 2 and 5), and IRA provisions (RIA Chapter 2.6.8)

[482] [EPA-HQ-OAR-2022-0829-0517, p. 1]

We list revisions to consumer savings and expenses completed for the FRM. Many revisions are in response to comments and recommendations made by commenters. For the sake of brevity, we consider this list of revisions to stand as our response to those comments. We discuss these issues further in the RIA.

- EPA has updated the dollars values to 2022 dollars.
- EPA has added PHEVs to our analyses and revised inputs accordingly.
- EPA has revised consumer estimates of miles drive per year to 15,000 miles per year, instead of 12,000.
- EPA has included revised estimates of each pre-existing line item. See RIA Chapter 4.2.2 for descriptions of line items as well as the following cross-referenced locations for descriptions OMEGA estimation approaches and procedures.
    - Purchase price: RIA Chapters 2.5 and 4.2.2
    - Average Sales Tax: RIA Chapter 4.2.2
    - Average Federal Purchase Incentive: RIA Chapter 2.6.8
    - Vehicle Miles Per Year: RIA Chapter 4.2.1 and 8.3
    - Annual Retail Fuel Expenses: RIA Chapters 2.6.6, 4.3.3, and 8.5
    - Annual Refueling Time: RIA Chapter 4.3.5
    - Annual Maintenance Expenses: RIA Chapter 4.3.7
    - Annual Repair Expenses: RIA Chapter 4.3.7
    - Annual Registration Expense: See Burnham, Gohkle, et al. (2021)
    - Annual Insurance Expense: RIA Chapter 4.3.6
    - Residential Charging Equipment and Installation Investments: RIA Chapter 5.3
- EPA has revised methods for estimates of refueling time (See RIA Chapter 4.3.5) and rebound (See RIA Chapter 8.3.3).
- EPA has revised the 8-year summary of expenses to include average sales taxes; we have not included property taxes due to their limited applicability.
- EPA has revised the 8-year summary of expenses to include the average estimated purchase incentive.
- EPA has revised the 8-year summary of expenses to include insurance.
- EPA notes that registration includes additional fees for PEVs.
- EPA has updated the range of optional costs associated with the installation of home charging.

- EPA has updated the average savings for PEV consumers compared to ICE vehicle consumers.
- EPA has added tables summarizing the lifetime expenses associated with sales weighted average vehicles in the No Action case and in the Central case.
- EPA has revised text in RIA Chapter 4 to reflect the above.
- EPA has revised text in RIA Chapter 4.2.2 to describe and substantiate our assumption of full pass through of technology costs and producer incentives to the consumer. We also assume that the consumer receives the full purchase incentive for which they are eligible.

We augment the clarifications, cross-references, and revisions provided above in RTC Chapter 13.4 with additional attention to affordability and consumer heterogeneity (i.e., consumers of all demographics, income levels, vehicle types). First, note that we address considerations of specific groups of vehicle consumers in RIA Chapter 4.2.3, including low-income consumers, consumers of lower-price new vehicles, and consumers of used vehicles. We also refer readers to RTC Chapter 13.2 where we discuss comments related to consumer demand and the diversity of vehicle consumers (i.e., consumer heterogeneity). We note that some commenters suggested a quantitative, rather than qualitative assessment of the above. First, we have conducted substantive quantitative analyses as evidenced throughout the Preamble, RIA, and RTC. At this time, the studies and data do not exist to quantitatively examine differences in PEV purchasing behavior across demographic groups, though there is recent evidence to suggest that the stereotypes of PEV buyers is breaking down (i.e., PEV consumers are becoming increasingly diverse and more representative of vehicle consumers (Fujita, Campbell, & Taylor, 2024) (Taylor, Fujita, & Campbell, 2024)..

Regarding vehicle affordability, comments centered around several themes. Comments were concerned with the price of vehicles, accessibility of vehicle ownership due to projected vehicle costs and related issues like financing, and the availability and costs of fueling and charging. Some commenters were also concerned with the impacts of the standards on vehicle choice, especially in the lower priced vehicle categories and markets and for members of disadvantaged communities. Most commenters link those concerns to plug-in electric vehicles. For example,

- Donna Jackson states that the rule “will create an economic hardship and serious decline in the standard of living for all Americans but especially black Americans”
- Joshua Linn states that “low-income households typically have lower demand for plug-in vehicles than high-income households (even putting aside the high up-front purchase price), and by shifting the market from gasoline to plug-in vehicles, the standards may reduce purchasing options for low-income households.
- Valero Energy Corporation states that “the reality is that most middle- and lower-income families simply cannot afford to purchase a new or used EV, even when taking into account available tax incentives and rebates.”
- Texas Public Policy Foundation states that “Rural and low-income communities, the people most affected by this regulation, likely will be the last to receive said recharging infrastructure”

- American Free Enterprise Chamber of Commerce states that “not all consumers can make purchasing decisions based on savings that they hope to experience years later.”

In response, first, our assessment projects there will be variation in the types of technologies that automakers adopt to meet the standards, providing consumers with vehicles with reduced GHG emissions and increased fuel economy and associated fuel savings via PEV and ICE vehicle technologies in the new vehicle market and eventually also in the used vehicle market. We expect that automakers recognize the diversity of their consumers and will leverage the flexibilities built into the standards to provide consumers with PEV and ICE vehicle choices over a wide range of utility and price points. Second, purchase incentives are available for eligible new and used PEVs for buyers who qualify (See RIA Chapter 2.6.8). Third, the price difference for PEVs is widely expected to narrow or disappear as the cost of batteries and other components fall in the coming years.[483] See Preamble Sections IV.C.1 and IV.C.6. Fourth, in our modeling, we assume that a mix of technologies will be used to meet the standards, and we demonstrate several potential compliance pathways.

These and other comments reference impacts on specific communities of vehicle prices, fuel and electricity prices, charging costs and time, and charging infrastructure as well as the approaches, methods, procedures, and resources used to estimate these and other quantities. In response to these and similar comments, we first refer readers to the revisions documented in RIA Chapter 4.2.2. We make clear that the revised summaries of consumer savings and expenses provided in RIA Chapter 4.2.2 are illustrative. These summaries provide sales-weighted average expense and savings information for prospective future consumers of new vehicles. These estimates are not intended to provide information tailored to any particular demographic group such as consumers of luxury or lower-priced new vehicles, rural or urban consumers, or households participating in the used vehicle market. While these estimates will have greater and lesser relevance to different individuals based on their individual circumstance, they nonetheless provide a reasonable analysis of consumer savings and expenses related to this nationwide regulation. Finally, we have qualitatively examined different impacts experienced by different groups. For example, we discuss low-income consumers, consumers of lower priced vehicles, and used vehicle consumers in RIA Chapter 4.2.3, and we address comments regarding our attention to consumer heterogeneity and purchase price and total ownership cost (TOC) parity in RTC Chapter 13.2.

Commenters also provided more favorable assessment of the effects of the standards on vehicle affordability, accessibility, and choice:

- Zero Emissions Transportation Association (ZETA) states that “EVs have [a] lower total cost of ownership than comparable ICE vehicles.”

- Environmental and Public Health Organizations argues that “PEVs are a great fit for the needs and demands of rural drivers,” noting, for example, that “trips in rural areas are longer than in urban areas” and therefore fuel savings would be greater.

- Energy Innovation cites a University of California, Berkeley, Grid Lab, and Energy Innovation study and found that the DRIVE Clean Scenario, “compared to the No

[483] International Council on Clean Transportation, "Assessment of Light-Duty Electric Vehicle Costs and Consumer Benefits in the United States in the 2022-2035 Time Frame," October 2022.

New Policy … [would result] in approximately $2.7 trillion in consumer savings through 2050 … a household savings of about $1000 per year on average over 30 years."

- Joshua Linn states that "the standards will increase sales of plug-in vehicles while simultaneously making gasoline vehicles more fuel efficient. Both changes reduce fuel costs for drivers, which disproportionately benefits low-income households because they spend a much larger share of their income on gasoline than do high-income households."

Among the commenters who contrasted higher upfront purchase expenses and lower operating costs under the standards for all vehicles and particularly for BEV and ICE vehicles, some were critical of the tradeoff arguing that higher upfront costs were too much of a burden especially for lower income households, while others argue that operating savings are important to many consumers across all demographic groups and income levels.

- American Free Enterprise Chamber of Commerce et al. states that "not all consumers can make purchasing decisions based on savings that they hope to experience years later."
- Environmental and Public Health Organizations noted that "BEV ownership, combined with supportive policies will benefit lower-income consumers." More specifically, the state, "While upfront BEV cost concerns may serve as an initial barrier to lower-income consumers, a suite of targeted policies can mitigate this concern."

In response, we acknowledge the many commenters who noted the rising average price of a new vehicles, and we are aware of the strong relationship between new vehicle prices and used vehicle prices. We emphasize that many factors contribute to the rising average price of vehicles, such as fleet mix, larger size, increased performance, vehicle amenities, and increased fuel efficiency. We also note that this historical trend, though likely to continue, is not inevitable. Tradeoffs are inherent in the vehicle purchase process, and this condition may be especially important for "Americans who cannot afford [for] car prices to increase." However, the vast majority of American households own a vehicle, and for the many Americans who do purchase new and used vehicles, those consumers experience the fuel saving benefits associated with vehicles with reduced GHG emissions and improved fuel economy, whether or not consumers consider it fully at the time of purchase.

14 - Vehicle sales

Comments by Organizations

Organization: Alliance for Automotive Innovation

National EV sales have demonstrated consistent linear growth, but nothing like the growth in market share that EPA is projecting for the future (Figure 3). In the first quarter of 2023, automakers sold about 305,000 electric vehicles (EVs), including battery, plug-in hybrid, and fuel cell electric vehicles) in the United States, representing 8.6% of overall light-duty vehicle sales. Year-over-year (YoY), market share increased 2.7 percentage points (pp) compared to the first quarter of 2022.31 [EPA-HQ-OAR-2022-0829-0701, pp. 30-31]

31 See past editions of "Get Connected: Electric Vehicle Report" for previous quarters.

[See original comment for Figure 3: U.S. EV (BEV, PHEV, and FCEV) market share, January 2020 through March 2023.32] [EPA-HQ-OAR-2022-0829-0701, pp. 30-31]

32 Alliance for Automotive Innovation, Get Connected: Electric Vehicle Quarterly Report 2023 (Q1) (Jun. 26, 2023). Available at https://www.autosinnovate.org/posts/papers-reports/get-connected-2023-q1.

EPA's Proposed Rule is projected to require BEV market share that exceeds that of the most mature and forward-leaning EV market in the U.S. Comparing EPA-projected BEV share to California zero-emission vehicle (ZEV) mandate requirements,33 EPA projects greater overall U.S. BEV market share than would be required in California and Section 177 states under the ZEV Mandate that seeks to ban the sale of internal combustion engine (ICE) vehicles by 2035. Figure 4 summarizes the electrification rates projected in the NPRM against the penetration rates required in California's ZEV Mandate. California requires at least 34% BEV market share in 2027, reaching 66% in 2032. EPA's proposed rule exceeds these rates in every year from 2027-2032 and by as much as 6 percentage points in 2030. [EPA-HQ-OAR-2022-0829-0701, pp. 31-32]

33 See 13 C.C.R. § 1962.4.

[See original comment for Figure 4: Comparison with California] [EPA-HQ-OAR-2022-0829-0701, pp. 31-32]

Organization: Alliance for Consumers (AFC)

Moreover, EPA has failed to consider the interplay between the current profits that automakers earn on ICE vehicles as opposed to the losses that most automakers are incurring in their sale of EVs. For example, a recent Ford Motor Company 10-k filing identified a relatively common reality for automakers: "our larger, more profitable vehicles had an average contribution margin that was 118% of our total average contribution margin across all vehicles, whereas our smaller vehicles had significantly lower contribution margins." Ford Motor Company 2021 10-K at 35.3 In short, this identifies the reality that larger, primarily ICE cars and trucks are cross-subsidizing the sale of money-losing EVs to a substantial degree. Yet EPA fails to adequately address the effects of removing a majority of ICE cars from the road and replacing them with EVs in terms of the ability of traditional automakers to continue pricing EVs at current, money-losing levels. Indeed, the same recent Ford Motor Company 10-k notes that EV mandates like what EPA has proposed in this rule: "may increase the cost of vehicles by more than the perceived benefit to consumers and dampen margins." Ford Motor Company 2021 10-K at 35. [EPA-HQ-OAR-2022-0829-0534, pp. 4-5]

3 Available at https://s201.q4cdn.com/693218008/files/doc_financials/2021/q4/Ford- 2021-10-K-Report.pdf.

Organization: American Free Enterprise Chamber of Commerce (AmFree) et al.

EPA concludes that manufacturers are already on track to transform the nation's automotive industry and projects that the number of available models will grow from 68 today to 180 by model year 2025. 88 Fed. Reg. at 29,190, 29,312. In large part, the agency supports these expectations with announce- ments that various manufacturers have released outlining plans to shift product development toward electrification in the coming decades. See id. at 29,190, 29,192–93. As EPA acknowledges, however, these announcements “are not binding and often are conditioned as forward-looking and subject to uncer- tainty.” Id. at 29,193. They do not prove how many models will actually be available by the time of the compliance period. [EPA-HQ-OAR-2022-0829-0683, pp. 20-21]

Manufacturers may significantly revise their plans or fail to meet their tar- gets—as has happened many times before. Tesla, for example, has fallen re- peatedly fallen behind schedule. In November 2017, the company introduced an electric semi-truck prototype and set a production date for December 2019, but following the exit of an executive and “a series of supply chain issues,” the company pushed the production date back nearly three years (to 2022). Nora Naughton, Another Tesla Semi Was Spotted Apparently Broken Down on the Side of the Road, Bus. Insider (Jan. 20, 2023), https://tinyurl.com/38x8xkvc. In De- cember 2017, Tesla unveiled a second-generation Roadster and said that the vehicle would launch in 2020. See Dan Mihalascu, Tesla Roadster “Hopefully” Entering Production In 2024: Elon Musk, Inside EVs (May 17, 2023) (“Tesla Road- ster”), https://tinyurl.com/39a5jn4d. In 2020, however, the model “was de- layed to 2021, and then pushed back by a year every year.” Id. It is “three years overdue at this point,” and at a recent shareholder meeting, CEO Elon Musk “push[ed] back the car another year, ‘hopefully’ to 2024.” Id. And in 2019, Tesla unveiled the Cybertruck and said that it would be available for sale in 2021. See Jack Ewing, Tesla’s Pickup Truck Is Coming Soon. Maybe., NY Times (Feb. 6, 2023) (“Tesla’s Pickup”), https://tinyurl.com/3d7f9tv7; Lora Kolodny, Tesla Unveils Its First Electric Pickup, The Cybertruck, Starting at $39,900, CNBC (Nov. 21, 2019), https://tinyurl.com/je4esevt. Now production is not expected to begin until the end of 2023. Ewing, Tesla’s Pickup. [EPA-HQ-OAR-2022-0829-0683, pp. 20-21]

Other manufacturers have also experienced setbacks. General Motors, for example, recently “dialed back” an electric-vehicle sales target by more than two years, “citing startup issues with a new battery plant in Ohio.” Bart Ziegler, Electric Vehicles Require Lots of Scarce Parts. Is the Supply Chain Up to It?, Wall St. J. (Nov. 12, 2022), https://tinyurl.com/ynkuw9bd. Stellantis “previously had a stated 2025 target but scrapped it in favor of a new 2030 target.” Bloom-bergNEF, Zero-Emission Vehicles Factbook: A BloombergNEF Special Report Pre- pared for COP27, at 48 (Nov. 2022), https://tinyurl.com/2dyrxn66 (“Zero-Emis- sion Vehicles Factbook”). Lordstown Motors suspended production and deliveries of its electric pickup truck in February 2023 to address performance and quality issues with certain components, see Michael Wayland, Lordstown Halts Production, Shipments of Endurance Electric Trucks to Address Quality Issues, CNBC (Feb. 23, 2023), https://tinyurl.com/ykjwtz39, and last week it filed for Chap- ter 11 bankruptcy protection, after having “produce[d] only 65 of its Endurance pickups since the company’s 2018 founding,” Jeanne Whalen & Hamza Sha- ban, Lordstown Motors Files for Bankruptcy and Sues Foxconn, Wash. Post (June 27, 2023), https://tinyurl.com/35ekmhje. And Ford has fallen far behind on filling purchase orders for the F-150 Lightning pickup truck. See Luc Olinga, Ford Suffers Another Setback, TheStreet (Mar. 11, 2023), https://ti-nyurl.com/ymuuy5nv. [EPA-HQ-OAR-2022-0829-0683, p. 21]

These real-world examples demonstrate that far-in-advance announcements (often in the face of significant political pressure) do not reliably indicate whether electric vehicles will get to the market on time, in the amounts prom- ised, or even at all. Model year 2032 could come and go with far fewer electric models than EPA assumes. [EPA-HQ-OAR-2022-0829-0683, p. 21]

In any event, EPA does not indicate whether additional electric-vehicle of- ferings in other segments that more typical consumers could afford are likely to surface by the time the proposed rule takes effect. And there is reason to doubt that affordable offerings will materialize in time. One recent article notes that legacy automakers are "spending much of their effort producing vehicles that are above the median average annual US household income," and although "some EVs" will soon appear at lower prices, it is unclear whether those models will stay in the lower price brackets. Charette, Convincing Consumers (internal quo- tation marks omitted). Already, various manufacturers such as General Motors and Ford have had to increase the prices of their lower-end models to keep up with industry pressures. Id. For example, last year Ford's least expensive F-150 Lightning Pro model was offered for $41,769; this year, the price has jumped more than 38 percent, to $57,869. Id. Untapped segments of the light- and me- dium-duty market may therefore see little, if any, traction in the near future. [EPA-HQ-OAR-2022-0829-0683, p. 24]

Organization: American Fuel & Petrochemical Manufacturers

EPA likewise assumes that the IRA and the BIL funds will be adequate to build the necessary electrification infrastructure. It is uncertain that (1) critical minerals will be available to manufacture ZEV batteries (see Section I.A.1); (2) consumers will buy EVs at the rate assumed by EPA (see Section IV.B.2); and (3) there will be ample electricity to power these vehicles (see Sections I.B and IV.B.3).127 What is certain is that the Proposal's timeline is unachievable and completely detached from reality.128 EPA also improperly relied on the general characterization of recent years of the light-duty and medium-duty market as supplemented by incentives in the BIL and IRA to support its proposition that there will be a rapid increase in ZEV market penetration. Setting aside the laws of supply and demand and the fact that the future availability of ZEVs is insufficient to meet the ZEV adoption requirements proposed by EPA (as discussed further below), EPA improperly relies on the number of models currently available on the free market as a surrogate for the number of actual units sold and in use. The underlying reality is that without federal regulation requiring vastly increased ZEV penetration, providing automakers certainty for long-term planning, automakers could not financially justify long-term investment in a technology with tepid consumer demand. The referenced electrification projections may be a function of OEMs striving to create certainty and minimize risk as they attempt to comply with forthcoming regulations. Indeed, the CEO of the Alliance for Automotive Innovation recently questioned the feasibility of the Proposed Rule – stating that the proposal was too aggressive and could benefit China: [EPA-HQ-OAR-2022-0829-0733, pp. 29-30]

127 Id.

128 Id.

I've said the EPA proposal wasn't feasible without certain public policies and in light of today's market and supply chain conditions .. . . There's not enough charging and uncertain utility and grid capacity. Here's the big one – and where China looms largest – essentially no domestic or allied supply of battery critical minerals, processing, and components until 2025 (and even then, nowhere near enough to supply what's needed).129 [EPA-HQ-OAR-2022-0829-0733, pp. 29-30]

129 John Bozzella, EPA's EV Rules: What it Means for China and the U.S Auto Market. June 12, 2023, available at https://www.autosinnovate.org/posts/blog/epas-ev-rules-what-it-means-for-china-and-the-us-auto-market (accessed June 23, 2023).

As EPA acknowledges, the facts show that only between 2.2 and 4.4 percent of light duty vehicles produced in 2021 were electric, rising to about 8.4 percent in 2022.133 Production may or may not translate into sales and vehicle registration. State-by-state EV registration data shows that the percentage of EV registrations relative to all registered vehicles ranged from 0.15 percent in Mississippi to 4.01 percent in California.134 Thus, the ambitions of even the most aggressive OEM from a ZEV adoption rate perspective would require unprecedented sales over the next seven years.135 [EPA-HQ-OAR-2022-0829-0733, p. 31]

iv. Vehicle readiness.

1. Technology readiness.

The proposed rule identified various LMD ZEVs available in the marketplace or in production, as well as select manufacturer goals and commitments to producing LMD ZEVs by a certain timeframe. However, there is significant uncertainty regarding EPA's expectation for rapid availability of ZEV powertrains on the proposed rule's timeline. OEM goals and commitments, coupled with IRA/BIL funding may help to increase the availability of LMD ZEVs; however, it will be extremely challenging to meet the proposal's implementation schedule. Based on EIA projections, it seems highly unlikely that vehicles will be available at the rates EPA is projected for the 2027-2032 timeframe. [EPA-HQ-OAR-2022-0829-0641, pp. 14-15]

Even with a fully stocked LMD ZEV market, key barriers to entry include customer uptake, capital costs to purchase vehicles, and infrastructure readiness. [EPA-HQ-OAR-2022-0829-0641, pp. 14-15]

The AEO 202359 contains long term projections based on current laws and regulations in place at the time of modeling. As part of that modeling, the AEO includes projections for vehicle sales and vehicle sales projections include consumer choice modeling60. EIA's consumer choice modeling includes fuel choice, sales penetration among similar technologies, market share among different technology sets, and vehicle attributes (i.e., sales price, fuel economy, battery replacement costs, range, etc.). EIA reported that for the first time since 2010, critical mineral prices increased “significantly” in 2022 resulting in the first year to year increase in electric vehicle battery prices. According to AEO projections, which consider current policies and regulations, and consumer choice, BEV sales penetration remains well below EPA’s estimates in the proposed rule, which are induced by its proposed stringent standards. EPA must explain why its projections differ so significantly from EIA. Furthermore, EIA61 projects electric vehicles to be less competitive from a cost standpoint than gasoline powered vehicles in the much larger non-luxury market. [EPA-HQ-OAR-2022-0829-0641, p. 19]

61 61 U.S. Energy Information Administration. “Issues in Focus: Inflation Reduction Act Cases in the AEO2023.” March 2023. Annual Energy Outlook 2023. https://www.eia.gov/outlooks/aeo/IIF_IRA/.

Vehicles powered by internal combustion engines (ICE) offer “outstanding “drivability and reliability” according to the Department of Energy62 and “increasing the effciency of internal combustion engines (ICEs) is one of the most promising and cost-effective approaches to dramatically improving the fuel economy of the on-road vehicle fleet in the near- to mid- term.” Increasing sales of EVs does not necessarily mean they are more reliable. According to this survey data63 “[e]lectric cars are less reliable” than cars powered by petroleum, where software related problems cause reliability issues for consumers. In a Consumer Reports survey,64 data reported by EV owners indicate that EVs, as a category, have “more frequent problems” compared to conventional vehicles. EPA should take into account these factors in their analysis. [EPA-HQ-OAR-2022-0829-0641, p. 19]

No-Action EV Scenario Assumption

The regulation accepts as a baseline a 40% BEV share of new vehicle sales by 2030 as part of the assumed no-action scenario.123 This scenario appears to be driven by OEM announcements for future technology penetration for vehicles sold in the U.S.124 [EPA-HQ-OAR-2022-0829-0641, pp. 47-49]

123 Draft Regulatory Impact Analysis EPA-420-D-23-003 April 2023, Table 13-67.

124 40 CFR Parts 85, 86, 600, 1036, 1037, and 1066 [EPA–HQ–OAR–2022–0829; FRL 8953–03– OAR] page 29192 Table 1.

Table 13-67: Projected BEV Penetrations, No Action – Combined [EPA-HQ-OAR-2022-0829-0641, pp. 47-49]

Manufacturer	2027	2028	2029	2030	2031	2032
BMW	30%	35%	42%	43%	42%	42%
Ford	29%	26%	32%	35%	36%	36%
General Motors	22%	29%	33%	38%	38%	37%
Honda	30%	35%	40%	42%	41%	40%
Hyundai	29%	36%	42%	43%	43%	42%
JLR	26%	32%	37%	38%	38%	38%
Kia	26%	32%	38%	38%	38%	38%
Mazda	28%	34%	40%	42%	42%	41%

Toyota	29%	32%	39%	41%	40%	39%
Volvo	26%	33%	39%	41%	40%	39%
VW	31%	36%	41%	43%	42%	42%
Total	27%	32%	37%	40%	40%	39%

Table 1. Example of U.S. electrified new sales percentages implied by OEM announcements for 2030 or before [EPA-HQ-OAR-2022-0829-0641, pp. 47-49]

2022 US Sales Rank (1)	OEM	Share of Total U.S. Sales	Stated EV Share in 2030 (2)	Powertrain (3)	Implied OEM Contribution to 2030 Total PEV Market Share
1	General Motors	16.4%	50%	PEV	8.2%
2	Toyota	15.4%	33%(4)	BEV	5.1%
3	Ford	13.1%	50%	BEV	6.5%
4	Stellantis	11.2%	50%	BEV	5.6%
5	Honda	7.2%	40%	BEV	2.9%
6	Hyundai	5.7%	50%	BEV	2.8%
7	Nissan	5.3%	40%	BEV	2.1%
8	Kia	5.0%	45%	BEV	2.3%
9	Subaru	4.1%	40%	BEV	1.6%
10	Volkswagen, Audi	3.6%	50%	BEV	

					1.8%
11	Tesla	3.4%	100%	BEV	3.4%
12	Mercedes-Benz	2.6%	100%	BEV	2.6%
13	BMW	2.6%	50%	BEV	1.3%
14	Mazda	2.1%	25%	BEV	0.5%
15	Volvo	0.8%	100%	BEV	0.8%
16	Mitsubishi	0.6%	50%	PEV(5)	0.3%
17	Porsche	0.5%	80%	BEV	0.4%
18	Land Rover	0.4%	60%	BEV	0.3%
19	Jaguar	0.07%	100%	BEV	0.07%
20	Lucid	0.02%	100%	BEV	0.02%
	Total	100.9%			48.6%

OEM technology announcements have not always translated to implementation. For example: [EPA-HQ-OAR-2022-0829-0641, pp. 47-49]

• GM had made the claim in 2007 that they would have 1 million fuel cells on the road by 2012.125 [EPA-HQ-OAR-2022-0829-0641, pp. 47-49]

125 https://www. reuters.com/article/us-gm-fuelcells/gm-aims-to-be-first-to-make-1-million-hydrogen-cars-exec- idUSSHA9988820071114.

• This claim was never reached, and only limited fuel cell vehicles have ever been produced by GM. [EPA-HQ-OAR-2022-0829-0641, pp. 47-49]

• Ford made the claim in 2001 that their SUVs would increase their fuel economy by 25% by 2005.126 [EPA-HQ-OAR-2022-0829-0641, pp. 47-49]

126 https://www.autoweek.com/news/a2108121/fords-goal-boosting-suv-fuel-economy-2005-proves-elusive/.

• This claim was only reached after the global recession in 2008 forced buyers out of choosing the larger vehicles they were consuming prior to the recession. [EPA-HQ-OAR-2022-0829-0641, pp. 47-49]

Even the President of the United States isn't the best source of forecasting automotive technology. In the 2011 State of the Union speech, President Obama claimed that there would be

1 million EVs on the road by 2015.127 The reality was only ~200,000 electric vehicles were on the roads in 2015 and it would take another 6 years (2021) for the 1 million EV goal to finally be reached. [EPA-HQ-OAR-2022-0829-0641, pp. 47-49]

127 https://www1.eere.energy.gov/vehiclesandfuels/pdfs/1_million_electric_vehicles_rpt.pdf.

Furthermore, we also question the agency's use of these forward-looking statements as a basis of fact when establishing the baseline cost assumption. The forward-looking statements on BEV penetration rates by the OEMs are predicated on expectations of potential regulatory standards set by the agency. This circular reasoning cannot support EPA's proposal here as the referenced forward-looking statements are largely a function of OEMs striving to create certainty and minimize risk as they attempt to comply with forthcoming regulations. [EPA-HQ-OAR-2022-0829-0641, pp. 47-49]

Organization: Arizona State Legislature

5. The proposed rule relies on erroneous assumptions about vehicle costs. EPA's projections of vehicle costs rely on federal tax credits juicing consumer demand, but prices have increased and few vehicles qualify for the tax credits. [EPA-HQ-OAR-2022-0829-0537, p. 2]

Organization: California Attorney General's Office, et al.

1. There Are Significant Public and Private Investments in and Demand for Zero-Emission Vehicles

Zero-emission-vehicle technologies are widely used in vehicles today to control emissions and their deployment is increasing at a rapid pace. For example, in 2020, the U.S. market penetration of electric vehicles108 was just 2.2%; in 2021, it was 4.4%; and, in 2022, electric vehicles were estimated to reach 8.4% market share. 88 Fed. Reg. at 29,189. This dramatic growth is expected to continue, and forecasts estimate that electric vehicle market share will climb to 40-50% in 2030109 given government policies, manufacturer plans, and growing consumer demand. [EPA-HQ-OAR-2022-0829-0746, p. 18]

108 "Electric vehicles" refers to plug-in electric vehicles, which includes battery electric vehicles and plug-in hybrid electric vehicles.

109 Javier Colato and Lindsey Ice, U.S. Bureau of Labor Statistics, Charging into the future: the transition to electric vehicles (Feb. 2023), available at https://www.bls.gov/opub/btn/volume-12/charging-into-the-future-the-transition-to-electric-vehicles.htm#:~:text=S%26P%20Global%20Mobility%20forecasts%20electric,surpassing%2050%20per cent%20by%202030; Sean Tucker, Kelley Blue Book, More Than Half of Car Sales Could Be Electric by 2030 (Oct. 4, 2022), accessible at https://www.kbb.com/car-news/study-more-than-half-of-car-sales- could-be-electric-by-2030/.

In addition to federal- and state-level laws and policies, "[m]any automakers have detailed plans to electrify large portions of their fleets over the next decade, with some announcing goals for fully electrified lineups within five years."123 These announcements cover the range of zero-emission vehicle technologies, including hydrogen fuel cell electric vehicles. The number of electric vehicle models available for sale in the United States has more than doubled from about 24 in model year 2015 to about 60 in model year 2021, and is expected to increase to more than 180 models by 2025. 88 Fed. Reg. at 29,312. [EPA-HQ-OAR-2022-0829-0746, p. 21]
